Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects,

when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Move

To move (translate) geometry objects, in the **Geometry** toolbar, from the **Transforms** ( ) menu, select **Move** ( ). You can also right-click the **Geometry** node to add this node from the **Transforms** submenu.

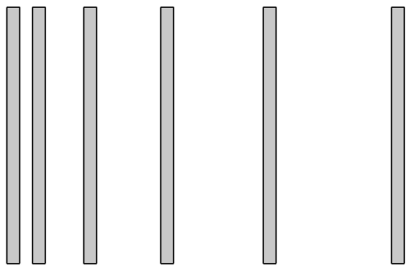

Figure 7-53: Using the Move feature to create a nonuniform array of the selected objects.

Then enter the properties of the move operation using the following sections:

INPUT

Select the geometry objects that you want to move in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Move** node, choose **Manual** to select geometry objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

DISPLACEMENT

From the **Specify** list, choose **Displacement vector** (the default) or **Positions**.

If you choose **Displacement vector**, specify the displacement in each direction by entering **x**, **y**, and **z** (not all fields are available in 1D and 2D geometries); **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes. To create several identical objects moved using different displacements, enter a comma-separated or space-separated list of displacements in these fields, or click the **Range** button ( ) to use the **Range** dialog for specifying a range of displacements for moving multiple copies.

If you choose **Positions**, choose **Vertex** (the default) or **Coordinates** from the **Old position** list to specify the old (original) position. If you choose **Vertex**, select a vertex from some geometry object in the **Graphics** window; otherwise, specify the old position using coordinates. Likewise, choose **Vertices** (the default) or **Coordinates** from the **New position** list to specify the new (destination) positions. Defining the move operation using positions can be useful in the following situations:

- To move an object so that a given vertex gets certain coordinates. For example, make the *r*-coordinate exactly 0 in an axisymmetric model.

- To move a geometry object so that a given vertex coincides with vertices of another geometry object. If more than one vertex is selected, the moved object will be copied to match the number of new positions, as shown in Figure 7-54.

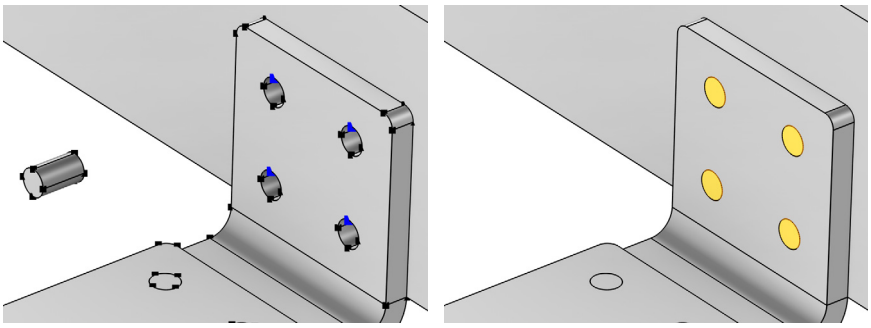

Figure 7-54: Selecting four vertices (blue) as new positions for the bolt (left), generates four copies of the bolt (yellow) that matches the holes (right).

- To move a geometry object so that a point with given coordinates (for example, the origin of a sphere) is moved to a vertex of another geometry object.

Example of a Nonuniform Array Spacing

In the **x** displacement field, enter for example `f({range(0,1,10)})`, where `f` is a function, for example `{range(0,1,10)}^2+{range(0,1,10)}`, as shown in Figure 7-53. Then, use a second **Move** feature to move the resulting moved objects in the *y* direction and, possibly, a third **Move** feature for the *z* direction.

COORDINATE SYSTEM

The coordinate system in which the displacement coordinates above are interpreted (in 3D geometries only). From the **Take work plane from** list, select **This sequence** (the default) to use a work plane earlier in the same geometry sequence, or choose a part instance earlier in the sequence to choose a work plane from that part. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the **Graphics** window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the displacement).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Offset

Use the **Offset** ( ) node to offset the edges of 2D curve or solid objects in the normal direction, as shown in Figure 7-55.

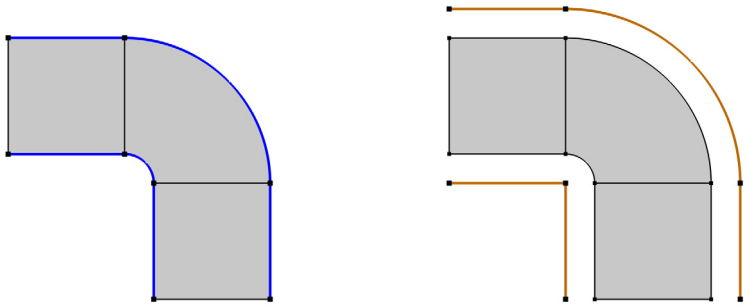

Figure 7-55: Offsetting some of the boundaries (blue) of the solid domain. The resulting curves are highlighted in yellow.

Enter the properties of the offset operation using the following sections:

INPUT

From the **Geometric entity level list**, choose the level of the entities to offset: **Object**, **Domain**, or **Boundary** (that is, edges in 2D). Then select the objects, domains or edges that you want to offset in the **Graphics** window. The objects or entities appear in the **Input entities** list. If the geometry sequence includes user-defined selections above the **Offset** node, choose **Manual** to select objects or entities, or choose one of the selection nodes from the list next to **Input entities**.

Click the **Active** button to toggle between turning ON and OFF the **Input entities** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

For solid objects and domains the exterior edges will be offset to generate a new solid object.

OPTIONS

Enter a **Distance** for the offset. Switching between a positive and negative number reverses the offset direction. The default 0 distance for the offset creates a copy of the input edges.

Select the **Reverse side** checkbox (cleared by default) to reverse the offset direction. This is equivalent to changing the sign of the offset distance.

When offsetting edges of convex corners the operation can create new edges by several methods to close the gap that would result otherwise. From the **Convex corner handling** list, choose one of the other available options:

- **Fillet** (default) to add circular arcs that are tangent to both offset edges of convex corners, as shown in Figure 7-56.
- **Tangent lines**, to create edges, which are tangent to the offset edges in convex corners, up to their intersection point, as shown in Figure 7-56.

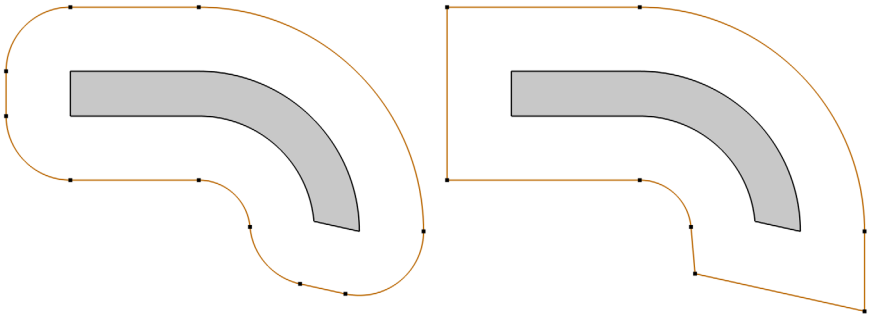

Figure 7-56: Offsetting all boundaries of the solid object using the options Fillet (left) and Tangent lines (right), respectively.

- **Extend edges**, to extend the straight and circular offset edges in convex corners until they intersect. Other offset edges are extended by the use of circular arcs with the same tangent and radius of curvature as the offset edge, as shown in Figure 7-57.
- **No connection**, to offset the edges without connecting them together, as shown in Figure 7-57.

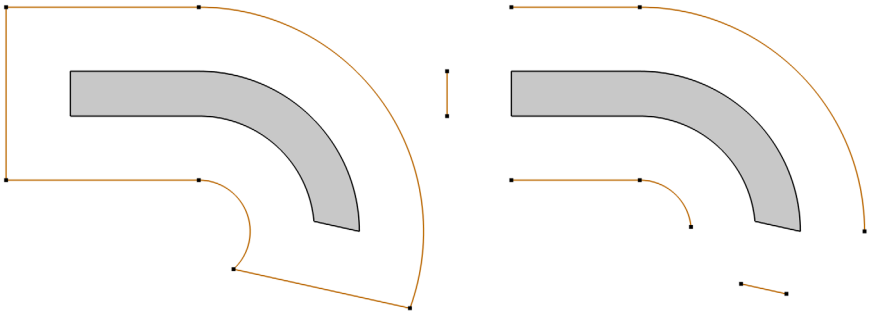

Figure 7-57: Offsetting all boundaries of the solid object using the options Extend edges (left) and No connection (right), respectively.

When offsetting edges of concave corners select the **Trim intersections** checkbox (selected by default) to trim the intruding parts of intersecting offset edges.

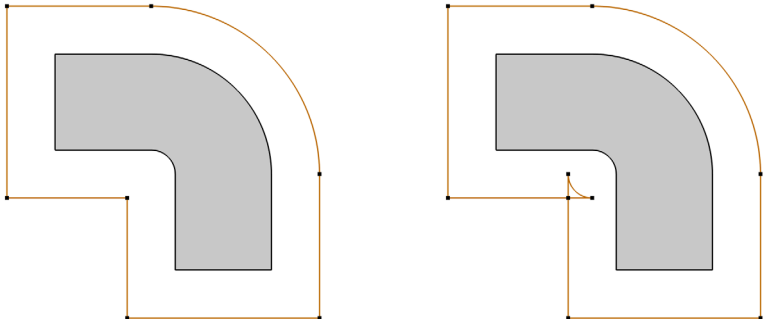

Figure 7-58: Offsetting all boundaries of the solid object with the setting Trim intersections on (left) and off (right), respectively.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Parameter Check

You can add a **Parameter Check** node ( ) to a geometry part or a geometry sequence to check the values of the input parameters (or local or global parameters). Such a check can be useful to make sure that a parameter value stays within a certain range, especially for input parameters to geometry used in geometry models. The check gives an error or warning if the condition that you provide is nonzero (true). For example, `r>30[mm]` displays the given message if the value of the parameter `r` exceeds 30 mm. Put the node at a position before the use of the parameter

if you want the error or warning to appear before using the parameter that you want to check when building a geometry feature. The error appears in an **Error** window and also as an **Error** subnode under the **Parameter Check** node. The warning appears as a **Warning** subnode under the **Parameter Check** node. You enter the condition, type of message, and message to display in the following section:

PARAMETER CHECK

In the **Condition** field, type an expression in terms of the parameters (global, local, and input parameters). When you build the feature, an error or warning occurs if the expression is nonzero.

In the **Message type** list, select if to display an **Error** or a **Warning** and type the error or warning message to display if the condition is fulfilled in the **Message** field.

See *Cracking of a Notched Beam*: Application Library path **Geomechanics_Module/Damage/notched_beam_damage**.

Part Instance

Use a **Part Instance** node to call and instantiate a geometry part in the model component's geometry sequence. The geometry part can be a global part defined under one **Global** > **Parts** of a locally defined part.

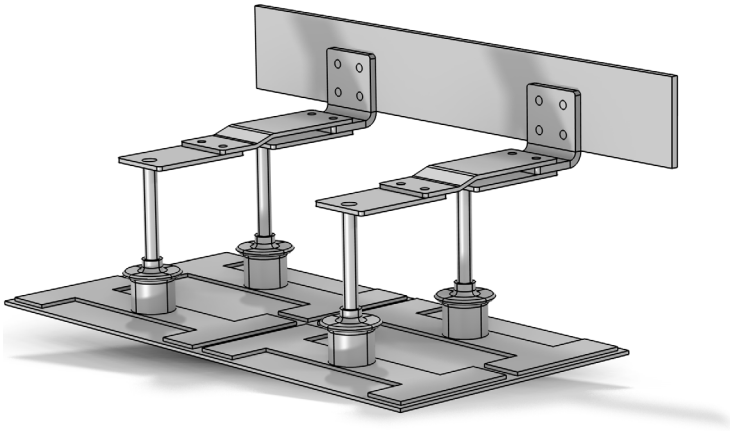

Figure 7-59: Using Part Instance nodes to instantiate the different parts of this busbar assembly.

To create an instance of a geometry part, right-click a geometry and select one of the global parts from the **Parts** submenu. This adds a **Part Instance** node ( ), which builds an instance of the part with new values of its input parameters (arguments). Enter the properties of the part instance using the following sections:

PART

Choose the part to create an instance of from the **Part** list. You can choose among the parts defined under **Global** > **Parts**. You can also choose **Local part** (the default if no other parts exist), which means that the part is defined by the **Local Part** node (in 3D) beneath the **Part Instance** node. To choose the part from the Part Libraries, click **Choose from Library**. You can then choose a part and click **Add to Geometry**. The part then also appears under **Global** > **Parts**.

INPUT PARAMETERS

The **Name** column of the table contains the input parameters required by the part. In the **Expression** column, enter the corresponding expressions. The expressions can contain parameters defined under **Global Definitions**. The defaults are the default expressions defined in the **Input Parameters** section for the part that you create an instance of. The values of the expressions appear in the **Value** column. The **Description** column contains the descriptions given by the part.

You can import or load data in files from a spreadsheet program, for example, with the **Load from file** button ( ) and the **Load** dialog that appears. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window. Data must be separated by spaces or tabs. If the license includes LiveLink™ *for* Excel® you can also load input parameters from a Microsoft Excel Workbook spreadsheet.

THUMBNAIL

This section contains the associated descriptive image of the part, if available in the loaded part contains a thumbnail image. See Creating a Part for information about adding thumbnail images to parts.

POSITION AND ORIENTATION OF OUTPUT

Use this section to specify the translation and rotation to apply to the output objects (not in 1D).

In 3D, this transformation is done in two steps:

- The first step is to transform the output objects so that a chosen coordinate system from the part matches a given coordinate system defined by some feature preceding the Part Instance. Both coordinate systems are defined as the local coordinate system of a work plane. By default, the first step does nothing.
- The second step is to transform the output objects using a displacement and a rotation.

In 2D, only the second step of the transformation is available.

Coordinate system in part

Choose the coordinate system from the part from the **Work plane in part** list. You can choose among all work planes defined in the part. You can also choose **xy-plane**, which corresponds to the global coordinate system (this is the default). The selected work plane becomes the “base plane” for the part instance’s position.

Coordinate system to match

From the **Take work plane from** list, select T**his sequence** (the default) to use a work plane earlier in the same geometry sequence, or choose a part instance earlier in the sequence to choose a work plane from that part. In both cases, you select the work plane to match in the **Work plane** list. The default is **xy-plane**, which corresponds to the global coordinate system. The work plane to match is visualized in the graphics.

Displacement

Enter values or expressions for the **xw**, **yw**, and **zw** coordinates (SI unit: m) to add a displacement vector relative to the coordinate system to match.

Rotation

In 3D, from the **Specify** list, choose **Axis of rotation** (the default), **Euler angles (Z-X-Z)**, or **Edge** as the way to specify the rotation.

- For **Axis of rotation**, select an **Axis type**: **xw-axis**, **yw-axis**, **zw-axis** (the default), **Cartesian**, or **Spherical**. For any choice, enter a **Rotation angle** (SI unit: degrees; default 0) to specify the rotation. If **Cartesian** is selected, enter Cartesian coordinates values for **xw**, **yw**, and **zw** (default values 0, 0, and 1, respectively, corresponding to the global *zw*-axis) to specify the axis vector. If **Spherical** is selected, specify the axis vector using spherical angles **theta** and **phi** in degrees (default: 0).

- For **Euler angles (Z-X-Z)**, enter values for the intrinsic Z-X-Z Euler angles α, β, and γ in the corresponding text fields (in degrees; the default values are 0).
- For **Edge**, select a straight edge in the **Graphics** window by first enabling the selection in the **Straight edge** list. Using a preselection, you can add it using the **Add to Selection** button (+). Use the **Clear Selection** button ( ) to remove the selected straight edge and the **Zoom to Selection** button ( ) to zoom into the selected straight edge.

In 2D, you can specify a displacement vector in the **x-displacement** and **y-displacement** fields and a rotation angle (in degrees) in the **Rotation angle** field.

OBJECT SELECTIONS

When you have built the Part Instance feature, the table shows the names of the output object selections that are defined by the part and there set to show in instances of the part. When you click a row in the table, the corresponding selection is highlighted in the graphics. These selections are available for use as input to following geometry features if kept, and also, optionally, available in the physics and materials, for example. You can unite selections from several **Part Instance** nodes using a cumulative selection. If you want a selection to contribute to a cumulative selection, choose that cumulative selection from the corresponding list in the **Contribute to** column. To contribute to a new cumulative selection, click the selection in the table and then the **New Cumulative Selection** button. This opens a dialog where you can specify the name of the cumulative selection. Select the **Keep** checkbox to keep the selection for use in other nodes in the geometry sequence below this node.

DOMAIN/BOUNDARY/EDGE/POINT SELECTIONS

These sections are similar to the **Object Selections** section. If the **Keep** checkbox is selected, the **Physics** (**Instances** when used in another geometry part; **3D** when used in a plane geometry for a work plane) checkbox, when selected (which it is by default), makes that selection also available when defining, for example, physics and materials (Physics), in the part instances (**Instances**), or in 3D (**3D**).

SELECTION SETTINGS

Select the **Keep noncontributing selections** checkbox to disable the **Keep** column and keep all selections that do not contribute to a cumulative selection. This setting is the default in the COMSOL API and corresponds to the behavior in earlier COMSOL versions.

ASSIGNED ATTRIBUTES

Select the **Construction geometry** checkbox to make the resulting objects available only in the feature's geometry sequence. For more information, see Construction Geometry.

See *Busbar Assembly Geometry — with Geometry Parts*: Application Library path **COMSOL_Multiphysics/Geometry_Tutorials/busbar_assembly_geometry**.

Partition Domains

The **Partition Domains** node ( ) provides an operation that partitions selected domains at specified locations, as shown in Figure 7-60 and Figure 7-61. You can specify the curves or surfaces for the partitioning in various ways (see the **Partition with** list information under **Partition Domains** below).

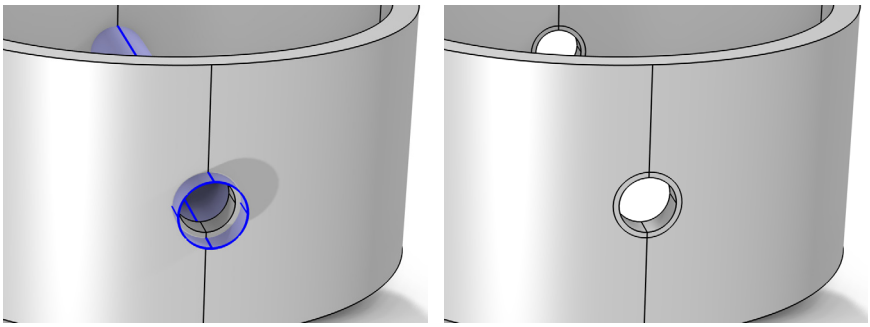

Figure 7-60: Partitioning the domain of a cylinder with a cylinder (blue) such that a finer mesh element size can be generated closest to the holes.

Partitioning domains can be useful in cases where a structured mesh would be a better choice than an unstructured mesh but the domains are not suitable for a mapped or swept mesh. A **Partition Domains** node can occur at any position in the geometry sequence; it works with output geometries before the **Form Union/Assembly** node, assembly geometries, and virtual geometries. The output of a **Partition Domains** node's partitioning operation includes the same number of geometry objects as the input to the partitioning. To add it to a 2D or 3D geometry, in the **Geometry** toolbar, from the **Boolean and Partitions** menu ( ), select **Partition Domains**. You can also right-click the **Geometry** node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

PARTITION DOMAINS

In the **Domains to partition** list, add the domains that you want to partition.

From the **Partition with** list in 2D, choose one of the following methods for defining the curves for partitioning the domains:

- Choose **Line segments between vertices** (the default) to define line segments using vertices (points) in the geometry, which you add to the **Vertices defining line segments** list.
- Choose **Lines through vertices** to define partitioning lines that pass through the vertices in the **Vertices defining lines** list. The lines through the vertices extend to the perimeters of the selected domains.
- Choose **Edges** to select edges in the geometry as the partitioning curves. Add the edges to use for partitioning to the **Edges** list.

- Choose **Extended edges** to use the lines and circles defined by straight and circular edges, respectively, as partitioning curves. Add the edges to use for partitioning to the **Straight or circular edges** list.

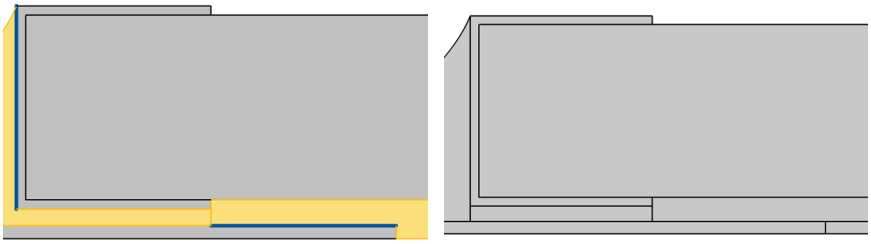

Figure 7-61: Left: Partitioning two domains (yellow) with the extension of two selected edges (blue). The result is shown in the image to the right.

- Choose **Objects** to use geometry objects that you add to the **Objects** list for partitioning the domains. The objects used for partitioning remain for further geometry operations.

Using the **Vertices defining line segments** or **Vertices defining lines** list, it is possible to select any number of vertices (greater than 1). The operation automatically groups the selected vertices into pairs according to minimal distances and defines one partitioning line segment or line per pair.

From the **Partition with** list in 3D, choose one of the following methods for defining the surfaces for partitioning the domains:

- Choose **Work plane** (the default) to partition the domain using a work plane that you choose from the **Work plane** list. Click the **Go to Source** button ( ) to move to the **Work Plane** node for the selected work plane.
- Choose **Faces** to select faces in the geometry as the partitioning faces. Add the faces to use for partitioning to the **Faces** list.
- Choose **Extended faces** to use the surfaces defined by planar, cylindrical, and spherical faces as partitioning surfaces. Add the faces to use for partitioning to the **Planar, cylindrical, or spherical faces** list.
- Choose **Objects** to use geometry objects that you add to the **Objects** list for partitioning the domains. The objects used for partitioning remain for further geometry operations. When **Objects** is selected, you can clear the **Keep objects** checkbox (selected by default) to not keep the objects use for the partitioning in the resulting geometry.

The **Objects** option in the **Partition with** list is not available if the **Partition Domains** node appears after the **Form Union/Assembly** node.

You can change the settings for the **Repair tolerance** list if you experience problems with the partition operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6}.
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selections** checkbox to create predefined selections for all or some of domains, boundaries, edges, and points that the resulting objects consist of. Select **All levels**, **Domain selection** (the default), **Boundary selection**, **Edge selection** (3D only), **Point selection**, of **Off** from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list. These selections are available in all applicable selection lists under the physics, mesh, materials, and results branches but do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the selections contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list, or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

- Compose

Partition Edges

The **Partition Edges** node ( ) provides an operation that partitions selected edges at specified locations. You can specify the positions by entering parameters based on the arc length or by selecting existing vertices whose orthogonal projections on the edges specify the positions.

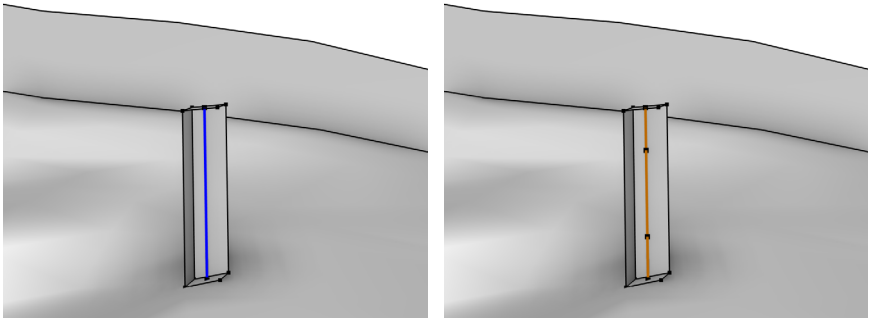

Figure 7-62: Partitioning an edge (blue) to set the physics properties of an injection well in the part in the middle.

A **Partition Edges** node can occur at any position in the geometry sequence; it works with output geometries before the **Form Union/Assembly** node, assembly geometries, and virtual geometries. To add it to a 2D or 3D geometry, in the **Geometry** toolbar, from the **Boolean and Partitions** ( ) menu, select **Partition Edges**. You can also right-click the **Geometry** node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

EDGE SELECTION

In the **Edges to partition** list, add the edges that you want to partition. If you select multiple edges and multiple vertices, then the number of edges and the number of vertices must be the same.

POSITIONS

Specify the positions of the vertices used to project for the edge partitioning. From the **Type of specification** list, choose **Arc length** (the default) to add one or more parameters for the edge partitioning in the **Relative arc length parameters** list. The relative arc length parameters are scalar values between 0 and 1, providing relative arc length values of each edge that define the location of the partitioning vertices. Alternatively, choose **Vertex projection** to add vertices to the **Vertices to project** list. Then each edge for which the orthogonal projection of the vertex occurs in the interior is partitioned at the projection.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

	• Partition Objects • Partition Domains • Partition Faces • Union • Difference • Intersection • Compose

Partition Faces

The **Partition Faces** node ( ) provides an operation that partitions selected faces at specified locations. You can specify the positions using curve segments between vertices, extended edges, or a work plane, as shown in Figure 7-63.

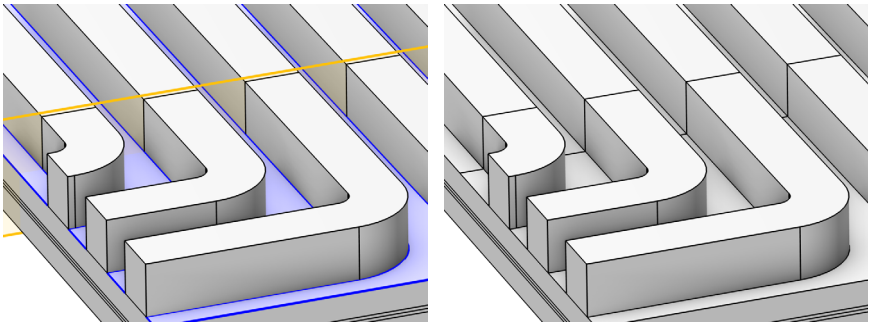

Figure 7-63: Left: Partitioning boundaries (blue) with a work plane (yellow). Right: The resulting geometry where it is now possible to generate a mapped mesh between the straight parts of the fuel cell channels.

A **Partition Faces** node can occur at any position in the geometry sequence; it works with output geometries before the **Form Union/Assembly** node, assembly geometries, and virtual geometries. To add it to a 3D geometry, in the **Geometry** toolbar, from the **Boolean and Partitions** ( ) menu, select **Partition Faces**. You can also right-click the **Geometry** node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

PARTITION FACES

First select the faces to partition in the geometry. The faces appear in the list under **Faces to partition**.

From the **Partition with** list, choose one of the following methods for defining the curves for partitioning the faces:

- Choose **Curve segments between vertices** (the default) to select vertices adjacent to the faces to partition. Add the vertices to use for partitioning to the **Vertices defining curve segments** list. The faces to partition is then partitioned along the curves (lines) connecting the selected vertices.
- Choose **Work plane** to partition the faces using a work plane that you choose from the **Work plane** list. Click the **Go to Source** button ( ) to move to the **Work Plane** node for the selected work plane.
- Choose **Extended edges** to partition the selected faces with extensions of adjacent edges by adding the edges to the **Planar edges** list.

Planar faces can only be partitioned by planar edges that are straight or circular while nonplanar faces can be partitioned by any type of planar edge.

You can change the settings for the **Repair tolerance** list if you experience problems with the partition operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6}.
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input

objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Partition Objects

The **Partition Objects** node ( ) provides a way to partition geometry objects as a Boolean operation, as shown in Figure 7-64. Partitioning geometry objects can be useful to create separate domains, to introduce an interior boundary, or to cut of a part of the original geometry that is not needed for the analysis, for example.

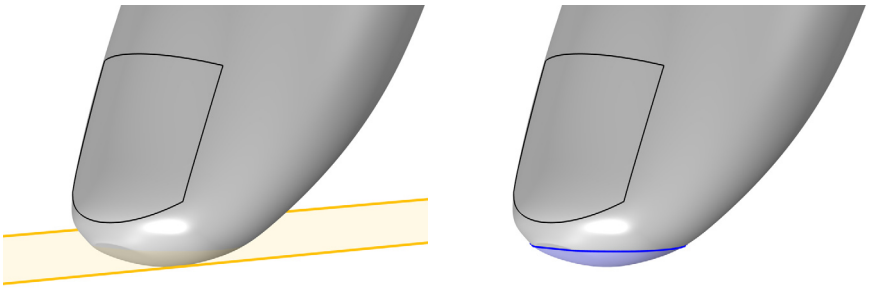

Figure 7-64: Partitioning the geometry of a finger with a work plane (yellow) to remove the tip of the finger (blue) to get a larger contact are with the flat surface of a sensor.

Using the **Partition Objects** node, you can partition a target object using a set of *tool objects* (geometry objects that are only used to partition — or tool — other geometry objects) or using an infinite plane defined by a **Work Plane** node (you do not need to draw anything in the work plane). The output of a **Partition Objects** node's partitioning operation includes the same number of objects as the input to the partitioning. To add it to a model, in the **Geometry** toolbar, from the **Boolean and Partitions** ( ) menu, select **Partition Objects**. You can also right-click the **Geometry** or a **Work Plane** > **Plane Geometry** node to add this from the **Boolean and Partitions** submenu. Then enter the properties of the partitioning operation using the following sections:

PARTITION OBJECTS

In the **Objects to partition** list, add the geometry objects that you want to apply a partition operation on. Click the **Active** button to toggle between turning ON and OFF the **Objects to partition** selections.

Select the **Keep objects to partition** checkbox to use the selected geometry objects to partition for further geometry operations.

From the **Partition with** list (3D only; for 2D, only objects can be used), select **Objects** (the default) to partition using the geometry objects that you add to the **Tool objects** list below, or select **Work plane** to partition using any of the added work planes.

- If you select **Objects**, add the geometry objects that you want to use as tool object to the **Tool objects** list. Click the **Active** button to toggle between turning ON and OFF the **Tool objects** selections. Those geometry objects

are only used to partition the geometry objects in the **Objects to partition** list and are not included in the finalized geometry used for defining materials and physics nodes. Select the **Keep tool objects** checkbox to use the selected tool objects for further geometry operations.

- If you select **Work plane**, select from the available work planes in the **Work plane** list. Click the **Go to Source** button ( ) to move to the **Work Plane** node for the selected work plane.

You can change the settings for the **Repair tolerance** list if you experience problems with the partition operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6}.
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep objects to partition** and **Keep tool objects** checkboxes so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input

objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Revolve

To revolve planar objects into 3D, right-click a geometry or a work plane node, and select **Revolve** ( ). Then enter the properties of the revolve operation, as shown in Figure 7-65.

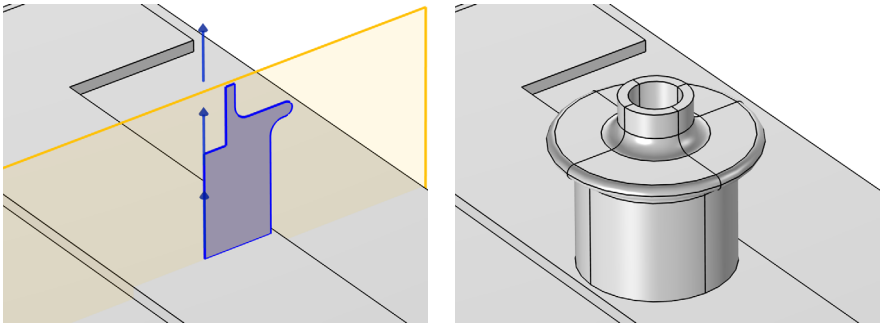

Figure 7-65: A 2D sketch (highlighted in blue) is revolved into a solid 3D object (right).

GENERAL

From the **Revolve from** list, select either of the following:

- Select **Work plane** to revolve objects from a work plane. In the **Work plane** list, select the work plane to revolve from. Select the objects that you want to revolve in the **Graphics** window. They appear in the **Input objects** list.
- Select **Faces** to revolve planar faces from the 3D geometry. Select the faces that you want to revolve in the **Graphics** window. These appear in the **Input faces** list. All selected faces must lie in the same plane.
- Select **Edges** to revolve edges from the 3D geometry. Select the edges that you want to revolve in the **Graphics** window. These appear in the **Input edges** list.
- Select **Vertices** to revolve vertices from the 3D geometry. Select the vertices that you want to revolve in the **Graphics** window. These appear in the **Input vertices** list.

Click the **Active** button to toggle between turning ON and OFF the input selections.

Select the **Unite with input objects** checkbox to unite the input objects with the revolved objects. Clear the **Unite with input objects** checkbox to keep the revolved objects separate from the input objects.

REVOLUTION ANGLES

Click the **Angles** button to specify the start angle (default: 0 degrees) and end angle (default value: 360 degrees; that is, a full revolution) of the revolution. If you click the **Full revolution** button you get a full revolution. This selection also enables the **Keep original faces** checkbox that controls if the original faces are kept in the revolved 3D geometry. Keeping these faces is necessary if you want to create a swept mesh. By default, COMSOL keeps such faces.

REVOLUTION AXIS

Select **2D** in the **Axis type** list to specify the revolution axis in the local coordinate system. When revolving work plane objects, the local coordinate system is defined by the work plane's coordinate system. When revolving planar faces, the local coordinate system is defined by the face with the smallest face number in the first geometry object in the geometry sequence. Select **3D** in the **Axis type** list to specify the revolution axis in the 3D coordinate system. Select **Edge** to specify an edge as revolution axis. Click the **Active** button to toggle between turning ON and OFF the **Straight edge** selection.

POINT ON THE REVOLUTION AXIS

Specify a point on the revolution axis in the local coordinate system in the **xw** and **yw** fields. Alternatively, if **Axis type** is **3D**, specify a point on the revolution axis in the 3D coordinate system in the **x**, **y**, and **z** fields.

DIRECTION OF REVOLUTION AXIS

Specify a direction vector for the revolution axis in the local coordinate system in the **xw** and **yw** fields. Alternatively, if **Axis type** is **3D**, specify a direction vector for the revolution axis in the 3D coordinate system in the **x**, **y**, and **z** fields.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

To revolve any selections from 2D to 3D, select the **Revolve selections from work plane** checkbox. You can also select the **Show in physics** (**Show in instances** if in a geometry part) checkbox to make the resulting 3D selections available in all applicable selection lists (in physics and materials settings, for example) or in instances of the part.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep** from the **Input object handling** list so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

- Work Plane
- Sweep
- Extrude

Rigid Transform

Use a **Rigid Transform** node to perform a rigid transform (translation and rotation) of 3D geometry objects. You can use this feature to position and orient geometry objects by matching a coordinate system (work plane) with another coordinate system (work plane) and then optionally performing a rotation and translation in the work plane's coordinate system.

To add a rigid transformation, in the **Geometry** toolbar, from the **Transforms** ( ) menu, select **Rigid Transform** ( ). You can also right-click the **Geometry** or a **Work Plane** feature to add this from the **Transforms** submenu.

Enter the properties of the rigid transform using the following sections:

INPUT

Select the geometry objects for which you want to perform a rigid transformation in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Rigid Transformation** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

COORDINATE SYSTEM FOR OBJECTS

Choose the coordinate system for the geometry objects from the **Work plane for objects** list. You can choose among all work planes in the geometry. You can also choose **xy-plane**, which corresponds to the global coordinate system (this is the default).

COORDINATE SYSTEM TO MATCH

From the **Take work plane from** list, select **This sequence** (the default) to use a work plane earlier in the same geometry sequence, or choose a part instance earlier in the sequence to choose a work plane from that part. To choose the coordinate system to match, select a work plane from the **Work plane** list. The default is **xy-plane**, which corresponds to the global coordinate system. The work plane to match is visualized in the graphics.

DISPLACEMENT

Enter values or expressions for the **xw**, **yw**, and **zw** coordinates (SI unit: m) to add a displacement vector relative to the coordinate system to match.

ROTATION

From the **Specify** list, choose **Axis of rotation** (the default, **Euler angles (Z-X-Z)**, or **Edge** as the way to specify the rotation.

- For **Axis of rotation**, select an **Axis type**: **xw-axis**, **yw-axis**, **zw-axis** (the default), **Cartesian**, or **Spherical**. For any choice, enter an **Angle** (SI unit: degrees; default 0) to specify the rotation (see *2D Settings* above). If **Cartesian** is selected, enter Cartesian coordinates values for **x**, **y**, and **z** (default values 0, 0, and 1, respectively, corresponding to the global *z*-axis) to specify the axis vector. If **Spherical** is selected, specify the axis vector using spherical angles **theta** and **phi** in degrees (default: 0).
- For **Euler angles (Z-X-Z)**, enter values for the intrinsic Z-X-Z Euler angles α, β, and γ in the corresponding text fields (in degrees; the default values are 0).
- For **Edge**, choose a straight edge as the axis of rotation and add it to the **Straight edge** list. Then enter an **Angle** (SI unit: degrees; default 0) to specify the rotation angle.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Rotate

Use the **Rotate** ( ) node to create one or multiple rotated copies with varying rotation angles, as shown in Figure 7-66 and Figure 7-67.

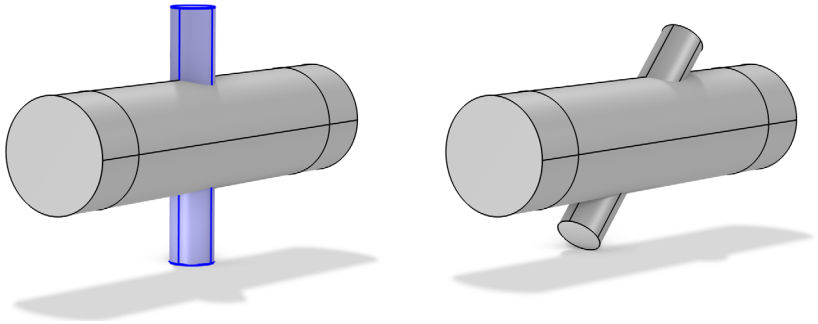

Figure 7-66: Rotating the smaller cylinder to be able to transmit the signal at an angle relative to the flow in an ultrasound flow meter.

To rotate geometry objects, in the **Geometry** toolbar, from the **Transforms** ( ) menu, select **Rotate** ( ). You can also right-click the **Geometry** or a **Work Plane** feature to add this from the **Transforms** submenu. Then enter the properties of the rotate operation using the following sections:

INPUT

Select the geometry objects that you want to rotate in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Rotate** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

ROTATION

2D Settings

In 2D, specify an **Angle** (in degrees; default: 0) for the rotation. To get several rotated objects, enter a list of angles separated with commas or spaces or using the `range` function. Click the **Range** button ( ) to define a range of angles using the **Range** dialog. For example, `range(0,45,315)` creates eight objects, one at the original position and seven rotated copies at 45 degrees distance around a full 360 degrees circle.

3D Settings

In 3D, use the following settings to specify the rotation.

From the **Specify** list, choose **Axis of rotation** (the default, **Euler angles (Z-X-Z)**, or **Edge** as the way to specify the rotation.

- For **Axis of rotation**, select an **Axis type**: **xw-axis**, **yw-axis**, **zw-axis** (the default), **Cartesian**, or **Spherical**. For any choice, enter an **Angle** (SI unit: degrees; default 0) to specify the rotation (see *2D Settings* above). If **Cartesian** is selected, enter Cartesian coordinates values for **x**, **y**, and **z** (default values 0, 0, and 1, respectively, corresponding

to the global *z*-axis) to specify the axis vector. If **Spherical** is selected, specify the axis vector using spherical angles **theta** and **phi** in degrees (default: 0).

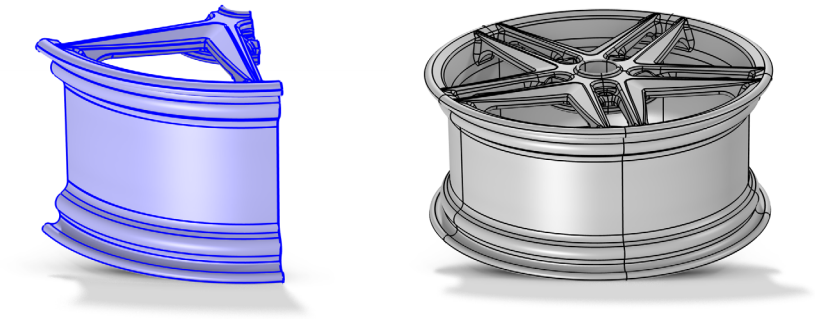

Figure 7-67: Rotating a sector of a wheel rim (left) to get the full geometry (right).

- For **Euler angles (Z-X-Z)**, enter values for the intrinsic Z-X-Z Euler angles α, β, and γ in the corresponding text fields (in degrees; the default values are 0).
- For **Edge**, choose a straight edge as the axis of rotation and add it to the **Straight edge** list. Then enter an **Angle** (SI unit: degrees; default 0) to specify the rotation angle.

CENTER OF ROTATION

This section is available in 2D and 2D axial symmetry. From the **Specify** list, choose **Position** (the default) or **Vertex**. For **Vertex**, choose a vertex to use as the center of rotation and add it to the **Center of rotation** list. Note that you cannot select auxiliary sketch vertices (for example, the center of a Circular Arc) in the **Vertex** selection.

When you specify the position, enter the center of the rotation in the **x** and **y** (for 2D); **r** and **z** (in 2D axial symmetry); and **xw** and **yw** in work plane fields.

POINT ON AXIS OF ROTATION

This section is available in 3D when you have selected **Axis of rotation** or **Euler angles** from the **Specify** list in the **Rotation** section.

Enter a point on the rotation axis in the **x**, **y**, and **z** fields.

COORDINATE SYSTEM

The coordinate system in which the point coordinates and axis of rotation above are interpreted (in 3D geometries only). From the **Take work plane from** list, select **This sequence** (the default) to use a work plane earlier in the same geometry sequence, or choose a part instance earlier in the sequence to choose a work plane from that part. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the **Graphics** window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the rotation axis position).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make

all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Scale

Use a **Scale** ( ) node to scale one or several geometry objects using an isotropic or anisotropic scaling.

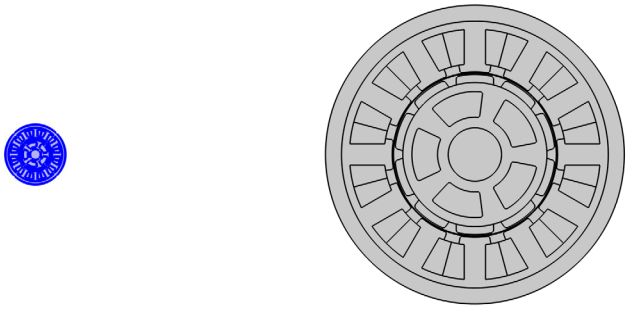

Figure 7-68: Scaling the instantiated parts of a permanent motor (left) to get the correct size (right).

To scale geometry objects, in the **Geometry** toolbar, from the **Transforms** ( ) menu, select **Scale** ( ). You can also right-click the **Geometry** or a **Work Plane** feature to add this from the **Transforms** submenu. Then enter the properties of the scale operation using the following sections:

INPUT

Select the geometry objects that you want to scale in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Scale** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

SCALE FACTOR

By default, you get an isotropic scaling. Specify the scaling factor in the **Factor** field.

To get an anisotropic scaling, change **Scaling** to **Anisotropic**, and specify separate scale factors for the coordinate directions in the **x**, **y**, and (3D only) **z** fields; **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes.

CENTER OF SCALING

Specify the centerpoint of the scaling by specifying **x**, **y**, and(3D only) **z**; **r** and **z** in 2D axial symmetry; **xw** and **yw** in work planes. This is the point that stays fixed during the scaling (that is, the point that the scaled geometry objects approach when the scale factor goes to zero).

COORDINATE SYSTEM

The coordinate system in which the center of scaling coordinates above are interpreted (in 3D geometries only). From the **Take work plane from** list, select **This sequence** (the default) to use a work plane earlier in the same geometry sequence, or choose a part instance earlier in the sequence to choose a work plane from that part. From the **Work plane** list, select **xy-plane** (the default, for a standard global Cartesian coordinate system) or select any work plane defined above this node in the geometry sequence. If you choose a work plane, the work plane and its coordinate system appears in the **Graphics** window, using an extra coordinate triad with the directions **xw**, **yw**, and **zw** (which are then used to specify the center of scaling).

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part, **Show in 3D** if in a work plane's plane geometry) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Split

The **Split** ( ) operation splits an object into its entities:

- A solid splits into solids corresponding to its domains.
- A surface object splits into surface objects corresponding to its faces.
- A curve object splits into curve objects corresponding to its edges.
- A point object splits into point objects corresponding to its vertices.
- A general (mixed) object splits into solids (corresponding to the domains), surface objects (corresponding to faces not adjacent to a domain), curve objects (corresponding to edges not adjacent to a face or domain), and point objects (corresponding to vertices not adjacent to an edge, face, or domain).

To split geometry objects into their entities, in the **Geometry** toolbar, from the **Conversions** menu, select **Split** ( ). Then enter the properties of the split operation in the **Input** section.

INPUT

Select the geometry objects to split on in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Split** node, choose **Manual** to select objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections). From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Sweep

Select **Sweep** ( ) from the **Geometry** toolbar to sweep one or several faces, edges, or points along a curve, as seen in Figure 7-69.

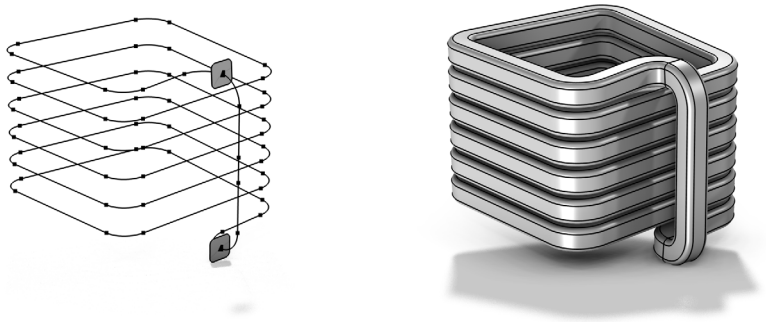

Figure 7-69: The geometry of a coil generated using two Sweep operations: one for the windings and one for the vertical connection.

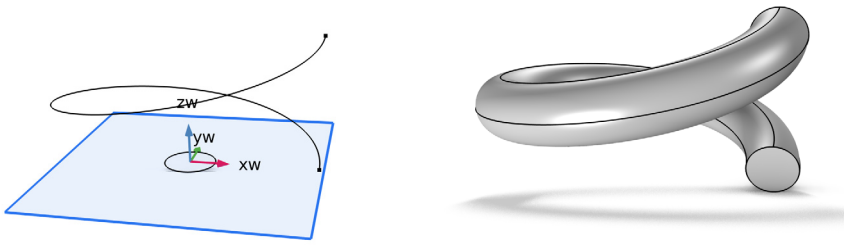
Then enter the properties of the sweep operation using the following sections:

CROSS SECTION

From the **Geometric entity level** list, choose the level of the entities to sweep: **Boundary**, **Edge**, or **Point**. Then select entities that you want to sweep in the **Graphics** window or use the **Selection List** window. Click the **Active** button to toggle between turning ON and OFF the **Entities to sweep** selections. If the geometry sequence includes user-defined selections above the **Sweep** node, choose **Manual** to select objects or entities, or choose one of the selection nodes from the list next to **Entities to sweep**.

When sweeping boundaries, select the **Create cross-sectional faces** checkbox (active by default) to make the sweep operation create cross-sectional faces between the sweep sections. Such cross-sectional faces can be useful, for example, for a swept mesh where you want to specify the mesh distribution for each section of the sweep.

Select the **Move to spine and match local coordinate systems** checkbox (not active by default) to move the cross section entities to the start of the spine curve. This is supported for cross sections drawn in a Work Plane and it also matches the origin and z direction of the Work Plane's coordinate system with the spine curve.



SPINE CURVE

Select the edges you want to sweep along in the **Graphics** window. More than one edge can be selected, but the selected edges must form a nonclosed connected chain. The edges appear in the **Edges to follow** list. Click the **Active** button to toggle between turning ON and OFF the **Edges to follow** selection.

Select the **Manual control of sweep direction** checkbox to change the **Reverse direction** setting to manually control in which direction of the spine to sweep the cross section. These checkboxes are only available when **Move to spine and match local coordinate systems** is not active.

The **Smooth edge connections** checkbox is selected by default. Clearing this checkbox means that transition zones are not added, which can give a better result in cases where the original edges already connect with a continuous tangent.

From the **Parameterization** list, select one of the following options:

- **Arc length** (the default) to use a parameterization based on the arc length of the spine curve.
- **Normalized arc length** to use a similar parameterization but with a normalized arc length (values 0–1).
- **Internal** to use the parameterization that is stored in the geometry's data structures. This option is useful when you want to use the parameterization of a Parametric Curve.

In the section **Alignment at start** select **Make spine perpendicular to entities to sweep** to modify the beginning of the spine curve to become perpendicular to the entities selected in the **Cross Section** section. Change the **Adjustment parameter length** (default 0.1) to modify how far along the spine curve the modification propagates. Note that the parameter is dependent on the **Parameterization** setting and either uses the unit of the geometry (for **Arc length**) or is unitless.

In the section **Alignment at end** select the **Make spine perpendicular to entities** checkbox to modify the end of the spine curve to become perpendicular to a selection of entities. Use this option to connect the end of the sweep with existing geometry with the addition of the option **Add twisting and scaling to match vertices** in the **Motion of Cross Section** section if the entities do not match up perfectly. With the **Make spine perpendicular to entities** checkbox selected, click the **Active** button to toggle between turning ON and OFF the **Entities to match** selections, then click to select entities in the **Graphics** window or use the Selection List. If **Geometric entity level** is **Edge** or **Point**, then the entities must span a plane. Change the **Adjustment parameter length** (default 0.1) to modify how far along the spine curve the modification propagates. Note that the parameter is dependent on the **Parameterization** setting and either uses the unit of the geometry (for **Arc length**) or is unitless.

INPUT OBJECT HANDLING

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

With the **Keep input objects** checkbox selected, select the **Include all inputs in Form Union/Assembly** checkbox to force the objects in the **Entities to Sweep** and **Edges to follow** lists to be included in the Form Union/Assembly operation. If the **Include all inputs in Form Union/Assembly** checkbox is not selected, these objects are automatically removed in the Form Union/Assembly operation if the **Entities to sweep** list or **Edges to follow** list contains all entities in the objects of the selected dimension.

MOTION OF CROSS SECTION

This section contains a number of properties that determine how the cross section is transformed when swept along the spine curve.

A curve parameter name can be defined in the **Parameter name** field. Use this parameter in the expressions defining scale factor and twist angle. The parameter is increasing along the chain of edges to follow and is dependent on the **Parameterization** setting. This is a local parameter used only for this operation.

Use the **Twisting** setting to control the twisting of the cross section along the sweep:

- Select **None** (default) to let cross sections for nearby points on the spine curve have as small rotation as possible relative to each other. In other words, the cross sections follow a *rotation-minimizing frame*. This makes the edges in the sweep direction locally parallel to the spine curve. This option corresponds to the option **Twist compensation** in earlier versions.
- Select **Follow projection of vector to normal plane** to let the orientation of the cross section be governed by a vector that is defined in the text fields **x**, **y**, and **z** that contain expressions that can depend on the parameter. The cross section will follow the projection of this vector to the spine curve's normal plane. For example, the default vector

(0, 0, 1) means that a vector in the initial cross section that is horizontal (in the xy-plane) will stay horizontal in all cross sections.

- Select **Follow curvature vector** to let the orientation of the cross section be governed by the spine curve's curvature vector (also called the normal vector), that is, the vector pointing toward the center of curvature. The local coordinate system formed by the spine curve's tangent vector, the curvature vector, and the binormal vector is called the *Frenet frame*. It is not uncommon that a curvature vector varies in a wild way, which creates a bad result.

Select the checkbox **Add twisting and scaling to match vertices** to select a vertex in the entity to sweep and to match with a vertex at the end. The additional twisting and scaling varies linearly with the parameter. Use this setting together with the setting **Make spine perpendicular to entities** in the **Spine Curve** section to connect the sweep with existing geometry. Click the **Swap Vertices** button (↕) to swap the vertices in the two lists.

From the **Additional twisting and scaling** section, modify the following settings to add extra scaling and twisting to the cross section. These settings are applied after matching vertices, if active.

The **Scale factor** field controls the size of the cross section, as a function of the parameter.

The **Twist angle** field contains an additional rotation angle for the cross section, as a function of the parameter.

ADVANCED SETTINGS

From the **Geometry representation** list, select **Spline** (the default) to represent the swept object using splines, or **Bézier**, to represent the swept object using Bézier curves. With the option **Bézier** selected, the spine curve is represented by a sequence of many Bézier curves instead of a few spline curves. In addition to the cross section faces that are created between each pair of edges (if **Create cross-sectional faces** is selected), the operation creates cross section edges and vertices corresponding to the swept entities between each pair of adjacent Bézier curves.

The value in the **Relative tolerance** field is a relative tolerance that controls the accuracy of the geometric representation of the swept object. The geometric representation is an approximation, which is necessary because it is not possible to exactly represent a swept object using NURBS (nonuniform rational basis splines). The default value is 10^{-4} (0.01%).

Internally, the software represents the swept object by B-spline curves and surfaces, which are computed to approximate the mathematical definition of the swept surface. The number of knot points in the splines increases automatically until the approximation satisfies the tolerance specified in the **Relative tolerance** field or until it reaches the number of knots specified in the **Maximum number of knots** field (default value: 1000).

If more than one edge is selected in the **Edges to follow** list, the **Direction-defining edge** controls which edge is used to define the positive sweep direction. The **Direction-defining edge** is automatically set when the first edge is added to the **Edges to follow** list, so usually it does not have to be changed manually.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

Tangent

Use a **Tangent** ( ) feature to create a line segment tangential to a specified edges, as shown in Figure 7-70.

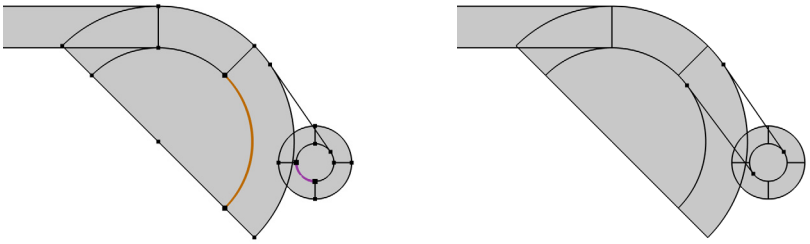


Figure 7-70: Creating a line tangent to the yellow and magenta colored edges (left).

To add a **Tangent** operation, in the **Geometry** (2D) or **Work Plane** (3D) toolbar, click **Tangent** ( ). You can also right-click the **Geometry** node to add this node from the context menu. Then enter the properties of the tangent.

TANGENT

Select the edge you want to tangent in the **Graphics** window. Only one edge can be selected. The edge appears in the **Edge to tangent** list.

Click the **Active** button to toggle between turning ON and OFF the **Edge to tangent** selections.

Parameter start guess is a number between 0 and 1 that specifies where on the edge the expected point of tangency is located. The tangent returned is the first tangent found starting the search from the start guess.

Type of tangent specifies how the endpoint of the tangent is specified. There are three options: **Edge–edge**, **Edge–point**, and **Edge–coordinate**.

When the type is edge–edge, you use the **Graphics** window to select a second edge to tangent. The edge appears in the **Second edge to tangent** box. The line segment created is tangent to both edges. Use **Parameter start guess for second edge** to specify the start guess for the second edge, it is a number between 0 and 1. Click the **Active** button to toggle between turning ON and OFF the **Second edge to tangent** selections.

When the type is edge–point, you use the **Graphics** window to select a point in the geometry as a tangent's endpoint. The point appears in the **Point** list.

When the type is edge–coordinate, manually specify the coordinates of the tangent's endpoint.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry par; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

ASSIGNED ATTRIBUTES

Select the **Construction geometry** checkbox to make the resulting objects available only in the feature's geometry sequence. For more information, see Construction Geometry.

Thicken

Use a **Thicken** ( ) operation to thicken 2D curve objects or edges in the normal direction and thereby convert them to 2D solid objects, as shown in Figure 7-71.

Figure 7-71: The geometry of a rubber boot seal is created by drawing curve (left) and using the Thicken operation to add a thickness to it (right).

To add a **Thicken** operation, in the **Geometry** toolbar (**Work Plane** toolbar when working in the plane geometry sequence of a work plane in 3D), **Conversions** menu click **Thicken** ( ). Then enter the properties of the thicken operation using the following sections:

INPUT

From the **Geometric entity level list**, choose the level of the entities to thicken: **Object** or **Boundary** (that is, edges in 2D). Then select the objects or entities that you want to thicken in the **Graphics** window. The curve objects or edges

appear in the **Input entities** list. If the geometry sequence includes user-defined selections above the **Thicken** node, choose **Manual** to select objects or entities, or choose one of the selection nodes from the list next to **Input entities**.

Click the **Active** button to toggle between turning ON and OFF the **Input entities** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

OPTIONS

Select an **Offset** — **Symmetric** (the default) or **Asymmetric**.

If **Symmetric** is selected enter a **Total thickness**.

If **Asymmetric** is selected enter an **Upside thickness** and a **Downside thickness**.

For symmetric thickening of open ended curves select how the line segments at the ends of the thickened object are generated. From the **Ends** list choose **Straight** (default) to generate straight edges in the normal direction to the input edge, or choose **Circular** to generate circular arcs tangent to the offset edges.

When offsetting edges of convex corners the operation can create new edges by several methods to close the gap that would result otherwise. From the **Convex corner handling** list, choose **Fillet** (default) to add circular arcs that are tangent to both offset edges of convex corners, or choose one of the other available options:

- **Tangent lines**, to create edges, which are tangent to the offset edges in convex corners, up to their intersection point.
- **Extend edges**, to extend the straight and circular offset edges in convex corners until they intersect. Other offset edges are extended by the use of circular arcs with the same tangent and radius of curvature as the offset edge.
- **No connection**, to offset the edges without connecting them together.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input

objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

	The Design Module supports thicken of 3D surface objects.

Union

Use a **Union** ( ) operation to create the union of selected geometry objects, as shown in Figure 7-72.

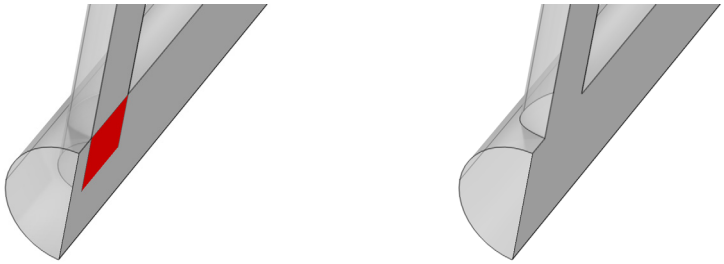

Figure 7-72: Using a Union operation to unite two cylinders of a reactor geometry with the Keep interior boundaries option cleared. A Clip Plane is used to show only half of the geometry with an opaque cross section of the solids. The red color on the cross section indicates an overlap between the two objects.

To add a **Union** operation, in the **Geometry** toolbar, from the **Boolean and Partitions** ( ) menu, select **Union** ( ). You can also right-click the **Geometry** node to add this node from the **Boolean and Partitions** submenu. Then enter the properties of the union operation.

UNION

Select the geometry object that you want to unite in the **Graphics** window. The objects appear in the **Input objects** list. If the geometry sequence includes user-defined selections above the **Union** node, choose **Manual** to select geometry objects, or choose one of the selection nodes from the list next to **Input objects**.

Click the **Active** button to toggle between turning ON and OFF the **Input objects** selections.

Select the **Keep input objects** checkbox to use the selected geometry objects for further geometry operations.

Create a geometry object without interior boundaries by clearing the **Keep interior boundaries** checkbox, as shown in Figure 7-73. This can be useful to simplify a geometry where the interior boundaries do not separate domains with different physics nodes or materials, for example.

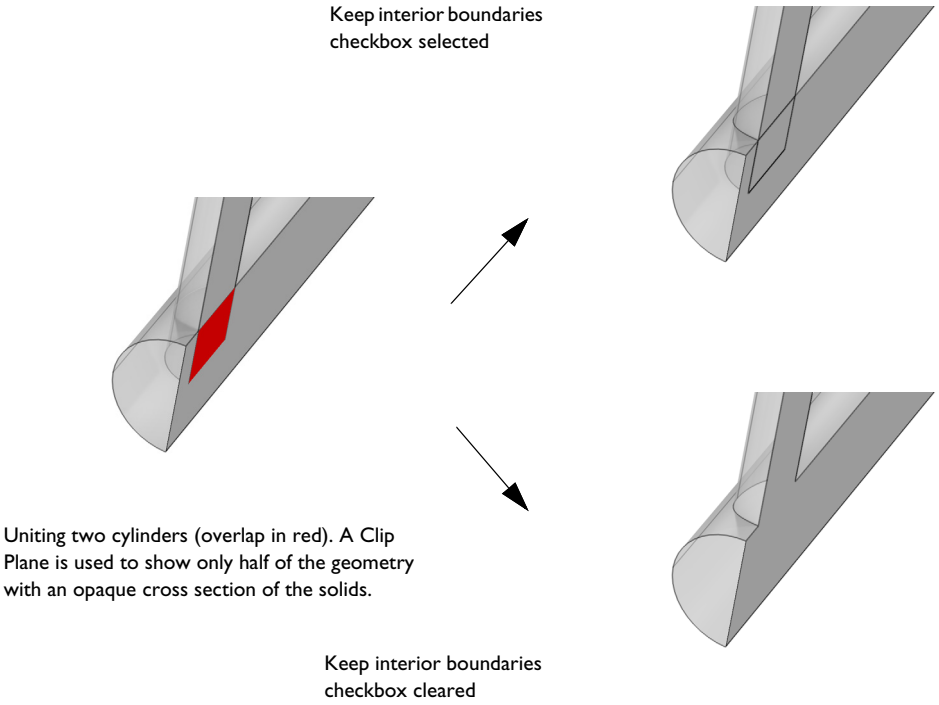

Figure 7-73: Uniting two overlapping cylinders (left) using the Union operation. With the option Keep interior boundaries on, the overlap is creating a separate domain (upper right). Turning off the option, the resulting geometry object contains only one domain (lower right). A clip plane with an opaque cross section is used for viewing purposes.

You can change the settings for the **Repair tolerance** list if you experience problems with the union operation. Geometric entities that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6}.
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, edges, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part; **Show in 3D** in a plane geometry under a work plane in a 3D component) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with

a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Cumulative Selection

If you want to make the resulting entities contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

SELECTIONS ON INPUT OBJECTS

If you have Named Selections that include entities on the input objects, select the **Propagate selections to resulting objects** (selected by default) checkbox to update the selections to corresponding entities on the output objects, when possible. Clear the checkbox to not propagate the selection to the resulting objects. This can be useful in combination with selecting the **Keep input objects** checkbox so that the selections refer only to the input objects.

ASSIGNED ATTRIBUTES

From the **Construction geometry** list choose **On** to make the resulting objects available only in the feature's geometry sequence. The default option **Inherit** means that the resulting objects become construction geometry if all input objects are construction geometry. Choose **Off** to never output construction geometry objects. For more information, see Construction Geometry.

- Partition Edges

Work Plane

To create a work plane for defining 2D objects in 3D (for example, for extruding a 2D object into a 3D object) or for defining the placement of the resulting objects of a Part Instance, in the **Geometry** toolbar, click **Work Plane** ( ) or right-click a 3D **Geometry** node and select **Work Plane**. Then enter the properties defining the location of the work plane in the following sections of its **Settings** window.

Using Work Planes

PLANE DEFINITION

Plane Type

The layout of the **Work Plane** section depends on the selection in the **Plane type** list, where you select how to define the work plane. Choose one of the following types:

- Quick (the default)
- Face parallel
- Edge parallel
- Edge angle
- Circle perpendicular
- Normal vector
- Vertices
- Coordinates
- Transformed

Quick

In the **Plane** list, select one of the global coordinate planes *xy*, *yz*, *zx*, *yx*, *zy*, or *xz*, denoting the first and second axes of the work plane's local coordinate system. Specify an offset using one of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance from the coordinate plane in the third axis' direction using the **z-coordinate**, **x-coordinate**, or **y-coordinate** field (default value: 0; that is, no offset).
- **Through vertex** to define the position of the work plane in the third direction by selecting a vertex. The work plane's position then contains that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset vertex** selections.

Face parallel

Select a planar face in the **Graphics** window that is parallel to the work plane you want to create with the **Planar face** list set to **Manual**, or choose any applicable geometry object or selection. The list below then shows the selected face. Click the **Active** button to toggle between turning ON and OFF the **Planar face** selections. Specify an offset using one of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance in the **Offset in normal direction** field. You then offset the work plane along the normal of the planar face. By default, the work plane's normal is the outward normal of the face in the **Planar face** list. The default value: 0; that is, no offset.
- **Through vertex** to define the position of the work plane in the third direction by selecting a vertex. The work plane's position then includes the position of that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset vertex** selections.

To reverse the direction of the *z*-axis of the work plane's coordinate system, select the **Reverse normal direction** checkbox. This also swaps the coordinate axes in the work plane to preserve the positive orientation of the local coordinate system.

Edge parallel

Select a planar edge (that is not straight) in the **Graphics** window that is parallel to the work plane you want to create with the **Planar curved edge** list set to **Manual**, or choose any applicable geometry object or selection. The list below then shows the selected edge. Click the **Active** button to toggle between turning ON and OFF the **Planar curved edge** selections.

Specify an offset using one of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance in the **Offset in normal direction** field. You then offset the work plane along the normal of the plane containing the edge. The default value: 0; that is, no offset.
- **Through vertex** to define the position of the work plane in the third direction by selecting a vertex. The work plane's position then includes the position of that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset vertex** selections.

To reverse the direction of the z-axis of the work plane's coordinate system, select the **Reverse normal direction** checkbox. This also swaps the coordinate axes in the work plane to preserve the positive orientation of the local coordinate system.

Edge angle

Activate the **Straight edge** list by first selecting its **Active** button and then select a straight edge with the **Straight edge** list set to **Manual**, or choose any applicable geometry object or selection. The list below then shows the selected edge. Similarly, activate the **Face adjacent to edge** list by first clicking its **Active** button and then select an adjacent face in the **Graphics** window or from the list. Also, specify a value in the **Angle between face and work plane** field (in degrees; the default value is 0). This results in a work plane through the given edge that makes the specified angle with the adjacent face.

By default, the origin of the local coordinate system coincides with the edge's end vertex, and the direction of the local x-axis is opposite to the direction of the edge. If you select the **Reverse normal direction** checkbox, the origin instead is at the start vertex, and the direction of the local x-axis coincides with the direction of the edge.

Circle perpendicular

Activate the **Circular edge** list by clicking its **Active** button. Then select a circular edge in the **Graphics** window. This results in a work plane perpendicular to the given circular edge. Use the **Point on plane** list to choose a vertex that the plane should go through:

- The edge's **Start vertex** (the default)
- The edge's **End vertex**.
- Some **Other verte**x, which you can choose from the **Vertex** list that opens.

You can then rotate the work plane around the normal direction of the circle's plane by specifying an **Angle offset** (in degrees; default value: 0 degrees). You can also reverse the work plane's normal direction using the **Reverse normal direction** checkbox.

The origin of the local coordinate system is at the circle's center. The local x-axis goes through the circle. Thus, if the geometry is rotationally symmetric, the symmetry axis coincides with the local y-axis. You can use this type of work plane together with a **Cross Section** node to get a 2D axisymmetric geometry corresponding to a rotationally symmetric 3D geometry.

Normal vector

Use this work plane type to orient an object so that one of its planar faces gets a prescribed normal vector.

Under **Normal vector**, in the **x**, **y**, and **z** fields (SI unit: m), enter the components of the normal vector.

Under **Point on plane**, from the **Specify** list, choose **Coordinates** (the default) or **Vertex**. For **Coordinates**, enter the coordinates for a point on the plane in the **x**, **y**, and **z** fields (SI unit: m). For **Vertex**, select a vertex in the geometry, or if available, use a user-defined vertex selection.

Vertices

In each of the lists **First vertex**, **Second vertex**, and **Third vertex**, select a vertex by first clicking the corresponding **Active** button and then selecting a vertex in the **Graphics** window. This creates a work plane parallel to a plane through the three vertices.

Specify an offset in the **Offset in normal direction** field (default value: 0; that is, no offset). The origin of the local coordinate system is located above the first vertex, and the vector to the second vertex becomes the local x-axis. Reverse the directions of the local z-axis and y-axis by selecting the **Reverse normal direction** checkbox.

Coordinates

This choice creates a work plane through the three points with the given coordinates. The origin of the local coordinate system coincides with **Point 1**. The x-axis of the local coordinate system is in the direction of the vector from **Point 1** to **Point 2**. The positive direction of the y-axis is determined by the condition that the vector from **Point 1** to **Point 3** has a positive y-component.

Transformed

Use the work plane type to create a work plane using a transformation of another work plane. From the **Take work plane from** list, select **This sequence** (the default) to use a work plane earlier in the same geometry sequence, or choose a part instance earlier in the sequence to choose a work plane from that part. From the **Work plane to transform** list, select an available work plane (for example, **Work Plane 1**) from the selected geometry sequence or select **xy-plane** (the default).

Under **Displacement**, enter the desired displacements in the work plane's x, y, and z directions in the **xw**, **yw**, and **zw** fields, respectively. The defaults are 0 (that is, no displacement). The displacements are specified in the local coordinate system of the input work plane before the rotation (below) is applied.

Under **Rotation**, from the **Specify** list, choose **Axis of rotation** (the default, **Euler angles (Z-X-Z)**, or **Edge** as the way to specify the rotation.

- For **Axis of rotation**, select an **Axis type**: **xw-axis**, **yw-axis**, **zw-axis** (the default), **Cartesian**, or **Spherical**. For any choice, enter an **Angle** (SI unit: degrees; default 0) to specify the rotation (see *2D Settings* above). If **Cartesian** is selected, enter Cartesian coordinates values for **x**, **y**, and **z** (default values 0, 0, and 1, respectively, corresponding to the global z-axis) to specify the axis vector. If **Spherical** is selected, specify the axis vector using spherical angles **theta** and **phi** in degrees (default: 0).
- For **Euler angles (Z-X-Z)**, enter values for the intrinsic Z-X-Z Euler angles α, β, and γ in the corresponding text fields (in degrees; the default values are 0).
- For **Edge**, choose a straight edge as the axis of rotation and add it to the **Straight edge** list. For **Edge**, select a straight edge in the **Graphics** window by first enabling the selection in the **Straight edge** list. Using a preselection, you can add it using the **Add to Selection** button ( ). Use the **Clear Selection** button ( ) to remove the selected straight edge and the **Zoom to Selection** button ( ) to zoom into the selected straight edge.

Enter an **Rotation angle** (SI unit: degrees; default 0) to specify the rotation angle for the transformation.

LOCAL COORDINATE SYSTEM

In this section you specify the local coordinate system in the work plane for most work plane types.

In the **Quick** work plane type:

- In the **Origin** list, choose the location of the origin of the work plane's coordinate system: **Global** (the default) or **Vertex projection**. In the latter case, also pick a vertex for the origin, which you add to the list under **Vertex for origin** (manually or by choosing an applicable geometry object or selection).
- In the **Local x-axis** list, choose how to define the local x-axis: **Natural** (the default), which means that the local x-axis corresponds to the first direction in the plane; for example, the y direction for a yz-plane. Alternatively, choose **Through vertex projection** to define the local x-axis through a vertex projection. Then choose a vertex for the local x-axis that you add to the **Vertex for axis** list (manually or by choosing an applicable geometry object or selection).

In the **Face parallel** plane type:

- In the **Origin** list, choose the location of the origin of the work plane's coordinate system: **Center of face** (the default), **Bounding box corner**, or **Vertex projection**. In the last case, choose a vertex for defining the origin that you add to the **Vertex for origin** list.
- In the **Local x-axis** list, choose how to define the local *x*-axis: **First parameter direction** (the default) or **Second parameter direction**, which are the local parameter directions of the face (represented by the variables `s1` and `s2`, respectively). Alternatively, choose **Through vertex projection** to define the local *x*-axis through a vertex projection. Then choose a vertex for the local *x*-axis that you add to the **Vertex for axis** list.

In the **Edge parallel** plane type:

- In the **Origin** list, choose the location of the origin of the work plane's coordinate system: The **Start vertex** (the default) or **End vertex** of the edge, or **Vertex projection**. In the last case, choose a vertex for defining the origin that you add to the **Vertex for origin** list.
- In the **Local x-axis** list, choose how to define the local *x*-axis: **Tangent direction** (the default), which means that the local *x*-axis follows the direction of the edge's tangent. Alternatively, choose **Through vertex projection** to define the local *x*-axis through a vertex projection. Then choose a vertex for the local *x*-axis that you add to the **Vertex for axis** list.

In the **Quick**, **Face parallel**, **Edge parallel**, **Edge angle**, **Circle perpendicular**, **Normal vector**, and **Vertices** work plane types:

- Enter displacements within the plane in the **xw-displacement** and **yw-displacement** fields if you want to move the origin of the local coordinate system. The displacements are specified in the original local coordinate system, before the rotation angle (below) is applied. The defaults are 0.
- Enter a rotation angle in the **Rotation** field if you want to rotate the local coordinate system. The default is 0 degrees; that is, no rotation. In the **Normal vector** case, the default `yw`-axis goes in the direction (–`ny`, `nx`,0), where (`nx`, `ny`, `nz`) is the given normal vector, except if the plane is parallel with the *xy*-plane, in which case the direction is (0, 1, 0).

The **Show in graphics** checkbox is selected by default to display the local coordinate system. Clear this checkbox to remove the display of the local coordinate system.

UNITE OBJECTS

By default, the COMSOL Multiphysics software unites all objects in the 2D work plane, which can make it easier to, for example, extrude the 2D geometry into a 3D geometry object. This checkbox also determines which finalization node will be automatically added if you select to add a virtual operation to the work plane sequence. When **Unite objects** is selected, a **Form Union** node will be added by default and when it is cleared, a **Form Assembly** node will be added by default.

Clear the **Unite objects** checkbox if you do not want to unite the separate 2D geometry objects in the work plane. If **Unite objects** is selected, you can change the settings for the **Repair tolerance** list if you experience problems with the unite operation. Objects that have a distance less than the repair tolerance are merged.

- The default value in the **Repair tolerance** list is **Automatic**, which for 3D objects represented using the CAD kernel determines the repair tolerance internally. For 3D objects represented using the COMSOL kernel, and for 2D and 1D objects, **Automatic** means a relative repair tolerance of 10^{-6}.
- Choose **Relative** to enter a value for the **Relative repair tolerance** field (the default is determined by the main **Geometry** node's setting). This value is relative to the largest absolute value of the coordinates of all input objects.
- Choose **Absolute** to enter a value for the **Absolute repair tolerance** field (the default is determined by the main **Geometry** node's setting; SI unit: m). This value uses the same unit as the geometry sequence's length unit.

When you build this feature, the relative and absolute repair tolerances are set to the values that are used (with a precision of two digits), which can be useful when you have set **Repair tolerance** to **Automatic**.

PART INSTANCES

This section is only available for work planes in geometry parts.

Select the **Show work plane in instances** checkbox (selected by default) to make the work plane available in the **Part Instance** nodes' settings.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting objects selection** checkbox to create predefined selections (for all levels — objects, domains, boundaries, and points — that are applicable) in subsequent nodes in the geometry sequence. To also make all or one of the types of resulting entities (domains, boundaries, edges, and points) that the resulting objects consist of available as selections in all applicable selection lists (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show in instances** if in a geometry part) list: **All levels**, **Object selection** (in geometry parts only), **Boundary selection**, **Edge selection**, or **Point selection**. The default is **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. Select **Off** to not make any selection available outside of the geometry sequence. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors.

Under **Selections from plane geometry**, select the **Show in physics** (**Show in instances** if in a geometry part) checkbox to show selections from the work plane's plane geometry in the physics or in part instances. For example, a selection in the plane geometry can be used as the boundaries for a boundary condition in the 3D physics.

Cumulative Selection

If you want to make the resulting entities that the 2D geometric objects in the work plane consist of contribute to a cumulative selection, select a cumulative selection from the **Contribute to** list (the default, **None**, gives no contribution), or click the **New** button to create a new cumulative selection (see Cumulative Selections).

ASSIGNED ATTRIBUTES

Select the **Construction geometry** checkbox to make the resulting objects available only in the feature's geometry sequence. For more information, see Construction Geometry.

DRAWING IN THE WORK PLANE

To go to the planar geometry, click the **Go to Plane Geometry** button ( ) in the **Settings** window's toolbar, or click the **Plane Geometry** node that appears under the **Work Plane** node. To create 2D objects in the work plane, right-click in the **Graphics** window, select a primitive, and start drawing using the Sketch drawing tools. Option to add virtual operations to simplify the 2D geometry before going to 3D.

For a tutorial using the 2D Sketch drawing tools, see *Light Bulb Geometry*: Application Library path **COMSOL_Multiphysics/Geometry_Tutorials/light_bulb_geometry**.

EMBEDDING THE WORK PLANE IN THE 3D GEOMETRY

To embed the 2D work plane geometry in the 3D geometry, build the Work Plane feature by either right-clicking the **Work Plane** node and choosing **Build Selected** or selecting the **Work Plane** node and then clicking **Build Selected** or **Build All Objects**.

Virtual Geometry and Mesh Control Operations

VIRTUAL GEOMETRY OPERATIONS

For a 2D, 3D, work plane and geometry part (2D and 3D) sequences, you can add *virtual geometry operations* and *mesh control operations* after the **Form Union/Assembly** node to, for example, remove small details from the geometry and to prepare it for efficient meshing and analysis. Mesh control operations are not available in work plans and in parts. The geometry sequence before the **Form Union/Assembly** node defines the "real" (original) geometry. The geometry resulting from a virtual operation or a mesh control operation is referred to as a *virtual geometry*.

Use the **Remove Details** feature to automatically remove small details from the 3D geometry.

These virtual operations are available from the **Geometry** toolbar, **Virtual Operations** menu ():

TABLE 7-14: VIRTUAL OPERATIONS FOR 2D AND 3D MODELS.

ICON	NAME	DESCRIPTION
	Remove Details	Remove details from the geometry automatically or by adding virtual subfeatures (3D only)
	Ignore Edges	Virtually remove isolated edges or edges adjacent to precisely two faces or between two domains
	Ignore Faces	Virtually remove isolated faces or faces between two domains (3D only)
	Ignore Vertices	Virtually remove isolated vertices or vertices adjacent to precisely two edges
	Form Composite Domains	Form virtual composite domains from sets of connected domains by ignoring the boundaries between the domains in each set
	Form Composite Edges	Form virtual composite edges from sets of connected edges by ignoring the vertices between the edges in each set
	Form Composite Faces	Form virtual composite faces from sets of connected faces by ignoring the edges between the faces in each set (3D only)
	Collapse Edges	Virtually collapse each edge into a vertex by merging its adjacent vertices
	Collapse Faces	Virtually collapse faces into edges or vertices by merging their adjacent opposite edges or collapsing all adjacent edges
	Collapse Face Regions	Virtually detect and collapse regions of faces narrower than a specified size
	Merge Edges	Virtually merge opposite edges adjacent to a face
	Merge Faces	Virtually merge opposite faces
	Merge Vertices	Virtually merge one adjacent vertex of an edge with the other adjacent vertex

MESH CONTROL OPERATIONS

The following mesh control operations are available from the **Geometry** > **Virtual Operations** menu ( ) and can be used to include ignored geometric entities for mesh control purposes to, for example, control the element sizing in a part of a domain:

TABLE 7-15: MESH CONTROL OPERATIONS.

ICON	NAME	DESCRIPTION
	Mesh Control Domains	To select domains for mesh control only.
	Mesh Control Edges	To use isolated edges, or edges adjacent to precisely two domains (in 2D) or two faces (in 3D), only for mesh control.
	Mesh Control Faces	To use isolated faces, or faces between two 3D domains, only for mesh control.
	Mesh Control Vertices	To use isolated vertices, or vertices adjacent to precisely two edges, only for mesh control.

Collapse Edges

The operation collapses an edge by removing it, merging its adjacent vertices to one, and reconnecting the adjacent edges to the *merged vertex*. Which vertex to keep is determined by geometrical criteria, but is typically the one with the most ingoing edges. All edges in the geometry must have distinct start and end points. The software will ensure this by not collapsing an edge if that would introduce edges that fail to meet the requirement.

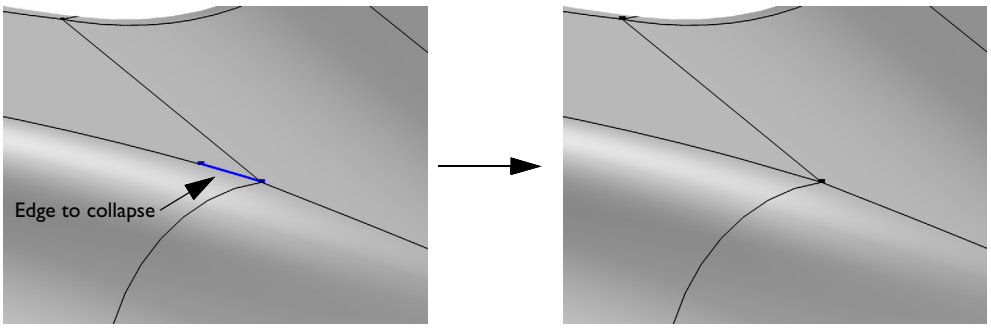

Figure 7-74: A short edge, highlighted in blue, which is collapsed into the vertex to the right, where four edges are connected.

For more control over which vertex to keep, refer to Merge Vertices. An alternative is to use the Ignore Vertices operation. The Remove Details operation provides a fully automated way to find and remove short edges within the whole geometry or a selection of entities.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Collapse Edges** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to collapse in the **Graphics** window. These then appear in the **Edges to collapse** list. If the geometry sequence includes user-defined selections above the **Collapse Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to collapse**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to collapse** selections.

Select the **Ignore merged vertices** checkbox to ignore the resulting merged vertices. A vertex can be ignored if there are exactly two edges connected to the it.

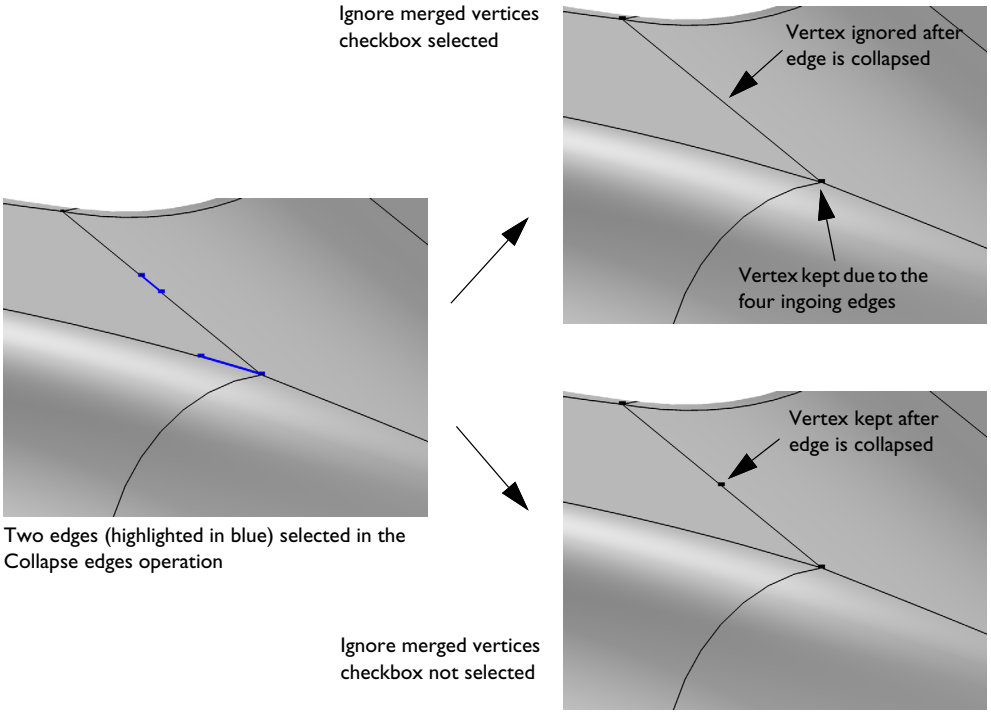

Figure 7-75: Two edges, highlighted in blue, to be collapsed. Leaving the Ignore merged vertices checkbox selected will ensure that resulting vertices are ignored (indicated by top arrow in upper right image). However, if there are more than two ingoing edges, the vertex will always be kept (bottom arrow in upper right image). If the Ignore merged vertices is cleared, all vertices are kept after the operation is built (indicated with arrow in the bottom right image).

- Merge Vertices
- Ignore Vertices
- Remove Details

Collapse Faces

The operation collapses a face by removing it, merging its adjacent opposite edges or collapsing all adjacent edges, and reconnecting the adjacent faces to the resulting merged edges. A small face with sides of similar length will typically be collapsed into a vertex, while a sliver face is more often collapsed into an edge, as shown in Figure 7-76.

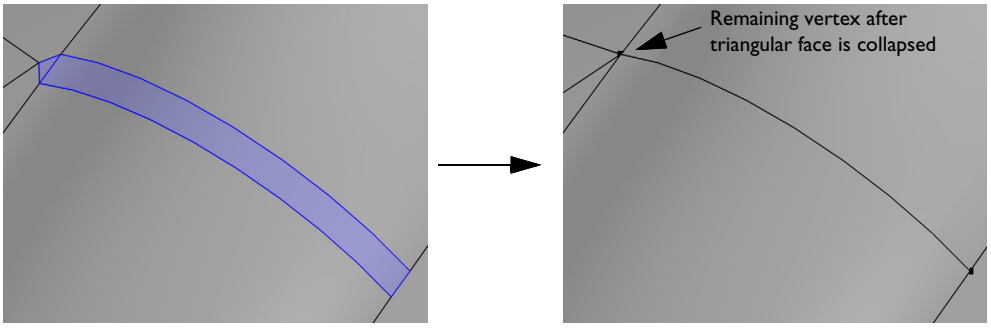

Figure 7-76: Collapsing two faces, highlighted in blue. The smaller triangular face is collapsed into a vertex (indicated with arrow in the right image) while the rectangular face is collapsed into the upper of its two longer edges.

Which edge to keep is decided based on geometrical and topological criteria. For example, if the tangent is continuous for two faces over an edge, that edge is more likely to be removed than one with noncontinuous tangent.

It is recommended to use this operation to remove faces that are significantly smaller or narrower than the desired local mesh element size. For more control over which edge to keep, refer to the Merge Edges operation. An alternative is to use the Ignore Edges operation. The Remove Details operation provides a fully automated way to detect and remove small and sliver faces within the whole geometry or a selection of entities.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Collapse Faces** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to collapse in the **Graphics** window. They then appear in the **Faces to collapse** list. If the geometry sequence includes user-defined selections above the **Collapse Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to collapse**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to collapse** selections.

Select the **Ignore merged entities** checkbox to ignore the resulting merged edges or vertices (if possible). A vertex will be kept if there are more than two edges connected to the vertex.

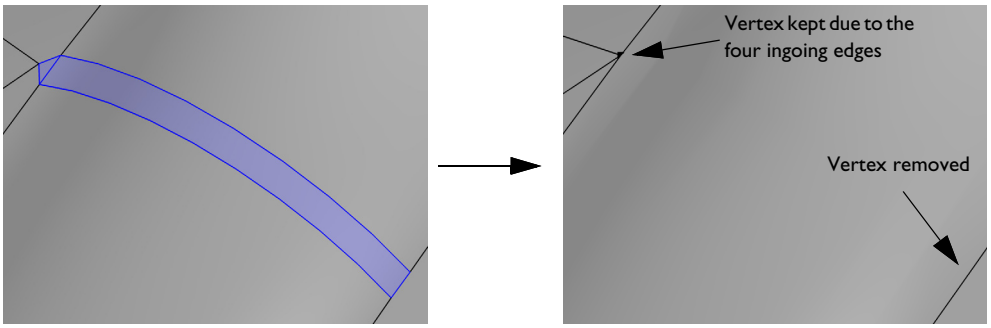

Figure 7-77: Collapsing the same two faces, highlighted in blue, as in Figure 7-76*, but this time with the checkbox Ignore merged entities selected. The small triangular face is still collapsed into a vertex (indicated by the upper-left arrow in the image to the right). As there are more than two ingoing edges into this vertex, it is kept. The rectangular face is collapsed into the upper of the two longer edges, which is then ignored. Note that the vertex on the edge in the lower-right corner has been ignored as there are only two ingoing edges (position indicated by lower-right arrow).*

The **Collapse to vertex tolerance** controls if a sliver face is collapsed into an edge or a vertex. By default, it is set to **Automatic**. The default tolerance used is 0.001 times the length of the longest edge of the geometry's bounding box. For more control, select **Manual** to enter a value in the **Maximum face perimeter** field that appears. The default value is 0.001. This tolerance is the maximum perimeter of a face to be collapsed into a vertex. If you build the operation with **Automatic** and then switch to **Manual**, the **Maximum face perimeter** field shows the value of the parameter that was used when the operation was built.

In the case of a face being collapsed into a vertex, it is typically collapsed into the vertex with the most ingoing edges. If that number is the same for all vertices, the face is collapsed to the vertex with the lowest index. With the default **Automatic** setting a sliver face is more likely to be collapsed into an edge, in which case the tolerance value

is set to a value smaller than the face perimeter. For a face that is collapsed to a vertex the tolerance value is larger than the face perimeter.

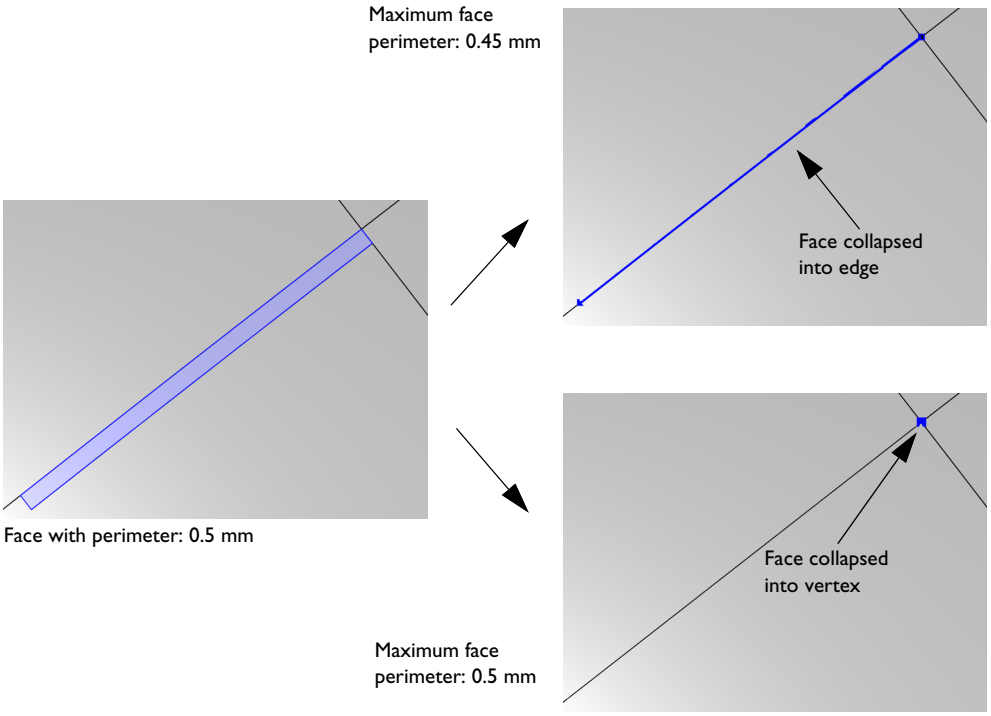

Figure 7-78: The face is collapsed into an edge when the Maximum face perimeter tolerance is set to 0.45 mm. With the tolerance set to 0.55, mm the face is collapsed into a vertex.

- Ignore Edges
- Form Composite Faces
- Merge Edges
- Remove Details

Collapse Face Regions

The **Collapse face regions** operation detects and removes narrow regions for a selection of faces. Narrow face regions is often the result of two edges meeting at a very sharp angle (see Figure 7-79) and may cause mesh refinements or even meshing failure. The operation detects narrow regions based on a specified width tolerance. To remove a narrow regions, the edges adjacent to it are first partitioned by creating vertices. Then, an edge with a length

according to the tolerance is created between the vertices to partition the face. Lastly, the sliver face created by the partitioning is collapsed into an edge, which leaves the original face with a less narrow region.

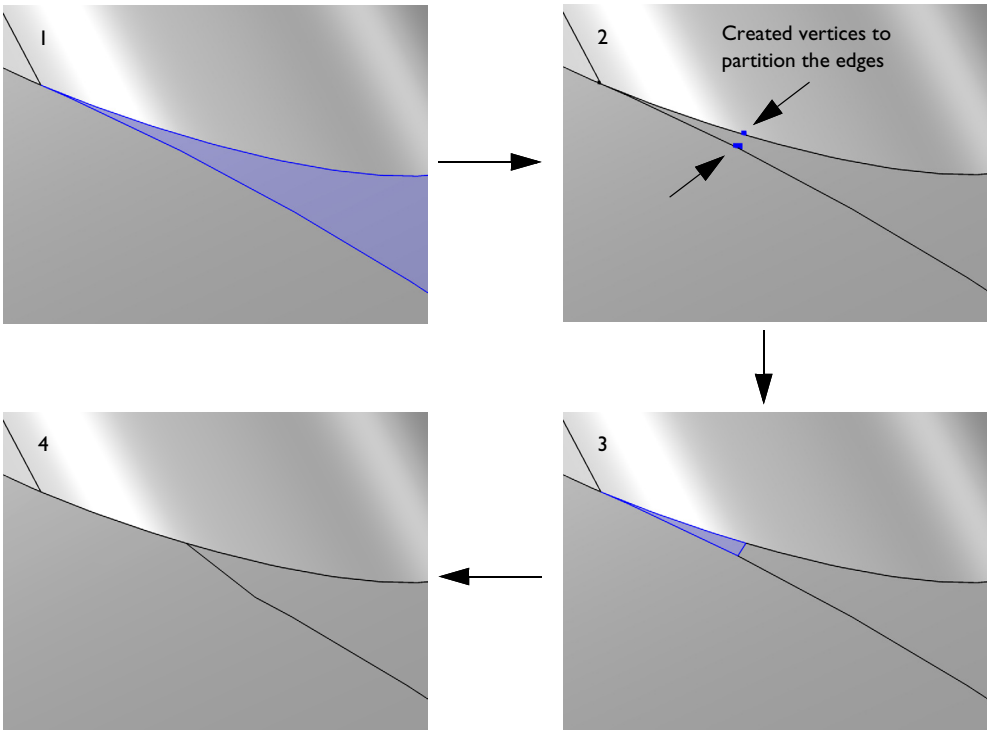

Figure 7-79: 1. The narrow region on the selected face occurs where two of the edges meet at a very sharp angle. 2. Based on a tolerance, the narrow region is detected and vertices are created to partition the edges. 3. The original face is partitioned by adding an edge between the vertices to isolate the narrow region of the face, highlighted in blue. 4. The newly created face is collapsed into one of its longer edges, thereby removing the narrow region.

In some cases, an alternative to collapsing a narrow face region could be to remove the edges that cause the narrow region by using the Ignore Edges operation. The Remove Details operation provides a fully automated way to find and remove narrow regions within a selection of boundaries or boundaries adjacent to a selection of domains.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Collapse Face Regions** ( ). You can also select it from the **Geometry** node's context menu's **Virtual Operations** submenu.

Enter the properties of the operation using the following sections:

INPUT

Select the faces for which you want to collapse narrow face regions in the **Graphics** window. They then appear in the **Faces** list. If the geometry sequence includes user-defined selections above the **Collapse Face Regions** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces**.

Click the **Active** button to toggle between turning ON and OFF the **Faces** selections.

The **Narrow regions tolerance** controls how much of a narrow region to collapse. By default, it is set to **Automatic**. The default tolerance used is 0.001 times the length of the longest edge of the geometry's bounding box. For more control, select **Manual** to enter a value in the **Maximum width** field that appears. The default value is 0.001. The tolerance is the maximum width of a face region to be considered as narrow. If you build the operation with **Automatic** and then switch to **Manual**, the **Maximum width** field shows the value of the parameter that was used when

the operation was built. A larger **Maximum width** will detect wider regions than a smaller value. It will also collapse a larger portion of the face, as shown in Figure 7-80.

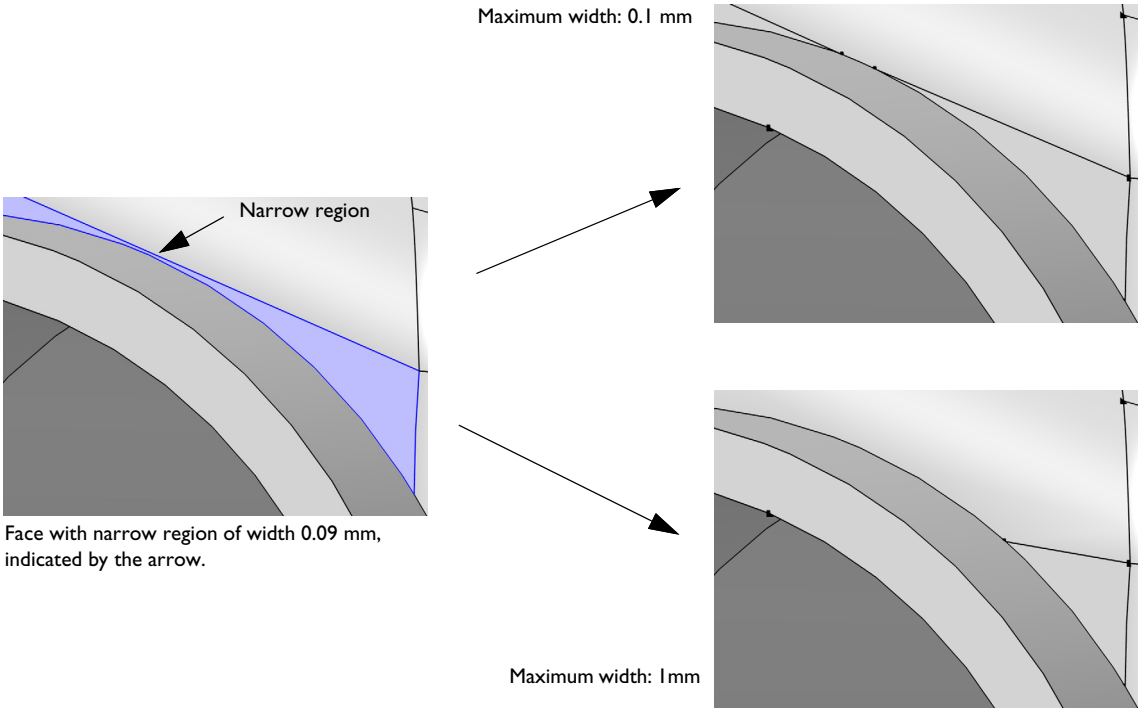

Figure 7-80: Collapsing a narrow face region with a smaller Maximum width value will keep a larger portion of the narrow region (upper-right image) while using a larger value for the Maximum width will remove more of the narrow region (lower-right image).

- Collapse Faces
- Ignore Edges
- Ignore Faces
- Merge Edges
- Remove Details

Form Composite Domains

The operation forms a composite domain for each connected domain component of the selected domains by ignoring the boundaries between the domains., see Figure 7-81. This means that it is possible to include several nonconnected groups of domains in the same operation.

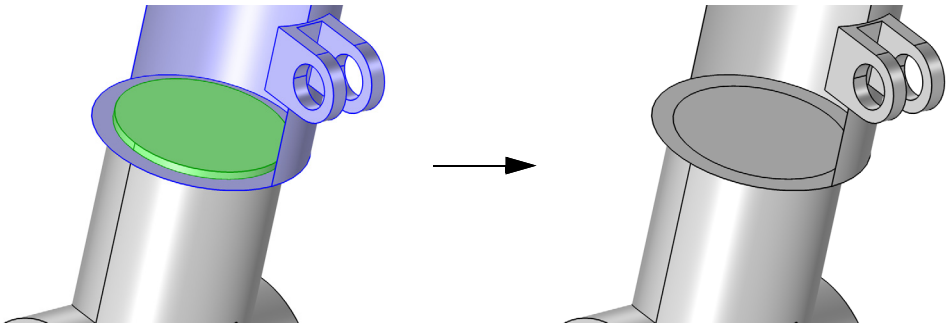

Figure 7-81: An object that extends into another object results in a thin disk-shaped domain, highlighted in green, after Form Union. By forming a composite domain the thin domain becomes part of one of its neighbors, in this case the domain highlighted in blue. Note that one face is hidden for better visibility.

Thin domains can require a very fine mesh to be well resolved. Forming a composite domain of the thin domain with a neighboring domain will remove the thin domain and therefore the need for a fine mesh. The same result can be achieved by using the Ignore Faces (3D) and Ignore Edges (2D). The Remove Details operation provides a fully automated way to find and remove thin and small domains.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Form Composite Domains** (or). Then enter the properties of the operation using the following sections:

INPUT

Select the domains that you want to composite in the **Graphics** window. They then appear in the **Domains to composite** list. If the geometry sequence includes user-defined selections above the **Form Composite Domains** node, choose **Manual** to select domains, or choose one of the selection nodes from the list next to **Domains to composite**.

Click the **Active** button to toggle between turning ON and OFF the **Domains to composite** selections.

Use the **Ignore adjacent vertices** (2D) or **Ignore adjacent edges and vertices** (3D) checkbox (default selected) to also remove the ignorable vertices (and edges in 3D) on the boundary of each resulting composite domain. In 3D, clearing the checkbox leaves edges and vertices adjacent to the faces that have been removed.

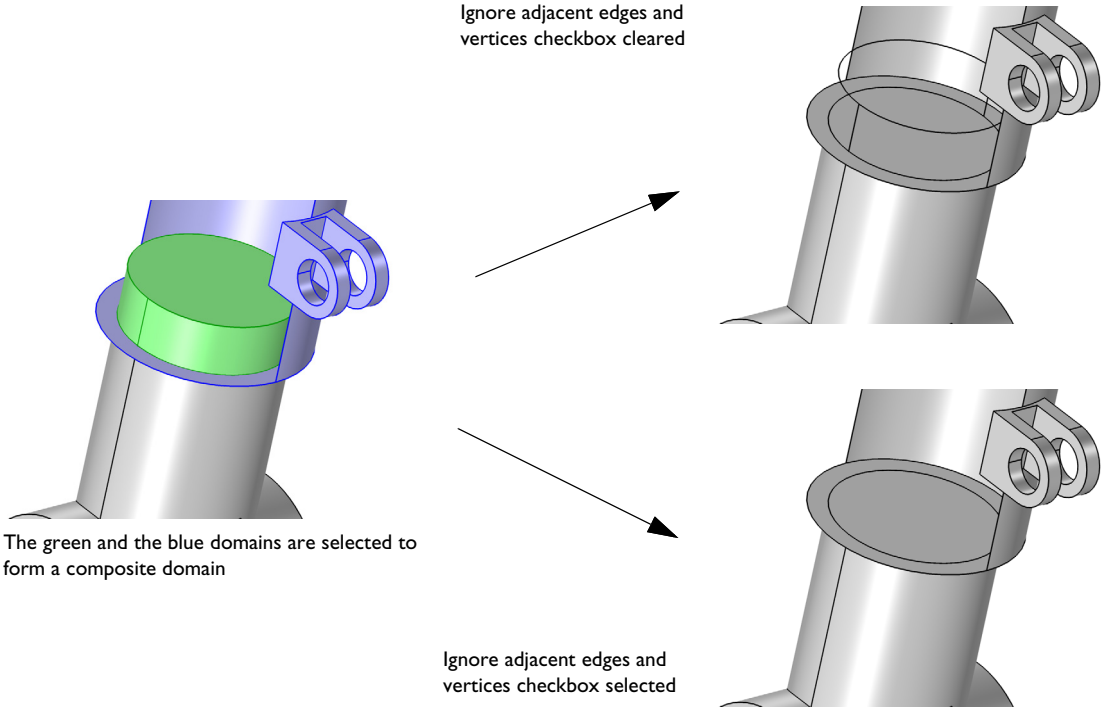

Figure 7-82: Forming a composite domain of the domains highlighted in green and blue. Note that one face of the blue domain is hidden for visibility. With the Ignore adjacent edges and vertices checkbox cleared the edges and vertices of the ignored faces are kept inside the geometry (upper-right image). With this checkbox selected the edges and vertices are automatically removed (lower-right image).

MESH CONTROL

Use the **Keep input for mesh control** checkbox to specify that the selected domains are composed in the geometry but are available individually when you build the mesh. This gives you more control of the meshing. A well partitioned geometry is more efficient to mesh and can, for example, make it possible to create a high quality hexahedral mesh through the sweep operations. See also Mesh Control Domains.

- Ignore Edges
- Ignore Faces
- Remove Details

Form Composite Edges

The Form composite edges operation forms a *composite edge* for each connected edge component of the selected edges by ignoring the vertices between the edges, as shown in Figure 7-83. This means that it is possible to include several nonconnected groups of edges in the same operation. A vertex is only ignored if there are two edges connected to the vertex. All edges in the geometry must have distinct start and end points. the software will ensure this by preserving or inserting extra vertices, if necessary.

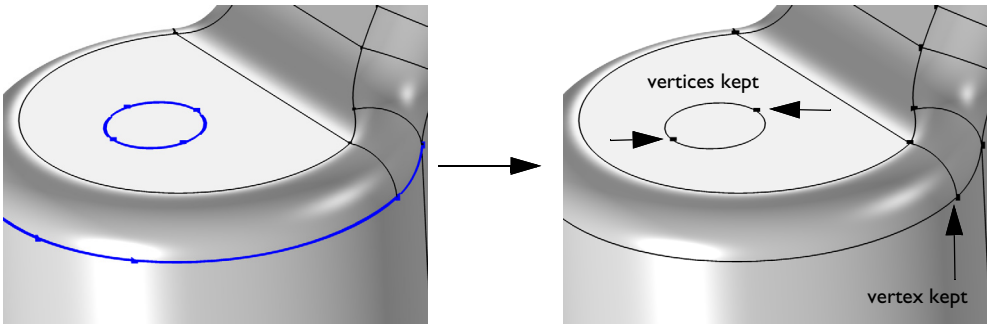

Figure 7-83: Forming composite edges will ignore the vertices between the edges highlighted in blue. The image on the right hand side shows the result after the operation is built. The two vertices (indicated by horizontal arrows) on the shorter circular edges are kept to ensure that the resulting edges have distinct start and end points. The vertex (indicated by the vertical arrow) along the longer circular edges is kept as there are more than two ingoing edges.

Removing vertices gives the mesh algorithm more freedom. A geometry vertex needs to be respected when creating a mesh, which may put unwanted constraints on the mesh if there are unnecessary vertices. Alternative operations to use are Collapse Edges, Ignore Vertices, and Merge Vertices. The Remove Details operation provides a fully automated way to create composite edges.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Form Composite Edges** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to composite in the **Graphics** window. They then appear in the **Edges to composite** list. If the geometry sequence includes user-defined selections above the **Form Composite Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to composite**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to composite** selections.

MESH CONTROL

Use the **Keep input for mesh control** checkbox to specify that the selected edges are composed in the geometry but the vertices are available individually when you build the mesh. See also Mesh Control Vertices.

- With the CFD Module and the Chemical Reaction Engineering Module, see *Syngas Combustion in a Round-Jet Burner*: Application Library path **CFD_Module/Nonisothermal_Flow/round_jet_burner**

	• Collapse Edges • Ignore Vertices • Merge Vertices • Remove Details

Form Composite Faces

The operation forms a composite face for each connected face component (of manifold type) of the selected faces by ignoring the edges between the faces, as shown in Figure 7-84. By default, the vertices adjacent to the ignored edges are also ignored to form composite edges. It is possible to include several nonconnected groups of faces in the same operation, as seen below.

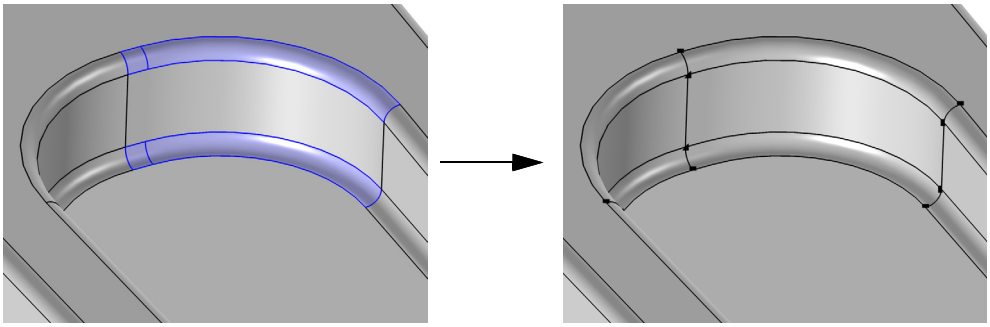

Figure 7-84: Forming composite faces of the selected faces highlighted in blue. As seen in the image to the left, it is possible to select several nonconnected groups of faces in the same Form composite faces operation.

For faces that are significantly smaller or narrower than the desired local mesh element size, it is recommended to use Collapse Faces. It is also recommended to keep edges in sharp corners of importance to the result. When a composite face is meshed, all mesh vertices are located on the face, but there is no guarantee that there will be mesh

vertices on the ignored edge. For example, forming a composite face of two planar faces in a 90 degree angle, some of the created triangular elements may not coincide with any of the original faces, as shown below.

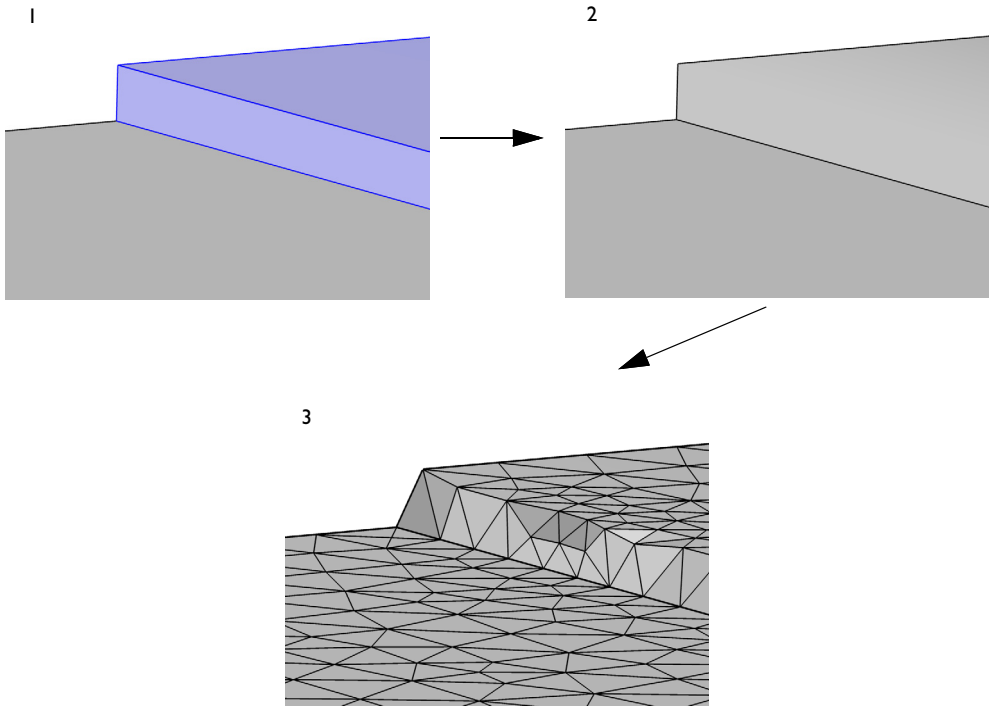

Figure 7-85: Possible effect of removing an edge in a sharp corner. 1. Two faces positioned in a 90 degree angle are selected (highlighted in blue) as input to the Form Composite Faces operation. 2. Resulting geometry after the edge connecting the two faces is removed. 3. This has the effect that the mesh elements do not have to respect this sharp corner, as shown here.

Tidying up a geometry to remove small and narrow faces gives the mesh algorithm more freedom to create a good quality mesh. An alternative is to use the Ignore Edges and Collapse Faces operations. The Remove Details operation provides a fully automated way to find sliver faces and form composite faces.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Form Composite Faces** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to composite in the **Graphics** window. They then appear in the **Faces to composite** list. If the geometry sequence includes user-defined selections above the **Form Composite Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to composite**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to composite** selections.

Use the **Ignore adjacent vertices** checkbox to also remove the ignorable vertices on the boundary of each resulting composite face. Keeping the adjacent vertices preserves the edge partitioning while forming composite faces, as shown in Figure 7-86.

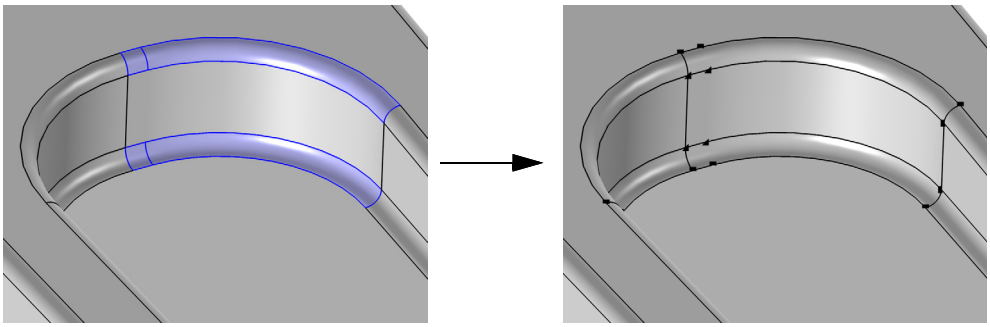

Figure 7-86: The same faces selected as in Figure 7-84, highlighted in blue, but with the checkbox Ignore adjacent vertices cleared. The image on the right hand side shows that the vertices have been preserved along the edges of the resulting composite faces.

MESH CONTROL

Use the **Keep input for mesh control** checkbox to specify that the selected faces are composed in the geometry but the edges are available individually when you build the mesh. See also Mesh Control Edges.

- Ignore Edges
- Collapse Faces
- Remove Details

Ignore Edges

The operation removes the selected edges that are either isolated, adjacent to precisely two faces (3D), or are located between two domains (2D). Edges are removed by ignoring them. The resulting larger faces are denoted composite faces.

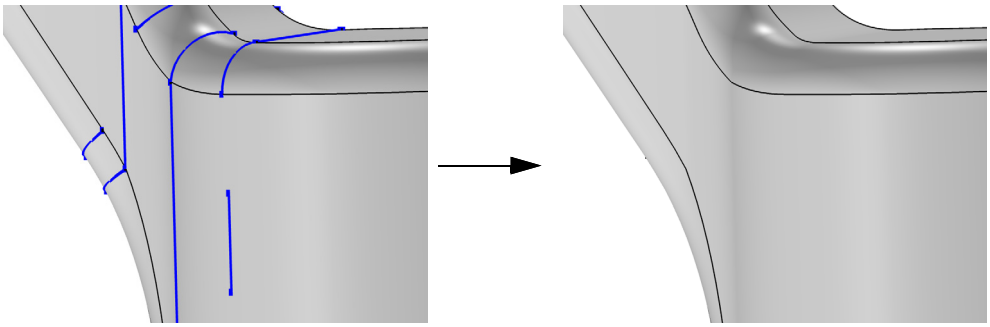

Figure 7-87: Ignoring the selected edges, highlighted in blue. The resulting geometry has larger composite faces. The vertices adjacent to the ignored edges are automatically ignored.

For faces that are significantly smaller or narrower than the desired local mesh element size, it is recommended to use Collapse Faces. It is also recommended to keep edges in sharp corners of importance to the result. When a composite face is meshed, all mesh vertices are located on the face, but there is no guarantee that there will be mesh vertices on the ignored edge. For example, ignoring an edge connected to two planar faces in a 90 degree angle, some of the created triangular elements may not coincide with any of the original faces, as shown below.

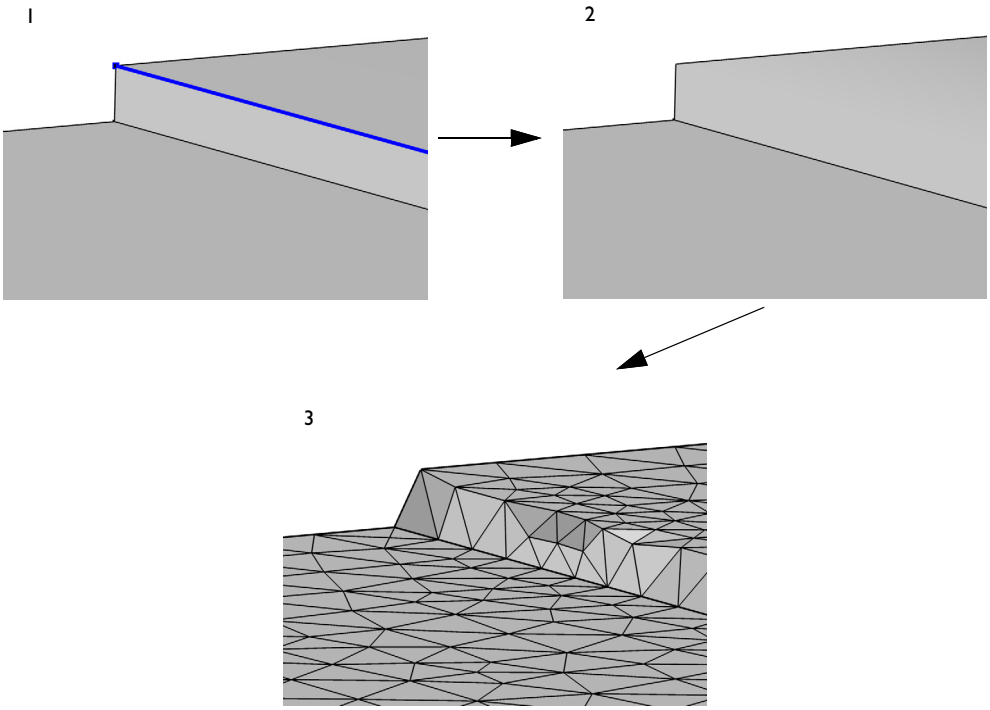

Figure 7-88: Possible effect of removing an edge in a sharp corner. 1. An edge connected to two faces positioned in a 90 degree angle is selected to be ignored (highlighted in blue). 2. Resulting geometry after the edge is removed. 3. This has the effect that the mesh elements do not have to respect this sharp corner, as shown here.

Tidying up a geometry to remove small and narrow faces gives the mesh algorithm more freedom to create a good quality mesh. An alternative is to use the Form Composite Faces and Collapse Faces operations. The Remove

Details operation provides a fully automated way to find sliver faces, small faces and narrow face regions and uses, among others, the Ignore edges operation to form composite faces.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Ignore Edges** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to ignore in the **Graphics** window. These then appear in the **Edges to ignore** list. If the geometry sequence includes user-defined selections above the **Ignore Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to ignore**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to ignore** selections.

Use the **Ignore adjacent vertices** checkbox to also remove the ignorable start and end vertices of the edges.

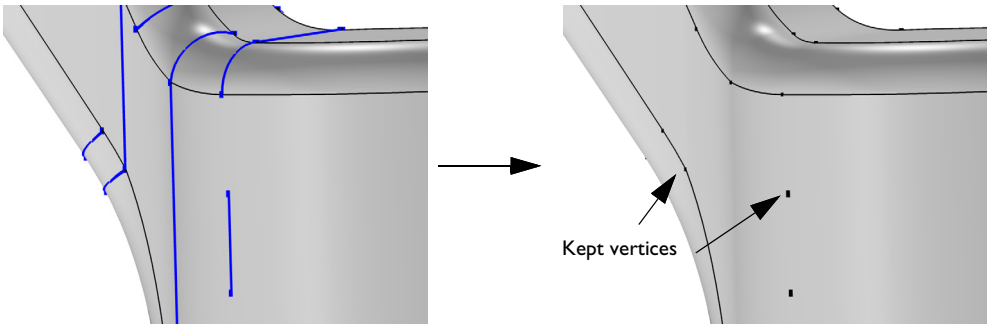

Figure 7-89: The same edges selected as in Figure 7-87, highlighted in blue, but with the Ignore adjacent vertices checkbox cleared. The right image shows that the vertices representing the start and endpoints of the edges have been preserved. The arrows in the image on the right hand side indicate two of the vertices that has been kept.

MESH CONTROL

Use the **Keep input for mesh control** checkbox to specify that the selected edges disappear from the geometry but become available when you build the mesh. You can, for example, use *mesh control edges* to control the element size inside a domain or to partition the geometry to use a mapped mesh. See also Mesh Control Edges.

- Form Composite Faces
- Collapse Faces
- Remove Details

	This operation is available for 3D models only.

The operation removes selected faces that are isolated or are located between two domains by ignoring them. *Composite domains* are formed which may simplify meshing the geometry, for example if narrow domain regions are avoided.

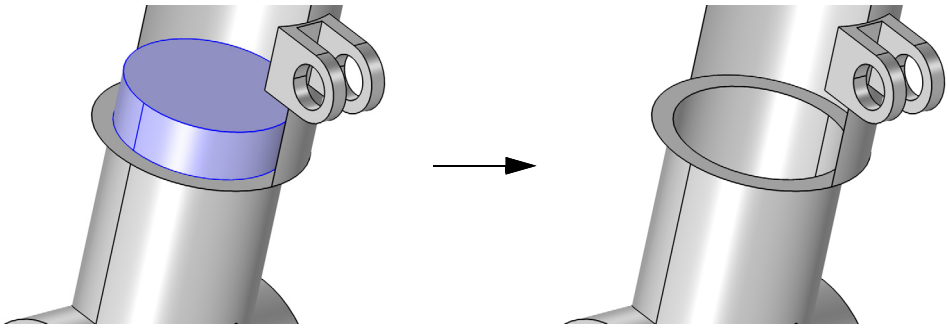

Figure 7-90: The Ignore faces operation removes the selected faces, highlighted in blue, to create one large domain. The resulting geometry has one composite domain after all the interior faces have been removed. To increase the visibility, one face of the upper part of the geometry has been hidden.

An alternative is to use the Form Composite Domains operation. The Remove Details operation provides a fully automated way to find and remove thin and small domains by ignoring faces.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Ignore Faces** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to ignore in the **Graphics** window. They then appear in the **Faces to ignore** list. If the geometry sequence includes user-defined selections above the **Ignore Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to ignore**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to ignore** selections.

Use the **Ignore adjacent vertices and edges** checkbox to also remove the ignorable vertices and edges adjacent to the faces. Clearing the checkbox still removes the faces, but keeps the vertices and edges adjacent to the ignored faces, as shown below.

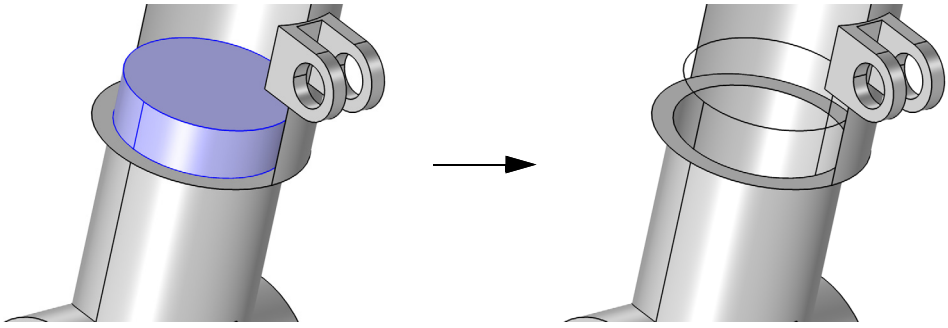

Figure 7-91: Faces selected to be ignored, highlighted in blue. One face is hidden to improve visibility. With the Ignore adjacent vertices and edges checkbox cleared, one composite domain is created, preserving the edges and vertices adjacent to the removed faces.

MESH CONTROL

Use the **Keep input for mesh control** checkbox to specify that the selected faces disappear from the geometry but become available when you build the mesh. You can, for example, use a *mesh control face* to partition the geometry to make it possible to sweep a hexahedral mesh. See also Mesh Control Faces.

- Form Composite Domains
- Remove Details

Ignore Vertices

The operation removes selected vertices that are isolated or are adjacent to precisely two edges. All edges in the geometry must have distinct start and end points. The software will ensure this by preserving or inserting extra vertices on the *composite edges*, if necessary.

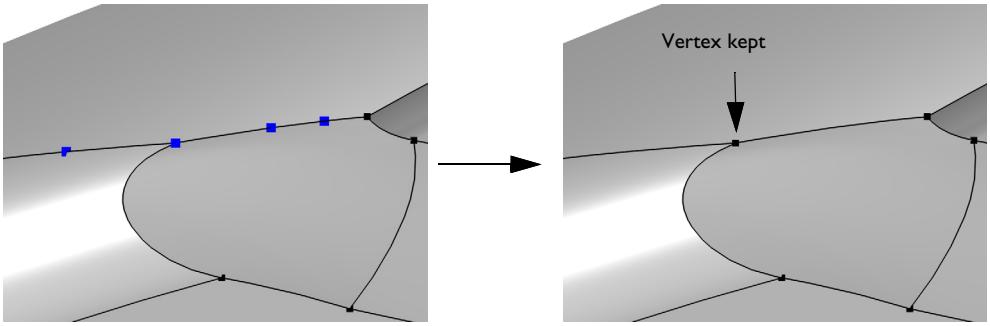

Figure 7-92: The vertices selected to be removed by the Ignore vertices operation, highlighted in blue. The vertices connected to only two edges have been removed, resulting in longer composite edges. One vertex is still kept (indicated by arrow in right image) as it is connected to more than two edges.

It is recommended to keep vertices in sharp corners of importance to the result. When a composite edge is meshed, all mesh vertices are located on the edge but there is no guarantee that there will be a mesh vertex on the ignored

vertices which, for example, means that if you ignore a vertex between two straight edges that are not collinear there can be one edge element that does not coincide with any original edge, as shown below.

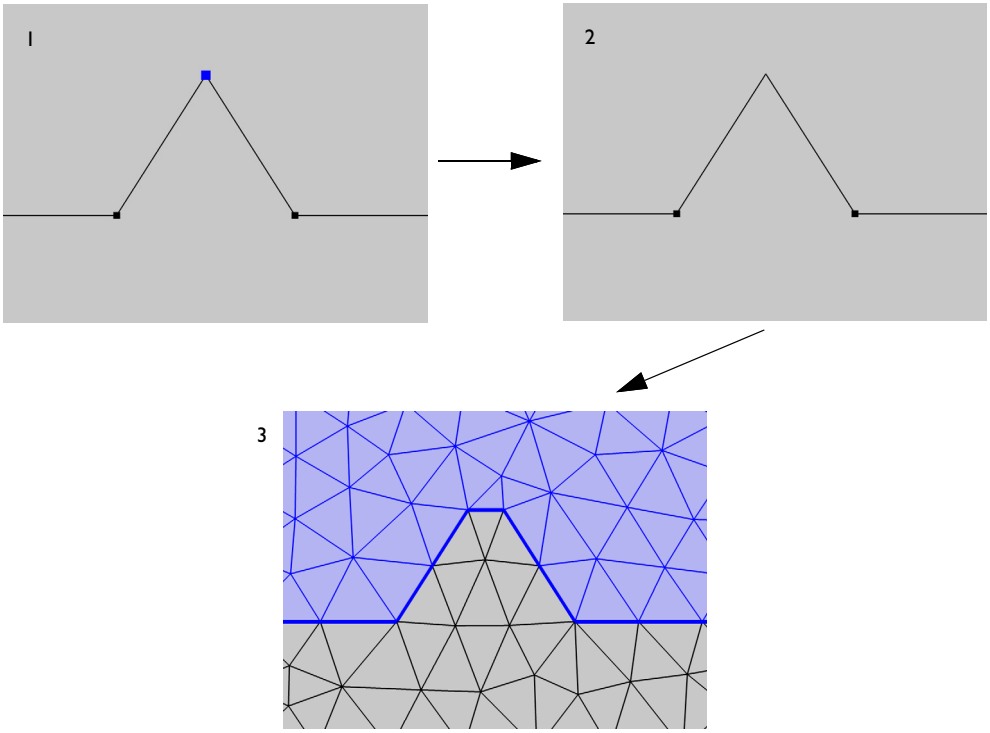

Figure 7-93: Possible effect of removing a vertex in a sharp corner. 1. A vertex connected to two edges selected to be ignored, highlighted in blue. 2. Resulting geometry after the vertex is removed. 3. This has the effect that the mesh elements do not have to respect this sharp corner, as shown here.

An alternative is to use the Form Composite Edges operation. The Remove Details operation provides a fully automated way to find and remove isolated vertices and vertices adjacent to two edges. The evaluation is based on an angle criterion to only remove vertices if the tangent is considered to be continuous.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Ignore Vertices** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the vertices (points) that you want to ignore in the **Graphics** window. These then appear in the **Vertices to ignore** list. If the geometry sequence includes user-defined selections above the **Ignore Vertices** node, choose **Manual** to select vertices, or choose one of the selection nodes from the list next to **Vertices to ignore**.

Click the **Active** button to toggle between turning ON and OFF the **Vertices to ignore** selections.

MESH CONTROL

Use the **Keep input for mesh control** checkbox to specify that the selected vertices disappear from the geometry but become available when you build the mesh. You can, for example, use a *mesh control vertex* to control the element size inside a domain. See also Mesh Control Vertices.

- Form Composite Edges
- Remove Details

Merge Edges

The operation merges opposite edges by collapsing the face between the edges. The edges selected to be removed are merged with the edges to be kept, and the faces adjacent to the removed edges are reconnected to the resulting merged edges. This is shown in Figure 7-94 and Figure 7-95.

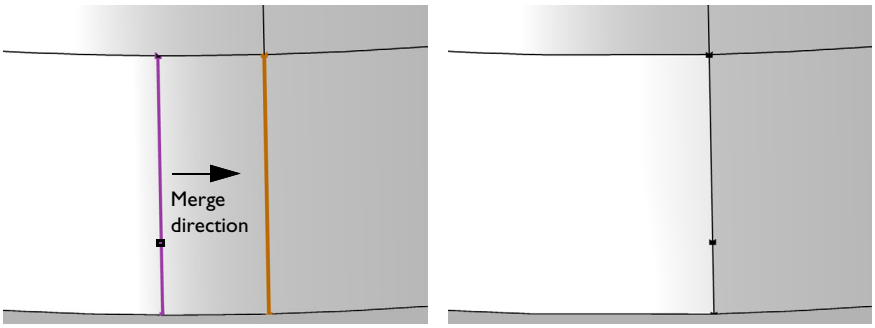

Figure 7-94: The edge highlighted in yellow is selected to be kept when merging the vertical edges for the rectangular face in the middle of the image. This means that the two vertical edges to the left (highlighted in magenta) will be merged

with the yellow vertical edge. The arrow in the left image indicate the direction of the merge. The image on the right shows the resulting geometry.

Figure 7-95: The edges highlighted in yellow are selected to be kept when merging the vertical edges for the rectangular face in the middle of the image. This means that the single vertical edge on the right hand side of the rectangular face (highlighted in magenta) will be moved to the left (direction indicated by the arrow in the left image). The edge, which is connected to the vertex at the top of the edge that is removed, is also moved together with the vertex. After the merge, this edge will connect to the vertex at the top of the edge that is kept. This is indicated by the arrow at the top of the image on the left. The image on the right shows the result.

Sliver and small faces can require a very fine meshes size, which can create meshes with many mesh elements. The Merge Edges, Collapse Faces, Form Composite Faces, and Ignore Edges operations provide a manual way to remove sliver and small faces, while the Remove Details operation is a fully automated way to prepare a geometry for meshing.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Merge Edges** ( ). Then enter the properties of the operation using the following sections:

EDGES TO KEEP

Select the edges that you want to keep in the **Graphics** window. They then appear in the **Edges to keep** list.

Click the **Active** button to toggle between turning ON and OFF the **Edges to keep** selections.

EDGES TO REMOVE

Select the edges that you want to remove in the **Graphics** window. They then appear in the **Edges to remove** list. Click the **Active** button to toggle between turning ON and OFF the **Edges to remove** selections.

- Collapse Faces
- Form Composite Faces
- Ignore Edges
- Remove Details

Merge Faces

The operation merges faces within a given maximum distance by collapsing the space between the selected faces, as shown in Figure 7-96. This means that you, for example, can bridge gaps between different parts of the geometry using this operation.

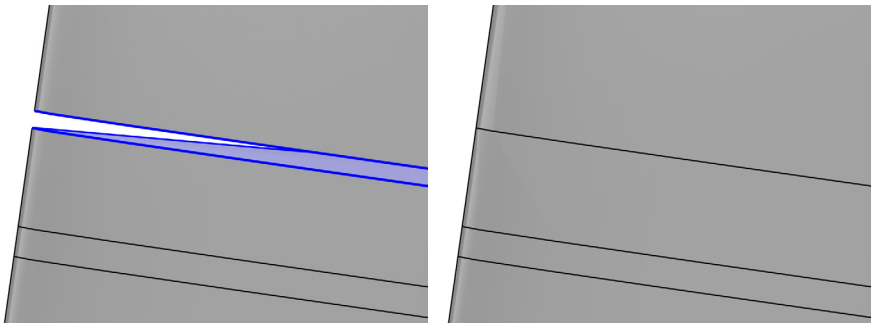

Figure 7-96: Merging two faces (blue) to collapse the gap between them. The result is shown to the right.

Thin gaps can result in only partial or no connection between parts. Perfectly touching parts are usually wanted for most physics simulations. A gap can also result in narrow domain regions if there is a surrounding air domain or similar. This will require a very fine mesh to be well resolved. Merging the faces adjacent to the gap will remove the thin narrow domain region and therefore the need for a fine mesh.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Merge Faces** ( ). Then enter the properties of the operation using the following sections:

FACE PAIRING

Use the setting **Pairing of faces to keep and remove** to specify how to input the faces to merge. Select **Automatic** (default) to select all faces to merge in one list and let the software decide which faces to keep and which faces to remove. Select **Manual** to manually select the faces to keep and then select the faces to remove, using the sections below.

For **Pairing of faces to keep and remove** set to **Automatic**, click the **Active** button to toggle between turning ON and OFF the **Faces to merge** selection. Select the faces that you want to merge in the **Graphics** window or add them from the **Selection List**. They then appear in the **Faces to merge** list.

For **Pairing of faces to keep and remove** set to **Manual**, click the **Active** button to toggle between turning ON and OFF the **Faces to keep** selection. Select the faces that you want to keep in the **Graphics** window or add them from the **Selection List**. They then appear in the **Faces to keep** list. Then, click the **Active** button to toggle between turning ON and OFF the **Faces to remove** selection. Select the faces that you want to remove in the **Graphics** window or add them from the **Selection List**. They then appear in the **Faces to remove** list.

MAXIMUM DISTANCE

Use the setting **Maximum distance** setting to specify the maximum distance to bridge when merging faces in the geometry. Choose **Relative** to enter a value in the **Relative distance** field. This value is relative to the length of the longest side of the geometry's bounding box. Select **Absolute** to specify a value in the **Absolute distance** field. When the operation is built with the setting **Automatic** (the default), the value in the **Absolute distance** field is automatically updated to correspond to the actually used distance. The automatic tolerance is based on the size of the bounding box of the mesh.

FACE MATCHING

The contents of this section differ depending on the setting **Geometry representation** in the **Settings** window of the **Geometry** node.

COMSOL Kernel

Select the checkbox **Force one-to-one** to force the faces on the remove side to be matched with the keep side without any imprints. This is useful when the shape is approximately the same and you want to match them exactly. Note that if the faces have too different shape, the merge will generally not be successful with this option.

CAD Kernel

Use the **Method** setting to specify the way to match a determined pair of faces to keep and remove. The method **Make imprints** means that the faces to keep make an imprint on the faces to remove and, symmetrically, the faces to remove make an imprint on the faces to keep. Then, only the overlapping imprints are merged. This is shown in Figure 7-97.

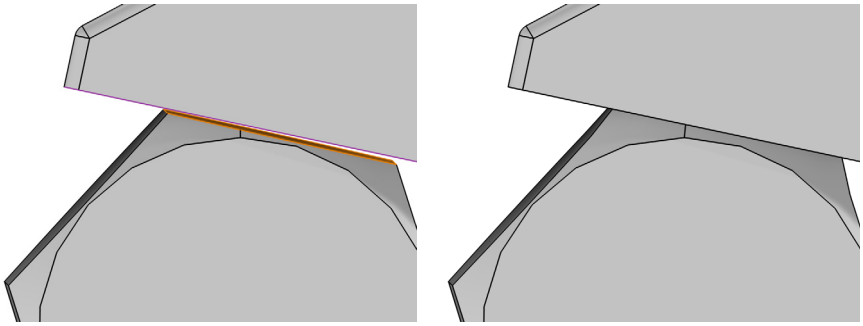

Figure 7-97: Merging faces by making an imprint on the bottom surface of the upper part.

Use the **Precision** field or slider to specify the accuracy of the imprint. A low precision will give a sloppier matching, meaning that face regions with approximately the same shape will be matched without imprinting, while high precision gives a more accurate imprint but also means that small faces and details can appear.

The method **One-to-one** forces the faces to remove to be matched with the keep side without any imprints. This is useful when the shape is approximately the same and you want to match them exactly. Note that if the faces have too different shape, the merge will generally not be successful with this option.

RESULTING FINITE VOIDS

The **Create domains** checkbox is selected by default to create domains from watertight void regions. If you do not want or need domains, clear this checkbox.

Merge Vertices

The operation merges two vertices by collapsing the edge between the vertices and reconnecting the edges adjacent to the removed vertex to the resulting merged vertex as shown in Figure 7-98. One vertex is selected to be kept, the other vertex is selected to be removed.

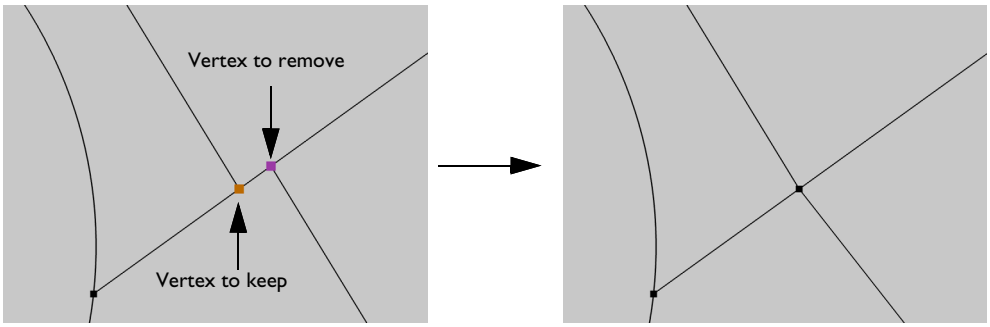

Figure 7-98: Merging two vertices to collapse a short edge. The end vertices of an edge are selected; one vertex is selected to be kept (highlighted in yellow in left image) and one to be removed (highlighted in magenta). This collapses the edge between the points into the vertex that was selected to be kept (image to the right).

Short edges can require a very fine meshes size, which can create meshes with many mesh elements. The **Merge Vertices**, Collapse Edges, Form Composite Edges, and Ignore Vertices operations provide a manual way to remove short edges, while the Remove Details operation is a fully automated way to prepare a geometry for meshing.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Merge Vertices** ( ). Then enter the properties of the operation using the following sections:

VERTEX TO KEEP

Click the **Active** button to toggle between turning ON and OFF the **Vertex to keep** selection. Select the vertex that you want to keep in the **Graphics** window. It then appears in the **Vertex to keep** list.

VERTEX TO REMOVE

Click the **Active** button to toggle between turning ON and OFF the **Vertex to remove** selection. Select the vertex that you want to remove in the **Graphics** window or add it from the **Selection List**. It then appears in the **Vertex to remove** list.

Mesh Control Domains

Use **Mesh control domains** for precise control of the mesh in specific regions of the geometry, without affecting the geometry used for assigning physics.

To fully resolve the gradients in a field in certain regions of a domain, a finer mesh may be required. One way to avoid refining the mesh in the entire domain, is to partition it, then assign a finer mesh size to the domain created by the partitioning, as shown in Figure 7-99. By designating the created domain as a *mesh control domain*, it will

only be visible in mesh mode, and only before the mesh is generated. As soon as the mesh is built inside the mesh control domains and adjacent domains, the faces and edges adjacent to the mesh control domains are removed.

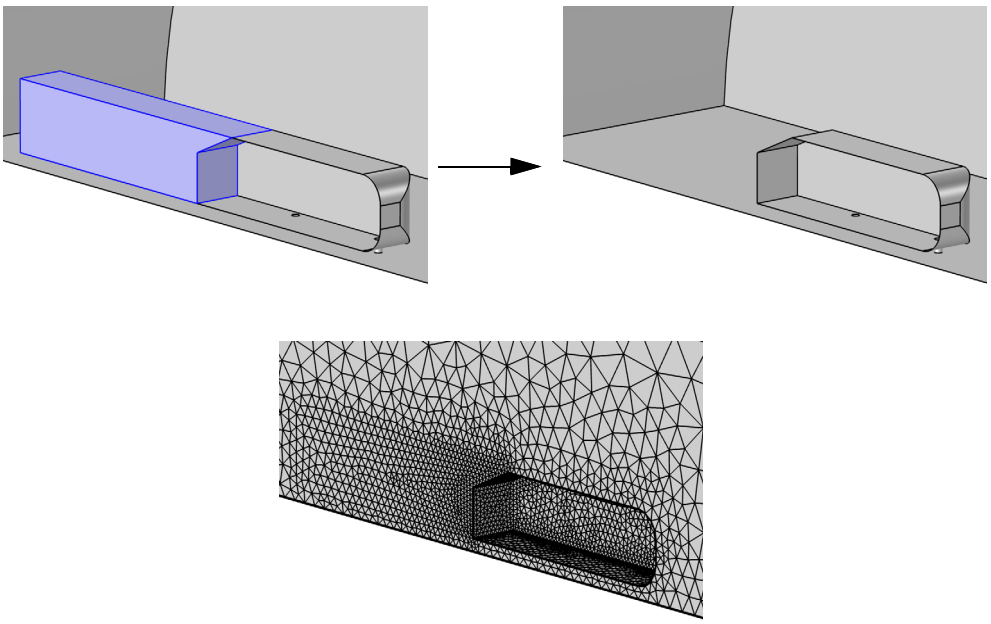

Figure 7-99: Domain highlighted in blue is designated as a mesh control domain, which means that the faces of this domain are removed and are only available when building the mesh. The image on the right hand side shows the geometry after the Mesh control domains operation has been built, which is the geometry displayed in physics settings. The bottom image shows the resulting mesh where the faces have been removed.

The operation removes the selected domains by composing them with adjacent domains as shown in Figure 7-99 and Figure 7-100. The faces (3D only) and edges become available when you build the mesh. This makes it possible to partition a domain to prepare it for swept meshing, or to control the mesh size in a specific region, without modifying the geometry that appears when assigning physics settings.

An advantage of working with mesh control domains is that when the faces have been removed, the mesher can move mesh vertices to make a smoother the size transition across the removed entities (see Figure 7-100). This behavior is controlled by the settings in the section **Control Entities** of the mesh operation used to mesh the domains.

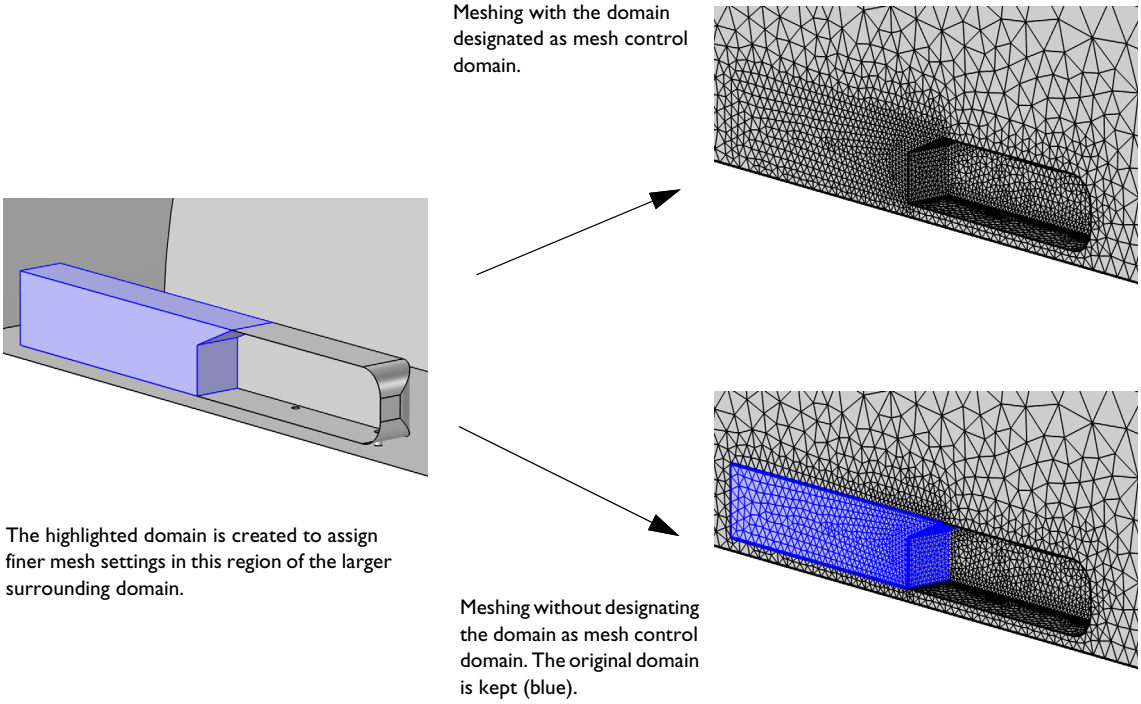

Figure 7-100: Comparing meshes where the Mesh control domains has been used vs. not used. A smaller domain added for the purpose of resolving the mesh in a region with steeper gradients (highlighted in blue in the image to the left). Designating the domain as a mesh control domain removes the faces of the selected domain and compose it with the adjacent domain (upper right image). The lower right image shows the mesh if the domain is not marked as a mesh control domain. This means that the face, edge, and domain partitioning are preserved. Compare the meshes on the right-hand side to see the effect of smoothing the size transition across removed mesh control entities.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Mesh Control Domains** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the domains that you want to use for mesh control in the **Graphics** window. They then appear in the **Domains to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Domains** node, choose **Manual** to select domains, or choose one of the selection nodes from the list next to **Domains to include**.

Click the **Active** button to toggle between turning ON and OFF the **Domains to include** selections.

Mesh Control Edges

Use **Mesh control edges** for precise control of the mesh in specific regions of the geometry, without affecting the geometry used for assigning physics.

To fully resolve the gradients in a field in certain regions of a domain (2D) or on faces (3D), a finer mesh may be required. One way to avoid refining the mesh in the entire domain or face, is to partition it, then assign a finer mesh size to the domain or face created by the partitioning, as shown in Figure 7-101. By designating the created edges as a *mesh control edges*, they will only be visible in mesh mode, and only before the mesh is generated. As soon as the mesh is built in domains and faces adjacent to the mesh control edges, the designated edges are removed.

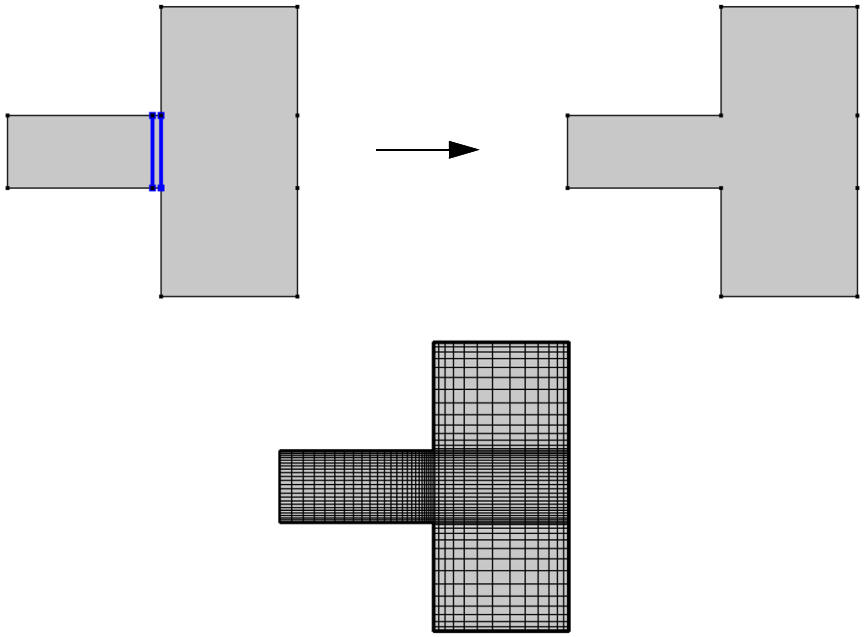

Figure 7-101: Edges highlighted in blue are designated as mesh control edges, which means that these edges are removed and are only available when building the mesh. The image on the right hand side shows the geometry after the Mesh control edges operation has been built, which is the geometry displayed in physics settings. The bottom image shows a mesh where the mesh control edges has made it possible to create a mapped mesh with edge distributions set to resolve the field in a GEC CCP reactor.

The operation removes a selection of edges that are isolated or that are adjacent to precisely two faces (in 3D) or two domains (in 2D, as shown in Figure 7-101). The edges act as a partitioning, and are removed from the geometry, but become available when you build the mesh. Use a mesh control edge to control the element size inside a domain, or to create a mapped mesh in regions, as shown below. Mesh control edges do not change the number of domains (2D) and edges displayed in the physics settings.

An advantage of working with mesh control edges is that when the edges have been removed, the mesher can move mesh vertices to make a smoother the size transition across the removed entities (see Figure 7-102). This behavior is controlled by the settings in the section **Control Entities** of the mesh operation used to mesh the domains.

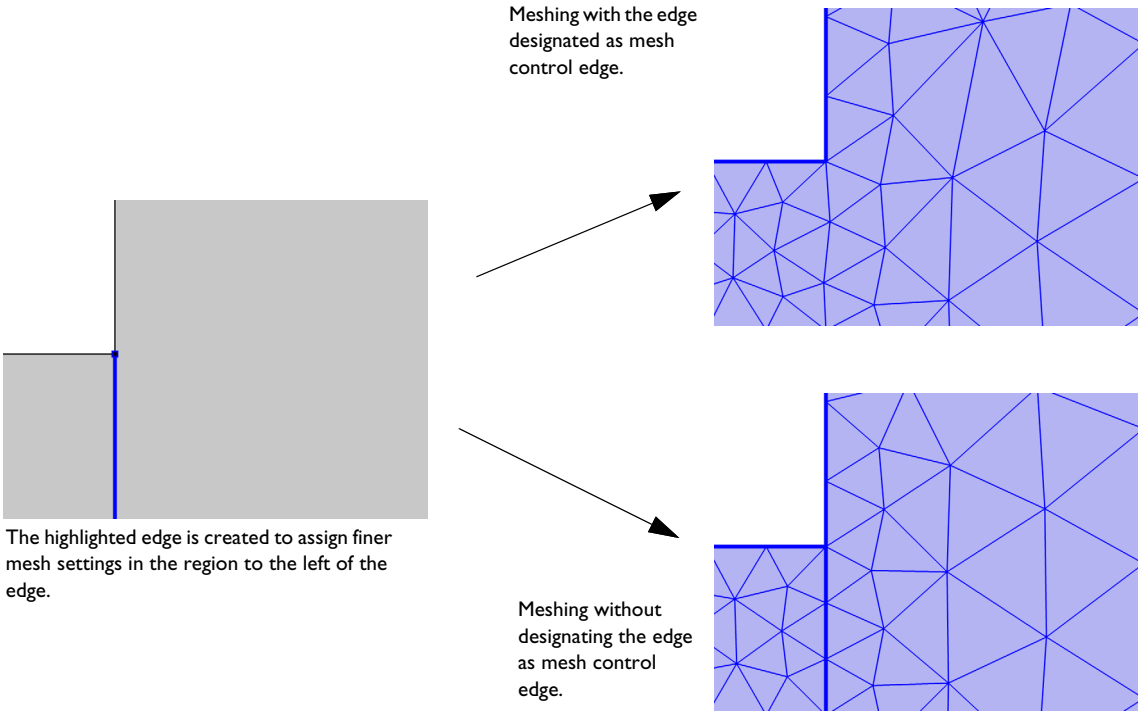

Figure 7-102: Comparing meshes where the Mesh control edges has been used vs. not used. The highlighted edge in the image to the left is added for the purpose of resolving the mesh in a region with steeper gradients. Designating the edge as a mesh control edge removes the edge and composes the two domains (2D) adjacent to the edge (upper right image). The lower right image shows the mesh if the edge is not marked as a mesh control edge. This means that the edge and domain partitioning are preserved. Compare the meshes on the right hand side to see the effect of smoothing the size transition across removed mesh control entities.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Mesh Control Edges** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the edges that you want to use for mesh control in the **Graphics** window. They then appear in the **Edges to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Edges** node, choose **Manual** to select edges, or choose one of the selection nodes from the list next to **Edges to include**.

Click the **Active** button to toggle between turning ON and OFF the **Edges to include** selections.

Use the **Include adjacent vertices** checkbox to specify if the operation also include the ignorable start and end vertices of the edge.

Mesh Control Faces

Use **Mesh control faces** for precise control of the mesh in specific regions of the geometry, without affecting the geometry used for assigning physics.

To fully resolve the gradients in a field in certain regions of a domain, a finer mesh may be required. To reduce the memory required to solve the model, a swept mesh can sometimes be used. For geometries where it is not possible to sweep a mesh in the entire domain, partition the domain, then sweep the mesh in the domain created by the partitioning, as shown in Figure 7-103. By designating the created face as a *mesh control face*, it will only be visible

in mesh mode, and only before the mesh is generated. As soon as the mesh is built inside the domains adjacent to the face, the face itself and the edges adjacent to the mesh control face are removed.

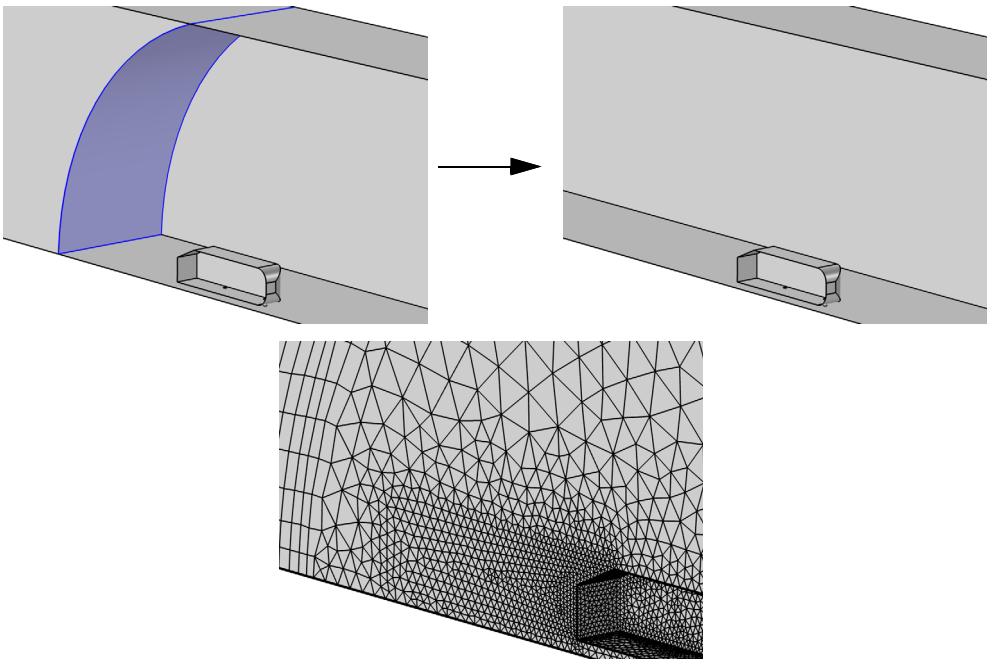

Figure 7-103: Face highlighted in blue is designated as a mesh control face, which means that the faces is removed and is only available when building the mesh. The image on the right hand side shows the geometry after the Mesh control faces operation has been built, which is the geometry also displayed in physics settings. The bottom image shows the resulting mesh where the face have been removed.

The operation removes the selected faces that are isolated or are located between two domains by ignoring them and composing the adjacent domains as shown in Figure 7-103 and Figure 7-104. The faces become available when you build the mesh. This makes it possible to partition a domain to prepare it for swept meshing, or to control the mesh size in a specific region, without modifying the geometry that appears when assigning physics settings.

An advantage of working with mesh control faces is that when the faces have been removed, the mesher can move mesh vertices to make a smoother the size transition across the removed entities (see Figure 7-104). This behavior is controlled by the settings in the section **Control Entities** of the mesh operation used to mesh the domains.

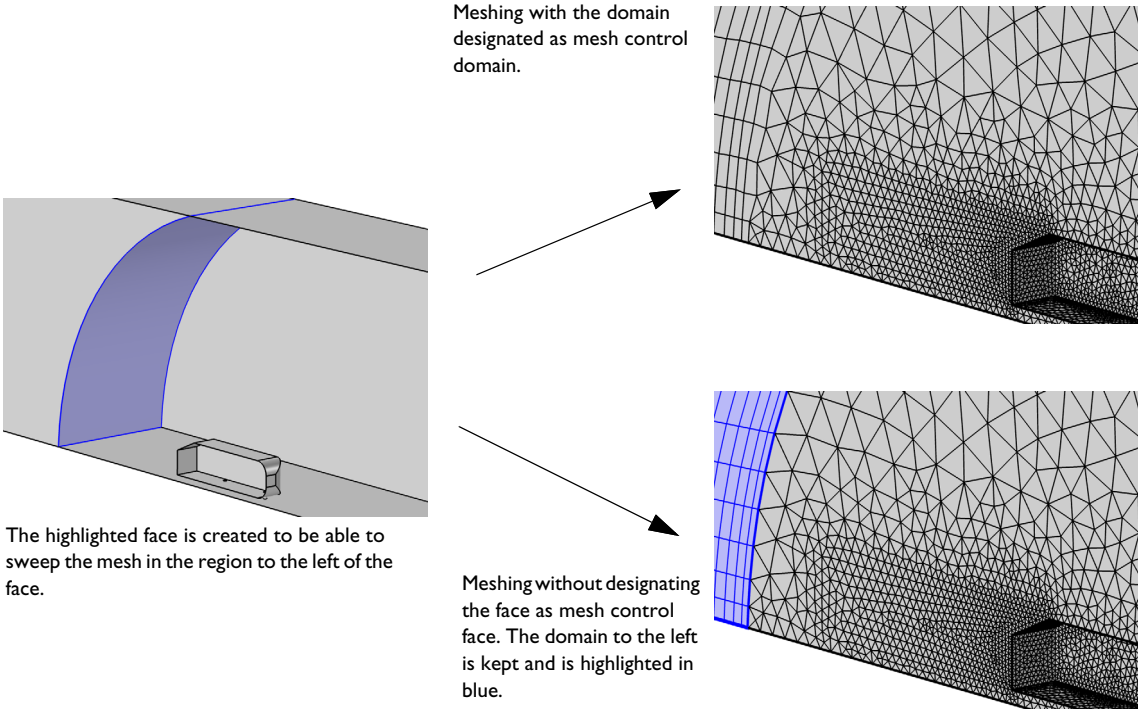

Figure 7-104: Comparing meshes where the Mesh control faces has been used vs. not used. A face added for the purpose of creating a swept mesh in the left part of the larger domain (highlighted in blue in the image to the left). Designating the face as a mesh control face removes the face and composes the adjacent domains (upper right image). The lower right image shows the mesh if the face is not marked as a mesh control face. This means that the face, edge, and domain partitioning are preserved. Compare the meshes on the right hand side to see the effect of smoothing the size transition across removed mesh control entities.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Mesh Control Faces** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the faces that you want to use for mesh control in the **Graphics** window. They then appear in the **Face to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Faces** node, choose **Manual** to select faces, or choose one of the selection nodes from the list next to **Faces to include**.

Click the **Active** button to toggle between turning ON and OFF the **Faces to include** selections.

Use the **Include adjacent vertices and edges** checkbox to specify if the operation also includes the ignorable vertices and edges adjacent to of the faces.

Mesh Control Vertices

Use **Mesh control vertices** for precise control of the mesh in specific regions of the geometry, without affecting the geometry used for assigning physics.

To fully resolve the gradients in a field in certain regions of a domain, on a boundary, or along an edge, a finer mesh may be required. One way to avoid refining the mesh in the entire domain, is to add a point, then assign a finer mesh size to the point, as shown in Figure 7-105. By designating the created point as a *mesh control vertex*, it will

only be visible in mesh mode, and only before the mesh is generated. As soon as the mesh is built inside the domains, on the boundaries, or on the edges adjacent to the point, the mesh control vertex is removed.

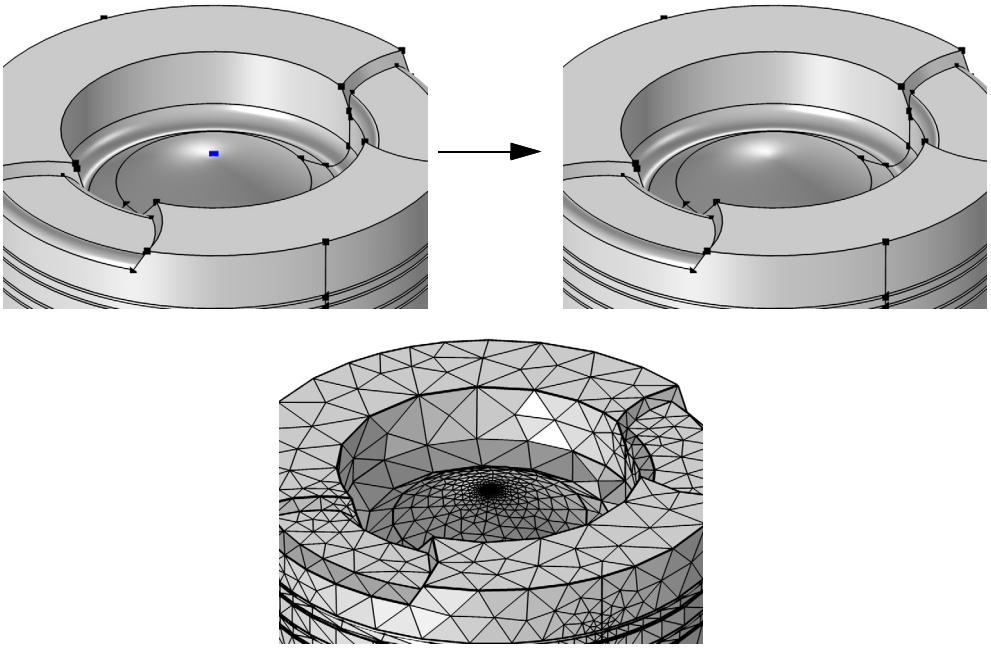

Figure 7-105: Point highlighted in blue is designated as a mesh control vertex, which means that the point is removed and is only available when building the mesh. The image on the right hand side shows the geometry after the Mesh control vertices operation has been built, which is the geometry displayed in physics settings. The bottom image shows the resulting mesh where the vertex have been removed.

The operation removes the selected vertices that are isolated or are adjacent to precisely two edges. This is done by ignoring the vertices and composing the adjacent edges, as shown in Figure 7-105 and Figure 7-106. All edges in the geometry must have distinct start and end points. The software will ensure this by preserving or inserting extra vertices on the *composite edges*, if necessary. The vertices become available when you build the mesh. This makes it possible to partition a face or an edge to prepare it for swept meshing, or to control the mesh size in a specific region, without modifying the geometry that appears when assigning physics settings.

An advantage of working with mesh control vertices is that when the vertices have been removed, the mesher can move mesh vertices to make a smoother the size transition across the removed entities (see Figure 7-106). This

behavior is controlled by the settings in the section **Control Entities** of the mesh operation used to mesh the edges, faces, and domains.

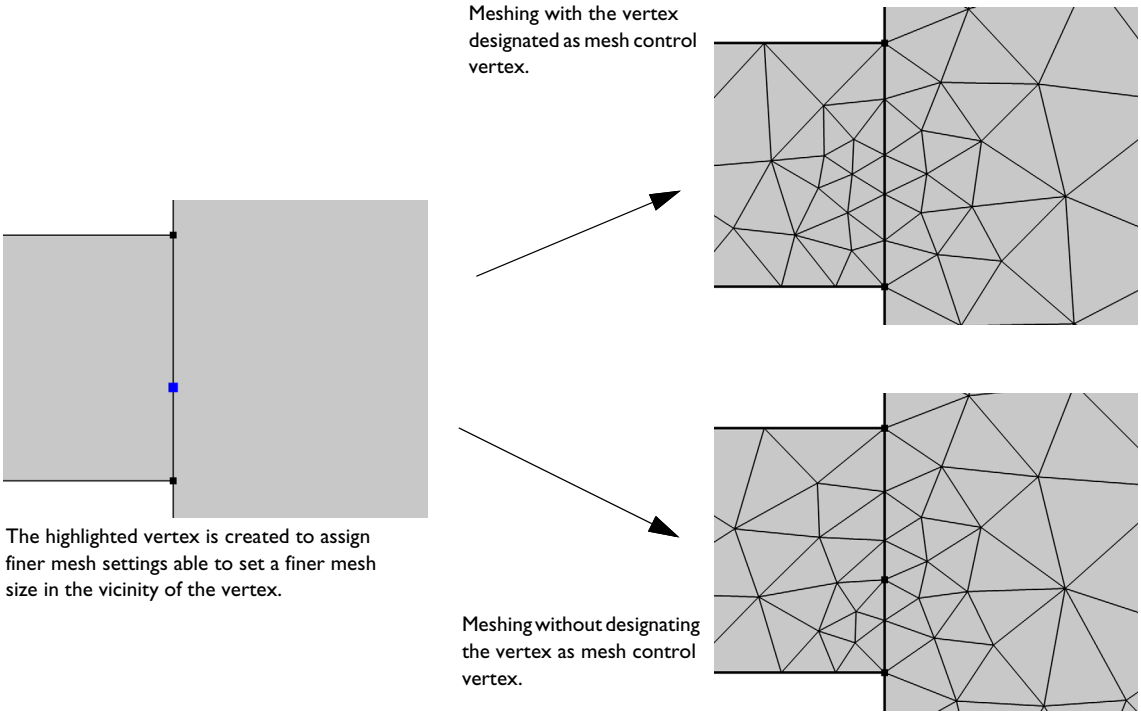

Figure 7-106: Comparing meshes where the Mesh control vertices has been used vs. not used. A vertex added for the purpose of resolving the mesh close to the vertex (highlighted in blue in the image to the left). Designating the vertex as a mesh control vertex removes the vertex and composes the adjacent edges (upper right image). The lower right image shows the mesh if the vertex is not marked as a mesh control vertex. This means that the face and edge partitioning are preserved. Compare the meshes on the right hand side to see the effect of smoothing the size transition across removed mesh control entities.

To use the operation, in the **Geometry** toolbar, from the **Virtual Operations** menu ( ), select **Mesh Control Vertices** ( ). Then enter the properties of the operation using the following sections:

INPUT

Select the vertices (points) that you want to use for mesh control in the **Graphics** window. They then appear in the **Vertices to include** list. If the geometry sequence includes user-defined selections above the **Mesh Control Vertices** node, choose **Manual** to select vertices, or choose one of the selection nodes from the list next to **Vertices to include**.

Click the **Active** button to toggle between turning ON and OFF active **Vertices to include** selections.

- Ignore Vertices
- Free Tetrahedral
- Free Triangular
- Free Quad
- Mapped
- Swept

This operation is available for 3D models only.

The operation **Remove Details** automatically finds and removes small details from the finalized geometry, that is the geometry after the **Form Union** or **Form Assembly** node has been built (see Figure 7-107). Small details include vertices with continuous tangent, short edges, small and narrow (sliver) faces, narrow face regions, and thin domains, which may all increase the number of mesh elements significantly. This, in turn, will lead to higher memory consumption. Small details may also influence the quality of the mesh elements, which may affect the possibility to reach a converged solution. Use **Remove Details** to be in control of where finer mesh is created by removing small details not needed for the simulations. Then, set finer mesh size settings only in regions of importance for the accuracy of the solution.

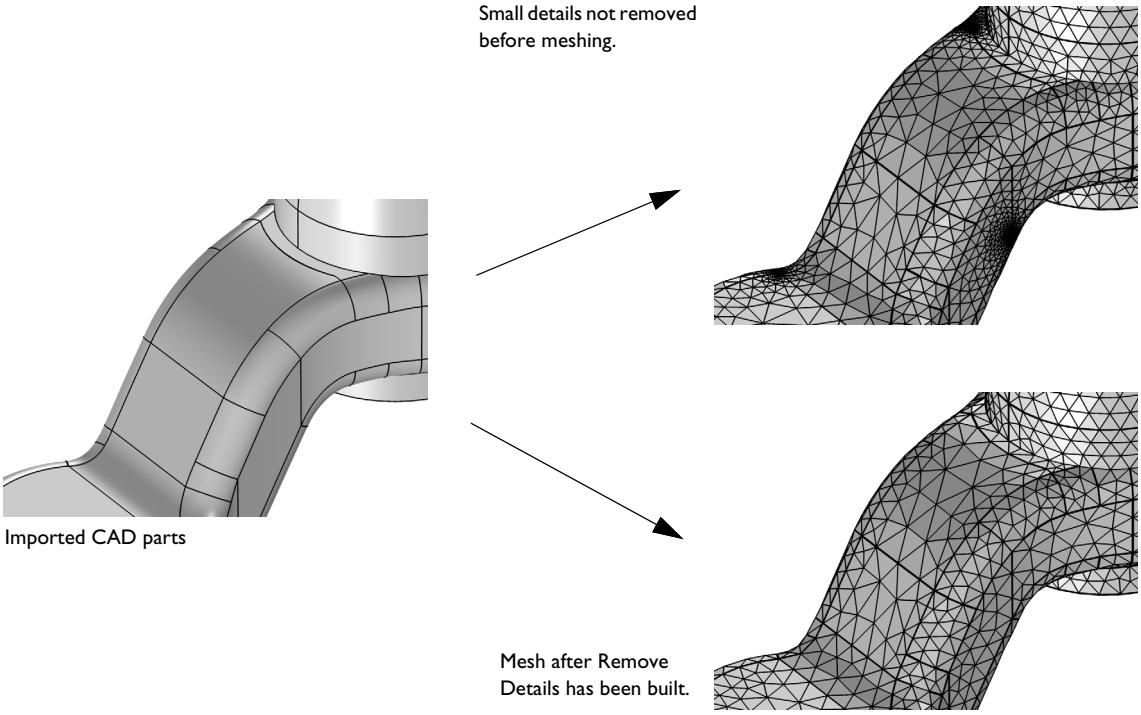

Figure 7-107: The Remove details operation helps to prepare a CAD design for meshing. The upper right image shows a mesh built on the original design. The black spots indicate that there are small details that require a fine mesh size to be well resolved by the mesh. Remove details successfully removes these small details and a coarser mesh can be built in the whole geometry (lower right image).

The **Remove Details** operation acts on the finalized object and can therefore detect and remove small details created when misaligned objects are united, for example, unintended overlap domains created by slightly overlapping objects. Details are removed by automatically generating a sequence of virtual operations, which are organized in passes with increasing tolerances to remove larger and larger details with each pass. The sequence always ends with a cleanup of edges and vertices.

A geometry may contain details of various sizes which may require different tolerances to remove. Also, some details, even though small, may be important for the simulation results. In these cases, add several **Remove Details** operations, active on the entire geometry or a selection of entities, and each with its own unique settings. Add manual virtual operations in addition to one or several **Remove Details** operations, as well as edit the sequence of

operations automatically generated by **Remove Details**. For details about available virtual operations, see links below the Information section.

To add a **Remove Details** node to a geometry sequence, from the **Virtual Operations** menu in the context menu when right-clicking a 3D **Geometry** node or directly from the **Geometry** ribbon toolbar, choose **Remove Details** ( ). The **Settings** window contains the following sections:

AUTOMATION

The default in the **Mode of operation** list is **Automatic**. Typically, use the automatic mode first. The **Remove Details** operation generates and builds a local sequence of virtual operations. You can then switch to **Manual** if needed to inspect the added virtual operations, fine-tune, and add more such operations. When you have built the **Remove Details** node and the **Mode of operation** list is set to **Manual**, the created virtual operations are available as subnodes to the **Remove Details** node. Alternatively, right-click the **Remove Details** node and choose **Edit Generated Sequence** ( ). You can also then right-click the **Remove Details** node to add more virtual operations. If you want to restore the generated sequence of virtual operations, choose **Reset to the Generated Sequence** ( ) from the **Remove Details** node's context menu.

The following sections are only available when the **Mode of operation** list is set to **Automatic**.

ENTITIES TO PROCESS

The default is to remove small details from the entire geometry. From the **Entities** list, choose **Selection** instead of **Entire geometry** to make a selection of entities for which you want to remove small details.

If you choose **Selection**, the **Geometric entity level** list appears with the options **Domain** (the default), **Boundary**, and **Edge**. If the geometry sequence includes user-defined selections, you can choose one of them from the **Selection** list; otherwise, or if you choose **Manual** from the **Selection** list, select entities from the **Graphics** window or by pasting selections into the list of selected entities.

DETAILS TO REMOVE

This section contains the following checkboxes that specifies what type of repair issues to address as well as the virtual operations used.

- **Vertices with continuous tangent**. This checkbox controls whether each vertex that is adjacent to two edges with C1 continuity across the vertex, and that is not isolated in any face, is ignored. Operation used: Ignore Vertices.

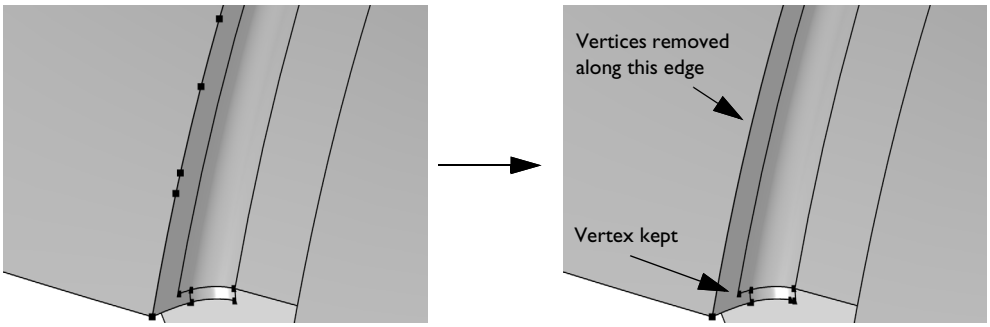

Figure 7-108: A geometry before (left) and after (right) applying Remove details. Four vertices with continuous tangent are removed and one vertex connected to two edges is kept as the edges form a sharp corner.

- **Short edges**. Operations used: Ignore Edges, Ignore Vertices, or Collapse Edges.

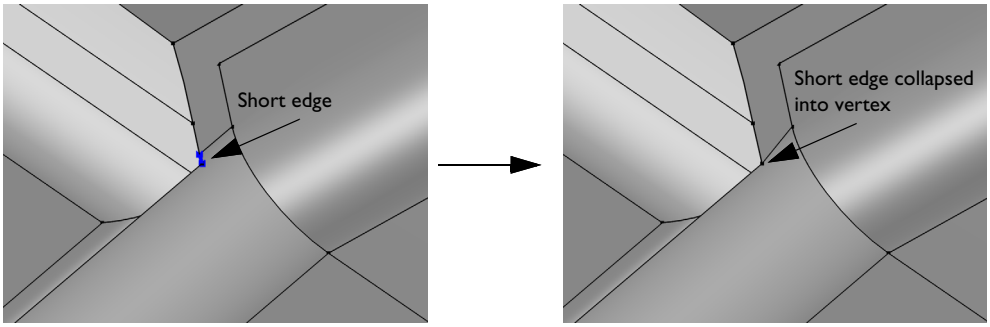

Figure 7-109: A short edge to be removed by Remove Details (left image). The image to the right shows the result after running the operation, which collapsed the edge into a vertex.

- **Small faces**. Operations used: Collapse Edges, Collapse Faces, or Ignore Edges.

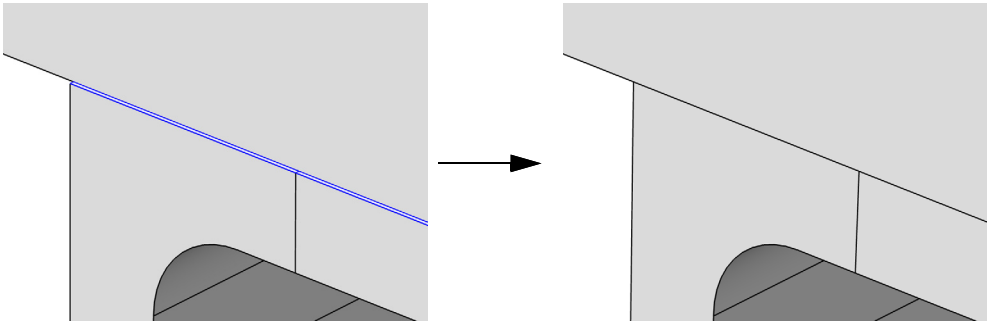

Figure 7-110: Sliver faces to be removed by Remove Details, highlighted in blue. The image to the right shows the result after running the operation, which collapsed the faces into edges.

- **Sliver faces**. Operations used: Collapse Faces or Ignore Edges.

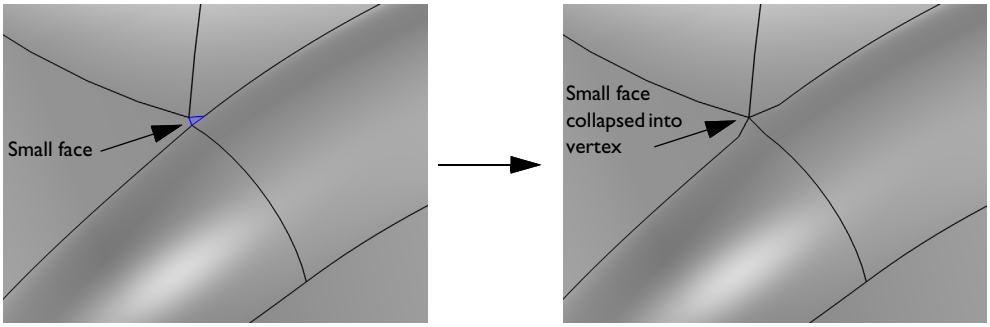

Figure 7-111: A small face to be removed by Remove Details (left image). The image to the right shows the result after running the operation, which collapsed the face into a vertex.

- **Narrow face regions**. Operations used: Collapse Face Regions or Ignore Edges.

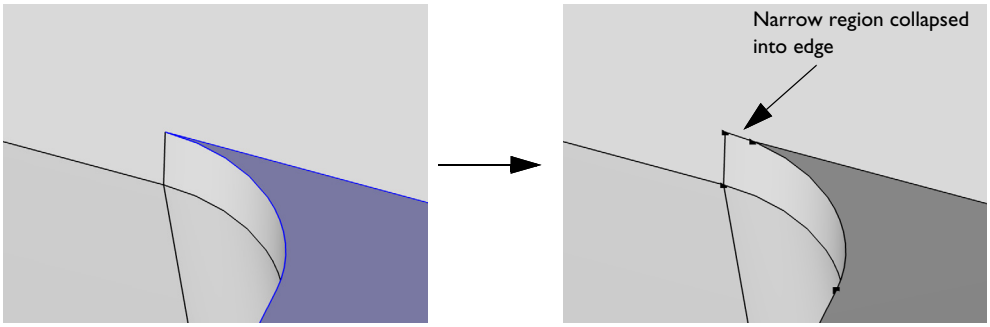

Figure 7-112: A face with a narrow region, highlighted in blue. The image to the right shows the result after running the operation, which collapsed the detected narrow region into an edge.

- **Thin domains**. When this checkbox is selected, the software automatically removes domains with a thickness less than the specified detail size (see below). Operations used: Collapse Faces and Ignore Faces.

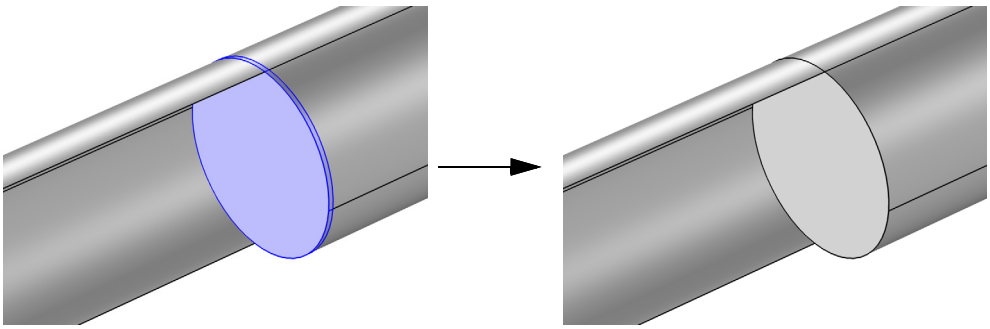

Figure 7-113: A thin domain, highlighted in blue, is collapsed into a face (image to the right) by the Remove Details operation.

	Not all types of details to remove are always applicable, depending on the chosen geometric entity level. For example, the **Thin domains** checkbox is only applicable if the selection is the entire geometry or a domain selection.

All checkboxes are selected by default. When the remove details operation has finished, information about the number of removed details appears in the table under **Information**.

PARAMETERS

In this section you can control the parameters that determine the size of details to remove.

From the **Detail size** list, choose **Automatic** (the default), **Relative**, or **Absolute**. If you choose **Relative** the **Maximum relative size** field appears. The default relative tolerance used is 0.001 which is relative to the length of the longest edge of the selection's bounding box. If you select **Absolute**, the **Maximum absolute size** field appears. The default tolerance used is 0.001 times the longest edge of the geometry's bounding box. When you build this feature, the **Maximum relative size** and the **Maximum absolute size** are set to the values that are used, which can be useful when you have set **Detail size** to **Automatic**.

The values in the **Continuous tangent tolerance** field (default value: 5 degrees) specifies the maximum allowed angular tangent deviation across a vertex or edge to be ignored.

INFORMATION

This section contains information about the removed details: In the **Type of removal** column, the types of details that have been removed are listed. In the **Removed entities** column, the number of entities for each type of remove operation is listed.

Click **Build Selected** ( ) (or press F7) to build the geometry up to and including this node, click **Build Preceding** ( ) (or press F6) to build the geometry up to the node preceding this node, or click **Build All** ( ) (or press F8) to build all nodes in the geometry sequence.

Meshing

This chapter describes meshing capabilities and meshing operations available for working with meshes in the software.

In this chapter:

- Meshing Overview
- Meshing Sequences
- Mesh Element Sizing
- Inspecting and Troubleshooting Meshes
- Importing and Exporting Meshes
- Combining Geometry and Mesh
- Meshing Operations and Attributes

Meshing Overview

This section gives an overview of different meshing concepts, the mesh elements, and a guide of the toolbar and menus to access the different Meshing Operations and Attributes.

In this section:

- Meshing Concepts
- Mesh Elements for 1D, 2D, and 3D Meshes
- Unstructured Meshes
- Structured Meshes
- The Mesh Toolbar
- The Model Builder Context Menu
- The Graphics Context Menu

Meshing Concepts

The **Mesh** (or) nodes enable the discretization of the modeling domain into small units of simple shapes, referred to as *mesh elements*. See The Mesh Node for more information.

A mesh is the result of building a meshing sequence. A meshing sequence consists of Meshing Operations and Attributes. The attribute nodes store properties that are used by the operations when creating the mesh.

Building an operation creates or modifies the mesh on the entities defined by the operation's selection. Some of the operations use properties defined by attributes; for example, Free Tetrahedral reads properties from the Size, Distribution, Size Expression and Corner Refinement attribute nodes. If you choose to import a mesh, the **Import** operation reads properties from the Transform attribute.

GLOBAL VS. LOCAL ATTRIBUTES

An attribute contains properties defined on a selection. You can add an attribute as a node in the meshing sequence (this is referred to as a *global attribute node*) or add it as a subnode to an operation node (a *local attribute node*). Global attribute nodes define mesh sizes for all subsequent operation nodes in the meshing sequence, either on the entire geometry or on a selection of entities. Properties defined in a local attribute are only used by the owning operation node and override the corresponding properties defined in global attribute nodes (on the same selection).

The identical mesh specification defined by a local attribute will be used in subsequent operations if the entities it is applied to are not modified. For more information, see Identical Mesh.

VISUALIZING THE MESH

The Graphics Window shows the resulting mesh from the operations that have been built. The result of subsequent operations is not visible. The last built operation becomes the *current node* and appears with a quadratic frame around the feature's icon ( ). The frame is green if the feature and all preceding features are built; that is, the mesh in the **Graphics** window is up to date. The frame is yellow if the feature or some preceding feature has been edited since it was built and needs to be rebuilt ( ).

See also Mesh Element Numbering Conventions in the *COMSOL Multiphysics Programming Reference Manual*.

A *geometric model* consists of domains, boundaries, edges (only 3D), and vertices (only 2D and 3D), that is referred to as *geometric entities*. Each geometric entity is represented in the mesh by at least one element, but typically consists of a connected set of mesh elements.

In 1D meshes, the domains (intervals) are represented by *edge elements*. The endpoints of the mesh elements are called *mesh vertices*. The boundaries (or vertices) defined in the geometry are represented in the mesh by boundary elements (*vertex elements*).

In 2D meshes, the domains are represented by *triangular* or *quadrilateral* mesh elements. The sides of the triangle and quadrilateral elements are called *mesh edges*, and their corners are mesh vertices. A mesh edge must not contain mesh vertices in its interior. The boundaries defined are discretized into *boundary elements* (edge elements), which must conform with the mesh elements of the adjacent domains. The geometric vertices (or points) are represented by vertex elements.

In 3D meshes, the domains are represented by *tetrahedral*, *hexahedral*, *prism*, or *pyramid* elements whose faces, edges, and corners are called *mesh faces*, mesh edges, and mesh vertices, respectively. The boundaries are discretized into triangular or quadrilateral boundary elements. The geometric edges are discretized into edge elements. Similar to 2D, the geometric vertices are represented by vertex elements.

For 3D meshing, platforms handle floating-point operations differently, which sometimes results in slight differences between identical model files that are generated on two different computers.

CONFORMING, NONCONFORMING, AND NONMATCHING MESHES

Meshes generated in the COMSOL Multiphysics software are *conforming* with a *geometric model*. In a *conforming mesh*, the intersection between any two elements in the mesh is defined by subelements (mesh face, mesh edge, or mesh vertex). Each mesh element belongs to exactly one geometric entity. For a mesh conforming with a geometry, each geometric entity is either unmeshed or fully meshed.

See The Mesh Node for more information about meshes defining their own geometric models.

A mesh of assembly type can either be conforming with a geometry where the **Form an Assembly** finalization action has been used, or it defines its own geometric model with two or more **Import** nodes in the meshing sequence. It can also be one **Import** node if the imported mesh file contains a mesh of assembly type. Regardless of its origin, an assembly type of mesh defines several disconnected components with duplicated boundaries, edges, and points where the components are touching. The boundary meshes at touching surfaces between two parts do not need to define geometrically matching mesh vertices and elements. The image to the left in Figure 8-1 shows a *nonmatching* assembly mesh with two disconnected components. The exploded view to the right shows that the

two components are indeed disconnected. The mesh contains 21 mesh vertices and 20 triangle elements, 2 domains (indicated by yellow and green colors), 8 edges, and 8 points.

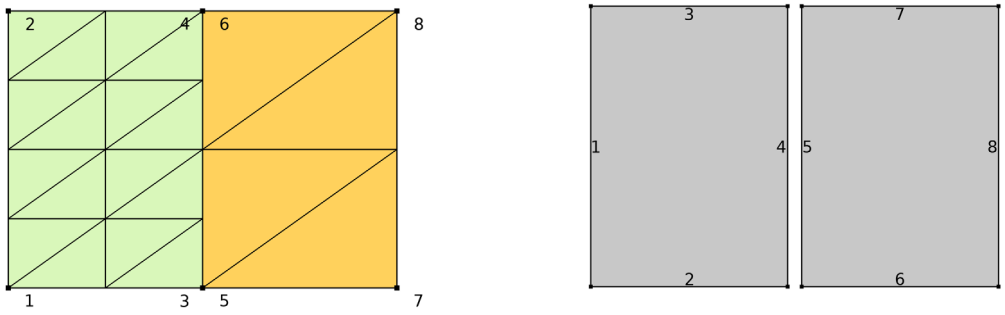

Figure 8-1: The left image shows a nonmatching assembly mesh. The right image shows the geometric model of the mesh in an exploded view where the disconnected components and the duplicated boundaries (edges) are seen more clearly.

To connect the physics in disconnected components, set up **Identity Boundary Pairs** and add pair boundary conditions in the physics interfaces. See About Pairs for more information. Alternatively, if you want to connect the meshes (and avoid setting up pairs), use a Merge Entities operation (supported in 3D only) to merge the boundaries of the disconnected components.

When importing *nonconforming* mesh data, the **Import** operation will typically create edge and boundary elements of the mesh edges and boundaries corresponding to each nonconformity in the mesh, since these mesh edges and boundaries are typically only adjacent to one element each. In Figure 8-2, the image to the left shows the result after importing nonconforming mesh data, with so-called *hanging nodes*. The mesh contains 18 mesh vertices and 20 triangle elements, compared to the assembly mesh in Figure 8-1 which contains 21 mesh vertices. The resulting domains are connected in points 3, 4, and 6 with slit-like holes between the domains, as seen in the exploded view in the right image. Note that the mesh gets 2 domains (indicated by color), 10 edges, and 7 points.

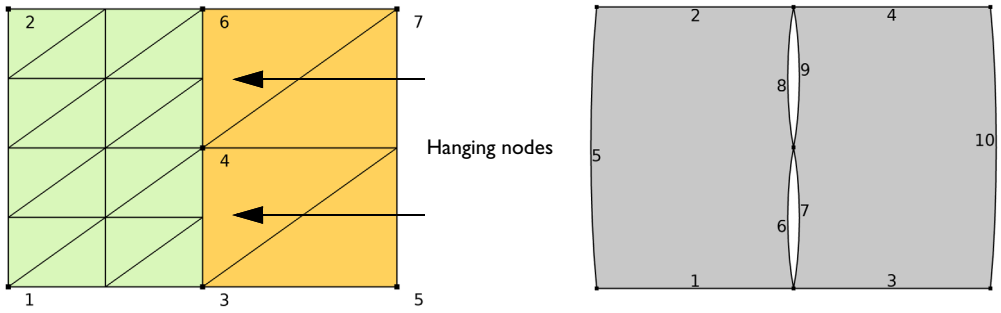

Figure 8-2: Two "hanging nodes" in an imported mesh (left). The image to the right shows the geometric model of the mesh in an exploded view where the slit-like holes and the duplicated boundaries (edges) are seen more clearly.

Similarly, import of nonconforming mesh data containing a 3D volume mesh typically result in many duplicated boundaries (faces) with slit-like pocket holes. Such a mesh is not well suited for simulations in COMSOL

Multiphysics. Use the mesh operation Merge Entities to merge the nearby faces defining the interface between two parts and to create a mesh that is connected across the interface, as seen in Figure 8-3.

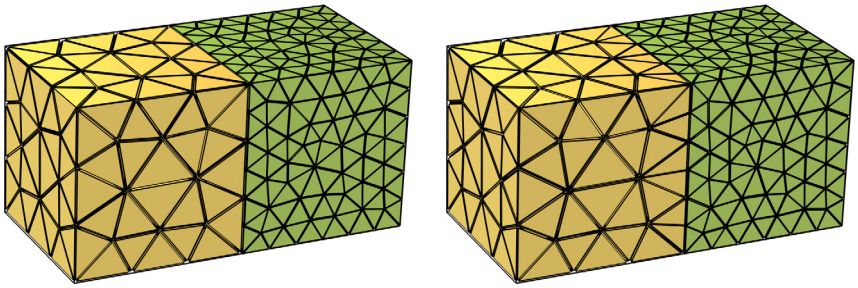

Figure 8-3: Imported nonconforming mesh data in 3D (left) and the mesh where the Merge Entities operation has been used to merge the adjacent faces.

Import of nonconforming mesh data with so called *hanging edges* results in an error. A hanging edge appears when two triangles (yellow mesh faces to the right in Figure 8-4) coincide with a quad (blue mesh face) with which they share mesh vertices.

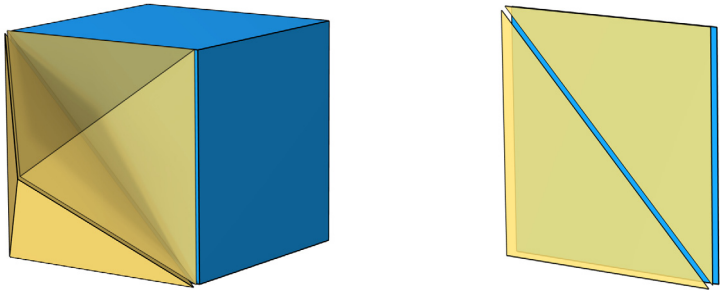

Figure 8-4: A hanging edge appears when the mesh faces of two tetrahedral elements (yellow) coincide with the mesh face of a hexahedral element (blue). The right image shows the triangle and quad mesh faces that share mesh vertices.

- For relatively small slit-like holes in a 3D face mesh, use Fill Holes to repair the slits. This is done in the tutorial *STL Import 1 — Repairing and Combining STL Files*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes**.
- For a 2D example with nonconforming mesh data, import the file `mesh_nonconforming.mphtxt` available in **COMSOL_Multiphysics/Meshing_Tutorials**.

Unstructured Meshes

You can generate unstructured meshes for all types of geometries, regardless of the space dimension, topology, or shape. If you have not defined or generated a mesh, the tetrahedral, or tet, mesher (3D) or triangle mesher (2D) automatically creates an unstructured mesh when a study is computed.

When the tet, triangle, or quad mesher are used, the number of mesh elements is determined by the shape of the geometry and various mesh parameters. See the Mesh Element Sizing section for more information.

2D UNSTRUCTURED MESHES

Use the triangle or quad meshers in 2D to create an unstructured mesh with triangular or quadrilateral elements. You can combine triangular and quadrilateral meshes by adding domains to the Domain list in the corresponding mesh operation's settings. From here, you can define specific meshing operations to each domain in your model.

- Free Triangular
- Free Quad

3D UNSTRUCTURED MESHES

The tet mesher generates an unstructured mesh with tetrahedral elements.

Free Tetrahedral

Structured Meshes

Compared to an unstructured mesh, the interior mesh vertices in a structured mesh are adjacent to the same number of elements.

STRUCTURED TRIANGLE MESHES

You can create a structured triangular mesh on domains in 2D and on faces in 3D by using the Convert operation. There is an option to either introduce a centerpoint (shown in Figure 8-5), or a diagonal edge to quadrilateral elements.

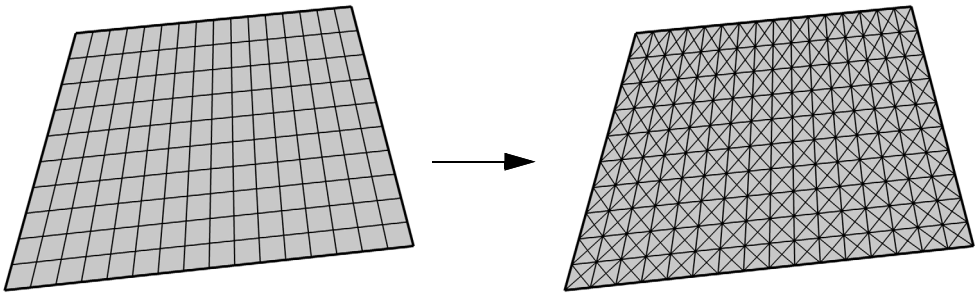

Figure 8-5: A centerpoint is inserted in each quad element, resulting in a structured triangular mesh.

MAPPED MESHES

The Mapped mesher generates a structured mesh with quadrilateral elements (as shown to the left in Figure 8-5).

SWEPT MESHES

The Swept operation generates a structured mesh (at least in the direction of the sweep) with prism or hexahedral elements, as shown in Figure 8-6.

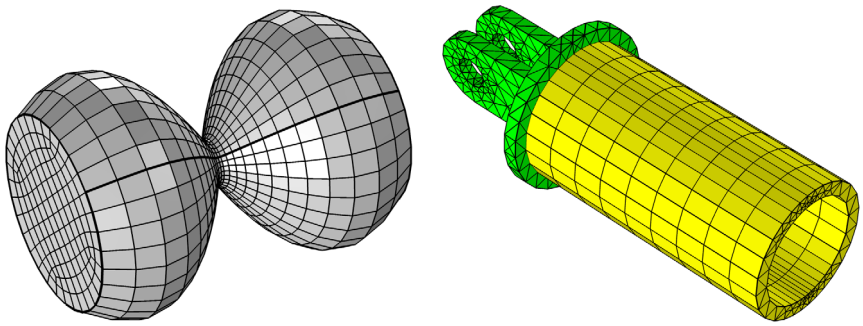

Figure 8-6: Swept meshes. The left image shows a hexahedral mesh. The image on the right-hand side shows a tetrahedral mesh (green) combined with a swept prism mesh (yellow).

2D AND 3D BOUNDARY LAYER MESHES

The Boundary Layers operation also generates a structured mesh. A boundary layer mesh has a dense element distribution in the normal direction along specific boundaries, integrating into an existing structured or unstructured mesh.

- In 2D, a layered quadrilateral mesh is used along the specified boundaries (see blue quads in Figure 8-7).
- In 3D, the boundary layer mesh is a layered prism mesh (see the yellow prisms in Figure 8-7) or a hexahedral mesh, depending on whether the corresponding boundary-layer boundaries contain a triangular or quadrilateral mesh.

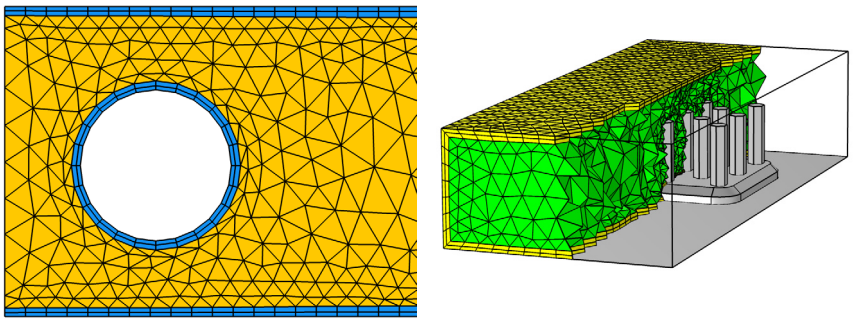

Figure 8-7: In 2D, the boundary layer mesh is always a quad mesh (blue in left image), while in 3D, the boundary layer elements can be either prism elements (yellow in right image) or hex elements.

This type of mesh is typically used for fluid flow problems in order to resolve the thin boundary layers along the no-slip boundaries. Boundary layer meshes can also resolve large temperature gradients close to heated surfaces subjected to sudden changes over time.

The Mesh Toolbar

After a Component has been added to the model, the **Mesh** ribbon toolbar (Windows) or the **Mesh** contextual toolbar (macOS and Linux) is made accessible. Click the **Mesh** ribbon tab to open the **Mesh** ribbon toolbar

(Windows). Click a meshing sequence node in the **Model Builder** and the **Mesh** toolbar displays on the COMSOL Desktop (macOS and Linux).

- For a list of the different options available in the toolbar, see Mesh Toolbar
- The section Meshing Operations and Attributes contains information of all available operations and attributes.

In general, the instructions throughout the documentation indicate that you click a button on a **Mesh** toolbar, no matter what operating system you are running.

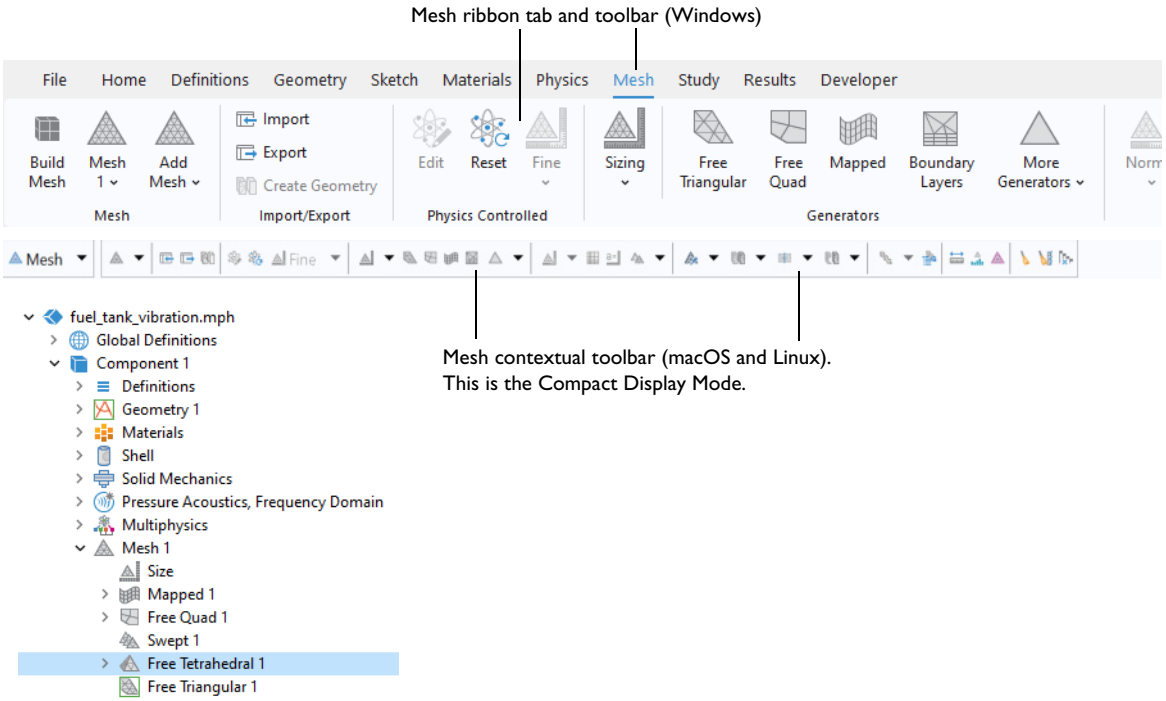

Figure 8-8: Click the Mesh ribbon tab to open the Mesh ribbon toolbar (Windows users, top). For macOS and Linux, click the Mesh node or any of the subsequent operation or attribute nodes to open the Mesh contextual toolbar (bottom). Only some of the available buttons are shown in this image.

PREDEFINED MESH ELEMENT SIZES

The following table shows the icons on the menus for selecting predefined mesh element sizes. There are nine predefined sizes, ranging from Extremely fine to Extremely coarse, as seen in Table 8-1. For more information about controlling the mesh size, see Mesh Element Sizing.

TABLE 8-1: PREDEFINED ELEMENT SIZE ICONS.

ICON	NAME	ICON	NAME
	Extremely Fine		Normal
	Extra Fine		Coarse

TABLE 8-1: PREDEFINED ELEMENT SIZE ICONS.

ICON	NAME	ICON	NAME
	Finer		Coarser
	Fine		Extra Coarse
			Extremely Coarse

GEOMETRIC MEASUREMENTS

To measure the volume, area, or length of a selected domain, face, or edge, respectively, click the **Measure** button ( ). The result displays in The Messages Window. Using this button, it is also possible to view the coordinates of a selected vertex, the distance between two selected vertices, or the number of entities and the geometry representation (only if you have license for the CAD Import Module) of a geometry object.

The Mesh Toolbar in 1D and 2D contains a subset of the tools in the 3D toolbar. See also Measuring Geometry Objects and Entities.

- The COMSOL Desktop
- The Graphics Context Menu
- The Model Builder Context Menu
- Clearing or Deleting a Mesh
- Meshing Operations and Attributes

The Model Builder Context Menu

In addition to adding mesh operations and attributes from The Mesh Toolbar and The Graphics Context Menu, right-click a node in the Model Builder to open a context menu. Depending on the selected node, the menu will

contain Meshing Operations and Attributes that you can choose. The type of meshing sequence also influences the content in the menus. Figure 8-9 shows the context menu when clicking the **Mesh** node.

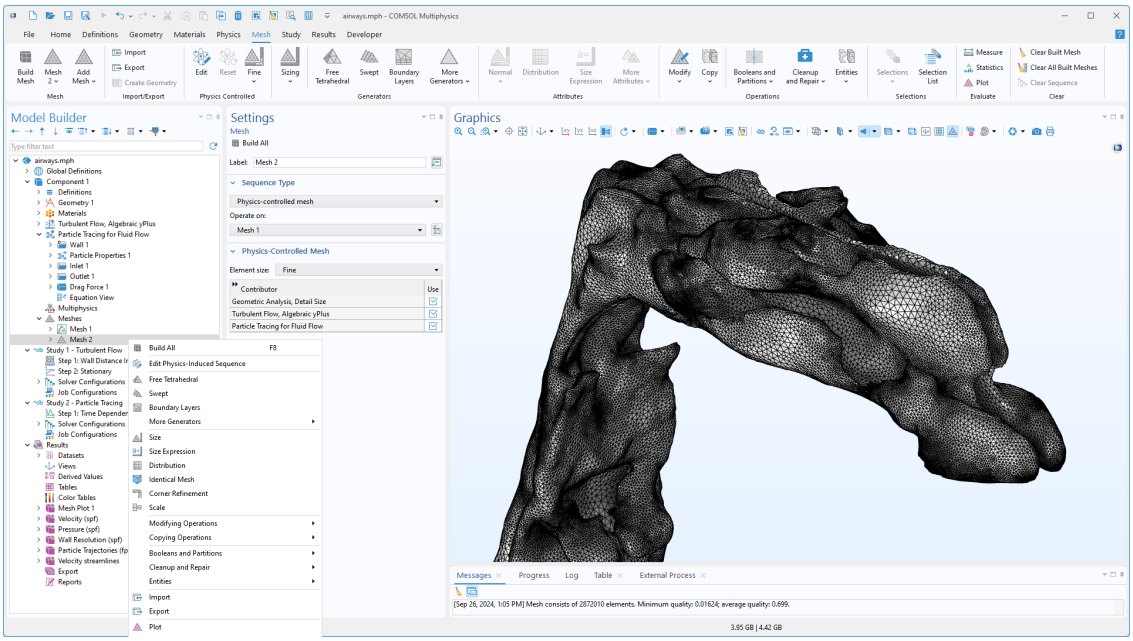

Figure 8-9: The Model Builder context menu when clicking the Mesh node.

- Opening Context Menus and Adding Nodes
- The Graphics Context Menu
- The Model Builder Context Menu
- Clearing or Deleting a Mesh
- Meshing Operations and Attributes

The Graphics Context Menu

Right-click anywhere in the **Graphics** window to open a menu that gives quick access to mesh operations (see Table 8-6) that you can apply in the current context. There are also options to hide entities, add entities to a selection, measure entities, and show the statistics of a mesh.

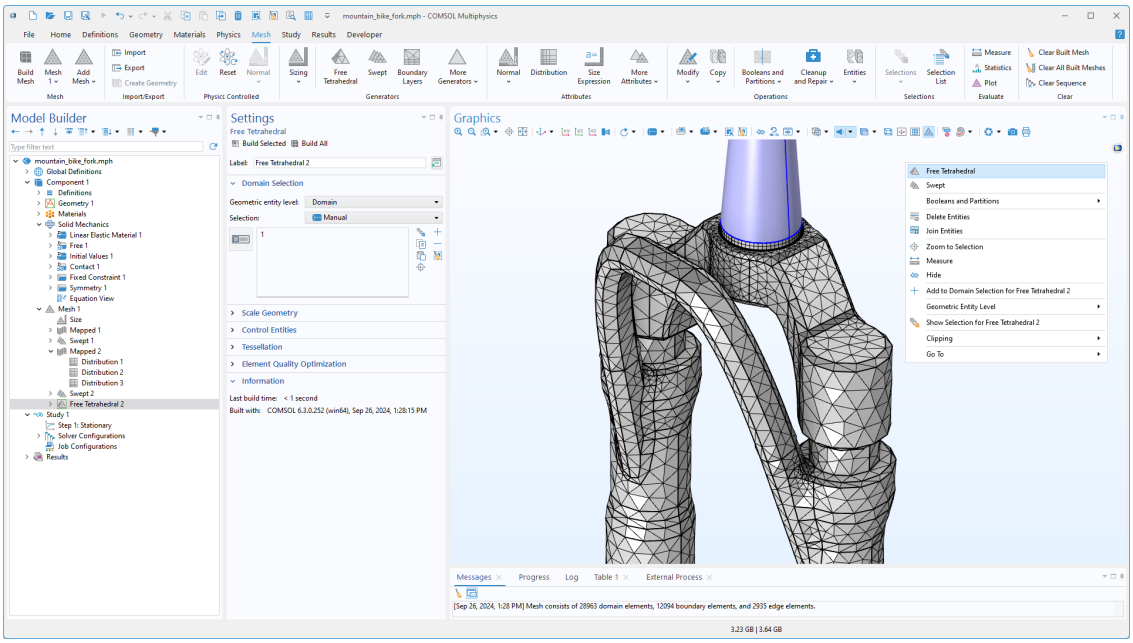

Figure 8-10: The graphics context menu provides quick access to actions and operations that are applicable in the current context. Here, a boundary has been preselected (highlighted in blue).

These different aspects will influence the context:

- The **Sequence type** of the **Mesh** node. Having an empty mesh, a mesh generated based on a geometry, or an imported mesh will all result in different content in the menu. For example, operations associated with imported meshes will not appear in the menu if the mesh is generated based on a geometry.
- If there is a preselection of entities or not. Selecting some boundaries will give a list of operations that support boundary input. A selection of domains will instead show a menu with operations that support domain input.
- The selected entities are unmeshed, partially meshed, or completely meshed. For a preselection where all selected entities are meshed, only operations that can modify a mesh will show up, while the menu for a partially meshed or unmeshed preselection will contain operations that generate meshes.
- The current **Settings** window. For **Settings** windows of a mesh operation, there will be an option to show the current selection. There is typically also an option to add preselected entities to the selection of the operation.

SETTINGS TO CONTROL THE AUTOMATIC BUILD OF MESH OPERATIONS

You can configure the software to build certain mesh operations automatically when you add them from a nonempty preselection. For example, if you select a boundary on a 3D geometry, then right-click in the **Graphics** window, and from the context menu select Free triangular, the operation can be built automatically after it is added to the meshing sequence. The behavior can be controlled with settings on two levels:

- A preference setting controls the default in new meshes.

- Override the preference setting for a mesh sequence in The Mesh Node settings and the Mesh Parts settings. See the respective sections for more information on the settings.

- About Context Menus in the Graphics Window
- The Mesh Node
- Mesh Parts
- Meshing Operations and Attributes
- The Mesh Toolbar
- The Model Builder Context Menu

Meshing Sequences

You create a mesh by building a meshing sequence, which contains a number of Meshing Operations and Attributes as nodes in the sequence. For the default physics-controlled mesh type, the software sets up the meshing sequence automatically. Edit the physics-controlled sequence or set up the meshing sequence manually using the user-controlled mesh sequence type. The operations will always be built top-down. The attributes will also be read in that order which means that the last attribute on a selection is the one that defines the Mesh Element Sizing.

In this section:

- The Mesh Node
- Editing and Resetting a Physics-Controlled Sequence
- Adding, Editing, and Building Meshing Operations and Attributes
- Finalizing the Mesh
- Meshes Generated by Adaptation
- Locking the Mesh
- Mesh Parts

The Mesh Node

When you add a new Component to the Model Builder, a meshing sequence is added by default in the **Mesh** node (or). You can add more meshing sequences to the Component by right-clicking the **Component** node and selecting **Add Mesh**, or by selecting the same option from The Mesh Toolbar. When a Component has more than one meshing sequence, they are collected under a **Meshes** node. To add new meshing sequences to such a Component, you can alternatively right-click **Meshes**.

GEOMETRIC MODEL

The **Mesh** icon ( ) means that the mesh is conforming with the *geometric model* of the component's geometry, which is the result of the geometry operations in the component's **Geometry** node. The **Mesh** node icon ( ) decorated with the geometry compass means that the meshing sequence defines its own geometric model, for example a mesh sequence where you import a mesh. A green or yellow frame around the **Mesh** node icon ( ) means that the physics is defined on the geometric model defined by this mesh.

To change the geometric model on which the physics is defined, go to the **Settings** window for the Component. Under the section **Geometric Model**, set **Physics defined on** to an available geometry or meshing sequence (see also Geometric Model).

A meshing sequence defines its own geometric model if it contains operations that can change the number of geometric entities, for example by introducing new boundary partitions. Such operations are the ones from the categories Cleanup and Repair, Booleans and Partitions, Entities, and the **Import** operation.

Depending on the **Physics defined on** setting for the component, an added mesh either operates on the geometry sequence or the mesh that currently defines the geometric model of the component.

Geometry Dimensions, Geometry Objects, and Geometric Entities

When, inside a meshing sequence that is conforming with a geometry, add an operation that can change the number of geometric entities, the following happens:

- The current mesh is imported to a new meshing sequence that defines its own geometric model. This mesh is not connected to the geometry.
- The mesh operation is added to the new meshing sequence.
- This new meshing sequence is set as the component's geometric model on which the physics is defined.

For a mesh sequence that defines its own geometric model, and the mesh is not an imported mesh with higher-order elements, the higher-order nodes are placed based on curved faces determined by the linear mesh. For more information, see Imported Meshes and Element Orders.

The **Mesh** node's **Settings** window contains the following sections:

SEQUENCE TYPE

From the list, choose **Physics-controlled mesh** (the default) to let the physics interfaces determine the meshing sequence according to the **Physics-Controlled Mesh** section below, or choose **User-controlled mesh** to control the mesh directly using subnodes to this **Mesh** node, such as Meshing Operations and Attributes.

Operate on points to the geometric model on which the mesher is operating. This information is only shown when needed. Click the **Go to Source** ( ) button to go to the node it operates on.

For a mesh sequence that defines its own geometric model, add another **Mesh** node that operates on the first mesh to get access to the sequence types **Physics-controlled mesh** and **User-controlled mesh**. For a mesh that is operating on the component's geometry, the sequence type **Physics-controlled mesh** is available only when, in the **Settings** window for the Component, the Geometry is selected from the **Physics defined on** list.

If you select **Physics-controlled mesh** in the **Sequence type** list in the **Settings** window of a **Mesh** node and build the meshing sequence, COMSOL Multiphysics creates a mesh that is adapted to the current physics interface settings in the model. The default is to use physics-controlled mesh. For example, for a fluid flow model you get a somewhat finer mesh than for general physics with a boundary layer mesh along the no-slip boundaries. If you want to modify the overall element size of the physics-induced mesh, select another element size from the **Element size** list in the **Settings** window of the main Mesh node and rebuild the mesh. If you change the physics interface settings in the model and rebuild the meshing sequence, COMSOL Multiphysics creates a new mesh adapted to the new physics interface settings.

A physics-induced mesh is not adapted by numerical error estimates — that type of adaptive meshing is provided by mesh adaptation in the solver sequence. See Meshes Generated by Adaptation.

In a user-controlled mesh, it is possible to manually build and edit the meshing sequence using the meshing techniques described below.

If you select **User-controlled mesh** from the **Sequence type** list in the main **Settings** window for a **Mesh** node, the program adds a **Size** node and a node for the default mesh generator (Free Triangular in 2D and Free Tetrahedral in 3D). If the **Sequence type** list is set to **Physics-controlled mesh** and you add a **Size** node, for example, the meshing sequence switches to **User-controlled mesh**, but no default mesh generator is added.

It is only possible to choose **Physics-controlled mesh** if the geometry sequence defines the *component's geometric model*, on which the physics is applied. A mesh that defines its own geometric model can only have the sequence type **User-controlled mesh**.

When running a study with adaptation, the solver will automatically set up new adapted meshes which will be noted **Controlled by adaptation study** and the study will be selected in the list. The mesh will be automatically updated when rerunning the study. Click the button **Disconnect from Study and Edit** to be able to inspect and edit the meshing sequence. A disconnected mesh will not be updated when rerunning the study. For more information, see Meshes Generated by Adaptation.

If you select **Lock Mesh** ( ) from The Model Builder Context Menu, the mesh will be noted **Locked Mesh**. For more information, see Locking the Mesh.

In addition to the selection list, an information text can appear to clarify if the meshing sequence is conforming with the geometry or defines its own geometric model.

PHYSICS-CONTROLLED MESH

This section is only available when the sequence type is set to **Physics-controlled mesh**.

From the **Element size** list, choose an element size for the mesh, ranging from **Extremely coarse** to **Extremely fine** (default value: **Normal**).

In the table below, **Geometric Analysis, Detail Size**, all active physics interfaces, multiphysics couplings, and moving mesh features in the model component appear in the **Contributor** column. By default, all checkboxes under **Use** are selected so that the geometric analysis, all listed physics interfaces, and moving mesh features contribute to the mesh control suggestions. Clear some of the checkboxes if desired to control if the geometric analysis, which physics interfaces, and other features that contribute to the physics-controlled mesh. Some physics interfaces might have additional settings for mesh control. A separate section with these settings appears for every such physics interface if its corresponding **Use** checkbox is selected. See the documentation for each individual physics interface for more details.

BUILD SETTINGS

This section is available when the sequence type is set to **User-controlled mesh** and for Mesh-Based Cleanup nodes.

Select the **Build new operations automatically** checkbox to allow new operation for this mesh to build automatically. Clear the checkbox to require that the **Build Selected** or **Build All** buttons are clicked in order for the operations to build. The default value is controlled by the preference setting **Mesh** > **Build new operations automatically**. Select the **In new meshes** preference setting to always build operations directly, unless overridden by the settings in the individual **Mesh** nodes.

When the mesh defines its own geometric model and the physics is defined on this geometric model, the setting **Build automatically when leaving mesh** appears. This setting controls if the meshing sequence is automatically built (selected by default) when going to another node in the model builder where the geometric model of the mesh is used. For example, when defining materials or physics settings.

See Adding, Editing, and Building Meshing Operations and Attributes for more information about building meshing sequences.

PHYSICS RELATED SECTIONS

This section is only available when using certain kinds of physics. See the documentation for each individual physics interface for more information.

For examples of user-controlled meshing sequences, see

- *Using Meshing Sequences*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/meshing_sequence**.
- *Swept Meshing of a Bracket Geometry*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/bracket_swept_mesh**

Editing and Resetting a Physics-Controlled Sequence

To edit a physics-induced meshing sequence, click **Edit** ( ) in the **Mesh** toolbar, select **User-controlled mesh** in the **Sequence type** list, or right-click the **Mesh** node and select **Edit Physics-Induced Sequence** ( ). This is done automatically if an error occurs, so that the error can be investigated in detail. The program then adds the operations and attributes under the main **Mesh** node that together build the physics-controlled mesh.

By doing this, the sequence is no longer updated according to changes that applied to the physics interface settings in the model.

If you right-click the **Mesh** node and select **Reset to the Physics-Induced Sequence** ( ) or click **Reset** ( ) in the **Mesh** toolbar, the sequence or operations and attributes is reset to the physics-induced sequence. However, the type of the sequence is still **User-controlled mesh**. To switch back to physics-controlled meshing, select **Physics-controlled mesh** in the **Sequence type** list in the **Settings** window of the mesh node. If you add a node to the sequence, the type of the sequence automatically switches to **User-controlled mesh**.

See The Mesh Node for more information about sequence types and the settings of a meshing sequence.

Adding, Editing, and Building Meshing Operations and Attributes

If you select **User-controlled mesh** as the sequence type in The Mesh Node, add individual Meshing Operations and Attributes to manually set up a meshing sequence. This section describes how to add operations and attributes in the meshing sequence, how to edit them, and how to build them.

ADDING MESH OPERATIONS AND ATTRIBUTES

Right-click a **Mesh** node (or) in the Model Builder and then select an operation or attribute from The Model Builder Context Menu. Attributes can be added as local attributes by right-clicking on an operation in the Model Builder. It is also possible to add operations and attributes from The Mesh Toolbar or from The Graphics Context Menu. Enter the properties of the operation or attribute as described below.

EDITING MESH OPERATIONS AND ATTRIBUTES

To edit a mesh operation or attribute, select it in the tree, and make changes in the **Settings** window that appears. In numerical fields you can enter expressions that contain global parameters. The icons of operations and attributes that you have edited display with an asterisk (*) at the upper-right corner of the icon ( ) in the **Model Builder**.

The following operations are marked with a yellow triangle at the lower-right corner of the icon to indicate that they need to be rebuilt. To see the result of your edits in the **Graphics** window, use the methods described below to either **Build Selected** or **Build All** nodes.

BUILDING SELECTED MESH OPERATIONS

To build all operations (if needed) from the first up to the selected one:

- In a **Settings** window, click the **Build Selected** button ( ).
- Right-click an operation under the **Mesh** node and select **Build Selected** ( ).
- Select the operation in the Model Builder and press F7.

BUILDING ALL MESH OPERATIONS

To build all operations in the meshing sequence, including Finalizing the Mesh (if needed):

- In a **Settings** window, click the **Build Mesh** button ( ).
- Right-click the main **Mesh** node ( ) and select **Build All**.
- Select the **Mesh** node in the Model Builder and press F8.
- In the **Home** or **Mesh** toolbars, click **Build Mesh** ( ).

	Using Meshing Sequences: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/meshing_sequence**

	See The Mesh Node for more information about sequence types, adding more meshing sequences, and the mesh sequence settings.

Finalizing the Mesh

The **Finalize** node ( ) ends a meshing sequence of user-controlled type that also defines its own geometric model. It performs an associativity update for geometric entity numbers. You cannot delete, disable, or move the **Finalize** node.

	See The Mesh Node for more information about meshes that define their own geometric models.

If the setting **Build automatically when leaving mesh** is selected in The Mesh Node, the software automatically builds all nodes in a meshing sequence, including the **Finalize** node, if you select another node in the Model Builder where the entities of the mesh are used. This typically happens when you go to the Materials node or a physics interface.

BUILDING SEVERAL MESHING SEQUENCES THAT DEFINE GEOMETRIC MODELS

It is possible to add several meshes that define their own geometric models, that you can use to set up the geometric multigrid solver with multiple meshes. See The Mesh Node for information on how to add meshing sequences and The Geometric Multigrid Solver with Several Meshes for information about setting up the multigrid solver manually.

The **Mesh** node ( ) under **Meshes** that has a frame around its icon defines a topology and is referred to as the component's geometric model, or the *primary sequence*, on which the physics is defined. All of the other **Mesh** nodes must define a geometric model that is topologically similar to the one defined by the primary sequence. Two

geometric models are considered to be similar if they have the same number of geometric entities and their points have the same coordinates.

When you build and finalize a nonprimary sequence, the COMSOL Multiphysics software first builds and finalizes the primary sequence. If the build of the primary sequence fails or if the geometric models defined by these two sequences are not similar, an error occurs.

- Importing Meshes
- Multigrid
- The Mesh Node

Meshes Generated by Adaptation

The solvers can generate adapted meshes for several problem types. See Adaptation and Error Estimates and The Adaptive Solver Algorithms and Error Estimation.

The meshes generated by the stationary or eigenvalue adaptive solver are based on the original meshing sequence and can be modified. The settings window for such a meshing sequence shows a reference to the generating study in the **Adaptation study** list. Click the **Go to Source** button ( ) to move to that generating study. Click the **Disconnect from Study and Edit** button, or right-click the **Mesh** node and select **Disconnect from Study and Edit**, to unlock the sequence and enable editing. Note that unlocking the sequence disconnects the mesh from the study that generated it; if you run the study again, this mesh is ignored and a new meshing sequence is generated. However, you can manually select this meshing sequence in the mesh selection of a study step, to run the study on the adapted and modified mesh.

Adapted meshes generated by the time-dependent adaptive solver are generated directly by the solver and cannot be further edited. If you alter the geometry, these meshes are no longer compatible with the geometry and are therefore removed. If you want to keep an adapted mesh even if the geometry is altered, select to disconnect from the study, and then select to lock the mesh (if not already locked). For more information, see the section Locking the Mesh.

Locking the Mesh

Locking the Mesh

Use the action **Lock Mesh** ( ) to convert the current meshing sequence to a single **Mesh** node holding only its output mesh. Locking a mesh is useful if you want to keep an adapted mesh but need to clear the solution data that

generated the adapted mesh. Another case is if you know that you will work with a fixed mesh, and want to save disk space. This mesh is locked and independent of any other data in the model.

While it is possible to undo this action, it is not possible to later unlock the mesh to reconstruct the sequence that generated it. If you need to modify a locked mesh in some way, add a new **Mesh** node in the same Component and add a Copy operation to copy the locked mesh to the domains in the geometry. After that, it is possible to modify the mesh as discussed in the section Modifying the Element Size Using Refine and Adapt. For a locked mesh that defines its own geometric model, add an **Import** operation instead of a **Copy** operation.

The **Compact History** action is not supported for models including a locked mesh.

The lock action is only available from The Model Builder Context Menu. The mesh remains connected with the geometry for exact placement of higher-order nodes of curved elements. The connection to the geometry also means that, if the geometry is modified, the locked mesh, which is connected with the old geometry, will become disconnected from the geometry. Use the option **Disconnect from Geometry** ( ) on a locked mesh to manually break the connection with the geometry. Then the mesh will define its own geometric model and be independent of the geometry. A locked mesh will define its own geometric model if the original mesh defines its own geometric model.

- Meshes Generated by Adaptation

Mesh Parts

You can use mesh parts for importing and preparing a mesh for use in a geometry sequence or meshing sequence. A mesh part is defined by an imported mesh from an STL, VRML, NASTRAN, MPHBIN, or MPHTXT file, mesh data imported from results, or from some other meshing sequence. In addition, you can use mesh import operations to delete or partition parts of the mesh, for example, to prepare the imported mesh for use in a geometry sequence or meshing sequence, where you refer to the mesh part in an **Import** node. To insert the mesh into the new component, you can use a **Copy** node in the meshing sequence, where you use the mesh from the mesh part as the source.

When importing a NASTRAN file in the mesh part, it might include material definition, variables, and selections. All those properties are transferred to the component where you import the mesh part.

You can add mesh parts from the **Global Definitions** node ( ) by right-clicking it and, from the **Mesh Parts** submenu, select **3D Part**, **2D Part**, or **1D Part**. If a **Mesh Parts** node ( ) already exists under **Global Definitions**, you can add another mesh part by right-clicking it and then select **3D Part**, **2D Part**, or **1D Part**.

Under a **Mesh Part** node you add nodes for importing and modifying an externally generated mesh. An **Import** node (see Importing Meshes) is automatically added to import a mesh. In 2D and 3D, you can then add additional nodes for partitioning the mesh, deleting and joining entities, creating entities, and Remeshing Imported Meshes. Such operations can be useful to define additional domains, for example. There is also a **View** node with view settings (see User-Defined Views) below the mesh feature nodes.

In a geometry sequence or part you can create an instance of the mesh part by right-clicking the **Geometry** node and adding an **Import** node (see Import in the Geometry Modeling and CAD Tools chapter). Then choose **Mesh**

or STL (in 3D) or **Mesh** (in 1D and 2D) from the **Source** list and choose the mesh part from **Mesh** list below to use the mesh part in the geometry sequence.

The **Settings** window for a **Mesh Part** node contains the following sections:

MESH SETTINGS

Select the **Build new operations automatically** checkbox to allow new operations for this mesh part to build automatically. Clear the checkbox to require that the **Build Selected** or **Build All** buttons are clicked in order for the operations to build. The default value is controlled by the preference setting **Mesh** > **Build new operations automatically**. Select **In new meshes** checkbox to always build operations directly, unless overridden by the settings for an individual mesh part.

UNITS

For mesh files that are unitless, the physical size of an imported mesh is independent of the length unit of the mesh part. For mesh files that define a unit, the imported mesh is scaled to match the unit of the mesh part, if the **Use units** checkbox is selected. You can also select this checkbox to use the length unit and angular unit (which you specify using the **Length unit** list and **Angular unit** list, respectively) in the nodes appearing under the **Mesh Part** node and to specify the length unit of the resulting file when exporting the mesh to a file format that supports length units.

If the mesh part and the component referring to the mesh part have different unit systems, the resulting geometry is scaled.

STL Import 1 — Repairing and Combining STL Files: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes**

Mesh Element Sizing

The mesh resolution and Mesh Element Quality are important aspects to consider when validating a model. The goal is to resolve details in the geometry and solution well enough while at the same time use a coarse enough mesh to get a solution in a reasonable time.

When you build a mesh in the software without doing any modifications, a Physics-Controlled Mesh is built. This means that the software controls the mesh resolution by setting up a suitable sequence of Meshing Operations and Attributes in the background.

To manually assign sizes on individual entities, select to edit the physics-controlled mesh, then select to add Attributes. Use predefined sizes or define customized size parameters, expressions, or distributions. See also Editing and Resetting a Physics-Controlled Sequence and Adding, Editing, and Building Meshing Operations and Attributes.

In this section:

- Controlling the Mesh Size Using Attributes
- Preparing the Geometry for Meshing Using Geometry Cleanup
- Controlling the Mesh Size Using Mesh Control Entities
- Modifying the Element Size Using Refine and Adapt

Controlling the Mesh Size Using Attributes

The size of the elements generated by the mesh operations is determined by mesh parameters. The parameters are in turn are controlled by the attributes Size, Size Expression, Distribution, and Corner Refinement (see Figure 8-11 for the settings in a Size node).

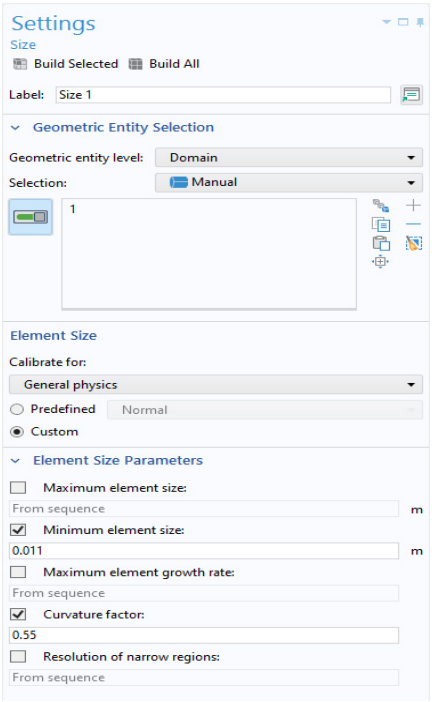

Figure 8-11: An example of custom element mesh sizes. You can also select Predefined element sizes.

You can define mesh parameters using numerical values, globally defined parameters, and built-in mathematical and physical constants.

There are nine predefined sizes to choose from in the Size attribute, ranging from Extremely fine to Extremely coarse. The sizes of the generated mesh elements are determined by absolute mesh size parameters that can be viewed and edited for a user-controlled mesh. The absolute element size parameters depend on the size of the geometry's bounding box. For example, if half of the geometry is deleted, the bounding box will be smaller. As a result, the maximum element size and minimum element size will be smaller compared to before, even though the same predefined element size has been used. For more information about the different size parameters and how to edit them, see Element Size Parameters.

Attributes contain size properties defined on a selection. For a user-controlled mesh, it is possible to manually modify the individual size parameters and selection of an attribute. See The Mesh Node and Editing and Resetting a Physics-Controlled Sequence for more information about sequence types. You can add a global attribute node directly under the **Mesh** node, or add it as a local attribute node under an operation node. Properties defined in a local attribute are only used by the owning operation node while the global attribute nodes define mesh sizes for the whole meshing sequence, either on the entire geometry or on a selection of entities. If more than one attribute is applied on the same selection of entities, the last attribute in the sequence defines the size.

For a local Size attribute, select the **Custom** option button to modify individual size parameters. If the checkbox next to a size parameter is not selected, the value is taken from attributes above in the sequence (see Figure 8-11). To have full control over a size parameter, select its checkbox.

Use a Size Expression attribute to define the size of the mesh elements as function of coordinates, parameters, materials, and variables. You can also use global functions, and variables evaluated from solutions in the size

expression. Using a coordinate based expression is a useful alternative to creating additional geometric entities in a region of your geometry where you need finer mesh (see Figure 8-12).

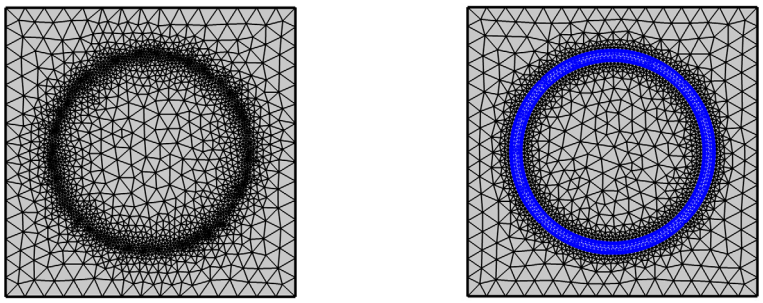

Figure 8-12: Refined meshes obtained in two different ways. Using the Size expression max(abs(sqrt(x^2+y^2)-0.35),0.01) (left) and applying a Size attribute with the predefined size Extremely fine in the ring shaped region (right).

It is possible to scale the properties of other attributes using a Scale attribute. An imported mesh can be scaled using a Transform attribute.

	For a tutorial about how to change the mesh size parameters to adjust the element size, see *Adjusting the Element Size for the Unstructured Mesh Generator*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/piston_mesh**.

	• Size • Distribution • Size Expression • Scale • Transform

Preparing the Geometry for Meshing Using Geometry Cleanup

To avoid unnecessary mesh refinements and bad quality elements relating to small details in the geometry, use Geometry Cleanup to prepare the geometry for meshing (see Figure 8-13). Small details, such as vertices with continuous tangent, short edges, small and narrow (sliver) faces, narrow face regions, and thin domains, can result in a high mesh resolution as each entity needs to be resolved by at least one mesh element. Small details can also influence the quality of the mesh elements, which might affect the possibility to reach a converged solution. See the section Mesh Element Quality for more information about element quality measures.

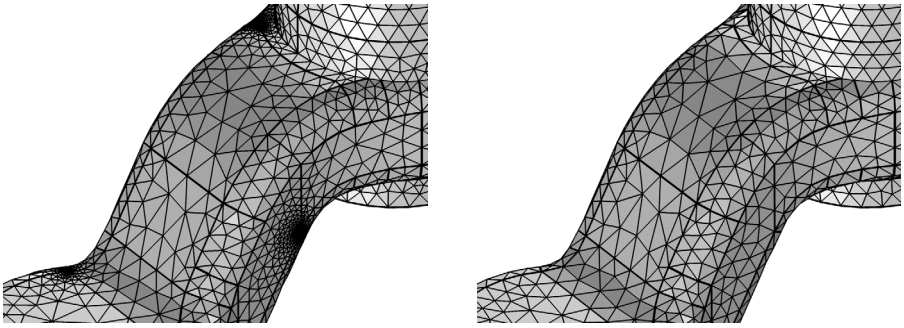

Figure 8-13: Comparing the mesh of a CAD geometry before and after building Remove Details.

Geometry Cleanup automatically detects and removes small details from the geometry. Modify the detail size to remove more or less details in the geometry. After running the cleanup, resolve the mesh only in regions of importance for the accuracy of the solution.

For more information geometry cleanup, refer to the section Geometry Cleanup

Controlling the Mesh Size Using Mesh Control Entities

The most straightforward way to control the mesh size in a part of a domain or on part of a boundary is to partition the geometry in such a way that a mesh Size can be assigned on the entity in question. However, the additional domain, face, or curve is typically not wanted when assigning materials and physics. Mark the additional entity as a mesh control entity to remove it from the view once it has been meshed.

For example, add a rectangle inside a 2D domain to resolve the mesh inside the rectangle (see right image in Figure 8-14). Mark the resulting edges as a mesh control entity to remove it from the geometry when defining the physics and materials. An advantage is that the final mesh need not respect the mesh control edges exactly; it is used only to control element size and then the mesh is smoothed, as shown in the left image below.

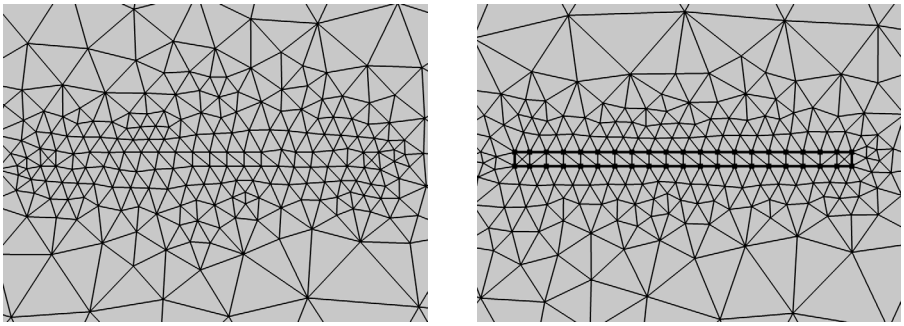

Figure 8-14: Comparison of meshes when Mesh control entities is used vs. not used for the interior boundaries.

Another situation where mesh control entities are useful is when you need precise control of the mesh in certain regions of the geometry. In these regions you typically use a structured mesh with distribution nodes to control the mesh. In other regions of the geometry you can use an unstructured mesh.

Building a boundary layer mesh adjacent to an internal boundary means that the boundary layer mesh need to respect them. This can lead to low-quality elements at acute angles and even meshing failures. Mark internal boundaries that are not needed with respect to materials and physics as mesh control entities to give boundary layer mesher more freedom to move mesh nodes and construct a better mesh.

See the suggested tutorials for each of the Mesh Control Operations.

- For more information about the different operations, refer to the section Virtual Geometry and Mesh Control Operations
- Working with Geometric Entities
- Named Selections

Modifying the Element Size Using Refine and Adapt

All meshes can be modified using the Refine and Adapt operations. The **Refine** operation splits elements a specified number of times by inserting new mesh vertices and mesh edges in the existing elements (see the upper right image in Figure 8-15). For a larger mesh, it is often quicker to refine an existing mesh instead of remeshing with finer mesh size settings. The **Adapt** operation is more general and can both refine and coarsen meshes based on a solution's error estimate, an absolute size, or an isotropic metric (see the lower right image in Figure 8-15). The operation is free to move mesh vertices and also remove mesh vertices. The **Adapt** operation can also be used to improve the quality of an imported surface mesh, as discussed in the section Remeshing Imported Meshes.

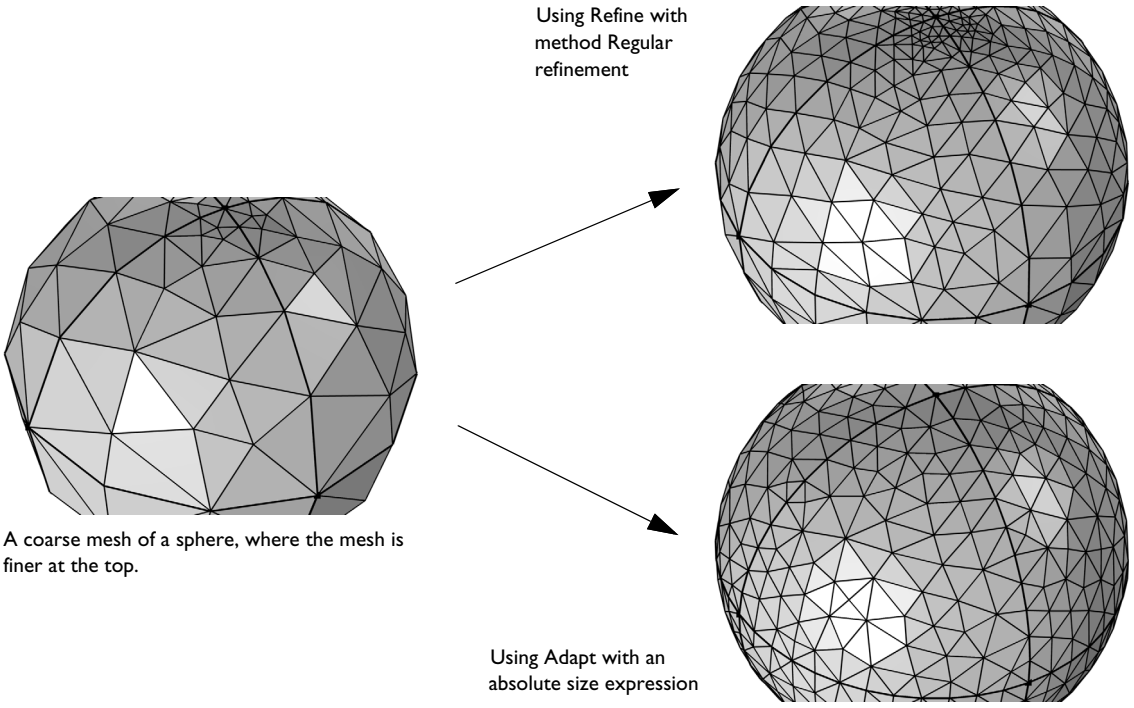

Figure 8-15: Comparison of meshes modified by Refine and Adapt. The Refine operation refines all mesh elements, also the smaller ones at the top of the sphere. The Adapt operation coarsen the mesh at the top and refines the larger elements, resulting in more uniform mesh sizes.

Both operations place new and moved mesh vertices on a higher order representation of the faces and edges. This means that a refined mesh will resolve curved faces better. See Figure 8-15 where the spherical shape is better resolved in the images to the right.

For more information about modifying a mesh based on an error estimate, see the section Meshes Generated by Adaptation.

Inspecting and Troubleshooting Meshes

To evaluate if the mesh is good enough for the problem at hand, it is important to investigate the Mesh Element Quality. The Mesh Statistics, Mesh Plots, and Information, Warning, and Error Nodes for Meshing Operations are all useful tools to inspect a mesh. The last sections provide assistance when problems appear.

In this section:

- Mesh Element Quality
- Mesh Statistics
- Mesh Plots
- Information, Warning, and Error Nodes for Meshing Operations
- Avoiding Inverted Mesh Elements
- Troubleshooting Tetrahedral Mesh Generation
- Troubleshooting Boundary Layer Mesh Generation

- Errors, Warnings, and Information
- Analyzing Model Convergence and Accuracy
- Achieving Convergence When Solving Nonlinear Equations
- Physics-Related Checks and Guidelines
- Geometric Variables, Mesh Variables, and Variables Created by Frames

Mesh Element Quality

The mesh resolution and mesh element quality are important aspects to consider when validating a model. Low mesh resolution — in relation to the variations in the solution and the geometry — can lead to inaccurate results. See Mesh Element Sizing for more information. A low mesh element quality — which measures the regularity of the mesh elements' shapes — can lead to inverted mesh elements (see Avoiding Inverted Mesh Elements) and to high condition numbers for the Jacobians, which in turn can cause convergence issues. The mesh element quality is a dimensionless quantity between 0 and 1, where 1 represents a perfectly regular element, in the chosen quality measure, and 0 represents a degenerated element. COMSOL Multiphysics includes the following mesh quality measures:

- **Skewness**, which is the default quality measure in Mesh Statistics and Mesh Plots, is a measure of the equiangular skew is defined as the minimum of the following quantity:

$$1 - \max\left(\frac{\theta - \theta_e}{180 - \theta_e}, \frac{\theta_e - \theta}{\theta_e}\right)$$

  where θ is the angle over a vertex (2D) or edge (3D) in the element, θ_e is the angle of the corresponding edge or vertex in an ideal element, and the minimum is taken over all vertices (2D) or edges (3D) of the element.
- **Maximum angle**, which is based on the largest angle in the element. If no angle is larger than the largest angle of the corresponding optimal element, the quality is one; otherwise, the measure shows how much larger the angle is. This quality measure is insensitive to element anisotropy.
- **Volume versus circumradius**, which is based on a quotient of the element volume and the radius of the circumscribed sphere (or circle) of the element. This quality measure is sensitive to large angles, small angles, and anisotropy.

- **Volume versus length**, which is based on a quotient of element edge lengths and element volume. This quality measure is primarily sensitive to anisotropy.
- **Condition number**, which is based on the element dimension divided by the condition number (in the Frobenius norm) of the matrix transforming the element to a reference element.
- **Growth rate**, which is a measure of local (anisotropic) growth rate. Let $s_\alpha(\boldsymbol{E})$ denote the element size of an element $\boldsymbol{E}$ in a spatial direction α, and let $\boldsymbol{E}_\alpha$ denote the element neighbor of $\boldsymbol{E}$ in the direction α. The growth rate measure is then the minimum of the quotient $\min(s_\alpha(\boldsymbol{E}), s_\alpha(\boldsymbol{E}_\alpha))/\max(s_\alpha(\boldsymbol{E}), s_\alpha(\boldsymbol{E}_\alpha))$, where α is taken over all directions. For a uniform sized mesh, the growth rate will be 1.
- **Curved skewness**, which is defined as the elementwise product of skewness and `reldetjacmin`, which is a measure of the deformation when generating the higher-order element (see Table 5-10 in the Global and Local Definitions chapter). When curved skewness is evaluated in Mesh Statistics, the deformation always uses the second-order Lagrange geometry shape function. If you want to evaluate curved skewness for some other geometry shape function, you can do so by evaluating the built-in variable `qualcurvedskewness` on a mesh dataset with the desired setting or a solution dataset. If you plot the mesh from the solution dataset, you will measure the same deformation as in your solution. If you use a mesh dataset, you need to set the desired geometry shape function explicitly in the settings for the dataset. The default geometry shape function for the mesh dataset is linear, which makes skewness and curved skewness equivalent. You can use a plot of the curved skewness to find badly shaped mesh elements.

The `qualcurvedskewness` measure is equivalent to `qualskewness` for face elements not adjacent to domain elements in 3D.

- **Custom expression** (available in the Settings window of Mesh Plots), where your can enter a custom expression for the mesh quality (using the variables listed below, for example). The expression must evaluate to scalar values from 0 to 1.

Below is a list of all built-in variables available for these mesh quantities. For more built-in mesh variables, see Table 5-10 in the Global and Local Definitions chapter.

- `h`, the local mesh size.
- `qualskewness`, the skewness mesh quality measure, which is the default mesh quality measure.
- `qualmaxangle`, the maximum angle mesh quality measure.
- `qual`, the volume versus circumradius quality measure.
- `qualvollength`, the volume versus length mesh quality measure.
- `qualcondition`, the condition number mesh quality measure.
- `qualgrowth`, the growth rate mesh quality measure.
- `qualcurvedskewness`, the quality measure of the deformation when generating higher-order elements.

All these variables are also available in variants for the various frames in a moving mesh or deformed geometry simulation, for example. Append `_geometry`, `_mesh`, or `_spatial` to the base variable name to evaluate the quantity in the geometry frame, mesh frame, or spatial frame, respectively.

Using built-in variables without a frame suffix refers to the material frame if several frames are used.

For quadrilateral and hexahedral elements with a large aspect ratio, which can appear in boundary layers, for example, the default mesh quality measure — skewness — and the maximum angle and quality measures report a high mesh quality, whereas the volume versus circumradius and the volume versus length quality measures report a low mesh quality because those measures take the aspect ratio into account.

In general, if a mesh with a low mesh quality has been generated, an **Information** node appears. See the sections Displaying Mesh Element Quality and the Mesh Element Size and Information, Warning, and Error Nodes for Meshing Operations for more information on how to locate the elements of low quality.

For examples of how to inspect your mesh, see:

- Mesh (Export)
- Mesh Report Node

Mesh Statistics

For statistical information about the mesh element quality, right-click the **Mesh** node ( ) and select **Statistics** ( ). The **Statistics** window includes information about the minimum and average mesh element quality, a mesh element quality histogram, and more. The histogram shows the relative frequency of mesh elements with different quality values. Click the **Statistics** ( ) button in the **Mesh** toolbar to print the total number of elements, the minimum element quality, and the average element quality in The Messages Window. Note that the skewness element quality measure is used for the values printed to the **Messages** window.

The **Statistics** window contains the following sections:

GEOMETRIC ENTITY SELECTION

Define the geometric entities for which you want to display the statistics. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to view statistics for the entire mesh.
- Choose **Domain** to specify the domains for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window or choose **All domains**.

- Choose **Boundary** to specify the boundaries for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the boundaries in the **Graphics** window or choose **All boundaries**.
- Choose **Edge** to specify the edges for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the edges in the **Graphics** window or choose **All edges**. This option is only available in 3D.
- Choose **Point** to specify the points for which the statistics is displayed. Choose **Manual** in the **Selection** list to select the points in the **Graphics** window or choose **All points**. This option is only available in 2D and 3D.

ELEMENT QUALITY

From the **Quality measure** list, choose the mesh quality measure to use for the mesh statistics:

- **Skewness**, the default quality measure
- **Maximum angle**
- **Volume versus circumradius**
- **Volume versus length**
- **Condition number**
- **Growth rate**
- **Curved skewness**

For more information about these mesh quality measures, see Mesh Element Quality.

STATISTICS

In this section you find information on the status of the mesh: for example, if the mesh is empty, if the selection contains domains without mesh, or if an imported mesh contains second order elements. You can select the element type for which you want to see statistics from the **Element type** list. The default is to display statistics for **All elements**. The statistics includes the number of mesh elements of different types, such as tetrahedral elements and triangular elements. In the element statistics section below — for example, **Domain element statistics** — you find information about:

- The number of elements.
- The minimum and average element quality, based on the selected mesh quality measure. The element quality is a scalar value between 0 and 1, where a higher number indicates a higher mesh element quality.
- The element volume ratio or area ratio, which is the ratio between the volumes (areas) of the largest and smallest element.
- The mesh volume or area (the total volume or area for the mesh), or the mesh edge length when applicable.

Not all these quantities are available for all options in the **Element type** list.

ELEMENT QUALITY HISTOGRAM

This section displays a histogram plot of the mesh element quality, using the selected mesh quality measure, for the specified element type and selection. The x-axis represents the element quality, and the y-axis represents the number of elements of similar quality. The absolute value of the mesh element quality is always between 0 and 1, where 0.0 represents a degenerated element and 1.0 represents the best possible element.

You can also create a histogram plot of the mesh element quality over the total area or volume of the elements by adding a Histogram plot to a 1D Plot Group and using a variable for a mesh quality measure as the expression.

See also Quality of Elements in the *COMSOL Multiphysics Programming Reference Manual*

For a tutorials showcasing the use of mesh Statistics, see

- *Swept Meshing of a Bracket Geometry*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/bracket_swept_mesh**
- *Submarine Cable 7 — Geometry & Mesh 3D*: Application Library path **ACDC_Module/Tutorials,_Cables/submarine_cable_07_geom_mesh_3d**

Mesh Plots

Visualizing different aspects of a mesh in a Mesh plot is a useful tool to inspect different aspects of a mesh. It is possible to color the elements on faces and in domains with respect to their type to get a feeling for how different types of elements fit together in the mesh. It can also be useful to shrink the elements to see more than the first layer of elements in the view. After having a look in the Mesh Statistics to see the minimum element quality in the mesh, a mesh plot can give an understanding of where the elements of worst quality are located. See the examples below and the suggested tutorial models for more inspiration.

DISPLAYING MESH ELEMENT QUALITY AND THE MESH ELEMENT SIZE

You can visualize the mesh element quality and the mesh element size by plotting the mesh. The Mesh plot under Results has many more visualization options compared to the mesh view in the component. You can use a Mesh dataset or evaluate on a Solution dataset. If you use a Solution dataset, you get the mesh used for that solution. For a mesh in a component, the following steps display the mesh element quality or mesh element size:

1 Click **Plot** ( ) in the **Mesh** toolbar, or right-click the **Mesh** node and select **Plot** ( ). This creates a mesh dataset and a plot group with a **Mesh** plot node ( ). By default, this plot shows the mesh element quality based on the skewness quality measure with the maximum and minimum element quality displayed at the color bar.

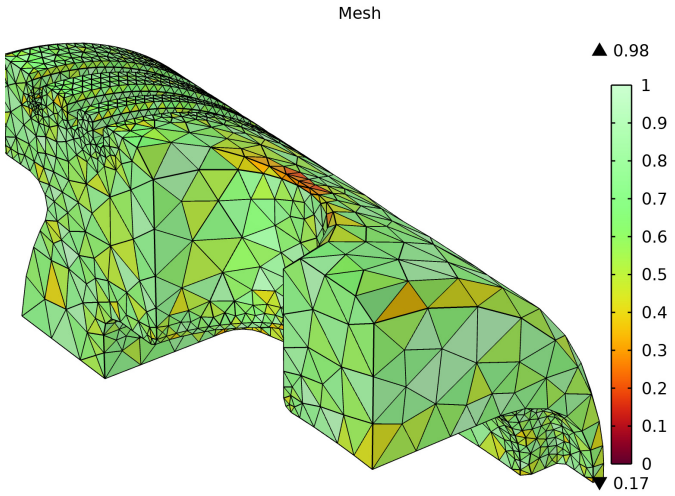

Figure 8-16: Default mesh plot displaying the skewness quality measure. The maximum and minimum element quality are displayed at the color bar.

2 Clear the checkbox **Color range [0,1]** to let the color legend range from the minimum to maximum element quality.

3 Drag the **Color calibration parameter** slider to change where the middle of the color range is located. Move the slider to a negative value to highlight elements of lower quality more clearly.

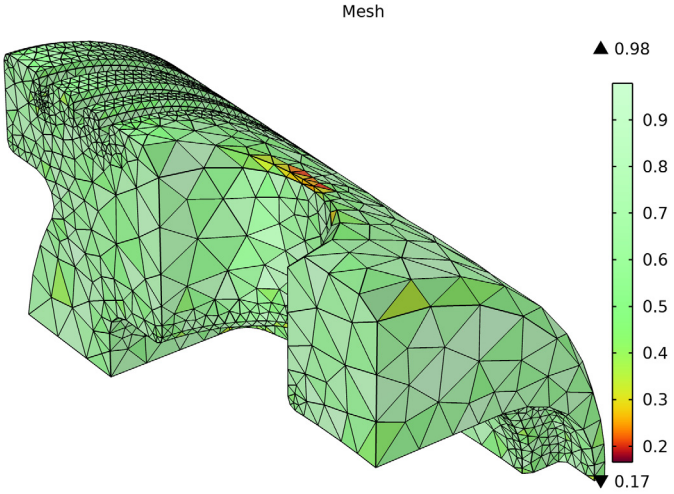

Figure 8-17: Resulting mesh plots when setting the Color calibration parameter to a small and high value, respectively.

4 You can change the mesh quality measure to display from the **Quality measure** list. See Mesh Element Quality for more information about the quality measures.

5 In the **Settings** window for **Mesh**, select **Size** instead of **Quality** from the **Element color** list to plot the mesh element size instead.

6 Select the **Element Filter** checkbox and enter a logical expression in the **Expression** field to filter out which mesh elements to plot. For example, to only plot elements of quality below `0.001`, enter `qualskewness<0.001` as the expression. It is also possible to filter based on spatial coordinates (for example, `x<0`) to see the mesh in a cross section.

7 To visualize curved elements (for elements of order two or higher), go to **Datasets** > **Mesh 1** and change the **Geometry shape function** list to the desired order.

The **Geometry shape function** setting is a postprocessing setting only and does not influence the discretization used when solving.

8 In the Settings window for **Mesh Plot 1** > **Mesh 1**, select **Node points: Geometry shape function** to also plot higher order node points in the mesh.

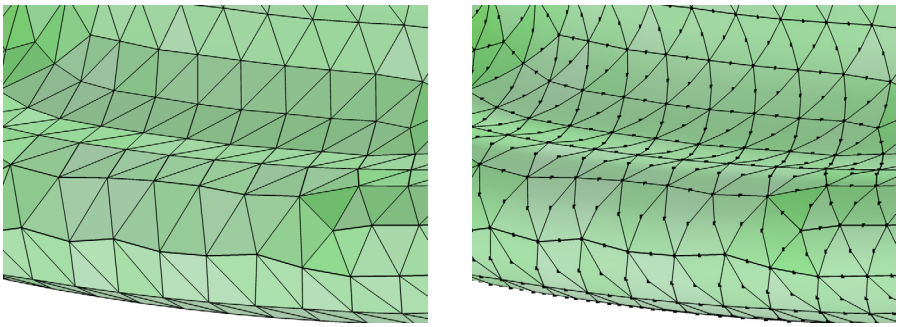

Figure 8-18: Mesh plot of the linear mesh (left) and the curved, second order elements with associated higher order node points (right).

Alternatively, you can access the built-in variables for mesh element quality (`qual*`) and mesh element size (`h`) in a surface plot, for example:

1 Under **Results** ( ), right-click **Datasets** ( ) and select **Mesh** ( ).

Add a 2D or 3D Plot Group using the Mesh dataset as the group's dataset, and then add a Surface or Volume plot. For example, in a **2D Plot Group** > **Surface** node ( ), click the **Replace Expression** ( ), select **Mesh** > **qualskewness - Element quality** from the predefined quantities, **Mesh** > **h - Element size**, or one of the other quantities for mesh. Then, click the **Plot** button ( ).

Information, Warning, and Error Nodes for Meshing Operations

The software provides automatic detection of details and regions that might cause problems. Depending on the severity of the problem, the meshing operations display the information in Information Nodes, Warning Nodes, or Error Nodes.

INFORMATION NODES

Information nodes ( ) appear when a mesh can be built but the meshing algorithms determine that there is something that might deserve your attention. This can be very small geometry details (small faces, short edges, and so on) or that mesh elements of low quality appeared. Check the information message and any selection of entities to determine if something needs to be modified and how. Low quality elements can lead to difficulties for the solver to converge or make the solution sensitive to small changes in the mesh.

The element quality measure skewness is used when the minimum element quality is displayed. See Mesh Element Quality for more information about quality measures.

For elements of low quality, it is useful to plot elements as described in Displaying Mesh Element Quality and the Mesh Element Size. Use the information about the minimum element quality in the **Information** node to set an appropriate value for the Element Filter expression.

The **Information**, **Warning**, and **Error** nodes, and their subnodes often contain selections or coordinates that highlight where the problem is located in the geometry.

CENTER, ZOOM, AND CLIP AROUND COORDINATES

Information, **Warning** and **Error** nodes can contains details with coordinates for the location of the problem, indicated by red points in the **Graphics** window. Select a location from the list and click the **Center at Coordinates** button to automatically center the camera and zoom in on the problematic area. For 3D meshes, click the **Clip Around Coordinates** button to add a Clip Sphere around the coordinates. This makes it easier to investigate the problematic area, especially if it is located inside a complex geometry. Click the **Remove Clipping** button in the Settings window to remove the Clip Sphere.

WARNING NODES

Warning nodes (⚠) appear when a mesh can be built but might need some extra tuning to be suitable for simulations. Check the warning message and any selection of entities. There is often more than one level of warnings providing details of the cause, so check all subnodes if any. It is possible to continue the simulation with warning nodes in the meshing sequence and you might still get a valid result. However, if you get problems in the simulation or obtain unexpected results, the warnings might indicate the cause. Warning nodes can also appear elsewhere in the model tree (for example, for an operator that requires some argument that is missing).

ERROR NODES

If a problem occurs when you build a meshing sequence, it continues if possible; otherwise, the build stops. Continuing means that geometric entities where the operation failed are skipped and the problems are reported as **Error** nodes (⊗) under the operation node. The build process continues with remaining nodes in the meshing sequence.

If the mesh generation cannot continue, all building stops. The operation gets Warning status if some entities could be meshed, indicated by an orange triangle in the lower-right corner of the operation's icon (see Dynamic Nodes in the Model Builder). If nothing could be built, the operation gets Error status, which the program indicates by adding a red cross in the lower-right corner of the operation's icon. If the operation is part of a sequence build, the build stops and the preceding node becomes the current node.

When the building of the meshing sequence is completed, an error window appears to show the first error reported. If there are several errors, you have to manually inspect the sequence for **Information**, **Warning**, and **Error** nodes.

Consider if any simplification can be made to the geometry. For example, run Geometry Cleanup to automatically remove small details like short edges or narrow face regions indicated by **Information**, **Warning**, and **Error** nodes. Rebuild the mesh. If errors still remain, lower the mesh element size. See Controlling the Mesh Size Using Attributes for more information.

Avoiding Inverted Mesh Elements

This section will go through how to avoid inverted mesh elements while solving. Refer to Information, Warning, and Error Nodes for Meshing Operations for information about avoiding bad quality elements when building the mesh.

INVERTED MESH ELEMENTS

If you have a mesh that is coarse along a curved boundary, you might encounter problems with inverted mesh elements. This means that a mesh element is wrapped inside-out or has zero area (in 2D) or volume (in 3D). More precisely, there is some coordinate for which the Jacobian matrix for the mapping from local to global coordinates has a negative or zero determinant. In most cases, the linear (straight) mesh elements that you see in a mesh plot are not inverted, but the higher-order curved mesh elements used for computing the solution might be. Studying the linear minimum element quality therefore does not reveal the presence of inverted mesh elements in most cases.

Inverted mesh elements in themselves do not pose any immediate threat to the overall accuracy of your solution. However, if you are using an iterative solver, it might fail to converge. If you reach convergence and the solution looks good, it likely is. It is worth bearing in mind that the faces where there are inverted elements are less than perfectly resolved. If these faces are important for your results, you might want to pursue a mesh without inverted elements or at least make sure that the mesh resolution is sufficiently fine to guarantee an accurate solution. The easiest way to get an idea of the accuracy is to try a few different meshes and see how the solution changes. If the variation does not exceed your limits of acceptance, you are fine.

The solver prints a message about inverted curved elements to the **Messages** window and corresponding warnings to the **Log** window if they appear. **Warnings** (⚠) nodes also appear in the solver sequence where the inverted mesh elements appear. If you are using a **Free Tetrahedral** node to create the mesh, the **Avoid inverted curved elements** checkbox is selected by default in the node's **Settings** window under **Element Quality Optimization** to reduce the risk of inverted curved elements.

For a moving mesh, the mesh can become inverted, in which case an error occurs. In the **Error** (⊗) node, which appears in the solver sequence, information about the location of the inverted elements appears.

Visualizing Inverted Linear Elements

If you experience inverted mesh elements while meshing or while importing meshes, create Mesh Plots with the logical expression `qual<eps`. The plot then shows both the inverted mesh elements, for which the mesh quality is negative, and the totally degenerated elements, for which the mesh quality is zero or very close to zero. The quality measure `qual` always uses the linear elements.

Visualizing Inverted Curved Elements

If the method used to avoid inverted elements fails, it can happen that inverted elements are present in the mesh you solve on, as described in the first section. You can visualize inverted mesh elements using the built-in `qualcurvedskewness` variable, the elementwise product of skewness and `reldetjacmin`, which is a measure of the deformation when generating the higher-order element. A minimum value less than zero for an element means that the element is wrapped inside-out; that is, it is an inverted curved mesh element.

Use the nonlinear quality measure `qualcurvedskewness` (Curved skewness) to plot or evaluate inverted curved elements. Add a Mesh Plots with an element filter set to `qualcurvedskewness<0` to include only the inverted

elements. Note that the curved quality can only be evaluated on full-dimensional elements, that is volume elements in 3D and surface elements in 2D. Change the Geometry shape function setting to the appropriate higher order shape function for the Mesh dataset. Use the expression `qualcurvedskewness<0.1` to include also highly curved and low quality elements.

Visualizing Inverted Elements in a Deformed Mesh

If inverted mesh elements occur while deforming a mesh, check the **Error** ( ) node in the solver sequence, to see information about the location of the inverted elements.

To inspect problematic areas in 2D, add a Surface plot, plotting the expression `qualskewness` using the solution dataset. Select the Wireframe checkbox in the surface plot to see the individual deformed mesh elements. For 3D, it can be useful to create similar plots using Slice plots for different cross-sections. Use the locations in the Error node as a guidance on where to locate the Slices.

If remeshing of a deformed mesh fails, the problematic mesh is available as a **Problematic Deformed Mesh** ( ) node under **Meshes**, so that you can inspect the mesh around the coordinates for the inverted mesh elements.

CURVED INTERIOR DOMAIN ELEMENTS

In many situations, the inverted elements can be fixed by curving elements inside the domain to match the boundary. You find the **Avoid inverted elements by curving interior domain** checkbox, which controls if elements inside the domain are curved, in the **Settings** window for the **Component** node. The default behavior is to curve interior domain elements when needed. In 3D, this setting also has the effect that elements inside a face can be curved to match the face edges.

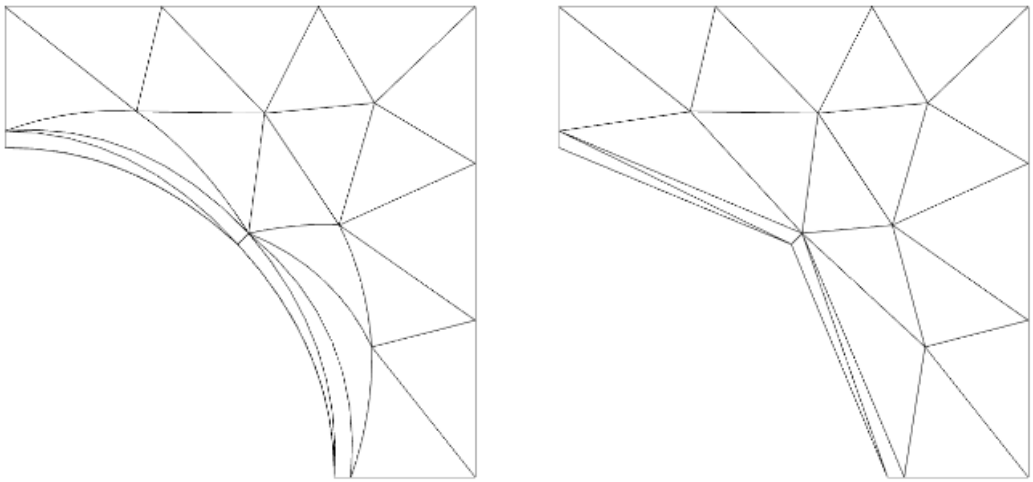

Figure 8-19: Curved interior mesh elements (left) and the corresponding linear mesh (right).

In some situations, it is impossible to avoid the inverted elements no matter how the interior mesh elements are curved. This can, for example, happen if the domain becomes infinitely thin where two circles (or cylinders in 3D) touch, or if the mesh is extremely coarse and does not approximate the true geometry shape well enough. Then the higher-order node points (that control the curving) are moved away from the geometry boundaries, typically making the elements less curved than they should be according to the geometry. When this happens, the solver will print information indicating how many points were moved and how much in the **Log** window.

The algorithm for avoiding inverted elements by curving interior domains does not guarantee that symmetry properties in the mesh are retained. If such symmetry properties are important, then clear **Avoid inverted elements by curving interior domain** checkbox.

Visualizing the Geometry Approximation

The `geomapproxdist` variable indicates, for each element, how far a node point in the element was moved from the geometry. To see the parts of the geometry that are affected, add Mesh Plots with surface plots of `geomapproxdist`, or make a volume plot with an element filter set to `geomapproxdist>0`.

MODIFYING THE GEOMETRY OR MESH

To reduce problems with badly shaped elements or geometry approximations you can try any of the following:

- Create a Swept 3D mesh instead of using the tet mesher.
- Avoid small curved boundaries such as fillets unless they are important for the result. If they are important, they must be meshed with sufficiently small elements. Use Delete Fillets to find and remove fillets of a specified radius. For more information, see Removing Small Geometric Entities with the Defeaturing Tools in the *Introduction to the CAD Import Module*.
- Avoid infinitely narrow regions in domains and on faces. If two faces (or edges) of the boundary to a domain are tangent to each other along a curve or in a point, element will be inverted or nearly inverted where the domain becomes infinity thin. To remove narrow face regions, use Remove Details. Read more in the section Preparing the Geometry for Meshing Using Geometry Cleanup.

USING LINEAR INTERIOR DOMAIN ELEMENTS

If you disable the use of curved interior domain elements, the solver tries to avoid inverted elements by linearization. This is done by reducing the geometry shape function order for the corresponding elements to first order. By default, the solver does this automatically. Alternatively, you can avoid problems with inverted mesh elements by using linear geometry shape function order for all elements. You do this by choosing, for example, **Linear** from the **Geometry shape function** list in the **General** section of the **Settings** window for the main **Component** node.

Linearized elements and shape function will affect the accuracy of the solution.

Visualizing Linearized Elements

The variable `linearizedelem` is 1 in elements that are linearized and 0 elsewhere. You can use this variable to identify mesh elements with linearized elements. For example, use `linearizedelem` as the expression in Mesh Plots.

Troubleshooting Tetrahedral Mesh Generation

This section gives you some suggestions about how to solve problems that you might encounter when creating tetrahedral meshes.

REMOVE UNWANTED GEOMETRY DETAILS

Sometimes, the geometry contains small features, like sliver faces and short edges that you do not want to resolve at all. Use Geometry Cleanup in the sequence to remove unwanted details in the geometry. See also Preparing the Geometry for Meshing Using Geometry Cleanup for more information.

If you have a license for the CAD Import Module, you can also use CAD defeaturing operations to simplify the geometry. See Repairing and Defeaturing for more information.

BUILD A FINER MESH

As a general rule, it is easier to construct a mesh with smaller elements than a mesh with larger elements. If you get errors or low-quality elements when you try to mesh certain domains, try to decrease the element size using appropriate Size attributes on these domains. See Editing and Resetting a Physics-Controlled Sequence and Controlling the Mesh Size Using Attributes for more information.

USE AN APPROPRIATE MINIMUM ELEMENT SIZE

If your geometry contains details that are very small compared to the total volume of the mesh, you must ensure that the **Minimum element size** parameter in the corresponding Size attribute is of the same order of magnitude as the smallest detail you want to resolve. If this parameter is too large, you get Information nodes when building the node. For example, the Information message “Edge is much shorter than the specified minimum element size” indicates that there are edges significantly shorter than the specified minimum element size. The resulting mesh gets badly shaped elements.

To locate small details, such as short edges and sliver faces, you can add and build a Free Tetrahedral node with normal size settings. Doing this results in warnings with selections that point you to the corresponding small entities. You can also inspect the mesh visually to locate unexpected small elements. See Information, Warning, and Error Nodes for Meshing Operations.

PARTITION THE GEOMETRY INTO SIMPLE DOMAINS

If the geometry includes complex domains or complex faces that you have trouble meshing, you can try to partition the geometry into less complex entities. On a philosophical level, this method could be classified as a “divide and conquer” strategy. It is often possible to use the Partition Objects geometry feature to partition a complex domain

into two domains. You can use a Mesh Control Faces node to make this partitioning visible only when building the mesh (see Controlling the Mesh Size Using Mesh Control Entities).

To split a solid geometry object into parts using an empty Work Plane, place the work plane where you want to cut the domain. Then add a **Partition Objects** or **Partition Domains** node from the **Boolean Operations** submenu, and select **Work plane** from the **Partition with** list in the **Settings** window for **Partition**.

Information, Warning, and Error Nodes for Meshing Operations

For a tutorial on how to edit the mesh size parameters, see *Adjusting the Element Size for the Unstructured Mesh Generator*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/piston_mesh**.

In *Introduction to the CAD Import Module*:

- See the tutorial for an example that uses Information nodes to find and remove small details in a geometry.
- See the tutorial Removing Small Geometric Entities with the Defeaturing Tools for an example that uses the CAD Defeaturing tools to remove fillets.

Troubleshooting Boundary Layer Mesh Generation

The boundary layer meshing algorithm is sensitive to the topology of the model geometry. If you get an error when trying to build a Boundary Layers node, try the following:

- Remove unnecessary interior boundaries, such as boundaries resulting from Boolean operations of geometry objects that do not separate materials or physics. Sometimes, it is possible to draw the geometry differently to avoid the boundaries. Another alternative is to use Ignore Faces to ignore the boundaries (Ignore Edges in 2D). The third alternative to do this is to mark these boundaries as mesh control entities in the geometry sequence. Once you have removed unnecessary boundaries, mesh the domains using a tetrahedral or a swept mesh. When the domains are meshed, the mesh control entities are automatically removed, and you can insert boundary layers, ignoring the interfering boundaries. See Controlling the Mesh Size Using Mesh Control Entities for more information.
- Use boundary layer mesh **Trimming** instead of **Splitting**. By default, the boundary layer mesher creates a boundary layer split at each sharp corner in 2D and along each sharp edge in 3D. To still resolve the mesh at the sharp corners where the mesh is trimmed, add a Corner Refinement. This setup is the default for the Physics-Controlled mesh for fluid flow.

- To turn off boundary layer splits, see Boundary Layers.
- See Information, Warning, and Error Nodes for Meshing Operations for tips on how to inspect problematic areas.

Importing and Exporting Meshes

It can be useful to import meshes already created by external software or, alternatively, to export a mesh generated by COMSOL Multiphysics into other software. Importing an externally generated mesh can be helpful when a mesh is already saved in a file and recreating the geometry would be difficult and time consuming.

When the quality of the mesh needs to be improved, or a different element size is needed, it is possible to remesh imported meshes without creating a geometry first.

In this section:

- Importing Meshes
- Importing NASTRAN Meshes
- Importing 3MF, PLY, STL, and VRML Meshes
- Importing Mesh Data from Results
- Remeshing Imported Meshes
- Exporting Meshes

Importing Meshes

You can import a mesh from a COMSOL Multiphysics native file, from another meshing sequence, or from a results Dataset. In 3D you can also import meshes from NASTRAN, STL, VRML, sectionwise, PLY, and 3MF files. In 2D you can also import meshes from NASTRAN (the third coordinate must then be the same for all mesh vertices) and from sectionwise files.

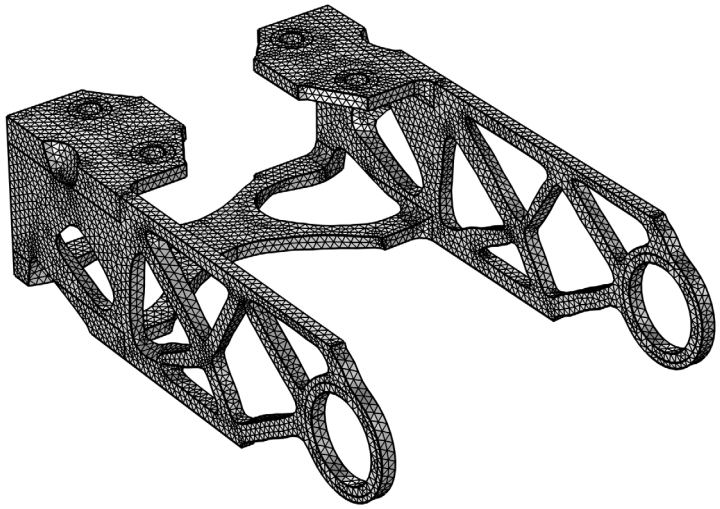

Figure 8-20: The remeshed topology-optimized geometry of a bracket.

In this section:

- Imported Meshes and Element Orders
- Importing Meshes from Files with Length Unit
- Importing Externally Generated Mesh Data
- Import of Native Files and Meshing Sequences

- Detect Faces (3D) and 2D Settings
- Detect Edges (3D)
- Entity Selections

IMPORTED MESHES AND ELEMENT ORDERS

When a mesh is conforming with a geometry, elements are curved using the geometry, according to the specified geometry shape function. If the mesh defines its own geometric model, as is the case for imported meshes, there are two possibilities:

- The mesh contains second-order elements. This information is used to place the higher-order nodes for all geometry shape functions. If the order is cubic or higher, the higher-order nodes are inserted on the boundary based on interpolation using the second-order element data. If the order is linear, the second-order information is ignored. The COMSOL Multiphysics native format and NASTRAN format support storing second-order elements.
- The mesh is linear. COMSOL Multiphysics estimates the shape of faces and curves from its linear elements to place higher-order nodes. To use a linear geometry representation when solving (default behavior for version 5.6 and earlier), set the **Geometry shape function** to **Linear Lagrange** as described in the section Curved Mesh Elements. The formats 3MF, STL, PLY, and VRML always contain linear elements.

If the imported mesh contains second-order elements, the Mesh Statistics includes the following information: **Imported mesh with second-order elements**.

A 1D mesh with second-order elements is linearized when imported.

IMPORTING MESHES FROM FILES WITH LENGTH UNIT

When you import mesh from a file that defines a length unit, the import operation scales the imported mesh to match the length unit of the Component with the **Mesh** node containing the corresponding **Import** node. For an **Import** node under a **Mesh Part** node, the import operation scales the mesh if the **Use units** checkbox is selected.

IMPORTING EXTERNALLY GENERATED MESH DATA

It is possible to import externally generated mesh data using a COMSOL mesh file. The file format contains a section with mesh vertices coordinates, followed by sections with mesh element information, divided into separate subsections for each mesh element type (see Mesh in the chapter *The COMSOL File Formats* in the *COMSOL Multiphysics Programming Reference Manual*).

Importing Incomplete Mesh Data

A COMSOL Multiphysics mesh contains elements for all space dimension levels. For example, a tetrahedral mesh consists of domain (tetrahedra), boundary (triangles), edge, and vertex elements. Furthermore, each element has an index to the geometric entity it belongs to. If a mesh file is incomplete — for example, if it only contains tetrahedra — the **Import** operation automatically generates the missing element data. To illustrate this behavior, import the file `mesh_example_1.mphtxt` from

```
applications/COMSOL_Multiphysics/Meshing_Tutorials/
```

This file contains domain elements only with geometric entity information dividing the mesh into two domains. Now, export the imported mesh to a file using the default settings. Then, compare the resulting file (see `mesh_example_4.mphtxt`) with the file `mesh_example_1.mphtxt` and note that the exported file contains complete mesh information; that is, it contains domain elements, boundary elements, edge elements, vertex elements, and geometric entity information.

To add volume mesh to an imported surface mesh, add a Create Domains to form domains inside watertight regions, and add a Free Tetrahedral to generate a tetrahedral mesh in the unmeshed domains. Remeshing Imported Meshes discuss the options to improve the quality of a face mesh, if needed.

Transferring Domain Information

If you have an externally generated mesh with a predefined partitioning of the elements, you can transfer this partitioning to COMSOL Multiphysics by specifying geometric entity information in the `.mphtxt` file. To illustrate this, import the file `mesh_example_2.mphtxt`. This file contains domain elements only, without any geometric entity information. The imported mesh consists of one domain only. Note that the imported mesh from the file `mesh_example_1.mphtxt` consists of two domains according to the given geometric entity information.

Transferring Boundary Information

To transfer boundary partitioning information of an externally generated mesh you need to include boundary elements with the corresponding geometric entity information in the `.mphtxt` file. To illustrate this, import the file `mesh_example_3.mphtxt` with the **Boundary partitioning** option set to **Minimal**. This file contains domain and boundary elements with geometric entity information defining 5 boundaries. Note that the imported mesh also has 5 boundaries. Now import the file `mesh_example_1.mphtxt` that has no boundary information, using the same import settings. Note that the imported mesh now has 3 boundaries only because the Minimal option generates the minimal possible partitioning that is required by the topological criteria.

See Conforming, Nonconforming, and Nonmatching Meshes for import of nonconforming mesh data.

IMPORT OF NATIVE FILES AND MESHING SEQUENCES

Use an **Import** node ( ) to import a mesh from a file, from another meshing sequence, or from a mesh part. To position, rotate, and scale the mesh, use one or several Transform attributes.

For information about the native file formats, see:

- Sectionwise Data Format
- Native Binary Data Files and Text Data Files

To use an imported mesh together with geometry, use either of the workflows described in the section Combining Geometry and Mesh.

To import additional meshes, add another **Import** node. Then COMSOL Multiphysics adds the elements of the newly imported mesh to the existing mesh.

Meshes from different **Import** nodes form an assembly. See Conforming, Nonconforming, and Nonmatching Meshes for more information about assembly type meshes.

Note that importing a mesh modifies the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Import** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for the import using the following sections:

IMPORT

In the **Source** list, choose the type of data to import: **Any importable file**, **Meshing sequence** (if applicable meshing sequences are available), and **COMSOL Multiphysics file** are always available. In addition to the native file formats, you can choose **NASTRAN file** and **Sectionwise file** in 2D and 3D. In 3D you can also choose **STL file** (stereolithography file), **PLY file** (Polygon File Format or Stanford Triangle Format file), **3MF file** (3D Manufacturing Format file), and **VRML file** (Virtual Reality Modeling Language file). Choose **Geometry sequence** to import a triangle mesh of the Component's geometry. Choose **Dataset** to import the visualization mesh of a Filter or Partition dataset. This option is only available if there is at least one **Filter** or **Partition** node under **Datasets** in **Results**.

For file import, specify the filename in the **Filename** field or click the **Browse** button ( ). You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

For import from another mesh in the model, select a meshing sequence or mesh part from the **Mesh** list below. To import a meshing sequence or a mesh part, click the **Import** button. For import of a dataset in the model, select a Filter or Partition dataset from the **Dataset** list below.

The **Compact History** action is not supported for models including a mesh imported from dataset.

If you have changed some property, the software automatically reimports the mesh when you click a build button. For import of a meshing sequence, select **Build source mesh automatically** (selected by default) to automatically build the source sequence and reimport the current version of the mesh. This is required when running a parametric sweep over some parameter that affects the source mesh.

For information on remeshing an imported mesh, see Remeshing Imported Meshes.

Properties for COMSOL Multiphysics File Import

In 3D, you can import 3D meshes and planar 2D meshes from COMSOL Multiphysics files (`.mphtxt` or `.mphbin`). Planar 2D meshes, imported to a 3D component, always appear at $z = 0$.

When you import a mesh from a COMSOL Multiphysics file that contains mesh selections, you need to select the **Import selections** checkbox (selected by default) to import the selections together with the mesh. If you choose to import mesh selections, corresponding selections are created and appear in the **Domain Selections**, **Boundary Selections**, **Edge Selections**, or **Point Selections** sections, depending on space dimension and the entity level for the imported selections. You can use the imported selections, for example, to add as a selection to a dataset or plot during postprocessing. See also Entity Selections below.

To import the second-order elements in 2D and 3D as linear elements (that is, ignoring node points not in element vertices), select the **Import as linear elements** checkbox (not selected by default).

Import of Domain Elements

In 3D, select the **Import domain elements** checkbox to import volumetric elements, such as tetrahedrons, hexahedrons, prisms, and pyramids. Clear this checkbox to only import boundary elements. The checkbox is selected by default for the following options from the **Source** list: **Meshing Sequence**, **COMSOL Multiphysics file**, **NASTRAN file**, and **Sectionwise file**. However, when the software adds the **Import** operation automatically in a new meshing sequence, the default is OFF for **Source: Meshing Sequence** to allow for editing.

Import of Unmeshed Domains

This setting is available with the following option from the **Source** list: **Meshing Sequence**.

In 3D, select the **Import unmeshed domains** to import domain information from the source meshing sequence. Clear this checkbox to get voids inside surface meshes that form watertight regions. Domains can be created later, if needed, using the Create Domains operation. When **Source** is set to **COMSOL Multiphysics file**, **NASTRAN**, or **Sectionwise**, the default is ON. For **Source: Sequence**, the default depends on how the operation is added. When you add the **Import** operation manually from The Mesh Toolbar or The Model Builder Context Menu, the default is OFF. When the software adds the **Import** operation automatically in a new meshing sequence, the default is ON.

Most physics require a mesh on the domains. Use the Free Tetrahedral, Swept and Boundary Layers operations to fill the unmeshed domains with domain elements.

Boundary Partitioning Properties

These settings are available with the following options from the **Source** list: **COMSOL Multiphysics file**, **Dataset**, **STL file**, **VRML file**, **NASTRAN file**, **PLY file**, **Sectionwise file**, and **3MF file**.

When a mesh is imported into COMSOL Multiphysics, the operation automatically determines a partitioning of the mesh into domains, boundaries, edges, and points. If the automatically performed partitioning does not match the requirements, you can use the **Boundary partitioning** list to control the partitioning:

- Select **Automatic** to let the software partition the boundary elements into boundaries automatically (the default setting).
- Select **Minimal** to make a minimal boundary partitioning. This is useful when you import a mesh from a measured geometry or a NASTRAN mesh with a predefined boundary partitioning. The automatic face partitioning is not desired then.
- Select **Manual** (in 2D) or **Detect boundaries** (in 3D) to manually control the partitioning. Both choices add a set of parameters that make it possible to influence the result of the partitioning algorithm; for the Detect boundaries case in 3D, the **Detect Faces** and **Detect Edges** sections appear, containing settings for controlling the face and edge partitioning, respectively.

DETECT FACES (3D) AND 2D SETTINGS

The partitioning algorithm aims to split boundary elements (edge elements in 2D, face elements in 3D) into boundary entities in such a way that no large angles appear between neighboring elements within the same boundary entity. In 2D, you can limit the angle between any two elements within the same boundary entity using the **Maximum angle within boundary** field. The maximum accepted neighbor angle can be set using the **Maximum neighbor angle** field (default: 40 degrees).

If the **Detect planar faces** checkbox (3D) or the **Detect straight edges** checkbox (2D) is selected (both are selected by default), the mesh import detects (approximately) planar faces or straight edges, respectively. The minimum size of a straight or planar boundary entity, relative to the entire boundary, can be set using the **Minimum relative length** field (2D) and **Minimum relative area** field (3D). The maximum accepted angle (in degrees) between elements for a boundary to be considered straight or planar can be set using the **Maximum deviation angle** field. If the **Detect adjacent fillet faces** checkbox (3D) is selected, the algorithm also searches for adjacent groups of boundary elements that form cylindrical faces.

DETECT EDGES (3D)

The partitioning algorithm aims to split edge elements into edge entities in such a way that no large angles appear between neighboring elements within the same edge entity. The maximum accepted neighbor angle can be set using the **Maximum edge neighbor angle** field (default: 60 degrees).

If the **Detect planar edges** checkbox is selected (it is selected by default), the mesh import detects (approximately) planar edges. The **Detection parameter** specifies to which extent the operation searches for planar edges. Use the slider to tune the detection level, where **Strict** means that only fully planar edges are searched for, and **Tolerant** means that the algorithm searches for planar edges with a wider tolerance. You can also enter the parameter value directly as a value between 0 (strict) and 1 (tolerant).

If the **Detect straight edges** checkbox is selected (it is selected by default), the mesh import detects (approximately) straight edges. The **Detection parameter** specifies to which extent the operation searches for straight edges. Use the slider to tune the detection level, where **Strict** means that only fully straight edges are searched for, and **Tolerant** means that the algorithm searches for straight edges with a wider tolerance. You can also enter the parameter value directly as a value between 0 (strict) and 1 (tolerant).

From the **Minimum edge length** list, choose one of the following options: **Automatic** (the default), **Relative**, or **Absolute** to specify the minimum required length of an edge to be detected. If you select **Relative**, specify a minimum relative length in the **Minimum relative length** field that appears, and if you select **Absolute**, specify a minimum absolute length in the **Minimum absolute length** field that appears.

ENTITY SELECTIONS

The sections **Domain Selections**, **Boundary Selections**, **Edge Selections**, and **Point Selections** appear after building the **Import** operation. The selections are generated during the import based on selections defined in the source. In the **Name** column, the name of each selection appears. For COMSOL Multiphysics file import, each name is by default the name of the selection in the imported file that appears in the **Name in file** column. Select the name in the **Name** column to highlight the selection in the **Graphics** window. You can change the name of a selection by editing the corresponding table entry in the **Name** column. Note that not all of these selection sections are available for all space dimensions.

The selections can be used to specify entity selections in operations and attributes within the same meshing sequence and, if the mesh defines the component's geometric model, for physics and material settings. For more information about the component's geometric model, see The Mesh Node.

For settings of other mesh import sources, see:

- Importing NASTRAN Meshes
- Importing 3MF, PLY, STL, and VRML Meshes
- Importing Mesh Data from Results
- Importing Geometry to Mesh

- Transform
- Remeshing Imported Meshes
- Creating Geometry from Mesh
- Modifying the Element Size Using Refine and Adapt

Importing NASTRAN Meshes

Use an **Import** node ( ) to import 3D meshes (and planar 2D meshes) in the NASTRAN bulk data format, the most common format for exchanging 3D meshes among programs.

Figure 8-21: The imported NASTRAN mesh used for the simulation in the tutorial Eigenvalue Analysis of a Crankshaft.

This format supports hundreds of NASTRAN entries describing elements, loads, and materials, making it possible to define a complete finite element model. When you import a NASTRAN bulk data file into COMSOL Multiphysics, the software only imports mesh and material information, while creating appropriate selections. For import in 2D, the third coordinate must then be the same for all mesh vertices. To position, rotate, and scale the mesh, use one or several Transform attributes.

See also:

- Imported Meshes and Element Orders for information about curved elements.
- Importing Externally Generated Mesh Data

To import additional meshes, add another **Import** node. Then COMSOL Multiphysics adds the elements of the newly imported mesh to the existing mesh.

Meshes from different **Import** nodes form an assembly. See Conforming, Nonconforming, and Nonmatching Meshes for more information about assembly type meshes.

The **Import** operation will change the number of entities in the mesh, so unless the meshing sequence is defining its own geometric model, a new meshing sequence of this type will be set up automatically. Then, the **Import** node will be added in the new sequence.

See The Mesh Node to read more about meshing sequences and meshes that define their own geometric models.

Note that importing a mesh modifies the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Import** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for the import using the following sections:

IMPORT

Specify the filename in the **Filename** field or click the **Browse** button. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

If you have changed some property, the software automatically reimports the mesh when you click a build button. For import of a meshing sequence, select **Build source mesh automatically** (selected by default) to automatically build the source sequence and reimport the current version of the mesh. This is required when running a parametric sweep over some parameter that affects the source mesh.

For information on remeshing an imported mesh, see Remeshing Imported Meshes.

Import of Materials

To import mesh and material data from a NASTRAN file, select **Mesh and materials** in the **Data to import** list. In this case, COMSOL Multiphysics creates **Material** nodes corresponding to the data in any MAT1 and MAT10 entries in the file. Furthermore, the thickness data of any PSHELL entry in the file is stored in a **Variables** node as long as it is greater than zero. To simplify the use of this data in physics interfaces, such as the **Shell** interface, an **Explicit** selection that contains all boundary faces associated with PSHELL entries, also becomes available. If the material data is not required, select **Only mesh** to import the mesh only.

Mesh information is read from different NASTRAN entries, including those for mesh elements of lower dimension. When this information is not complete in the file, COMSOL Multiphysics enriches the imported mesh data with boundary elements, edge elements, and vertex elements such that a valid mesh object is formed. Each element in the imported mesh receives a unique entity index.

For information on the NASTRAN entries that COMSOL Multiphysics supports, see `Import` in the *COMSOL Multiphysics Programming Reference Manual* (*Meshing*).

Partitioning of Entities and Creation of Selections

To use material data in the file to determine the partitioning of the elements, select the **Partition according to material data** checkbox (selected by default). The **Create selections** checkbox is selected by default to automatically generate selections deduced from the file. Domain, boundary, and edge selections are created for each property id (PID) of the elements in the file. Mesh elements associated with RBE entries (RBE2 and RBE3) can form selections of all geometric entity levels. The created selections appear in **Domain Selections**, **Boundary Selections**, **Edge Selections**, and **Point Selections** sections, depending on their entity levels. The origin of each created selection is described in the **Source in file** column. These selections become available for specifying geometric entities throughout the component — for instance, in Material nodes and physics interfaces. The **Allow partitioning of shells** checkbox is selected by default to allow the boundary partitioning algorithm to split the boundary entities that are defined based on the data in the file into smaller parts.

Import of Second-Order Elements

The import of NASTRAN files supports first-order (linear) and second-order elements. To import the second-order elements in the NASTRAN file as linear elements (that is, ignoring node points not in element vertices), select the **Import as linear elements** checkbox (not selected by default).

Import of Domain Elements

In 3D, select the **Import domain elements** checkbox to import volumetric elements, such as tetrahedrons, hexahedrons, prisms, and pyramids. Clear this checkbox to import boundary elements only. The setting is selected by default.

Boundary Partitioning Properties

When a mesh is imported into COMSOL Multiphysics, the operation automatically determines a partitioning of the mesh into domains, boundaries, edges, and points. If the automatically performed partitioning does not match the requirements, you can modify the face partitioning by manually adjusting the corresponding parameters. For details, see the section Boundary Partitioning Properties.

ENTITY SELECTIONS

The sections **Domain Selections**, **Boundary Selections**, **Edge Selections**, and **Point Selections** appear after building the **Import** operation. The selections are generated during the import based on selections defined in the source. In the **Name** column, the name of each selection appears. For NASTRAN file import, the source of each selection appears in **Source in file** column (that is, which information in the imported file that was used to generate the selection). Select the name in the **Name** column to highlight the selection in the **Graphics** window. You can change the name of a selection by editing the corresponding table entry in the **Name** column. Note that not all of these selection sections are available for all space dimensions.

The selections can be used to specify entity selections in operations and attributes within the same meshing sequence and, if the mesh defines the component's geometric model, for physics and material settings. For more information about the component's geometric model, see The Mesh Node.

For settings of other mesh import sources, see:

- Importing Meshes
- Importing 3MF, PLY, STL, and VRML Meshes
- Importing Mesh Data from Results
- Importing Geometry to Mesh

For a tutorial importing a NASTRAN mesh, see *Eigenvalue Analysis of a Crankshaft*: Application Library path **COMSOL_Multiphysics/Structural_Mechanics/crankshaft**.

- Transform
- Remeshing Imported Meshes
- Modifying the Element Size Using Refine and Adapt
- Creating Geometry from Mesh

Importing 3MF, PLY, STL, and VRML Meshes

Use an **Import** node ( ) to import a mesh from a **3MF**, **PLY**, **STL**, or **VRML** file. When you import a mesh, you can position, rotate, and scale the mesh by using one or several Transform attributes.

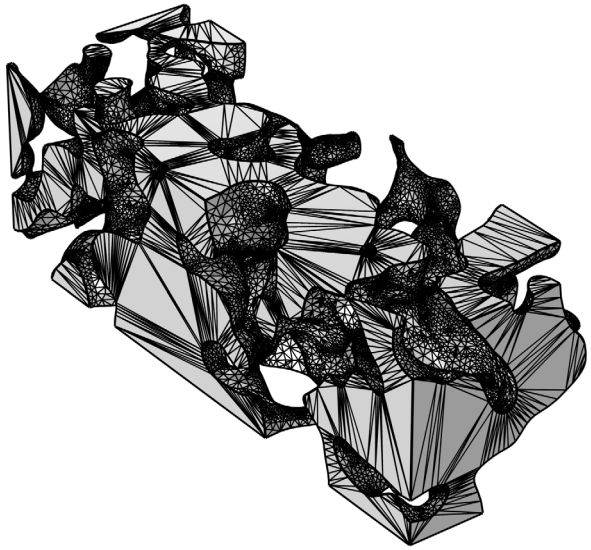

Figure 8-22: The fluid region in the tutorial Analyzing Porous Structures on the Microscopic Scale is imported from an STL file.

These formats can be imported in 3D models only.

To import additional meshes, add another **Import** node. Then COMSOL Multiphysics adds the elements of the newly imported mesh to the existing mesh.

Meshes from different **Import** nodes form an assembly. See Conforming, Nonconforming, and Nonmatching Meshes for more information about assembly type meshes.

See also:

- Imported Meshes and Element Orders for information about curved elements.
- Importing Meshes from Files with Length Unit
- Importing Externally Generated Mesh Data

Files of the formats 3MF, PLY, STL, and VRML typically contain triangle elements with small angles, large angles, and the mesh elements often vary a lot in size. Such meshes are not well suited for simulations and need to be remeshed or modified before generating a volume mesh.

For information on remeshing an imported mesh, see Remeshing Imported Meshes and Creating Geometry from Mesh.

Note that importing a mesh modifies the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Import** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for the import using the following sections:

IMPORT

Specify the filename in the **Filename** field or click the **Browse** button. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

Select the **Create domains** checkbox (selected by default) to automatically form domains for each (connected) finite void region that is defined by the imported surface mesh and analyze these domains with respect to the mesh that might already exist in the sequence.

Most physics require a mesh on the domains. See Remeshing Imported Meshes for more information.

Boundary Partitioning Properties

When a mesh is imported into COMSOL Multiphysics, the operation automatically determines a partitioning of the mesh into domains, boundaries, edges, and points. If the automatically performed partitioning does not match the requirements, you can modify the face partitioning by manually adjusting the corresponding parameters. For details, see the section Boundary Partitioning Properties.

Repair Tolerance and Selection for STL (Stereolithography) Files

These settings are available when the **Source** list is set to **STL file** for import of stereolithography files in 3D. Such files contain data for an unstructured triangulated surface.

The **Create selections** checkbox is selected by default to create a boundary selection of every `solid` section in the file during import. Typically, there is only one such section. In that case, a selection of the entire boundary is created. This happens also when the STL file is binary and can by definition have no `solid` sections. The created selections appear in a table in the **Boundary Selections** section that appears below the **Import** section. The table has two columns. In the right column, the name of the `solid` section that the selection has been created from appears. If the section is named or if the file is binary, the name is empty. If the **Create Domain** checkbox is selected and domains was successfully created, a table with selections for the domains appear under the **Domains Selections** section. The domain selection typically get the same name as the boundary selection for the boundaries that enclose the domain. The selections appear in the same order as the corresponding sections in the file. In the left column, the name of the selection appears. By this name, which can be changed, as well as dimension of the selection, you can find the selection in the model.

The repair tolerance assures that the imported mesh contains no holes and no triangles with sides shorter that the tolerance. Specify the **Repair tolerance** by selecting one of these options:

- **Automatic** (the default), to use a default tolerance value (10^{-8}).
- **Relative**, to specify a **Relative tolerance** (default: 10^{-8}). The relative tolerance value must be smaller or equal to 1.
- **Absolute**, to specify an **Absolute tolerance** (default: 10^{-8}) in the length unit specified in the Settings window for the **Geometry** node.

Tolerance for Merging of Vertices for 3MF, PLY, and VRML Files

These settings are available when the **Source** list is set to **3MF file**, **PLY file**, or **VRML file** for import of files of the 3MF, PLY, or VRML formats. Such files contain data for a surface mesh containing triangle or quadrilateral (PLY only) elements.

Select the **Merging coinciding mesh vertices** checkbox to merge mesh vertices that coincide within the merge tolerance during import. Specify the **Tolerance** by selecting one of these options:

- **Automatic** (the default), to use a default tolerance value (10^{-8}).
- **Relative**, to specify a **Relative tolerance** (default: 10^{-8}). The relative tolerance value must be smaller or equal to 1 and it translates to an absolute value by multiplying it with the largest coordinate in the mesh.
- **Absolute**, to specify an **Absolute tolerance** (default: 10^{-8}) in the length unit specified in the Settings window for the **Geometry** node.

ENTITY SELECTIONS

The sections **Domain Selections**, **Boundary Selections**, **Edge Selections**, and **Point Selections** appear after building the **Import** operation. The selections are generated during the import based on selections defined in the source. In the **Name** column, the name of each selection appears. For STL file import, the source of each selection appears in **Solid section in file** column (that is, which information in the imported file that was used to generate the selection). Select the name in the **Name** column to highlight the selection in the **Graphics** window. You can change the name of a selection by editing the corresponding table entry in the **Name** column. Note that not all of these selection sections are available for all space dimensions.

The selections can be used to specify entity selections in operations and attributes within the same meshing sequence and, if the mesh defines the component's geometric model, for physics and material settings. For more information about the component's geometric model, see The Mesh Node.

For settings of other mesh import sources, see:

- Transform
- Remeshing Imported Meshes
- Modifying the Element Size Using Refine and Adapt
- Creating Geometry from Mesh
- Create Domains

Importing Mesh Data from Results

Use an **Import** node ( ) to import mesh data from a Filter or Partition dataset. You can import mesh data from any simulation results. To position, rotate, and scale the mesh, use one or several Transform attributes.

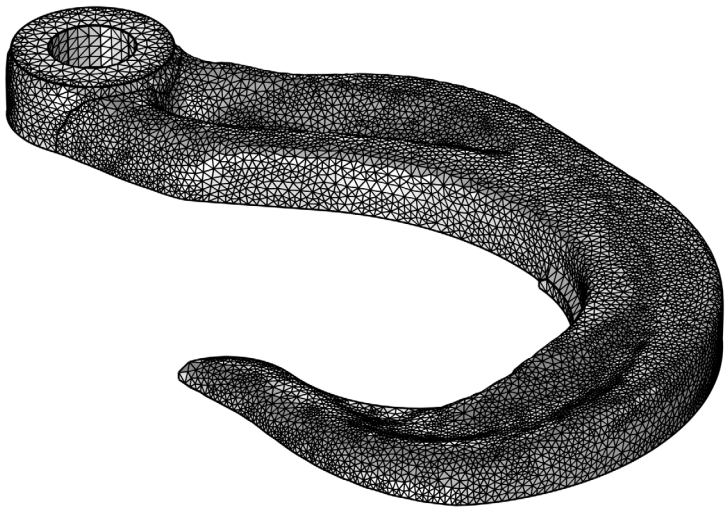

Figure 8-23: The verification study of the topology-optimized hook uses a remeshed mesh imported from a Filter dataset.

To use an imported mesh together with geometry, use either of the workflows described in the section Combining Geometry and Mesh.

To import additional meshes, add another **Import** node. Then COMSOL Multiphysics adds the elements of the newly imported mesh to the existing mesh.

Meshes from different **Import** nodes form an assembly. See Conforming, Nonconforming, and Nonmatching Meshes for more information about assembly type meshes.

Note that importing a mesh modifies the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Import** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for the import using the following sections:

IMPORT

In the **Source** list, choose **Dataset** to import the visualization mesh of a Filter or Partition dataset. This option is only available if there is at least one **Filter** or **Partition** node under **Datasets** in **Results**. Then, select a Filter or Partition dataset from the **Dataset** list below.

The **Compact History** action is not supported for models including a mesh imported from dataset.

Properties for Dataset Import

In 2D and 3D, it is possible to import the result of a Filter or Partition dataset evaluation. An example of where import of a dataset is used is when setting up a verification study for topology optimization results.

Select the **Import selections** checkbox (selected by default) to also import the selections defined by the component corresponding to the dataset. If you choose to import these selections, they will appear in the **Domain Selections**, **Boundary Selections**, **Edge Selections**, or **Point Selections** sections, depending on space dimension and the entity level for the imported selections. You can use the imported selections, for example, to add as a selection to a dataset or plot during postprocessing. See also Entity Selections below.

Import of Domain Elements

In 3D, select the **Import domain elements** checkbox to import volumetric elements, such as tetrahedrons, hexahedrons, prisms, and pyramids. Clear this checkbox to only import boundary elements. The default is OFF when **Source** is set to **Dataset**. Domain mesh elements can only be imported if the result that the dataset is evaluated on is defined on a domain mesh.

For **Dataset** import, it is recommended to import the boundary mesh only. See Remeshing Imported Meshes for information on how to improve the quality of the face mesh as well as building a volume mesh in the domains.

Most physics require a mesh on the domains. See Remeshing Imported Meshes for more information.

DETECT FACES (3D) AND 2D SETTINGS

The partitioning algorithm aims to split boundary elements (edge elements in 2D, face elements in 3D) into boundary entities in such a way that no large angles appear between neighboring elements within the same boundary entity. In 2D, you can limit the angle between any two elements within the same boundary entity using the **Maximum angle within boundary** field. The maximum accepted neighbor angle can be set using the **Maximum neighbor angle** field (default: 40 degrees).

If the **Detect planar faces** checkbox (3D) or the **Detect straight edges** checkbox (2D) is selected (both are selected by default), the mesh import detects (approximately) planar faces or straight edges, respectively. The minimum size of a straight or planar boundary entity, relative to the entire boundary, can be set using the **Minimum relative length** field (2D) and **Minimum relative area** field (3D). The maximum accepted angle (in degrees) between elements for a boundary to be considered straight or planar can be set using the **Maximum deviation angle** field. If the **Detect adjacent fillet faces** checkbox (3D) is selected, the algorithm also searches for adjacent groups of boundary elements that form cylindrical faces.

DETECT EDGES (3D)

The partitioning algorithm aims to split edge elements into edge entities in such a way that no large angles appear between neighboring elements within the same edge entity. The maximum accepted neighbor angle can be set using the **Maximum edge neighbor angle** field (default: 60 degrees).

If the **Detect planar edges** checkbox is selected (it is selected by default), the mesh import detects (approximately) planar edges. The **Detection parameter** specifies to which extent the operation searches for planar edges. Use the slider to tune the detection level, where **Strict** means that only fully planar edges are searched for, and **Tolerant** means that the algorithm searches for planar edges with a wider tolerance. You can also enter the parameter value directly as a value between 0 (strict) and 1 (tolerant).

If the **Detect straight edges** checkbox is selected (it is selected by default), the mesh import detects (approximately) straight edges. The **Detection parameter** specifies to which extent the operation searches for straight edges. Use the

slider to tune the detection level, where **Strict** means that only fully straight edges are searched for, and **Tolerant** means that the algorithm searches for straight edges with a wider tolerance. You can also enter the parameter value directly as a value between 0 (strict) and 1 (tolerant).

From the **Minimum edge length** list, choose one of the following options: **Automatic** (the default), **Relative**, or **Absolute** to specify the minimum required length of an edge to be detected. If you select **Relative**, specify a minimum relative length in the **Minimum relative length** field that appears, and if you select **Absolute**, specify a minimum absolute length in the **Minimum absolute length** field that appears.

ENTITY SELECTIONS

The sections **Domain Selections**, **Boundary Selections**, **Edge Selections**, and **Point Selections** appear after building the **Import** operation. The selections are generated during the import based on selections defined in the source. In the **Name** column, the name of each selection appears. For import of mesh data from results, each name is by default the name of the selection in the original geometry or mesh that appears in the **Name in source** column. Select the name in the **Name** column to highlight the selection in the **Graphics** window. You can change the name of a selection by editing the corresponding table entry in the **Name** column. Note that not all of these selection sections are available for all space dimensions.

The selections can be used to specify entity selections in operations and attributes within the same meshing sequence and, if the mesh defines the component's geometric model, for physics and material settings. For more information about the component's geometric model, see The Mesh Node.

For settings of other mesh import sources, see:

- Importing Meshes
- Importing NASTRAN Meshes
- Importing 3MF, PLY, STL, and VRML Meshes
- Importing Geometry to Mesh

For an example of Dataset import, see *Bracket — Topology Optimization*: Application Library path **Optimization_Module/Topology_Optimization/bracket_topology_optimization_stl**

- Transform
- Remeshing Imported Meshes
- Creating Geometry from Mesh
- Modifying the Element Size Using Refine and Adapt
- Filter (Dataset)
- Partition (Dataset)

To remesh imported meshes, add another Mesh sequence and use either a physics-controlled or a user-controlled mesh, as shown in Figure 8-24. With a volume mesh in the domains, the mesh is ready to be used for simulation. The physics is applied to the domains and boundaries defined by the mesh, so no geometry is needed.

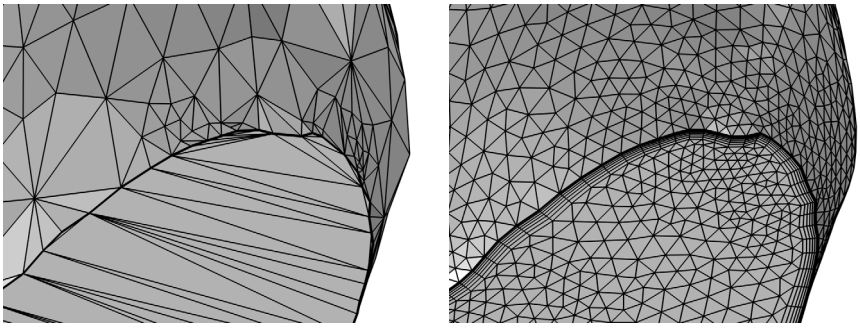

Figure 8-24: Remeshing an imported STL mesh (left) using a physics-controlled mesh for CFD (right).

For more information about the sequence types, see The Mesh Node.

ALTERNATIVE REMESHING OPTIONS

To remesh boundaries in the sequence where the mesh has been imported, for example to give better results in the Booleans and Partitions operations, use the operations Remesh Faces (3D), Remesh Edges, and Remesh Domains (2D).

Yet another alternative, is to generate a geometry from the imported mesh before creating a mesh for simulation. For more information about this workflow, see Creating Geometry from Mesh.

- *STL Import 1 — Repairing and Combining STL Files*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes**
- *Analyzing Porous Structures on the Microscopic Scale*: Application Library path **Porous_Media_Flow_Module/Fluid_Flow/pore_scale_flow_3d**
- *Spray Particle Deposition in Human Airways*: https://www.comsol.com/model/spray-particle-deposition-in-human-airways-125741

CLEANUP WIZARD

Run the **Cleanup Wizard** to remove small details in the geometric model of the mesh. It will detect small details, such as:

- Gaps
- Thin domains
- Narrow domain regions
- Narrow face regions
- Sliver faces
- Small faces
- Short edges

To open the **Cleanup Wizard**, choose one of the following:

- On The Mesh Toolbar, select **Cleanup and Repair** ( ) and choose **Cleanup Wizard** ( ).
- Right-click the **Mesh** node and choose **Cleanup Wizard** ( ) from the **Cleanup and Repair** menu.

The details will be removed using mesh operations, for example some of the Cleanup and Repair and Entities operations.

For more information about the **Cleanup Wizard** and its functionality, see Geometry Cleanup.

Exporting Meshes

You can export a mesh to a COMSOL Multiphysics file (`.mphbin` for a binary file format or `.mphtxt` for a text file format), to a NASTRAN® file (`.nas`, `.bdf`, `.nastran`, or `.dat`), or to a sectionwise text format.

A 3D mesh can also be exported to an STL binary or text file, a PLY binary or text file, or a 3MF file.

For information about the native file formats, see:

- Sectionwise Data Format
- Native Binary Data Files and Text Data Files

To open the **Export** window for exporting meshes, from the **Mesh** toolbar, click **Export** ( ), or right-click the **Mesh** node and select **Export** ( ) from the menu.

EXPORT

Select a file type among the available formats in the **File type** list and enter a filename including the path in the **Filename** field or click **Browse** ( ) to specify the filename. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

Click **Export** ( ) to export a mesh to the specified file. You can also click the downward arrow beside the **Export** button and choose **Export To** ( ) to open the fullscreen **Export** window for exporting a mesh to a database. A confirmation message appears in the **Messages** window.

EXPORTING TO A COMSOL MULTIPHYSICS FILE

If you export a mesh to a COMSOL Multiphysics binary (*.mphbin) or text (*.mphtxt) file, you specify the type of elements to export using the **Domain elements**, **Boundary elements**, **Edge elements** (available in 3D), and **Vertex elements** (available in 2D and 3D) checkboxes under **Data to export**. By selecting the **Geometric entity information** checkbox, the export operation also writes information on the corresponding geometric entity index for each element to the file. Select the **Selections** checkbox to also include selections that are defined on the current geometry in the mesh export. Such selections can then be included when importing a mesh. Select the **Export as second-order elements** checkbox (2D and 3D only) to export the mesh including second-order elements.

For export of second-order elements: the meshes will be extended into a quadratic mesh with second-order elements, either based on the underlying geometry, or a curved approximation of the mesh faces.

EXPORTING TO A NASTRAN FILE

If you export a 2D or 3D mesh to a NASTRAN file, you specify the type of elements to export using the **Domain elements** and **Boundary elements** (available in 3D) checkboxes. By selecting the **Geometric entity information** checkbox, the export operation also writes information on each element's corresponding geometric entity index to the corresponding property identification field of the resulting NASTRAN file.

Under **Output settings**, use the **Field format** list to specify if the output NASTRAN file will be stored in the **Small** field format (single precision), **Large** field format (default, double precision), or **Free** field format (comma separated). Clear the **Export as second-order elements** checkbox to export the linear element information only. By default, second-order elements (serendipity elements) are exported.

For export of second-order elements: the meshes will be extended into a quadratic mesh with second-order elements, either based on the underlying geometry, or a curved approximation of the mesh faces.

EXPORTING TO A SECTIONWISE FILE

You can export a 2D or 3D mesh to a sectionwise text file (*,txt). The sectionwise file contains a simplex partitioning of nonsimplex elements. Second-order information is ignored. The exported files include the following header: `% Model: Untitled.mph`

```
% Version: COMSOL 6.3.0.213
% Date: August 1 2024, 09:09
% Dimension: 3
% Nodes: 1375
% Elements: 6270
% Expressions: 0
% Description:
% Length unit: m
```

The number of expressions is 0, which means that the description becomes empty. After the header, the coordinate values for the mesh follow under `% Coordinates`.

The length unit is the only header field that is read, which is the case if imported to a Component or to a Mesh Part where the **Use units** checkbox is selected. See Importing Meshes from Files with Length Unit. When you export mesh to a sectionwise file from a **Mesh** node under a Component or from a **Mesh Part** node where the **Use units** checkbox is selected, the resulting file's length unit will be determined from the length unit of the **Geometry** node in the Component or the **Mesh Part** node, respectively.

When you select **Sectionwise file (*.txt)** from the **File type** list, you can then select **Domain elements** (the default), **Boundary elements**, or **Edge elements** (3D only) in the **Data to export** section to determine the level of the exported mesh data.

EXPORTING A 3D MESH TO AN STL FILE

You can export a 3D mesh containing face elements to an STL file (stereolithography file) in the binary or text format. Because the STL format only supports triangles, the export operation writes two triangles (defining a quad split) to the STL file for each quad element in the mesh. Second-order elements are converted to first-order elements.

EXPORTING A 3D MESH TO A PLY FILE

You can export a 3D mesh containing face elements to a PLY file (Polygon File Format or Stanford Triangle Format file) in the binary or text format. Second-order elements are converted to first-order elements.

EXPORTING A 3D MESH TO A 3MF FILE

You can export a 3D mesh containing face elements to a 3MF file (3D Manufacturing Format file). From the **Data to export** list, select **Entire boundary as a single 3MF surface object** (the default) to export the entire surface mesh as one 3MF object of Surface type, or select **Domains as separate 3MF model objects** to export the surface mesh of each domain as a separate 3MF object of Model type and the remaining surface mesh, corresponding to the faces that are not adjacent to any domain, as a 3MF object of Surface type. Because the 3MF format only supports triangles, the export operation writes two triangles (defining a quad split) to the 3MF file for each quad element in the mesh. Second-order elements are converted to first-order elements.

There is also a mesh export option available under **Results** > **Export** (see Mesh (Export)). Use this mesh export if you have computed a solution and want to export the mesh from a deformed configuration or a (geometric) parameter configuration, for example. When exporting the mesh under **Results** > **Export**, the COMSOL Multiphysics and STL (3D only) binary and text formats are available.

Combining Geometry and Mesh

When working with imported meshes, you may run into applications where you want to combine your imported mesh with an imported CAD part, CAD assembly, or with geometry created in COMSOL Multiphysics. The recommended workflow is to import the geometry to the mesh sequence and combine them using mesh operations.

COMSOL Multiphysics supports a variety of operations, for example, moving, scaling and rotating an imported mesh, combining the imported mesh with parameterized geometry to run parametric sweeps, and generating unstructured, structured, and boundary layer mesh in the domains. When creating geometry or importing CAD files for combining with an imported mesh, you can view the imported mesh with the geometry to help with positioning the design. This is done by creating a geometry object from the mesh.

In this section:

- Importing Geometry to Mesh
- Creating Geometry from Mesh

Importing Geometry to Mesh

Use a mesh **Import** node ( ) to import the Component's geometry directly to a meshing sequence. If the geometry intersects an imported mesh, use a Union operation to unite the two.

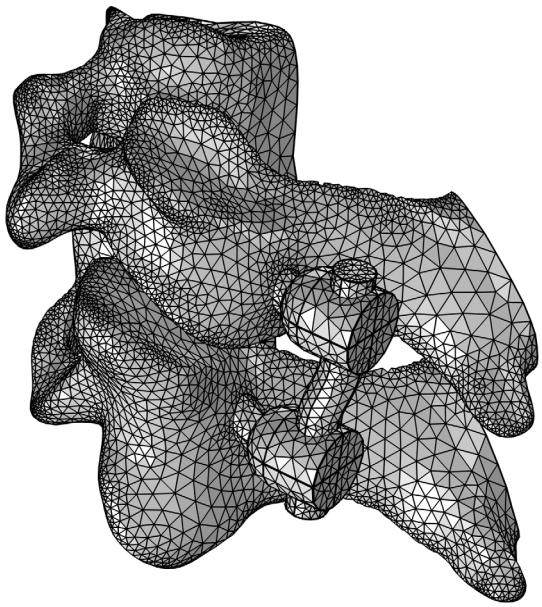

Figure 8-25: The geometry of two pedicle screws and a rod is imported to a mesh that already contains the imported STL mesh of two vertebrae and a disc.

This operation is available for 3D models only.

IMPORT

In the **Source** list, choose **Geometry sequence** and select a geometry sequence from the **Geometry** list below.

From the **Face mesh generation** list, select **Free triangular** (default) to import a triangle mesh, generated in the background by the Free Triangular operation. Specify the size of the triangles using the **Size** list, ranging from **Extremely fine** to **Extremely coarse** (default **Normal**). Select the **Resolve narrow domain regions** checkbox (default ON) to let the surface mesh be finer close to a thin region in the domain. Select the **Resolve geometric details** checkbox (default ON) to let the surface mesh be finer close to small details and curved faces. Clear the checkboxes to let the element size be determined by the **Size** setting only.

Select **Visualization** to import a visualization mesh of the geometry. Specify the level of detail for the triangulation using the **Detail** list, ranging from **Fine** to **Coarse** (default **Normal**).

To import a geometry sequence, click the **Import** button.

ENTITY SELECTIONS

The sections **Domain Selections**, **Boundary Selections**, **Edge Selections**, and **Point Selections** appear after building the **Import** operation. The selections are generated during the import based on selections defined in the source. In the **Name** column, the name of each selection appears. For import of geometry to mesh, each name is by default the name of the selection in the original geometry that appears in the **Source in geometry** column. Select the name in the **Name** column to highlight the selection in the **Graphics** window. You can change the name of a selection by editing the corresponding table entry in the **Name** column. Note that not all of these selection sections are available for all space dimensions.

The selections can be used to specify entity selections in operations and attributes within the same meshing sequence and, if the mesh defines the component's geometric model, for physics and material settings. For more information about the component's geometric model, see The Mesh Node.

For information about how to generate a mesh for simulation, see Remeshing Imported Meshes.

For settings of other mesh import sources, see:

- Importing Meshes
- Importing NASTRAN Meshes
- Importing 3MF, PLY, STL, and VRML Meshes
- Importing Mesh Data from Results

STL Import 2 — Combining Geometry with an Imported Mesh: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_2_combine_geom_mesh**

Creating Geometry from Mesh

A mesh imported into COMSOL Multiphysics can be used to construct a geometry. It is recommended to use such an object only as an aid Create a geometry object of the mesh, marking it as Construction Geometry, to use it as an aid when positioning the geometry, as shown in the suggested tutorial below.

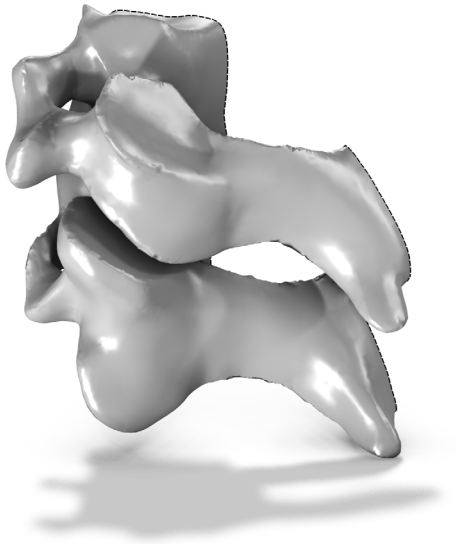

Figure 8-26: Importing the mesh of the vertebrae and disc into the geometry sequence as a construction object to help with the positioning of the geometry.

If the goal is to improve the quality of the imported mesh, it is recommended to remesh the faces in the meshing sequence, without creating a geometry. See Remeshing Imported Meshes for more information.

Boolean operations when one or more of the parts originate from mesh are much more stable to build in the meshing sequence. Import any geometry to the meshing sequence and use a mesh Union operation to unite them in the meshing sequence. See Importing Geometry to Mesh.

To create a geometry from a mesh, choose one of the following:

- Add an **Import** node to the geometry sequence and browse to import any supported mesh file.
- Select an existing mesh part or meshing sequence. In the **Mesh** toolbar, click **Create Geometry** ( ) or right-click and select it from The Graphics Context Menu.

The COMSOL Multiphysics software creates a new model Component of the same dimension as the current mesh. The geometry sequence in the new component has an Import node that imports the original mesh as geometry.

STL Import 2 — Combining Geometry with an Imported Mesh: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_2_combine_geom_mesh**

Meshing Operations and Attributes

A meshing sequence consists of Operations and Attributes. Among the operations, there are Generators that generate mesh elements, Modifying Operations that modify existing meshes, and Copying Operations to copy the meshes between components or entities in the same component. The last category of operations can change the number of entities in a mesh either by creating entities, or partition existing entities (Booleans and Partitions, Cleanup and Repair, and Entities).

The Attributes store properties that are used by the operation nodes when creating the mesh. You can also choose the Predefined Mesh Element Sizes to adjust the element size.

The tables below list available mesh operations, attributes, and actions relating to meshes. The tables are roughly organized based on where they appear on The Mesh Toolbar:

- Import/Export
- Physics Controlled
- Generators
- Attributes
- Operations
- Selections
- Evaluate
- Clear

TABLE 8-2: IMPORT/EXPORT

ICON	NAME	DESCRIPTION
	Import	To import a mesh from file, mesh sequence, mesh part, Filter dataset, Partition dataset, or to import a geometry to mesh. See Importing Meshes for more information
	Export	To export a mesh to file. See Exporting Meshes for more information.
	Create Geometry	To import a mesh from file, mesh sequence, mesh part, Filter dataset, or Partition dataset. See Creating Geometry from Mesh for more information.

TABLE 8-3: PHYSICS CONTROLLED

ICON	NAME	DESCRIPTION
	Edit	To edit a physics-controlled sequence. See Editing and Resetting a Physics-Controlled Sequence for more information
	Reset	To reset the sequence to the physics-controlled settings. See Editing and Resetting a Physics-Controlled Sequence for more information.

TABLE 8-4: GENERATORS

ICON	NAME	DESCRIPTION
	Boundary Layers	Create a boundary layer mesh — a mesh with dense element distribution in the normal direction along specific boundaries. This mesh is typically used for fluid flow problems to resolve the thin boundary layers along the no-slip boundaries.
	Edge	Create an edge mesh.
	Free Tetrahedral	Create an unstructured tetrahedral mesh. If no selection is specified, this feature creates a mesh on the remaining domains, boundaries, edges, and points.

TABLE 8-4: GENERATORS

ICON	NAME	DESCRIPTION
	Free Triangular	Create an unstructured triangular mesh on faces in 3D or domains in 2D. For imported meshes, only faces in 3D are supported.
	Free Quad	Create an unstructured quadrilateral mesh on faces in 3D or domains in 2D. For imported meshes, only faces in 3D are supported.
	Mapped	Create a structured quadrilateral mesh on boundaries in 3D and domains in 2D. For imported meshes, only faces in 3D are supported.
	Remesh Domains	Remesh domains in a mesh that defines its own geometric model.
	Remesh Edges	Remesh edges in a mesh that defines its own geometric model.
	Remesh Faces	Remesh faces in a mesh that defines its own geometric model.
	Swept	Create a swept mesh. In domain selection mode this button works in the same way as the Free Tetrahedral button. In boundary selection mode the software creates a swept mesh on the remaining domains using the selected boundaries as source faces.
	Vertex	Create a vertex mesh.

TABLE 8-5: ATTRIBUTES

ICON	NAME	DESCRIPTION
	Boundary Layer Properties	To specify the location of the boundary layers and the properties, such as the number and thickness of the boundary layers.
	Corner Properties	To specify specific properties for boundary layers in one or more corners.
	Corner Refinement	To specify a refinement in sharp corners. The node considers a vertex in 2D or an edge in 3D to be a sharp corner if the angle between the adjacent selected boundaries, with respect to the selected domain, is greater than a specified angle.
	Distribution	To specify the distribution of mesh elements along an edge or along a sweep.
	Edge Groups	To specify the four groups of edges around a boundary (3D) or domain (2D) that is used to determine the Mapped mesh of the boundary/domain.
	Edge Map	Specify two edges that determine the mapping from source to destination of a copy operation.
	Fixed Mesh	Selecting entities where the mesh is kept fixed when using the Remesh Faces and Remesh Domains operations.
	Identical Mesh	Specify identical mesh on pairs of faces or edges.
	One-Point Map	Specify two points that determine the mapping from source to destination of a copy operation.
	Scale	To scale the element size properties of other attribute nodes.
	Size	To specify the element size.
	Size Expression	To specify the size of mesh elements using an expression evaluated on the grid or on a solution.
	Transform	To specify a position, rotation, or to scale an imported mesh. Supported for the Import operation.
	Two-Point Map	Specify two point pairs that determine the mapping from source to destination of a copy operation.

OPERATIONS

TABLE 8-6: MODIFYING OPERATIONS

ICON	NAME	DESCRIPTION
	Adapt	Use adaptive mesh generation based on an error estimate from a computed solution.
	Convert	Convert quadrilateral meshes on faces to triangles or hexahedral meshes on domains into tets.
	Reference	Refer to another meshing sequence. Building a Reference node runs the operation nodes of the referenced sequence.
	Refine	Refine a mesh by splitting elements.

TABLE 8-7: COPYING OPERATIONS

ICON	NAME	DESCRIPTION
	Copy	Copy a mesh from another meshing sequence, typically of imported mesh type, or mesh part into a meshing sequence corresponding to a geometry. Can also be used to copy a mesh within the same meshing sequence.
2D 3D	Copy Domain	Copy a mesh between domains.
2D 3D	Copy Edge	Copy a mesh between edges. A 3D Copy Edge feature can also be used for destination edges of different shapes.
	Copy Face	Make a copy of a face mesh using a rigid body transformation with a scale factor.

TABLE 8-8: BOOLEANS AND PARTITIONS

ICON	NAME	DESCRIPTION
	Imprint	To split faces in a mesh by imprinting faces, edges, and vertices onto them.
	Intersect with Line	To split mesh elements and geometric entities of a 2D mesh with a straight line.
	Intersect with Plane	To split mesh elements and geometric entities of a 3D mesh with one or several planes.
	Partition with Ball	To split geometric entities in a mesh by an element set defined by a ball.
	Partition with Cylinder	To split geometric entities in a mesh by an element set defined by a cylinder.
	Partition with Box	To split geometric entities in a mesh by an element set defined by a box.
	Partition by Expression	To split geometric entities in a mesh by specifying a logical expression.
	Union	To merge adjacent mesh faces or unite partly overlapping face meshes to form overlap domains.
	Detect Faces	To partition faces of the mesh by searching for shapes that are likely to constitute separate faces.

TABLE 8-9: CLEANUP AND REPAIR

ICON	NAME	DESCRIPTION
	Cleanup Wizard	To clean up the geometric model of a mesh.
	Fill Holes	To repair an imported 3D surface mesh with minor holes.
	Collapse Entities	To collapse geometrical entities in meshes.
	Merge Entities	To merge geometrical entities in meshes.

TABLE 8-10: ENTITIES

ICON	NAME	DESCRIPTION
	Delete Entities	To delete geometric entities in a mesh that defines its own geometric model.
	Join Entities	To join adjacent geometric entities in a mesh.
	Create Domains	To create additional domains within watertight faces meshes.
	Create Edges	To create meshed edges in a mesh that defines its own geometric model.
	Create Faces	To create additional meshed faces within edge loops in a mesh that defines its own geometric model.
	Create Vertices	To create vertices in a mesh that defines its own geometric model.

SELECTIONS

Creating named selections in the Mesh sequence is supported for meshes that define their own geometric models, such as imported meshes. See Creating Named Selections in the Mesh Sequence for more information. For meshes conforming with geometry, either create the selections in the Geometry sequence or under Definitions. See Creating Named Selections and Creating Named Selections in the Geometry Sequence for more information.

TABLE 8-11: SELECTIONS

ICON	NAME	DESCRIPTION
	Adjacent Selection	To define a selection of entities that are adjacent to a specified selection. See Adjacent Selection (Mesh Sequences).
	Explicit Selection	To define an explicit selection of entities. See Explicit Selection (Mesh Sequences).
	Selection List	Click to open The Selection List Window. This window lists all geometric entities as well as all available named selections.

TABLE 8-12: EVALUATE

ICON	NAME	DESCRIPTION
	Measure	To measure a set of geometric objects or entities selected in the Graphics window. See Geometric Measurements for more information.
	Statistics	To show brief mesh statistics in the Messages window. For a more extensive statistics representation, open Mesh Statistics.
	Plot	To add a mesh plot. For information, see Mesh Plots.

TABLE 8-13: CLEAR

ICON	NAME	DESCRIPTION
	Clear Built Mesh	To remove the built mesh while keeping the sequence in order to later rebuild the mesh using the same settings. See also Clearing or Deleting a Mesh.
	Clear All Built Meshes	To clear all built meshes in the model while keeping the sequences in order to later rebuild the meshes.
	Clear Built Meshes	To clear all built meshes in the component while keeping the sequences in order to later rebuild the meshes. This action is only available from by right-clicking the **Meshes** node.
	Clear Sequence	To clear the sequence of all operations and attributes and also clear the built mesh.

Adapt

Use **Adapt** ( ) to modify an existing mesh based on an expression, typically by refining the mesh based on error information from a solution, as shown in Figure 8-27. The **Adapt** operation is used when setting up adaptive mesh refinement in the solver. The operation can also be used to modify the element size in a mesh based on a size expression, without the need for a solution.

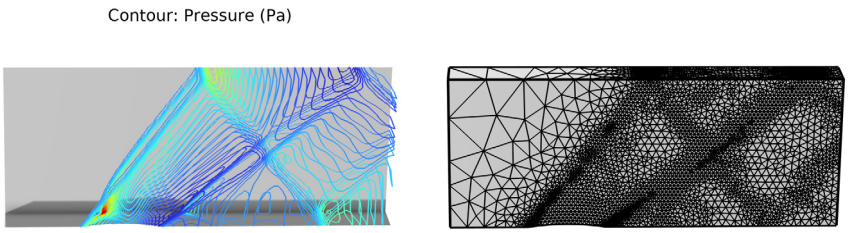

Figure 8-27: The mesh on the fluid domain is adapted based on the L2 norm of the error in the solution. The original mesh is coarsened close to the inlet on the left side and is refined based on how the small bump is affecting the flow.

Adapt nodes are part of meshing sequences that the adaptive solver creates. You can also add **Adapt** nodes by selecting entities in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window and select **Adapt** ( ) from the **Modifying Operations** menu. For more information, see The Graphics Context Menu.
- On The Mesh Toolbar select **Adapt** from the **Modify** ( ) menu.
- Right-click a 2D or 3D **Mesh** node and select **Adapt** ( ) from the **Modifying Operations** menu.

If you want to perform adaptive mesh refinement by manually adding an **Adapt** node, first create a new meshing sequence and copy the original mesh into that meshing sequence before adding an **Adapt** node.

The **Adapt** node's **Settings** window contains the following sections.

GEOMETRIC ENTITY SELECTION

From the **Geometric entity** list, choose **Entire geometry** (the default), **Domain**, **Boundary**, or **Edge** to select a set of entities for which the adaptation is active. Choose **Manual** in the **Selection** list to select the entities in the **Graphics** window or choose a named selection to refer to a previously defined selection.

ADAPTATION

From the **Solution** list, select the solution to use for evaluation, or choose **None** to not use any solution, but instead use the input mesh for the operation to evaluate on.

From the **Solution selection** list, select which solution to use to evaluate error estimates:

- Select **Use last** to use the last solution.
- Select **Use first** to use the first solution.
- Select **All** (the default for Eigenvalue studies) to use all solutions from that study.
- Select **Manual** to use a specific solution number that you specify as solution indices in the **Index** field.

In the **Weights** field (only available when **Solution selection** is **Manual** or **All**), enter weights as a space-separated list of positive (relative) weights so that the error estimate is a weighted sum of the error estimates for the various solutions (eigenmodes). The default value is 1, which means that all the weight is put on the first solution (eigenmode). That is, any omitted weight components are treated as zero weight.

From the **Type of expression** list, choose **Error indicator** (the default), **Absolute size**, or **Anisotropic metric**.

Error Indicator

If you select **Error indicator**, the following settings appear:

The **Error expression** list, where you can add expressions for the error, for example, in terms of the dependent variables (including the variables for error estimation). You can use any expression, including field variables and their derivatives, defined in the domain. Use the **Active** column to control which error expressions are active by selecting or clearing the corresponding checkbox.

The **Error order** column is available when **Element selection** is set to **Rough global minimum** and forms an array of h-exponents for the decrease of the error expression. This array has the same indexing as the error expression's indexing (for an error expression with two expressions, such as `errexpr1`, `errexpr2`, and error orders = 2, 3, it means that `errexpr1` = $O(h^2)$ and `errexpr2` = $O(h^3)$). When the adaptation method is used, these numbers are filled in automatically based on the **Residual order** and **Error estimate** settings (on the adaptation study). The shape functions can also influence this order. Note that these order numbers need to be positive to generate additional elements (element growth).

Use the **Move Up** (↑), **Move Down** (↓), **Add** (+)and **Delete** ( ) buttons as needed. If you use several expressions, such as one for each solution component, the error expressions are added to form the sum of all of them. Or right-click a table cell and select **Move Up**, **Move Down**, **Add**, or **Delete**.

Use the **Adaptation method** list (2D and 3D only) to control how to adaptively refine mesh elements. Select one of these methods:

- **General modification**, to use the current mesh as a starting point and modify it by refinements, coarsening, topology modification, and point smoothing. This is the default method. Use the **Allow coarsening** checkbox (selected by default) to control if mesh coarsening is used. If the mesh contains anisotropic elements (for example, a boundary layer mesh), it is best to disable mesh coarsening to preserve the anisotropic structure. If mesh coarsening is allowed, enter a **Maximum coarsening factor** (default: 5) if needed.
- **Regular refinement**, to make the solver refine elements in a regular pattern by bisecting all edges of an element that needs refinement.
- **Longest edge refinement**, to make the solver refine only the longest edge of an element by recursively bisecting the longest edge of edge elements that need refinement. This method is less suitable for models with nonsimplex elements.

Enter a value for the **Maximum number of refinements** (default: 5 in 2D and 3D; 16 in 1D), if needed.

Use the **Element selection** list to specify how the element refinement vector is determined from the error expression. Select:

- **Rough global minimum** to minimize the L_2 norm of the error by refining a fraction of the elements with the largest error in such a way that the total number of elements increases roughly by a factor greater than 1 specified in the accompanying **Element count growth factor** field. The default value is 1.7, which means that the number of elements increases by roughly 70%.
- **Fraction of worst error** to refine elements whose local error indicator is larger than a given fraction of the largest local error indicator. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the fraction contains the elements with more than 50% of the largest local error.
- **Fraction of elements** to refine a given fraction of the elements. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the solver refines about 50% of the elements with the largest local error indicator.

Absolute Size

If you select **Absolute size**, the following settings appear:

In the **Size expression** field, type an expression for the element size (in terms of variables defined by the solution).

When you evaluate on a solution, the spatial variables (and any other length dependent variable, such as the local mesh size `h`), has the units of the component. So if your 2D geometry uses km as the length unit and is a unit square, assuming the component uses the SI unit system, the range of x and y would be 0 to 1000 (m) on the same geometry. Also note that the evaluated value of the expression is interpreted as a length in the geometry's unit system.

Size expressions that can be evaluated on boundaries only cannot be used for geometries with domains, even if they are applied only on the boundary.

In 2D and 3D, use the **Adaptation method** list to control how to refine mesh elements. Select one of the following methods:

- **General modification**, to use the current mesh as a starting point and modify it by refinements, coarsening, topology modification, and point smoothing. This is the default method. Use the **Allow coarsening** checkbox to control if mesh coarsening is used. If the mesh contains anisotropic elements (for example, a boundary layer mesh), it is best to disable mesh coarsening to preserve the anisotropic structure.

It is not possible to coarsen hexahedral elements in the mesh.

- **Regular refinement**, to make the solver refine elements in a regular pattern by bisecting all edges of an element that needs refinement.
- **Longest edge refinement**, to make the solver refine only the longest edge of an element by recursively bisecting the longest edge of edge elements that need refinement. This method is less suitable for models with nonsimplex elements.

This is an advanced option, where it can be difficult to formulate a useful and nontrivial anisotropic measure.

If you select **Anisotropic metric** (2D and 3D only), the following settings appear:

In the matrix (2-by-2 in 2D; 3-by-3 in 3D) that appears, you can enter a metric in upper-triangular parts (the matrix is a positive definite symmetric matrix). The expressions for the metric can vary in space and include the local mesh element size `h`. The default value is a diagonal matrix with the diagonal elements set to `1/h`, which means "no modification" for an isotropic mesh. The interpretation of the matrix is as follows: The vector representing an edge of an element is transformed by the matrix in that point, and the length of the transformed vector is measured. If the length is shorter than 1.0, it is considered too short. If it is longer than 1.0, it is considered too long. This measure is used to control the adaptation.

External Changes

The following settings are available under **External changes** if the **Solution** list is set to **None**.

There is a caching scheme that caches various data required to compute the mesh size field. If you have changed something in the model that has not been picked up by the code and thus invalidated the cache, you can clear the cache by clicking **Reevaluate with Updated Model**.

The selection in the **Update when parameter is changed** list provides the possibility to have the cache cleared whenever the values of the selected parameter are changed.

FACE REPRESENTATION

Specify the representation to use for the adaptation. The setting only affects how mesh vertices are placed on curved faces.

The **Face representation** setting is only available for 3D meshes that define their own geometric model. A typical example is a mesh imported from file.

Select:

- **Linear** to place new or moved mesh vertices on the input mesh. A resulting refined mesh will keep the shape of the input mesh to a great extent, as seen in the upper right image in Figure 8-28.
- **Curved** to place new or moved mesh vertices on a curved surface approximation of the input mesh. On curved faces where the mesh has been refined, the resulting mesh will typically be smoother than the input mesh, as seen in the lower right image in Figure 8-28.

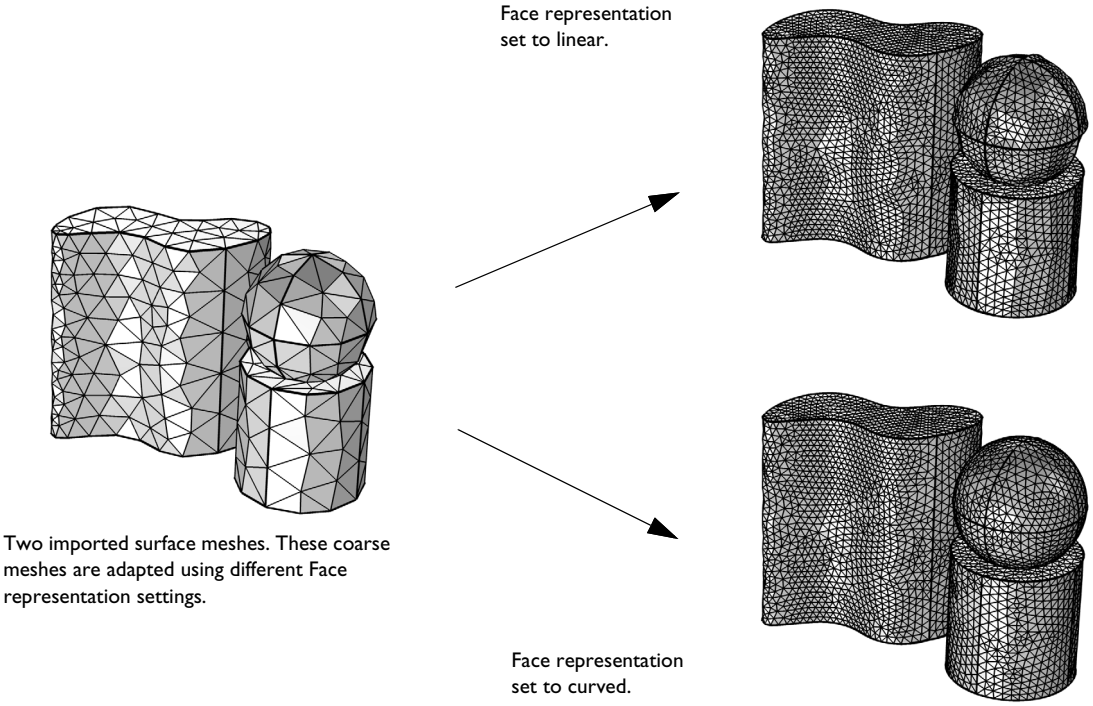

Figure 8-28: Two imported surface meshes (left) are refined using the Adapt operation. Set the Face representation to Linear to keep the shape of the input mesh to a greater extent (upper right). Use the setting Curved to get a smoother mesh as a curved approximation of the surfaces is used when placing the new mesh vertices (lower right).

- Modifying the Element Size Using Refine and Adapt

- For a tutorial using Adapt with a Size expression, see *Optimization of a Tesla Microvalve*: Application Library path **Optimization_Module/Topology_Optimization/tesla_microvalve_optimization**.

For examples where solvers generate adapted meshes, see:

- *Implementing a Point Source*: Application Library path **COMSOL_Multiphysics/Equation_Based/point_source**.
- *3D Supersonic Flow in a Channel with a Bump*, Application Library path **CFD_Module/High_Mach_Number_Flow/euler_bump_3d**.

Boundary Layers

Use **Boundary Layers** ( ) to create a boundary layer mesh with dense element distribution in the normal direction along selected boundaries, as shown in Figure 8-29. This type of mesh is typically used for fluid flow problems to resolve the thin boundary layers along the no-slip boundaries.

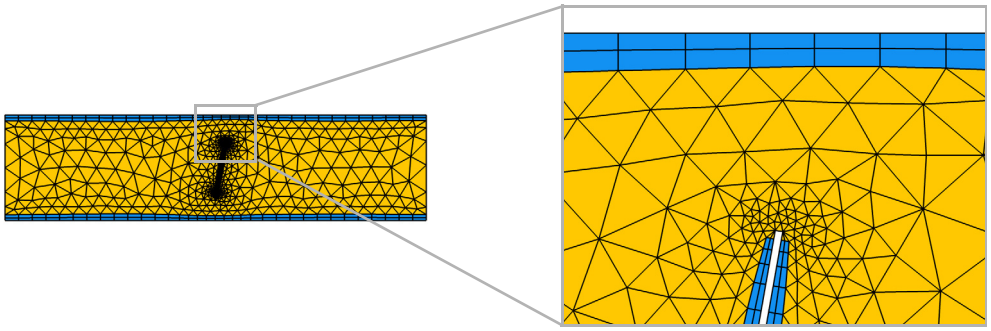

Figure 8-29: A channel in which a fluid flows from the left to the right and is hindered by a tilted blade in the middle of the channel. A boundary layer mesh is added to the wall boundaries (blue quad elements) to resolve the regions closest to the no-slip boundaries. The image to the left shows the full geometry while the image on the right-hand side shows a smaller portion of the geometry, zoomed in on the top of the blade.

	In 2D, a layered quadrilateral mesh is used along the specified no-slip boundaries, as shown in Figure 8-29.

	In 3D, the boundary layer mesh is a layered prism mesh or a hexahedral mesh depending on whether the corresponding boundary-layer boundaries contain a triangular or a quadrilateral mesh. Additional elements of an arbitrary type can also be inserted into the layers if needed.

When a **Boundary Layers** node is added, a Boundary Layer Properties node is automatically added as a subnode. Use this subnode to specify the boundary layers and the properties of the boundary layers. If you want to specify different boundary layer properties for more than one boundary selection, right-click the **Boundary Layers** node and add additional **Boundary Layer Properties** subnodes.

In 3D, for a mesh that defines its own geometric model, it is possible to create a boundary layer mesh in meshed domains. If the selected domains are not meshed, use a Free Tetrahedral operation to add a volume mesh before building the **Boundary Layers** node.

	See The Mesh Node to learn more about meshes that define their own geometric model.

To add a **Boundary Layers** node, select boundaries (2D and 3D) or edges (for a boundary layer mesh on boundaries in 3D) in the graphics, then choose one of the following:

- Right-click in the **Graphics** window and select **Boundary Layers** ( ) from the menu. For more information, see The Graphics Context Menu.
- On The Mesh Toolbar click the **Boundary Layers** button ( ).
- Right-click a 2D or 3D **Mesh** node and select **Boundary Layers** ( ).

Then enter the properties for the boundary layer mesher using the following sections:

GEOMETRIC ENTITY SELECTION

Specify the entities where a boundary layer mesh will be created by first choosing an option from the **Geometric entity level** list:

- Choose **Entire geometry** to specify boundary layer mesh for the entire geometry.
- Choose **Domain** to specify the domains where you want a boundary layer mesh. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains** to select all domains.
- Choose **Boundary** (available in 3D only) to select boundaries for which to generate a boundary layer mesh along its edges. Choose **Manual** in the **Selection** list to select the boundaries in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All boundaries** to select all boundaries. Use a Swept operation to sweep the face mesh in adjacent domains to create a volumetric boundary layer mesh.

CORNER SETTINGS

The following options for handling boundary layers at sharp corners are available from the **Handling of sharp corners** list (in 2D) and the **Handling of sharp edges** list (3D):

- Select **Splitting** (the default) to introduce boundary layer splits at sharp corners, as shown in Figure 8-30. In the **Split for angles greater than** field you specify the minimum angle between adjacent boundary layer boundaries for a split to occur. Control the maximum angle of the elements in the split region by the **Maximum angle per split** parameter.
- Select **Trimming** to trim the boundary layer mesh at sharp corners. In the **Trim for angles greater than** field you specify the minimum angle between adjacent boundary layer boundaries for trimming to occur. It is recommended to combine **Trimming** with a Corner Refinement node to refine the mesh further close to the sharp corner, as shown in Figure 8-30.
- Select **No special handling** to not use any special treatment at sharp corners, as shown below.

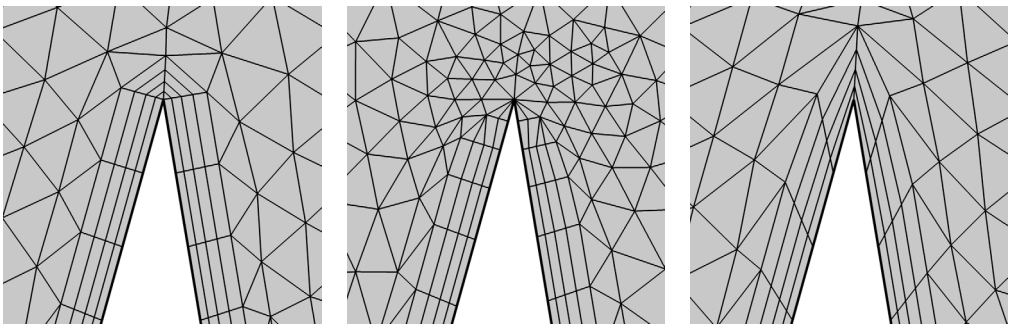

Figure 8-30: The different options for handling sharp corners: Splitting, Trimming with Corner Refinement applied, and No special handling.

In the **Maximum layer decrement** field you can specify the maximum difference in number of boundary layers between neighboring points on boundary layer boundaries.

In the section **Trimming in narrow corners**, specify the **Trim for angles less than**. This setting controls the maximum angle between adjacent boundaries for trimming to occur, as shown in Figure 8-31. For angles between a boundary layer boundary and any other boundary, half the **Trim for angles less than** is used.

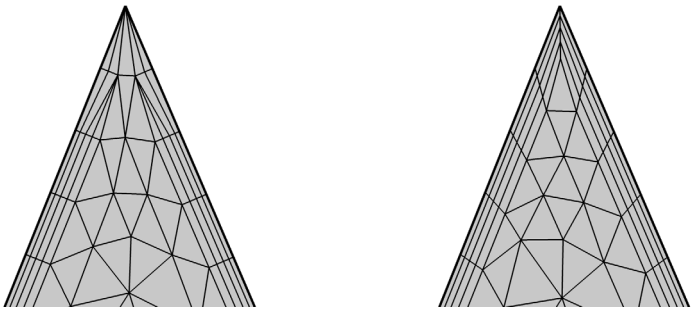

Figure 8-31: The boundary layer mesh in a 45 degree corner. With the Trim for angles less than set to 50 degrees, the corner is considered as narrow and trimming occurs. Setting the value to 40 degrees, avoids trimming in the corner.

TRANSITION

Select the **Smooth transition to interior mesh** checkbox to smooth the transition in element size from the boundary layer mesh to the interior mesh. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth from the boundary layer interface for the mesh vertices to be smoothed.

ADVANCED SETTINGS

Specify the boundary layer method to use. From the **Method** list, select **Latest version** (default) to use the most recent version of the boundary layer mesher, or select **Legacy version 6.1** or **Legacy version 6.0** to use similar methods as used in version 6.1 and version 6.0, respectively. For **Legacy version 6.0**, the directions in the boundary layers are kept straight in all layers, otherwise they may bend to improve the quality. The **Legacy version 6.1** option affects the deformation of the mesh to make room for the boundary layers; more recent versions of COMSOL Multiphysics provide a more sophisticated method that allows you to create thicker boundary layers with higher element quality.

- Boundary Layer Properties
- Corner Properties
- Corner Refinement
- Identical Mesh
- Structured Meshes

Boundary Layer Properties

Use the **Boundary Layer Properties** ( ) attribute to specify the location of the boundary layers and the properties, such as the number of layers and thickness of the boundary layers, as shown in Figure 8-32.

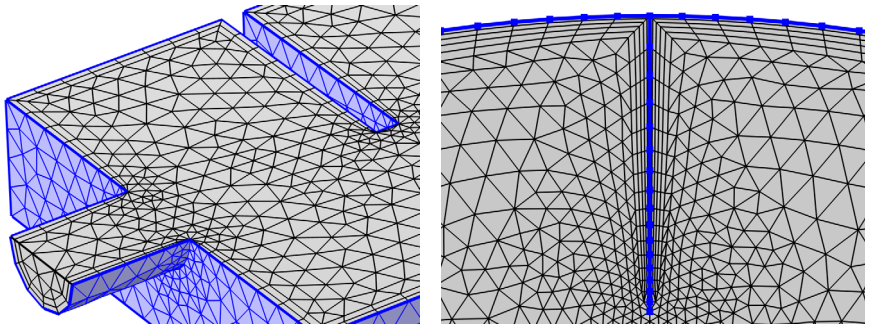

Figure 8-32: Boundary layers added to selected boundaries (highlighted in blue). Two element layers have been generated in the left mesh and five layers in the mesh on the right-hand side.

By default, one **Boundary Layer Properties** node is added as a subnode to a Boundary Layers node. To add additional nodes choose one of the following:

- Select the **Boundary Layers** node, select boundaries or edges in the **Graphics** window, and then choose **Boundary Layer Properties** from the **More Attributes** menu ( ) on The Mesh Toolbar.
- Right-click the **Boundary Layers** node and choose **Boundary Layer Properties** ( ).

Then enter the properties using the following sections:

GEOMETRIC ENTITY SELECTION

Define the edges (for faces in 3D) or boundaries where to add boundary layers. Choose **Manual** in the **Selection** list to select the entities in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All boundaries** or **All edges** to select all boundaries or edges respectively.

!	Setting **Geometric entity level: Domain** or **Boundary** in the Boundary Layers node changes the name of this section to **Boundary Selection** or **Edge Selection**, respectively.

LAYERS

The default **Number of layers** is 8.

The default **Stretching factor** is 1.2. This field is used to specify the increase in thickness between two consecutive boundary layers as a scaling factor; for example, entering `1.3` means that the thickness increases by 30% from one layer to the next.

To specify the thickness of the boundary layer mesh, choose an option from the **Thickness specification** list: **Automatic** (the default), **First layer**, or **All layers**.

- If **Automatic** is kept, for each boundary element, the local thickness of the first layer is computed as 5% of the height of the adjacent element (in the direction orthogonal to the boundary element). Enter the **Thickness adjustment factor** (default is 1) to specify a scaling of the thickness of the first layer.
- If **First layer** is selected, specify the **Thickness** of the first element layer — the layer adjacent to the corresponding boundary.
- If **All layers** is selected, specify the **Total thickness** of the boundary layer mesh.

The default thickness of the first layer and the total thickness of the boundary layer mesh are both determined from the specified element size in the sequence.

	The boundary layer meshing algorithm shrinks the boundary layers automatically if needed (for example, due to a narrow region); however, the stretching factor is always respected. In some cases the boundary layer meshing algorithm can choose to create fewer layers than specified. If this happens, Information Nodes appear with further information and locations.

	Boundary Layer Meshing — Exploring the Settings: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/valve_boundary_layers**.

	• Boundary Layers • Corner Properties • Scale • Global vs. Local Attributes

Collapse Entities

Use **Collapse Entities** ( ) to collapse boundaries or edges of a 3D mesh, as shown in Figure 8-33 and Figure 8-34. A domain without mesh can be collapsed if all surrounding surfaces are collapsed.

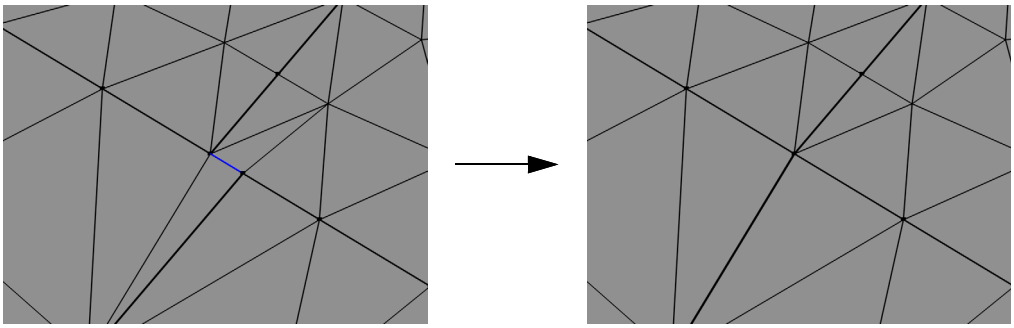

Figure 8-33: A short edge in the mesh is highlighted in blue (left). The image to the right shows the mesh after the edge has been collapsed.

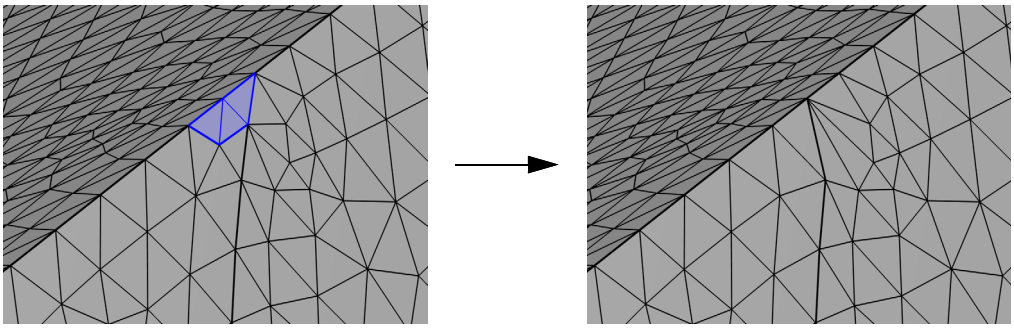

Figure 8-34: A small boundary in the mesh is highlighted in blue (left). The image to the right shows the mesh after the boundary has been collapsed.

	This operation is supported in 3D models only.

	• For more control over how boundaries are collapsed in a mesh, use Merge Entities and specify the edges to keep and the edges to remove. • If the mesh is conforming to a geometry, consider using Remove Details, Collapse Faces, or Collapse Edges to remove the entities already in the geometry.

To collapse entities in a mesh, select one or several entities in the mesh, then choose one of the following:

- Right-click in the **Graphics** window, and select **Collapse Entities** from the **Cleanup and Repair** menu. For more information, see The Graphics Context Menu.
- In The Mesh Toolbar, choose **Collapse Entities** ( ) from the **Cleanup and Repair** menu ( ).
- Right-click the **Mesh** node and choose **Collapse Entities** ( ) from the **Cleanup and Repair** menu.

Enter the properties for the **Collapse Entities** node using the following sections:

GEOMETRIC ENTITY SELECTION

Select the geometric entity level from the **Geometric entity level** list. The possible choices are **Entire geometry** (the default), **Boundary**, or **Edge**. For **Entire geometry**, the selection below is not available.

Click the **Active** button to toggle between turning ON and OFF selections. Select the edges or boundaries to collapse from in the **Graphics** window.

COLLAPSE ENTITIES

Use the **Maximum size** setting to control the size of the edges or boundaries to collapse in the mesh. Choose **Relative** to enter a value in the **Relative tolerance** field. This value is relative to the length of the longest side of the mesh bounding box. Select **Absolute** to specify a value in the **Absolute tolerance** field. This value is determined by measuring the size of the bounding box as well as the smallest entities in the selection, with a maximum value set by the size of the bounding box. The maximum value is not taken into account if only one entity is selected. When the operation is built with either of the settings **Automatic** (the default) or **Relative**, the values in the **Absolute tolerance** field is automatically updated to correspond to the actually used tolerance. The value is also shown in the **Information** section.

- Merge Entities
- Remeshing Imported Meshes

Convert

Use **Convert** (□◪) to convert quads to triangles in 2D (see Figure 8-35) and on boundaries in 3D. In 3D domains, you can also use the operation to convert hexahedra, prisms, and pyramids to tetrahedra.

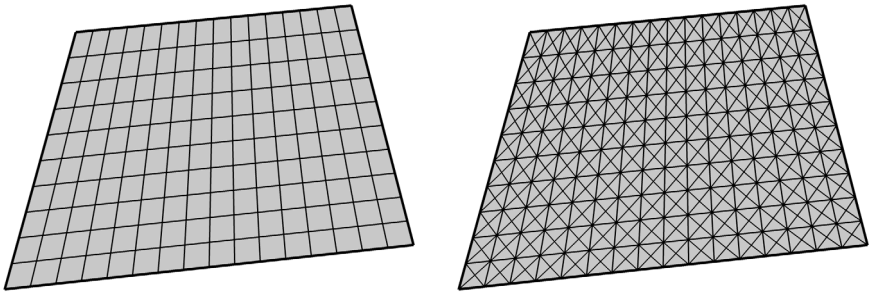

Figure 8-35: A centerpoint is inserted in each quad element, resulting in a structured triangular mesh (right).

To add a **Convert** node, select one or several entities in the mesh, then choose one of the following:

- Right-click in the **Graphics** window, and select **Convert** (□◪) from the **Modifying Operations** menu. For more information, see The Graphics Context Menu.
- In The Mesh Toolbar, choose **Convert** from the **Modify** menu ( ).
- Right-click the **Mesh** node and choose **Convert** (□◪) from the **Modifying Operations** menu.

Enter the properties for the **Convert** node using the following sections:

GEOMETRIC ENTITY SELECTION (3D) / DOMAIN SELECTION (2D)

First define the geometric entities where you want to convert the mesh elements. You choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to convert the mesh elements on all domains (and all boundaries in 3D).

- Choose **Domain** to specify the domains where you want to convert mesh elements. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains** to select all domains.
- Choose **Boundary** to specify the boundaries where you want to convert mesh elements. Choose **Manual** in the **Selection** list to select the boundaries in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All boundaries** to select all boundaries. This option is only available in 3D.

ELEMENT SPLIT METHOD

From the **Element split method** list, select **Insert diagonal edges** (the default setting) to split each quadrilateral element into two triangular elements and each hexahedral element into five tetrahedral elements, or select **Insert centerpoints** to split each quadrilateral element into four triangular elements and each hexahedral element into 28 tetrahedral elements. The conversion also affects quadrilateral elements on the boundaries of the specified domains in 3D.

- For a 3D mesh, see *Submarine Cable 7 — Geometry & Mesh 3D*: Application Library path **ACDC_Module/Tutorials,_Cables/submarine_cable_07_geom_mesh_3d**.

Copy Domain

Use **Copy Domain** (2D ( ) or 3D ( )) to copy meshes on domains using a rigid body transformation with a scale factor. The **Copy Domain** operation will automatically select a suitable copy type, or manually select to either copy a set of meshed domains onto each destination domain separately, or to copy each meshed domain onto a single unmeshed domain (as shown in Figure 8-36).

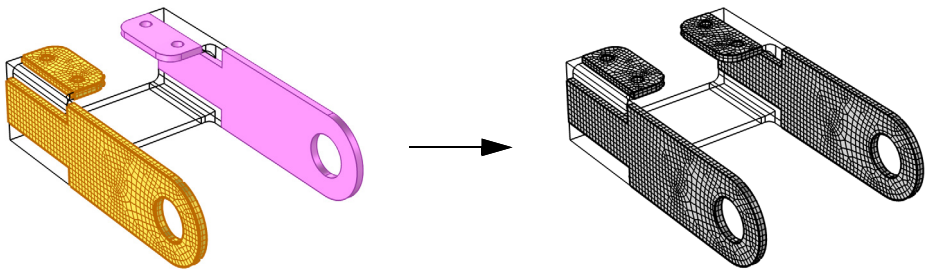

Figure 8-36: Copy the source mesh (yellow) to the destination domains (magenta) with a Copy Domain operation. The image to the right shows the resulting mesh after building the operation.

To ensure identical meshes on periodic and symmetric boundaries, consider using the Identical Mesh attribute instead of a copy operation.

Copying a mesh to a destination domain in 2D that is adjacent to a meshed domain is possible if the edges between these domains have the same number of elements as the corresponding source edges. The mesh on the destination edges is kept and the copied domain elements are modified to fit with this edge mesh.

Copying a mesh to a destination domain in 3D that is adjacent to a meshed domain is also possible if each face between these domains has a mesh isomorphic to a mesh of the corresponding source face. The mesh on the destination face is kept and the copied domain elements are modified to fit with this face mesh.

The edges around the source and destination domains in 2D are allowed to be partitioned differently but only in such a way that several edges of the source domain map to one edge of the destination edge. Not the other way around.

The faces around the source and destination domains in 3D are also allowed to be partitioned differently with exactly that same limitation as for edges in 2D (source to destination face mapping must be many-to-one).

If you copy between domains with a common boundary, the copy operation mirrors the mesh if the domains are symmetric (see the upper right image in Figure 8-40). If the domains are symmetric but separated from each other, you can enforce a mirrored mesh by adding an Edge Map or a Two-Point Map attribute that controls the orientation of the copied mesh.

To add a **Copy Domains** node, select one or several meshed source domains and unmeshed destination domains, then choose one of the following:

- In The Mesh Toolbar, choose **Copy Domain** from the **Copy** ( ) menu.
- Right-click the **Mesh** node and choose **Copy Domain** from the **Copying Operations** menu.

Then enter the properties for the copy operation using the following sections:

SOURCE AND DESTINATION DOMAINS

It is possible to copy a mesh from one or several source domains onto one or several destination domains. The source must be of exactly the same shape as the corresponding destination, up to a constant scaling factor. More precisely, the distance between any two geometry vertices on the destination is required to be the same, up to a constant scaling factor, as the distance between the corresponding geometry vertices on the source.

Click the **Active** button to toggle between turning ON and OFF selections. Select the domains to copy the mesh from in the **Graphics** window.

The source domains must be connected when the **Single copy (all-to-one)** option is specified. In an assembly, an identity pair is not sufficient to connect boundaries across parts. Instead, use the **Automatic** option or consider forming a union of the parts or splitting the destination boundary (using imprints, for example) so that the mesh copy is a one-to-one copy operation using two or more **Copy Domain** nodes.

SWAP SOURCE AND DESTINATION

Click the **Swap Source and Destination** button ( ) to switch source and destination selections. Edge map is available to be switched, if provided.

TYPE OF COPY

For settings information, see Type of Copy for the **Copy** operation.

CONTROL ENTITIES

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the

Maximum element depth to process field you can specify the maximum element depth, from the removed control entity.

To control the orientation of the source mesh on the destination when using the **Copy Domain** node, right-click and add an Edge Map, One-Point Map, or Two-Point Map node as a local attribute.

For tutorials using **Copy Domain**, see:

- *Piezoelectric Rate Gyroscope*: Application Library path **MEMS_Module/Piezoelectric_Devices/piezoelectric_rate_gyroscope**.
- *Vibrations of an Impeller*: Application Library path **Structural_Mechanics_Module/Dynamics_and_Vibration/impeller**.
- *Bracket — Topology Optimization*: Application Library path **Optimization_Module/Topology_Optimization/bracket_topology_optimization_stl**.

- Copy
- Copy Edge
- Copy Face
- Edge Map
- One-Point Map
- Two-Point Map

Copy Edge

Use **Copy Edge** (2D ( ) and 3D ( )) to copy the mesh from one edge to another edge. A 3D **Copy Edge** feature can also be used for destination edges of different shapes.

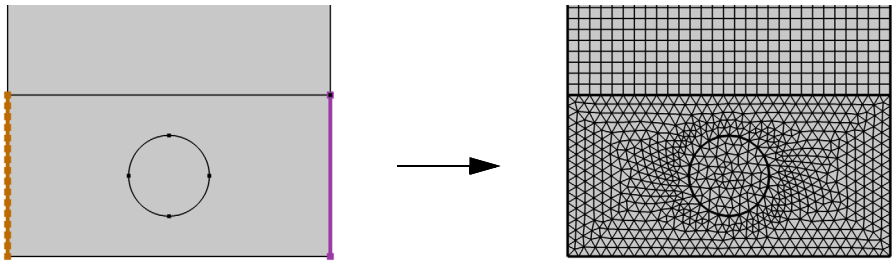

Figure 8-37: Copy the source mesh (yellow) to the destination edge (magenta) with Copy Edge. The image to the right shows the resulting mesh after building the complete mesh.

To ensure identical meshes on periodic and symmetric boundaries, consider using the Identical Mesh attribute instead of a copy operation.

To add a **Copy Edges** node, select one or several meshed source edges and unmeshed destination edges, then choose one of the following:

- In The Mesh Toolbar, choose **Copy Edges** from the **Copy** ( ) menu.
- Right-click the **Mesh** node and choose **Copy Edges** from the **Copying Operations** menu.

Then enter the properties for the copy operation using the following sections:

To copy a mesh between edges:

SOURCE AND DESTINATION EDGES

It is possible to copy a mesh from one or several source edges onto one or several destination edges. The source (or their combination, if many-to-one is used) must be a connected set of exactly the same shape as the corresponding destination, up to a constant scaling factor. More precisely, the distance between any two geometry vertices on the destination is required to be the same, up to a constant scaling factor, as the distance between the corresponding geometry vertices on the source.

Click the **Active** button to toggle between turning ON and OFF selections. Select the edges to copy the mesh from in the **Graphics** window.

!	The source edges must be connected when **Single copy (all-to-one)** option is specified. In an assembly, an identity pair is not sufficient to connect boundaries across parts. Instead, use the **Automatic** option or consider forming a union of the parts or splitting the destination boundary (using imprints, for example) so that the mesh copy is a one-to-one copy operation using two or more **Copy Edge** nodes.

SWAP SOURCE AND DESTINATION

Click the **Swap Source and Destination** button ( ) to switch source and destination selections. Edge map is available to be switched, if provided.

ORIENTATION

Select **Automatic orientation** to let the software determine the orientation of the source mesh on the destination automatically (this is the default), select **Same orientation** to let the source mesh be copied to the destination according to the direction of the edges, and select **Opposite orientation** to let the source mesh be copied to the destination in the opposite direction. Use the option **Show edge direction arrows** in the **View** node under the **Definitions** node to view the arrow direction.

TYPE OF COPY

For settings information, see Type of Copy for the **Copy** operation.

CONTROL ENTITIES

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the

Maximum element depth to process field you can specify the maximum element depth for the mesh vertices to be smoothed.

For tutorials using **Copy Edge**, see:

- *Voltage Induced in a Coil by a Moving Magnet*: Application Library path **ACDC_Module/Devices,_Motors_and_Generators/induced_voltage_moving_magnet**.
- *Porous Absorber*: Application Library path **Acoustics_Module/Building_and_Room_Acoustics/porous_absorber**.
- *Time-Domain Modeling of Dispersive Drude–Lorentz Media*: Application Library path **RF_Module/Tutorials/drude_lorentz_media**.

- Copy
- Copy Domain
- Copy Face

Copy Face

Use **Copy Face** ( ) to make a copy a boundary mesh using a rigid body transformation with a scale factor.

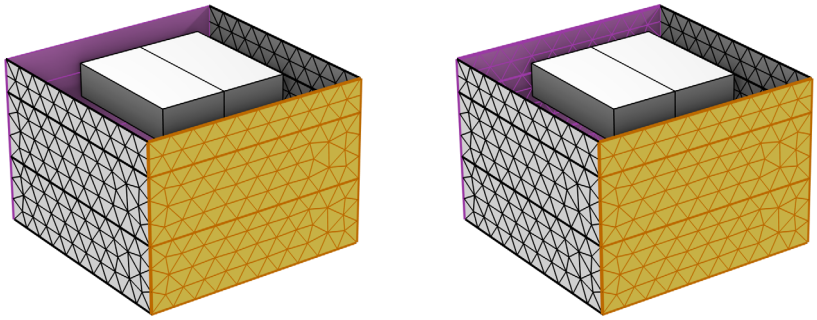

Figure 8-38: Copy the source mesh (yellow) to the destination faces (magenta) with Copy Face. Some boundaries are hidden for visibility.

This operation is supported in 3D models only.

To ensure identical meshes on periodic and symmetric boundaries, consider using the Identical Mesh attribute instead of a copy operation.

Copying a mesh to a face that is adjacent to a meshed face is possible if the edges between these faces have the same number of elements as the corresponding source edges. The mesh on the destination edges is kept and the copied face elements are modified to fit with this edge mesh.

The edges around the source and destination faces are allowed to be partitioned differently, but only in such a way that several edges of the source face map to one edge of the destination edge, not the other way around.

Copying a face mesh is only possible if the destination face is not adjacent to any meshed domain. The copy node overwrites any existing mesh on the destination face.

To add a **Copy Faces** node, select one or several meshed source boundaries and unmeshed destination boundaries, then choose one of the following:

- In The Mesh Toolbar, choose **Copy Faces** from the **Copy** ( ) menu.
- Right-click the **Mesh** node and choose **Copy Faces** from the **Copying Operations** menu.

Then enter the properties for the copy operation using the following sections:

SOURCE AND DESTINATION BOUNDARIES

It is possible to copy a mesh from one or several source boundaries onto one or several destination boundaries. The source (or their combination, if **Single copy (all-to-one)** is used) must be a connected set of exactly the same shape as the corresponding destination, up to a constant scaling factor. More precisely, the distance between any two geometry vertices on the destination is required to be the same, up to a constant scaling factor, as the distance between the corresponding geometry vertices on the source.

Click the **Active** button to toggle between turning ON and OFF selections. Select the boundaries to copy the mesh from in the **Graphics** window.

The source boundaries must be connected when the **Single copy (all-to-one)** option is specified as the **Type of Copy**. In an assembly, an identity pair is not sufficient to connect boundaries across parts. Instead, use the **Automatic** option or consider forming a union of the parts or splitting the destination boundary (using imprints, for example) so that the mesh copy is a one-to-one copy operation using two or more **Copy Face** nodes.

SWAP SOURCE AND DESTINATION

Click the **Swap Source and Destination** button ( ) to switch source and destination selections. Edge map is available to be switched, if provided.

TYPE OF COPY

For settings information, see Type of Copy for the **Copy** operation.

CONTROL ENTITIES

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the removed control entity.

To control the orientation of the source mesh on the destination when using the **Copy Face** node, right-click and add an Edge Map, One-Point Map, or Two-Point Map node as a local attribute.

For tutorials using **Copy Face**, see:

- *Magnetotellurics*: Application Library path **ACDC_Module/Devices,_Resistive/magnetotellurics**.
- *Vibrations of an Impeller*: Application Library path **Structural_Mechanics_Module/Dynamics_and_Vibration/impeller**.
- *A Micromachined Comb-Drive Tuning Fork Rate Gyroscope*: Application Library path **MEMS_Module/Sensors/comb_drive_tuning_fork_gyroscope**.

- Copy
- Copy Domain
- Copy Edge
- Edge Map
- One-Point Map
- Two-Point Map

Copy

Use **Copy** ( ) to copy meshes within the same meshing sequence or between different meshing sequences (belonging to the same or different components). The dimension of the source meshing sequence must be less than or equal to the dimension of the destination meshing sequence. You can also copy a mesh from a mesh part to the meshing sequence in a component.

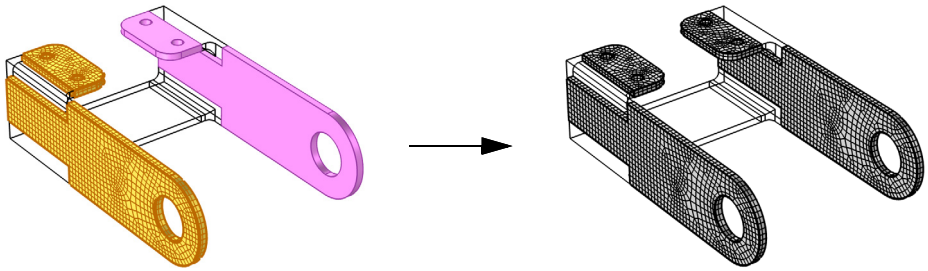

Figure 8-39: Copy the source mesh (yellow) to the destination domains (magenta) with a Copy operation using the method Array copy (one-to-one). The image to the right shows the resulting mesh after building the operation.

To control the orientation of the source mesh on the destination when using the **Copy** operation, right-click and add an Edge Map, One-Point Map, or Two-Point Map node as a local attribute. The attributes are available for 2D and 3D and when **Geometric entity level** is not **Entire geometry**.

To ensure identical meshes on periodic and symmetric boundaries, consider using the Identical Mesh attribute instead of a copy operation.

The **Copy** feature can be useful if you start off with an imported mesh and then want to modify it by adding a boundary layer mesh or running a solver that modifies it, such as the adaptive solver. It also makes it possible to add geometry, such as for defining a surrounding domain, to an imported mesh while still keeping the imported mesh on the “original geometry”. Use the following steps to copy an imported mesh into another component’s geometry:

1 Import a mesh to an empty component or create a mesh part.

2 Add a new component in which you import the mesh as a geometry.

3 Add more geometry if desired.

4 In the new component's meshing sequence, add a **Copy** feature that makes it possible to copy the imported mesh into this mesh.

5 Generate mesh on the additional geometry added in Step 3 or modify the mesh inserted in Step 4.

To copy a mesh between entities, select one or several meshed source entities and unmeshed destination entities, then:

- Right-click in the **Graphics** window, and select **Copy** ( ) from The Graphics Context Menu.
- In The Mesh Toolbar, choose **Copy** from the **Copy** ( ) menu.
- Right-click the **Mesh** node and choose **Copy** from the **Copying Operations** menu.

Then enter the properties for the copy operation using the following sections:

SOURCE MESH

From the **Mesh** list, select the meshing sequence or mesh part to copy from (or **None**, which is the default in 1D); then (for meshing sequences only) click **Copy** to copy the updated source mesh. By default, the meshing sequence in which the **Copy** node resides is selected. When this sequence is selected, the **Copy** button is unavailable. If you have parameterized the geometry or mesh and plan to run a parametric sweep, select the **Build source mesh automatically** checkbox to ensure that the source mesh and geometry are updated before copying. Otherwise, you have to manually rebuild the source mesh and click the **Copy** button if you want to use an updated source mesh. Click the **Go to Source** button ( ) to move to the main **Mesh** node of the source mesh.

The sections below are available for 2D and 3D meshes only.

DIMENSION

Select the geometric entity level of the copy from the **Geometric entity level** list. The possible choices are **Entire geometry**, **Domain** (the default), **Boundary**, or **Edge** (3D only). For **Entire geometry**, the sections below are not available.

SOURCE ENTITIES

Use this section to select the entities to copy mesh from in the specified source mesh. From the **Selection** list, choose **All domains** (for example) or choose **Manual** to pick the entities from the **Graphics** window. Click the **Active** button to toggle between turning ON and OFF selections. Select the entities to copy the mesh from in the **Graphics** window. If you activate this selection, the **Graphics** window shows the mesh of the source sequence such that you can select entities in this mesh.

Click the **Swap Source and Destination** button ( ) to swap the entities in the source list above and the entities in the destination list in the **Destination Entities** section below.

DESTINATION ENTITIES

This section is similar to the **Source Entities** section above, but you use it to define the geometric entities in the destination to which you want to copy the mesh.

TYPE OF COPY

Select **Automatic** (the default) to let the software determine the proper copy method, select **Single copy (all-to-one)** to let the entire source mesh be copied onto each destination entity separately, and select **Array copy (one-to-one)** to let each single source entity mesh be copied onto one entity per destination component.

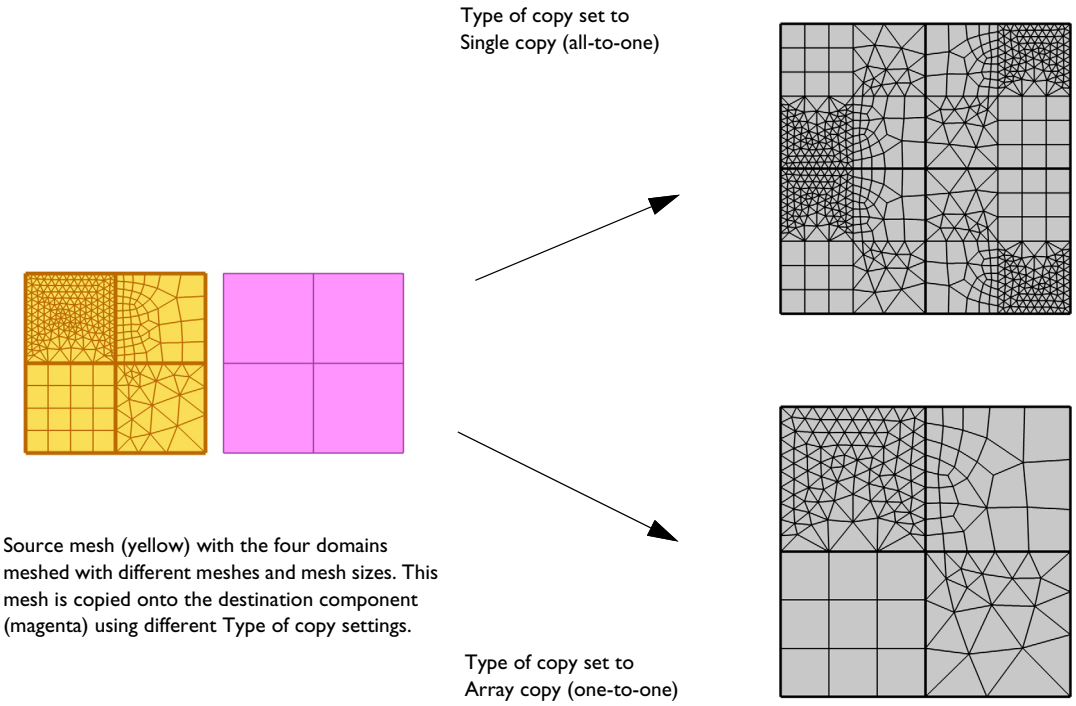

Figure 8-40: Copy of domain source mesh (highlighted in yellow) to the destination domains (highlighted in magenta). The result differs depending on which Type of copy setting is used. With the setting Single copy (all-to-one), the mesh of all source domains are copied to each of the destination domains (upper-right image). With the setting Array copy (one-to-one), the mesh of each source domain is copied to each destination domain (lower-right image).

Array copy (one-to-one) can be used only if a bijective transformation of source to destination can be found (a transformation that sets one-to-one mapping between source and destination).

The **Array copy (one-to-one)** setting also supports copy from one or several connected components of meshed domains, to several other similar components, as shown in Figure 8-41.

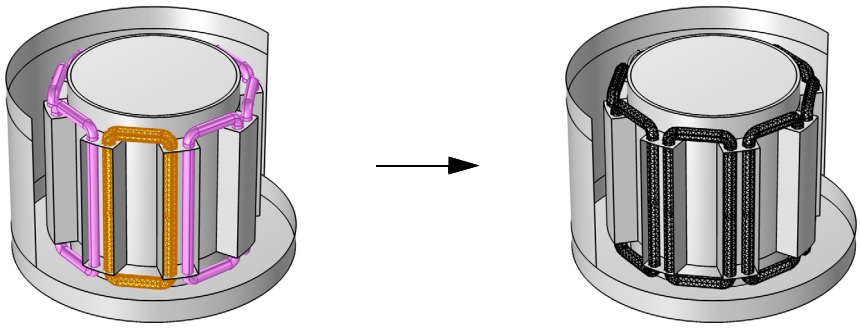

Figure 8-41: Array copy of the mesh in the source component (highlighted in yellow) to the destination components (highlighted in magenta). The resulting mesh is shown in the image to the right. Note that some faces are hidden for visibility.

Use the **Automatic** setting to let the software choose between **Single copy (all-to-one)**, **Array copy (one-to-one)**, or a mixture of the two. Figure 8-42 shows a mix of **Single copy (all-to-one)** and **Array copy (one-to-one)**.

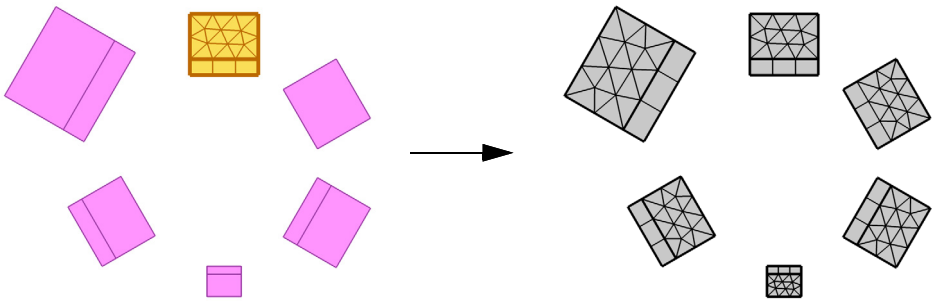

Figure 8-42: With Type of copy set to Automatic, it is possible to get a mix of Single copy (all-to-one) and Array copy (one-to-one). The source mesh (yellow) is copied to the destination domains (magenta) using one Copy operation with the Automatic setting. The first domain to the right of the source will be copied to using Single copy (all-to-one). The rest of the domain components are examples of Array copy (one-to-one) where the destination components have been rotated and some of them scaled to show the flexibility of the operation. The image to the right shows the resulting mesh.

CONTROL ENTITIES

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed control entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth, from the removed control entity.

For tutorials using **Copy**, see:

- *Electroplating of Multiple Components in a Rack*: Application Library path **Electrodeposition_Module/Tutorials/electroplating_rack**.

- Copy Edge
- Copy Domain
- Copy Face
- Edge Map
- One-Point Map
- Two-Point Map

Corner Properties

Use the **Corner Properties** attribute to override the corner settings of a Boundary Layers node for a selection of corners, as shown in Figure 8-43. This is useful if you want other corner properties for a smaller number of sharp corners.

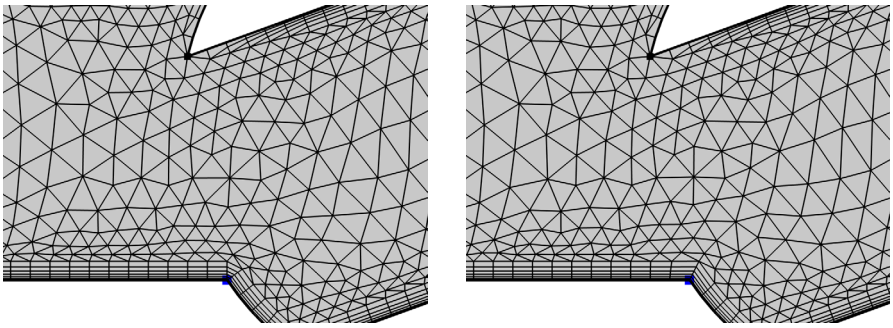

Figure 8-43: Specifying the lower sharp corner (blue) as Splitting (left) or No special handling (right) instead of the trimming done for the rest of the corners (upper sharp corner).

To add a **Corner Properties** node as a local attribute to a Boundary Layers node, select edges (3D) or points (2D and 3D) in the **Graphics** window, then choose one of the following:

- Right-click a **Boundary Layers** node and choose **Corner Properties**.
- Click to select a **Boundary Layers** node in the **Model Builder** window. On The Mesh Toolbar, select **Corner Properties** from the **More Attributes** menu.

Global vs. Local Attributes

GEOMETRIC ENTITY SELECTION

Define the edges (3D) or points (3D and 2D) where to modify the corner settings. Choose **Manual** in the **Selection** list to select the entities in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All edges** or **All points** to select all edges or points, respectively.

The name of this section changes depending on the dimension of the component. The names are **Geometric Entity Selection** (3D) or **Point Selection** (2D).

CORNER PROPERTIES

The following options for handling boundary layers at sharp corners are available from the **Corner handling** list:

- Select **Trimming** (the default) to trim the boundary layer mesh at the selected corners. Select the **Conditions** checkbox (default off) to specify at which angles to trim. For more information about the different settings, see Corner Settings for the **Boundary Layers** operation. Add a Corner Refinement attribute with the setting **Include only these corners** to specify a corner refinement for the trimmed corners.
- Select **Splitting** to introduce boundary layer splits at the selected corners. This option is not available for points in 3D when the **Boundary Layers** operation has a domain selection. Select the **Condition** checkbox (default off) to specify at which angles to introduce splits. For more details, see Corner Settings for the **Boundary Layers**

operation. If a Corner Refinement attribute is specified for all boundaries, use the **Exclude these corners** setting to exclude corners where **Splitting** has been specified.

- Select **No special handling** to not use any special treatment at the selected corners. If a Corner Refinement attribute is specified for all boundaries, use the **Exclude these corners** setting to exclude corners where **No special handling** has been specified.

Boundary Layer Meshing — Exploring the Settings:
Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/valve_boundary_layers**.

- Boundary Layers
- Boundary Layer Properties
- Corner Refinement

Corner Refinement

Use the **Corner Refinement** ( ) attribute to decrease the element size at sharp corners, as shown to the right in Figure 8-44. The node considers a vertex in 2D or an edge in 3D to be a sharp corner if the angle between the adjacent selected boundaries, with respect to the selected domain, is greater than a specified angle.

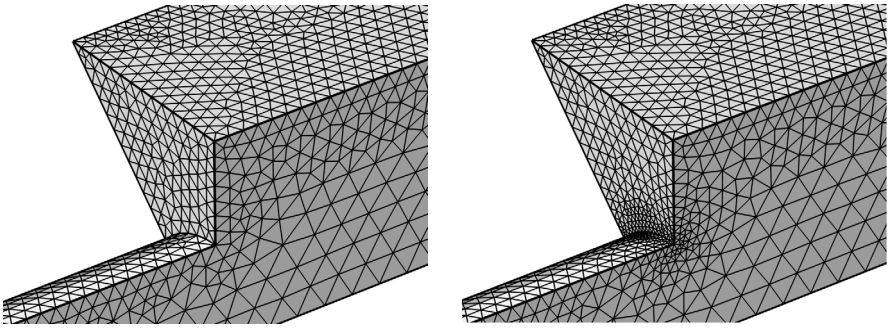

Figure 8-44: The default tetrahedral mesh for this backstep geometry (left). The image to the right shows how the tetrahedral mesh is refined close to the sharp corner when a Corner Refinement node has been added.

To add a **Corner Refinement** ( ) node, select boundaries in the graphics, then choose one of the following:

- Right-click a mesh operation and choose **Corner Refinement** ( ) to add it as a local attribute.

To add it as a global node in the meshing sequence:

- In The Mesh Toolbar, choose **Corner Refinement** from the **Sizing** ( ) menu.
- Right-click the **Mesh** node and choose **Corner Refinement** ( ).

Global vs. Local Attributes

If there are several Corner Refinement nodes in the sequence with a nonempty selection intersection, the mesh generator uses properties corresponding to the last **Corner Refinement** node in the sequence.

Then enter the properties using the following sections:

DOMAIN SELECTION

Specify the domains for which the node determines if the specified corners are sharp. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to specify that the attribute determines sharp corners with respect to all domains. The corner refinement also considers corners not adjacent to any domain.
- Choose **Domain** to specify the domains for which you want to determine sharp corners. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains** to select all domains.

By default, Domain Selections are **Active** (the **Active** button is ON).

BOUNDARY SELECTION

To specify the boundaries, click the **Active** button to turn it ON and select the boundaries in the **Graphics** window for which the corner refinement determines the sharp corners. When the boundary selection is **Active**, the **Domain Selection** section **Active** button is automatically turned OFF.

ANGLE

Use the **Minimum angle between boundaries** field to specify the minimum angle between a pair of adjacent boundaries in the boundary selection for the refinement factor to apply at the vertex in 2D and edge(s) in 3D between the two boundaries. If a boundary pair is adjacent to one domain on each side (interior boundary) the corner refinement determines the angle(s) on the side(s) corresponding to the specified domain(s).

Select the **Filter corners** checkbox (default off) and the settings in the **Filter Corner Selection** section to filter out a selection of the automatic selection of corners.

FILTER CORNER SELECTION

This section is only available when the **Filter corners** checkbox is selected.

Use these settings to specify corners to include or exclude from the automatic selection of corners. Choose **Manual** in the **Selection** list and click the **Active** button to turn it ON to select the entities in the **Graphics** window or from the **Selection List** window, choose a named selection to refer to a previously defined selection, or choose **All edges** or **All points** to select all edges or points, respectively. This is useful when another handling of a selection of sharp corners is specified in Corner Properties attributes.

REFINEMENT

Use the **Element size scaling factor** field to specify a refinement factor (<1) that scales the element size for the vertices in 2D and edges in 3D corresponding to the sharp corners.

For tutorials using **Corner Refinement**, see:

- *Boundary Layer Meshing — Exploring the Settings*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/valve_boundary_layers**.
- *Micromixer*: Application Library path **COMSOL_Multiphysics/Fluid_Dynamics/micromixer**.
- *Bimetallic Strip in Airflow*: Application Library path **CFD_Module/Fluid-Structure_Interaction/bimetallic_strip_fsi**.

Create Domains

Use **Create Domains** ( ) to create one domain for each (connected) finite void region that is defined by an imported 3D mesh and analyze these domains with respect to the mesh that might already exist in the sequence.

Domains are created automatically when Importing 3MF, PLY, STL, and VRML Meshes or when building the operations Create Faces and Fill Holes. If this automatic creation fails, repair the mesh, and add a **Create Domains** node.

This operation is available for 3D models only.

Together with the Free Tetrahedral operation, the **Create Domains** operation makes it possible to mesh an imported surface meshes without creating a geometry, as long as the imported surface mesh is of good quality. To improve the quality of a surface mesh, use Remesh Faces.

Add a **Create Domains** node, choose one of the following:

- Select **Create Domains** from the **Create Entities** menu ( ) in The Mesh Toolbar.
- Right-click the **Mesh** node and select **Create Domains**.

Most physics require a mesh on the domains. Use the Free Tetrahedral, Swept, and Boundary Layers operations to fill the domains with domain elements.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting domains** checkbox to create a predefined selection in subsequent nodes in the mesh sequence. To also make the selection available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), select the **Show in physics** (**Show outside part** if in a mesh part) checkbox. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

Note that creating domains can modify the number of geometric domains in the mesh. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Create Domains** node is added to this new sequence. For more information, see The Mesh Node.

- Create Faces
- Fill Holes
- Importing 3MF, PLY, STL, and VRML Meshes
- Remesh Faces
- Free Tetrahedral

Create Edges

Use **Create Edges** ( ) to create edges in a mesh by clicking on mesh edges in the graphics or by selecting existing points, as shown in Figure 8-45. It is possible to add a **Create Edges** node when the mesh sequence includes either an **Import** node or a **Create Vertices** node.

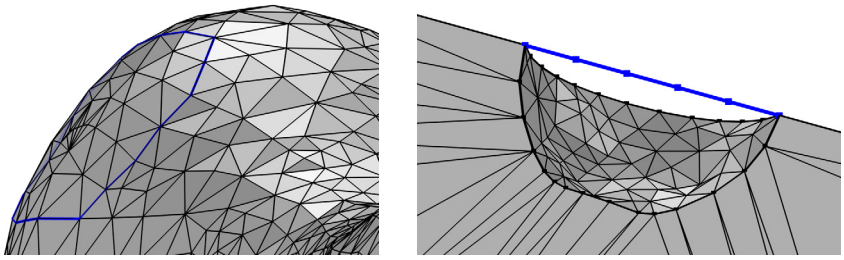

Figure 8-45: Clicking in the Graphics window to select mesh edges to convert into geometric edges (left). Connecting two selected points of an imported STL mesh with a meshed edge (right).

Note that creating edges can modify the number of geometric edges in the mesh. Thus, when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Create Edges** node is added to this new sequence. For more information, see The Mesh Node.

To add a **Create Edges** node, choose one of the following:

- For a 3D mesh, it is available from the **Create Entities** menu ( ) on The Mesh Toolbar. For 2D meshes, click the **Create Edges** ( ) button in the **Mesh** toolbar.
- Right-click the **Mesh** node and select **Create Edges** ( ). In 3D, do this from the **Create Entities** menu.

Choose between creating new meshed edges between vertices or converting existing mesh edges into edge elements. Edges between vertices can be created in empty space but also overlap existing mesh. Such an edge will not partition existing mesh elements. In 3D, it is possible to Imprint an edge on a boundary to partition the boundary elements with the edge. To partition a domain in 2D with a straight line, use Intersect with Line.

EDGE SPECIFICATION

From the **Specify** list, select **Mesh edges** (default) to convert mesh edges to edge elements. This is done by clicking on mesh edges in the **Graphics** window. Alternatively, choose **Vertices** to specify the positions of start and end vertices.

MESH EDGE SELECTION

Select the **Group by continuous tangent** checkbox (default OFF) to extend the selection of mesh edges to a chain of mesh edges that have continuous tangent. Modify the **Angular tolerance** setting to control which mesh edges to group together when **Group by continuous tangent** is selected.

Click the **Active** button to toggle between turning ON and OFF the mesh edge selection. This enables selection by clicking in the **Graphics** window. When the **Active** button is toggled ON, the **Mesh Rendering** will automatically be turned ON to facilitate the selection of vertices. Select a mesh edge to populate the table with the **x**-, **y**-, and (3D only) **z**-coordinates of the midpoint of the mesh edge. It is possible enter the exact **x**-, **y**-, and (3D only) **z**-coordinates manually in the table. Selected edges are highlighted in the Graphics. Click a second time on the same edge to remove it from the selection.

If you specify mesh edges and later modify the input mesh, the list of selected coordinates is updated to match the new mesh, if possible.

It is only possible to select mesh edges on boundaries in 3D which are visible in the **Graphics** window. Use **Click and Hide** and the clipping tools to get access to interior boundaries. Rotate the mesh to make the opposite side come into view.

STARTING VERTICES, END VERTICES

To create edges, select vertices in the **Starting Vertices** and **End Vertices** sections. Edges will be created from vertices in the selection in **Starting Vertices** to vertices in the selection in **End Vertices**. From each vertex in the selection in **Starting Vertices**, edges will be created to the closest vertices in the selection in **End Vertices**.

ELEMENT SIZE

To specify the size distribution of the edge mesh, select one of the methods from the **Size distribution type** list:

- Select **Element size** (the default) to specify the maximum element size (SI unit: m), which you enter in the **Maximum element size** field. The value is a relative number (default: 0.1 in 3D and 1/15 in 2D). This value is multiplied with the size of the bounding box.
- Select **Fixed number of elements** to use a fixed number of mesh elements, which you enter into the **Number of elements field** (default: 1).
- Select **Explicit distribution** to use an explicit, user-defined element distribution. To define the distribution of mesh elements, enter a vector-valued expression defining a strictly increasing sequence of nonnegative numbers (using comma-separated numbers) in the **Relative placement of vertices along edge** field, specifying the relative arc length values of the mesh vertices along the edge or boundary. Select the **Reverse direction** checkbox to reverse the direction of the explicit distribution.
- Select **Predefined distribution** to specify properties of a predefined distribution method where the element size can be exponentially or linearly increasing or decreasing. From the **Growth rate** list, select **Exponential** to let the distribution method be a geometric sequence and **Linear** for an arithmetic sequence. In addition, specify values in the **Number of elements** and **Element ratio** fields to determine the number and ratio of elements in the distribution. Select the **Symmetric distribution** checkbox to make the predefined size distribution symmetric. Select the **Reverse direction** checkbox to reverse the direction of the predefined distribution.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting edges** checkbox to create a predefined selection in subsequent nodes in the mesh sequence.

To create resulting face (3D) or domain (2D) selections, select the **Resulting small faces/domains** and **Complement faces/domains** checkboxes, respectively. Specify an **Area fraction** or use the accompanied slider to specify the maximum area of a small face as a fraction of the total area of the input faces. The rest of the input faces will be part of the complement selection. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), select the corresponding **Show in physics** (**Show outside part** if in a mesh part) checkbox. These selections do not appear as separate selection nodes in the model tree.

See *STL Import 1 — Repairing and Combining STL Files*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes**

- Create Faces
- Create Vertices

Create Faces

Use **Create Faces** ( ) to create meshed boundaries within selected edges in a surface mesh in 3D, as shown in Figure 8-46. The generated face will be as close to planar as possible and typically need to be remeshed to improve the quality of the triangles.

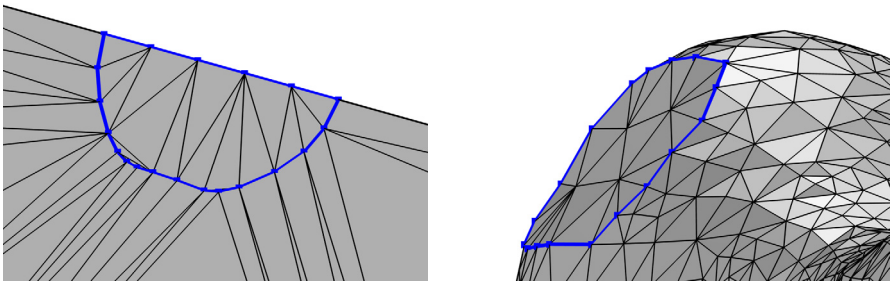

Figure 8-46: Creating meshed faces within selected edge loops (blue) using the Create Faces operation.

This operation is available for 3D models only.

Note that creating faces can modify the number of geometric boundaries in the mesh. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Create Faces** node is added to this new sequence. For more information, see The Mesh Node.

The created faces are formed using a simple surface mesh. You can add a Free Triangular to remesh the generated face. See also Remeshing Imported Meshes.

To add a **Create Faces** node, select edges in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Create Faces** ( ). In 3D, do this from the **Create Faces** menu.
- For a 3D mesh, it is available from the **Create Entities** menu ( ) on The Mesh Toolbar. For 2D meshes, click the **Create Faces** ( ) button in the **Mesh** toolbar.
- Right-click the **Mesh** node and select **Create Faces** ( ). In 3D, do this from the **Create Entities** menu.

Enter the properties for **Create Faces** using the following sections:

EDGE SELECTION

To create faces you need to define an edge selection. The selected edges must form simple loops; that is, there must be no ambiguity about how to draw the loops. You can select edges to form several loops in a single operation. Only edges adjacent to void or unmeshed domains can be selected. If you select the **Group adjacent edges** checkbox (it is selected by default), then, when an edge is selected (or deselected), the selection automatically extends to

neighboring edges that seem to be part of the loop. If you clear this checkbox, each edge can be selected (deselected) manually.

RESULTING ENCLOSED REGIONS

Select the **Create domains** checkbox (selected by default) to automatically form domains for each (connected) finite void region that is defined by the imported surface mesh and analyze these domains with respect to the mesh that might already exist in the sequence. Clear the checkbox to not form domains, for example if more repairing is needed before the mesh forms watertight regions. Consider to later add a Create Domains operation if you clear the checkbox.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting faces** and/or the **Resulting domains** checkboxes to create predefined selections in subsequent nodes in the mesh sequence. To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), select the **Show in physics** (**Show outside part** if in a mesh part) checkbox. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

Most physics require a mesh on the domains. Use the Free Tetrahedral, Swept, and Boundary Layers operations to fill the domains with domain elements.

- Remesh Faces
- Free Triangular
- Remeshing Imported Meshes
- Create Edges
- Create Domains
- Create Vertices
- Fill Holes

Create Vertices

Use **Create Vertices** ( ) to create vertices in a mesh. Convert existing mesh vertices into vertex elements or create new vertex elements, as shown in Figure 8-47. The new vertices can be created in empty space or be created to overlap existing mesh.

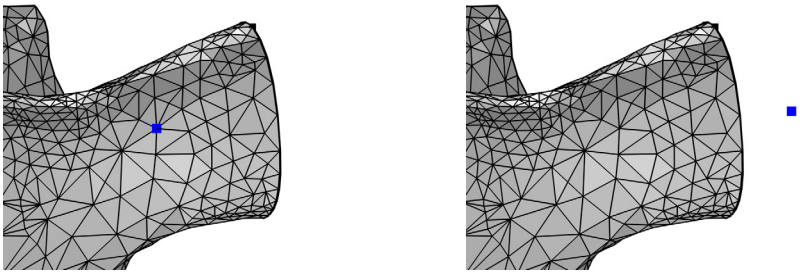

Figure 8-47: Creating geometric points (blue) by converting mesh vertices (left) or by specifying coordinates (right).

Note that this operation changes the geometric model by adding new edges and vertices. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Create Vertices** node is added to this new sequence. For more information, see The Mesh Node.

To add a **Create Vertices** node, choose one of the following:

- For a 3D mesh, it is available from the **Create Entities** menu ( ) on The Mesh Toolbar. For a 2D mesh, click the **Create Vertices** ( ) button.
- Right-click **Mesh** node and select **Create Vertices** ( ). In 3D, do this from the **Create Entities** menu.

Enter the properties for the **Create Vertices** node using the following sections:

VERTEX SPECIFICATION

For the **Specify** option, select **Mesh vertices** (the default) to specify positions by clicking on mesh vertices in the **Graphics** window. Alternatively, choose **Coordinates** to specify the positions of the vertices.

MESH VERTEX SELECTION

Click the **Active** button to toggle between turning ON and OFF the mesh vertex selection. This enables selection by clicking in the **Graphics** window. When the **Active** button is toggled ON, the **Mesh Rendering** will automatically be turned ON to facilitate the selection of vertices. It is possible enter the exact **x**-, **y**-, and (3D only) **z**-coordinates manually in the table, but the **Coordinates** vertex specification is better suited for this purpose. Selected vertices are highlighted in the Graphics. Click a second time on the same vertex to remove it from the selection. Use the buttons beside the table to remove rows, clear the table, load and save table data, and to zoom in on coordinates in the table. For txt files, use either the Spreadsheet Data Format or the Sectionwise Data Format. Make sure that the number of columns or entries per row correspond to the dimension of the mesh and that only coordinate data is included in the file.

If you specify mesh vertices by providing a list of coordinates, and later modify the input mesh, the list of selected coordinates is updated to match the new mesh, if possible.

It is only possible to select mesh vertices on boundaries in 3D which are visible in the **Graphics** window. Use **Click and Hide** and the clipping tools to get access to interior boundaries. Rotate the mesh to make the opposite side come into view.

COORDINATES

For the **Input format** setting, select **Componentwise** (the default) to enter arrays of the x, y, and z components. Valid inputs for the **x**, **y**, and **z** (3D only) fields are either arrays of the same length or scalars. If both arrays (of size bigger than one) and scalars are given, the scalars are interpreted as an array of constant value. Use the **Range** button ( ) if desired to create an array of coordinate values.

Alternatively, choose **Pointwise** to specify a table of coordinates. In each row in the table, enter comma-separated values for x, y, and z (3D only).

TOLERANCE

Use the **Relative snapping tolerance** field to specify a maximum distance within which the specified point will snap to the closest mesh element. If the point is not snapped to a mesh vertex, the element will be partitioned to conform with the added mesh vertex. In other words, if you add a point inside an element, it will be refined to include that point. If you create a vertex inside an unmeshed domain, the vertex will become adjacent to that domain. A vertex element will be created at the snapped point. If there are no such mesh vertices within the tolerance, both a mesh vertex and a vertex element will be created at the specified coordinates. The value in the **Relative snapping tolerance** field is relative to the size of the mesh including the added vertices. It is relative to the diameter of the bounding box and must therefore be given as a value between 0 and 1. The specified points are not allowed to be within the relative snapping tolerance of each other.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting vertices** checkbox to create a predefined selection in subsequent nodes in the mesh sequence. To also make the selection available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), select the **Show in physics** (**Show outside part** if in a mesh part) checkbox. These selections do not appear as separate selection nodes in the model tree.

- Create Edges
- Create Faces

Delete Entities

Use **Delete Entities** ( ) to delete geometric entities from a mesh, as seen in Figure 8-48.

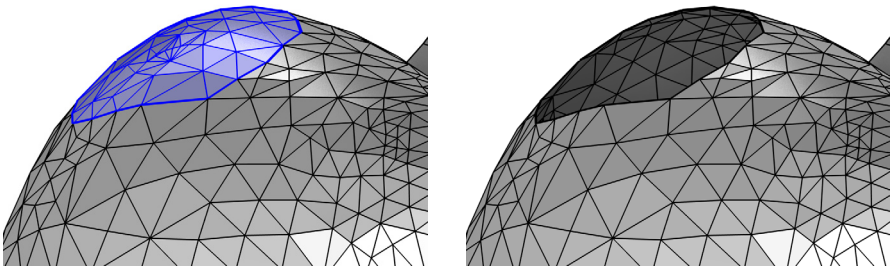

Figure 8-48: A boundary (blue) is deleted from a mesh.

To add a **Delete Entities** node, select the entities to delete in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Delete Entities** ( ).
- Click **Delete Entities** ( ) on The Mesh Toolbar.
- Right-click **Mesh** node and select **Delete Entities** ( ).

Note that deleting entities modifies the number of geometric entities in the mesh. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Delete Entities** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for **Delete Entities** using the following sections:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to delete. You choose the geometric entity level from the **Geometric entity level** list: Choose **Domain**, **Boundary**, **Edge**, or **Point** to specify the domains, boundaries, edges, or vertices, respectively, that you want to delete or choose a named selection to refer to a previously defined selection. Use **All domains**, **All boundaries**, **All edges**, or **All points** to select all entities of the specified dimension.

KEEP AS UNMESHED DOMAINS

In 3D, when **Geometric entity level** is set to **Domain**, select **Keep as unmeshed domains** (cleared by default) to only delete the domain elements while keeping the domains as unmeshed as well as keeping the adjacent meshed boundaries. Use the Free Tetrahedral operation to fill any unmeshed domain with tetrahedral elements.

ADJACENT ENTITIES

Select the **Delete adjacent lower-dimensional entities** checkbox to also delete the adjacent entities of lower space dimensions.

See *STL Import 1 — Repairing and Combining STL Files*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes**

- Free Tetrahedral
- Join Entities
- Create Faces
- Fill Holes

Detect Faces

Use **Detect Faces** ( ) to partition geometric boundary entities of an imported mesh by searching for shapes in the mesh that are likely to constitute faces, as seen in Figure 8-49.

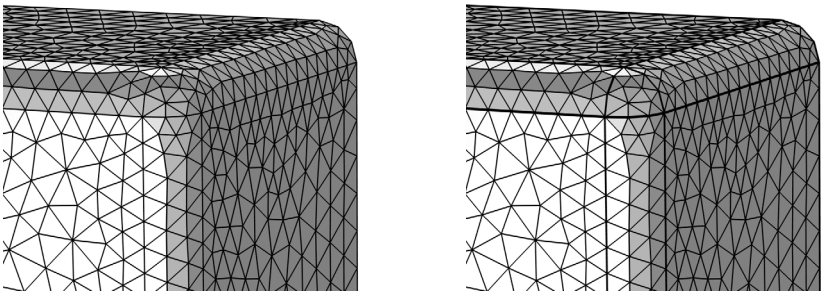

Figure 8-49: A mesh with one single face (left). The same mesh after building the Detect Faces operation that automatically partitions the boundary into planar surfaces and fillets.

To add a **Detect Faces** node, select boundaries in the **Graphics** window, then:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Detect Faces** ( ) from the **Booleans and Partitions** menu.
- Click **Booleans and Partitions** ( ) on The Mesh Toolbar and select **Detect Faces**.
- Right-click the **Mesh** node and select **Detect Faces** ( ) from the **Booleans and Partitions** menu.

Note that partitioning the faces in a mesh can modify the number of geometric boundaries in the mesh. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Detect Faces** node is added to this new sequence. For more information, see The Mesh Node.

Then use the following sections to specify the geometric boundary entities to split and the parameters of the partitioning algorithm:

BOUNDARY SELECTION

Select the geometric boundary entities that you want to split, choose a named selection to refer to a previously defined selection, or choose **All boundaries** to select all boundary entities.

FACE PARTITIONING

The partitioning algorithm splits the boundary elements along edges where the angle between neighboring boundary elements is large. Use the **Maximum neighbor angle** field to set the largest tolerated neighbor angle.

Select the **Detect planar faces** checkbox (selected by default) to also group approximately planar boundary elements into faces. Use the **Minimum relative area** field to limit how small these faces can be relative to all of the selected boundary entities. The maximum accepted angle between boundary elements in a planar face can be set with the

Maximum deviation angle field. If the **Detect adjacent fillet faces** checkbox is selected, the algorithm also searches for adjacent groups of boundary elements that form cylindrical faces.

Other ways of partitioning boundaries in a mesh:

- Create Edges
- Intersect with Plane
- Partition with Ball
- Partition with Box
- Partition with Cylinder
- Partition by Expression

Distribution

Use the **Distribution** ( ) attribute to specify the distribution of mesh elements along an edge, a boundary (in 2D), or along the sweep direction, as seen in Figure 8-50.

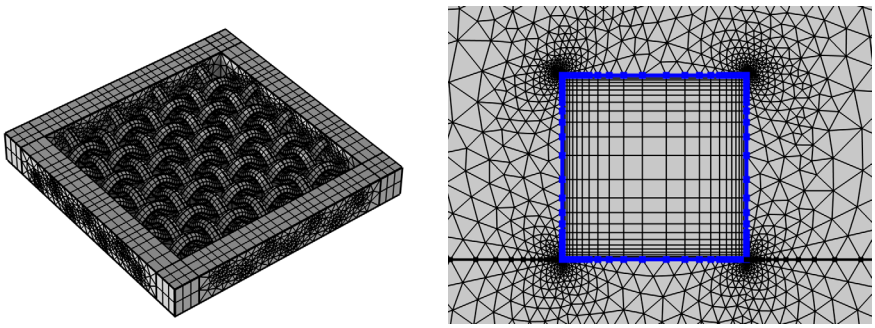

Figure 8-50: A swept mesh with applied distributions along the sweep directions, both along the woven fibers, and in the infinite element domains (left). The image to the right shows a 2D mesh with a predefined exponential distribution along the selected edges (blue).

It is possible to add **Distribution** nodes both as global nodes and as local nodes. If there are several **Distribution** nodes in the sequence with a nonempty selection intersection, the mesher uses properties corresponding to the last **Distribution** node in the sequence for each selection of entities. **Distribution** properties always override properties defined by **Size** nodes sharing the same selections.

To add a **Distribution** attribute as a global node, select edges (3D) or boundaries (2D) and choose one of the following:

- Right-click the **Mesh** node and select **Distribution** ( ).
- In The Mesh Toolbar, click **Sizing** ( ) and select **Distribution**.

To add a **Distribution** attribute as a local node, select edges (3D) or boundaries (2D) and choose one of the following:

- Right-click a mesh operation and select **Distribution** ( ).
- Select a mesh operation in the **Model Builder** tree and click the **Distribution** ( ) button in The Mesh Toolbar.

Global vs. Local Attributes.

GEOMETRIC ENTITY SELECTION

Define the geometric entities where you want to specify a distribution. Choose **Manual** from the **Selection** list to select the entities in the **Graphics** window or choose **All domains/boundaries/edges** to select all available entities of that level.

Choose the level of the geometry from the **Geometric entity level** list (only available for global attributes in 3D):

- Choose **Domain** to specify the domains for the distribution. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains** to select all domains.
- Choose **Edge** to specify the edges for the distribution. Choose **Manual** from the **Selection** list to select the edges in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All edges** to select all edges.

The name of this section changes depending on the dimension of the component. The names are **Edge Selection** (local attributes in 3D), **Boundary Selection** (2D), or **Domain Selection** (1D and 3D), respectively. For global attributes in 3D, the name is **Geometric entity level**.

DISTRIBUTION

There are three main types of distribution methods that you select from the **Distribution type** list:

- Select **Explicit** to use an explicit, user-defined element distribution. To define the distribution of mesh elements, enter a vector-valued expression defining a strictly increasing sequence of nonnegative numbers (using comma-separated numbers) in the **Relative placement of vertices along edge** field, specifying the relative arc length values of the mesh vertices along the edge or boundary. Select the **Reverse direction** checkbox to reverse the direction of the explicit distribution.
- Select **Fixed number of elements** (default) to use a fixed number of mesh elements, which you enter into the **Number of elements** field. Select the **Equidistant** checkbox to generate equally sized elements along the selected edges (3D) or boundaries (2D). The checkbox is only available for edge and boundary selections.
- Select **Predefined** to specify properties of a predefined distribution method that can be either an exponentially or a linearly increasing or decreasing element size; see below for details. See Figure 8-50 for an example of a predefined exponential distribution.

Settings for the Predefined Distribution Type

In the **Number of elements** field, enter the number of elements (the default is 5 elements). To specify the ratio in size between the last element and first element in the distribution, use the **Element ratio** field (the default value is 1.0; that is, the first and the last elements have the same size). From the **Growth rate** list, select **Linear** for an element distribution based on an arithmetic sequence or select **Exponential** for an element distribution based on a geometric sequence. Select the **Symmetric distribution** checkbox to get a symmetric distribution of elements. The **Element ratio** will then define the ratio between the element in the middle of the distribution and the last element. Select the **Reverse direction** checkbox to switch the element distribution to the opposite direction along the edge or boundary. If you have specified several edges in the selection, the **Reverse direction** checkbox refers to the edge in the selection

with the lowest entity number (the *primary* edge). For the other edges, their direction (with respect to the distribution) is such that the rotation with respect to the primary edge is minimized.

For tutorials where **Distribution** is used, see:

- *Swept Meshing of a Bracket Geometry*:
  Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/bracket_swept_mesh**.
- *Using Meshing Sequences*:
  Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/meshing_sequence**.

- Global vs. Local Attributes
- Mapped
- Edge
- Swept

Edge

Use **Edge** ( ) to mesh edges in 1D, 2D, and 3D. This is useful not only for intervals in 1D, but also for applications where the physics is solved on edges in 2D and 3D, as seen in Figure 8-51.

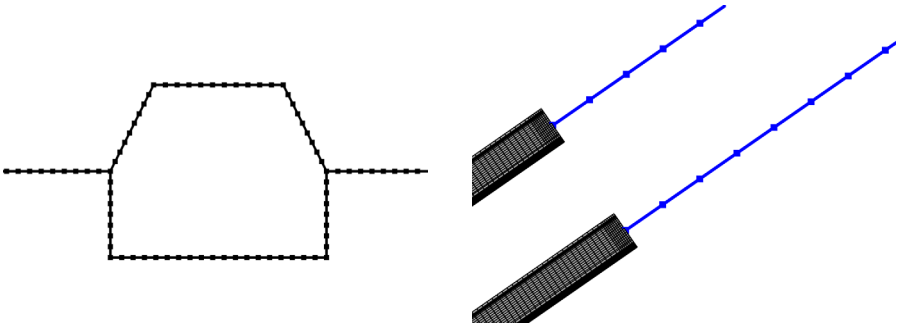

Figure 8-51: The image to the left shows the mesh for a pipe flow simulation on edges in 2D. The image to the right shows the edge mesh for beams (highlighted in blue) connected to solids.

You can control the number of elements and the distribution of elements in the edge mesh by using Size and Distribution nodes.

To add an **Edge** node, select edges in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window and select **Edge** ( ) from The Graphics Context Menu.
- In The Mesh Toolbar, choose **Edge** from the **More Generators** menu ( ) (3D and 2D components) or click **Edge** ( ) (1D components).
- Right-click the **Mesh** node and choose **Edge** ( ) (under **More Generators** in 3D).

Then enter the properties using the following sections:

ENTITY SELECTION

To define the edges where you want a create a mesh, first choose the level of the geometric entities from the **Geometric entity level** list:

- Choose **Entire geometry** to specify an edge mesh for the entire geometry.

- Choose **Remaining** to specify an edge mesh for remaining, unmeshed edges.
- Choose **Edge** (3D), **Boundary** (2D), or **Domain** (1D) to specify the edges for which you want to create a mesh. Choose **Manual** in the **Selection** list to select the edges in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All edges** (3D), **All boundaries** (2D), or **All domains** (1D) to select all edges.

CONTROL ENTITIES

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed Controlling the Mesh Size Using Mesh Control Entities. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth for the mesh vertices to be smoothed.

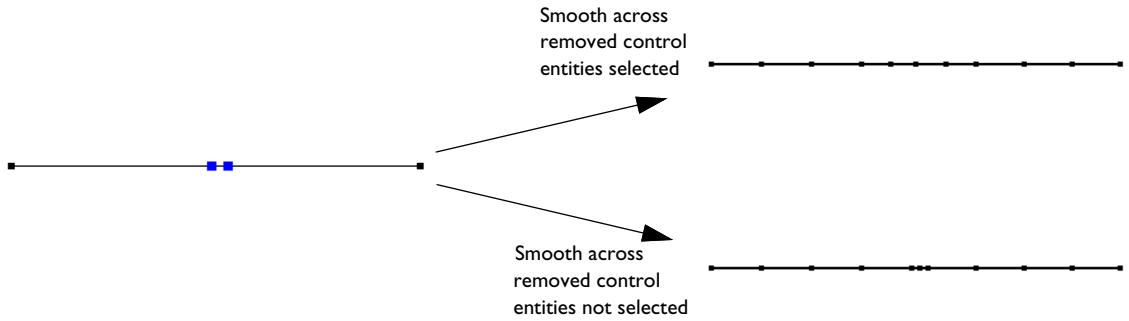

Figure 8-52: Comparing meshes where Smooth across removed control entities has been used vs. not used. The two vertices adjacent to the edge in the middle (highlighted in blue in left image) are designated as Mesh Control Vertices *and a finer mesh size is set on the edge between them. When all parts of the edge have been meshed, the vertices are removed, leaving only one single edge. With the Smooth across removed control entities checkbox is selected, the sizes of the edge elements are adjusted to get a smoother transition from large to small mesh elements (upper-right edge). Clear the checkbox to not adjust the mesh (lower-right edge).*

  Application Library path **Battery_Design_Module/Batteries,_General/lithium_sulfur**.

- Corner Refinement
- Distribution
- Identical Mesh
- Size
- Size Expression

Edge Groups

Use the **Edge Groups** ( ) attribute to specify the four groups of edges around a boundary (3D) or domain (2D) that are used to determine the Mapped mesh of the boundary/domain, as seen in Figure 8-53.

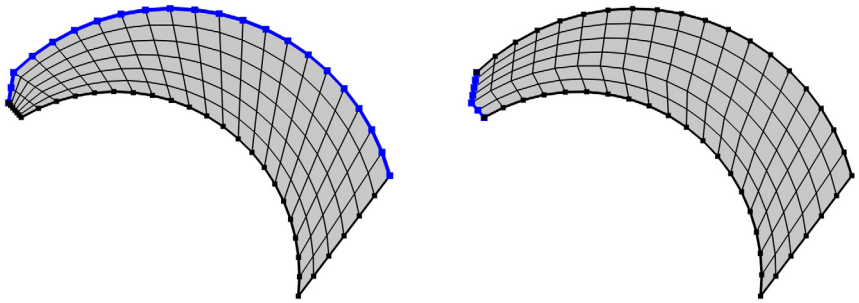

Figure 8-53: Grouping two of the five boundaries together (highlighted in blue) in two different ways results in different quad meshes on the domain.

For all the settings sections, click the **Active** button to toggle between turning ON and OFF selections.

To add an **Edge Groups** node, choose one of the following:

- Right-click Mapped and select **Edge Groups** ( ).
- Select the **Mapped** node in the **Model Builder**, click **More Attributes** ( ) on The Mesh Toolbar and select **Edge Groups**.

Then enter the properties using the following sections:

BOUNDARIES (3D) / DOMAIN SELECTION (2D)

Define the boundary/domain where you want to specify the edge groups. Choose **Manual** in the **Selection** list to select the boundary/domain in the **Graphics** window.

FIRST EDGE GROUP

Activate the **First Edge Group** list and select the edges for the first edge group in the **Graphics** window.

SECOND EDGE GROUP

Activate the **Second Edge Group** list and select the edges for the second edge group in the **Graphics** window.

THIRD EDGE GROUP

Activate the **Third Edge Group** list and select the edges for the third edge group in the **Graphics** window.

FOURTH EDGE GROUP

Activate the **Fourth Edge Group** list and select the edges for the fourth edge group in the **Graphics** window.

- Mapped
- Convert

Edge Map

Use the **Edge Map** ( ) attribute to specify the orientation of the source mesh on the destination for a Copy, Copy Face, Copy Domain, or an Identical Mesh node. Using this node, the source mesh of the copy operation is

transformed so that the source edge of the **Edge Map** node is mapped onto the destination edge with the specified orientation, as shown in Figure 8-54.

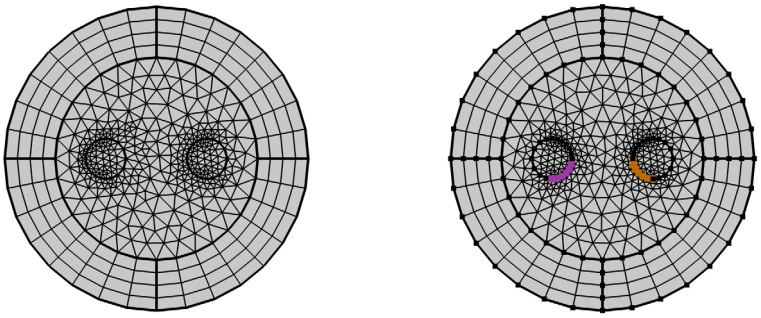

Figure 8-54: The left image shows the resulting mesh after copying the triangle mesh on the right circle to the left. The right image shows the resulting mesh with an Edge Map applied, generating a mirrored mesh on the circles. The yellow edge species the edge on the source that is mapped onto the magenta edge on the destination.

To add an **Edge Map** ( ) node, choose one of the following:

- Right-click the Copy, Copy Face, Copy Domain, or an Identical Mesh node and select **Edge Map** ( )
- Select the Copy, Copy Face, Copy Domain, or Identical Mesh node in the **Model Builder**, click **More Attributes** ( ) on The Mesh Toolbar and select **Edge Map**.

Then enter the properties using the following sections:

EDGES

Click the **Active** button to toggle between turning ON and OFF selections.

- Activate the **Source edge** list and select the edge that you want to define as the source edge in the **Graphics** window.
- Activate the **Destination edge** list and select the edge that you want to define as the destination edge in the **Graphics** window.

ORIENTATION

Select **Automatic orientation** to let the software determine the orientation of the mesh of the source edge on the destination edge (this is the default), select **Same orientation** to let the mesh of the source edge be copied to the destination edge according to the directions of the edges, or select **Opposite orientation** to let the mesh of the source edge be copied to the destination edge in the opposite direction.

	• Copy • Copy Domain • Copy Face • One-Point Map • Two-Point Map • Identical Mesh

Fill Holes

Use **Fill Holes** ( ) to repair an imported 3D surface mesh that might have minor holes, as seen in Figure 8-55.

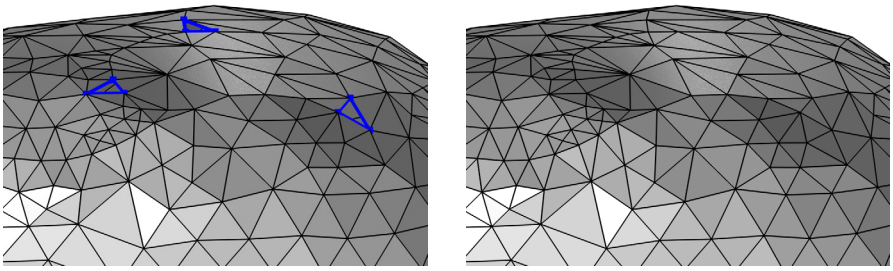

Figure 8-55: Repairing small holes, bounded by the blue edges, in a surface mesh using the Fill Holes operation (left). The right image shows the repaired mesh.

	This operation is available for 3D models only.

	Note that filling holes in the mesh can modify the number of geometric boundaries in the mesh. Thus, when you add this operation to a meshing sequence that conforms with the component's geometry, a new meshing sequence that defines its own geometric model is automatically created, and the **Fill Holes** node is added to this new sequence. For more information, see The Mesh Node.

To add a **Fill Holes** ( ) node, select one or more boundaries in which to fill holes, then choose one of the following:

- Right-click in the **Graphics** window and in The Graphics Context Menu, select **Fill Holes** ( ) from the **Cleanup and Repair** menu.
- In the **Mesh** toolbar, click **Cleanup and Repair** ( ) and choose **Fill Holes**.
- Right-click the **Mesh** node and choose **Fill Holes** ( ) from the **Cleanup and Repair** menu.

Enter the properties for the **Fill Holes** node using the following sections:

BOUNDARY SELECTION

The operation to fill a hole requires a face (boundaries) selection and finds holes in and between all selected faces. Only faces isolated in void or unmeshed domains can be selected.

FILL HOLES

Holes that have a perimeter less than the tolerance are filled. You specify the tolerance using the **Maximum hole perimeter** list:

- Select **Automatic** (the default) to use a tolerance that is 10 times the mean element size of the imported mesh.
- Select **Manual** to specify the tolerance (SI unit: m) in the **Perimeter** field.

The **Join with selected boundaries** checkbox is selected by default. If selected, the created mesh elements (triangles) that fill the hole are added to the surrounding face. If you clear this checkbox, or if the hole is adjacent to more than one face, the created mesh elements form a new face.

Select the **Create domains** checkbox (selected by default) to automatically form domains for each (connected) finite void region that is defined by the imported surface mesh and analyze these domains with respect to the mesh that

might already exist in the sequence. Clear the checkbox to not form domains, for example if more repairing is needed before the mesh forms watertight regions. Consider to later add a Create Domains operation if you clear the checkbox.

Most physics require a mesh on the domains. Use the Free Tetrahedral, Swept, and Boundary Layers operations to fill the domains with domain elements.

SELECTIONS OF RESULTING ENTITIES

Select the **Resulting domains** checkbox to create a predefined selection in subsequent nodes in the mesh sequence. To also make the selection available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), select the **Show in physics** (**Show outside part** if in a mesh part) checkbox. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

See *STL Import 1 — Repairing and Combining STL Files*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes**

- Create Faces
- Create Domains
- Free Triangular
- Remesh Faces
- Remeshing Imported Meshes
- Information, Warning, and Error Nodes for Meshing Operations

Fixed Mesh

Use the **Fixed Mesh** ( ) attribute to keep the mesh fixed on edges (3D) or boundaries (2D) while remeshing the faces (3D) or domains (2D), as shown in Figure 8-56.

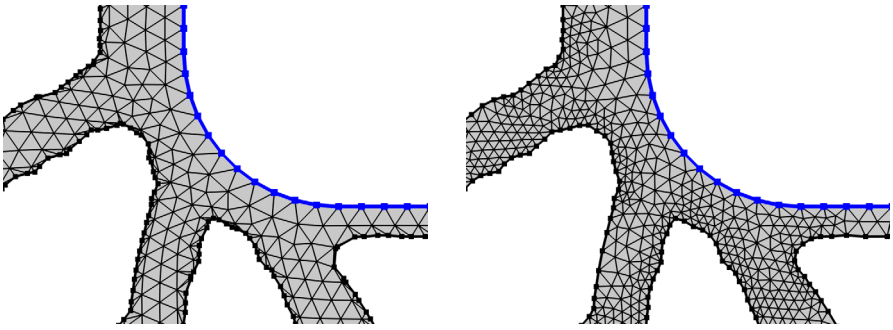

Figure 8-56: Keeping the selected edge mesh (blue) fixed when remeshing the domain.

To add a **Fixed Mesh** attribute as a local node, select faces (3D) or domains (2D) and choose one of the following:

- Right-click a Remesh Faces or Remesh Domains node and select **Fixed Mesh** ( ).
- Select a Remesh Faces or Remesh Domains node in the **Model Builder** tree and choose **Fixed Mesh** from the **More Attributes** ( ) menu in The Mesh Toolbar.

Global vs. Local Attributes.

GEOMETRIC ENTITY SELECTION

Define the geometric entities where you want to keep the mesh fixed. Choose **Manual** from the **Selection** list to select the entities in the **Graphics** window or choose **All boundaries/edges** to select all available entities of that level. If there are selections available, choose one of the selections from the list next to **Selection**.

Click the **Active** button to toggle between turning ON and OFF the entity selections. Select boundaries (2D) or edges (3D) in the **Graphics** window or from the **Selection List** window. The entities will be highlighted blue in the graphics and also appear in the selection of this section.

The name of this section changes depending on the dimension of the component. The names are **Edge Selection** (3D) or **Boundary Selection** (2D).

- Global vs. Local Attributes
- Remesh Faces
- Remesh Domains
- Remeshing Imported Meshes
- Information, Warning, and Error Nodes for Meshing Operations

Free Tetrahedral

Use **Free Tetrahedral** ( ) to create an unstructured tetrahedral mesh on a selection of domains, as shown in Figure 8-57. If no selection is specified, **Free Tetrahedral** creates a mesh on the remaining domains, boundaries, edges, and points. It inserts pyramids to match the tetrahedral mesh to any existing quad mesh on adjacent faces.

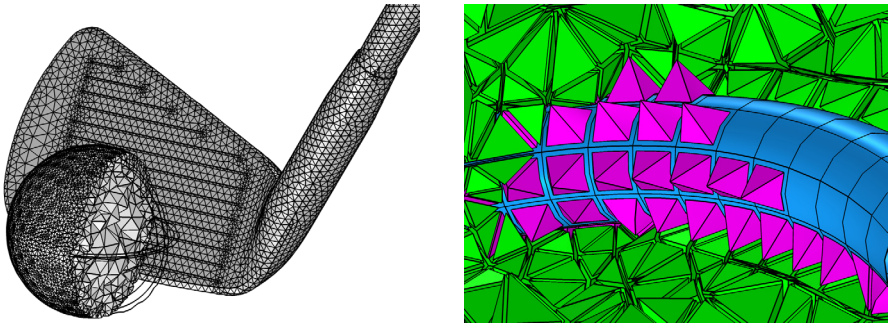

Figure 8-57: An unstructured mesh of a golf club and ball (left), created by the Free Tetrahedral operation. The image is accomplished by filtering out some elements in a Mesh plot. The image to the right pictures a tetrahedral mesh (green) where pyramids (magenta) are inserted to match to an existing quad mesh (blue) on the face of a bent pipe. Some elements have been filtered out and the remaining volume elements are shrunk with a factor 0.8.

The **Free Tetrahedral** operation is available both for meshing sequences that generate mesh for a geometry and for meshes that define their own geometric model.

See The Mesh Node for more information about meshes that define their own geometric models.

When you generate a mesh for a geometry, you can control the number, size, and distribution of elements by using one or several Size, Size Expression, Distribution, and Corner Refinement attributes.

For meshes that define their own geometric model, **Free Tetrahedral** ( ) has a default **Size** subnode which, in practice, defines the size on the same selection as for the parent node. This subnode cannot be deleted or disabled. You can add more **Size** attributes to further control the element size.

Refer to the section Remeshing Imported Meshes for more information and related tutorials.

To add a **Free Tetrahedral** node, select one or several domains in the **Graphics**, then choose one of the following:

- Right-click in the **Graphics** window and select **Free Tetrahedral** ( ) from The Graphics Context Menu.
- In the **Mesh** toolbar click the **Free Tetrahedral** ( ) button.
- Right-click the **Mesh** node and choose **Free Tetrahedral** ( ).

Then define the properties for the tetrahedral meshing operation using the following sections:

DOMAIN SELECTION

Define the domains where you want to create an unstructured tetrahedral mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify unstructured tetrahedral mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to create an unstructured tetrahedral mesh in the entire geometry.

For the options **Entire geometry** and **Remaining**, the operation will mesh all remaining entities, even those that are not adjacent to a domain.

- Choose **Domain** to specify the domains for which you want to create an unstructured tetrahedral mesh. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains** to select all domains.

SCALE GEOMETRY

To scale the geometry during the meshing operation, change the x-scale, y-scale, and z-scale to positive real numbers, as done for the mesh in Figure 8-58. If any of the scale factors are not equal to one (1), the software scales

the geometry in those directions before meshing. After meshing, it restores the geometry and mesh to fit the original size.

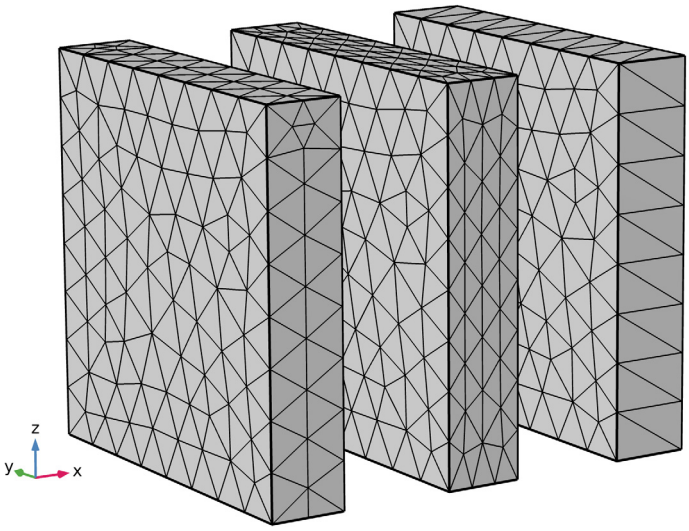

Figure 8-58: Three thin blocks with unstructured tetrahedral meshes. The first block (to the left) has no scaling applied. The geometry of the middle block is scaled with a factor 2 in the x direction and the last block (to the right) with a factor 0.5 in the x direction before they are meshed and restored back to their original size.

The scale factors make it possible to generate meshes that are anisotropic, and they are useful if the mesh generator creates many elements due to a thin geometry or if the mesh generation fails due to large aspect ratios in the geometry. Compare this to changing the **Resolution of narrow region** parameter in a mesh Size attribute to only affect the mesh size in narrow regions. Another alternative is using a Swept mesh operation for the thin parts of a geometry. The resulting hexahedral or prism elements usually have better element quality compared to the unstructured mesh after scaling the geometry. Consider using Remove Details to remove narrow face regions and thin domains, if not important to the simulation at hand. Yet another possibility is to simplify the geometry by using shell approximations in the physics, where appropriate.

CONTROL ENTITIES

!	This section is not available for meshes that define their own geometric models.

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed Controlling the Mesh Size Using Mesh Control Entities. You can specify the number of smoothing iterations in

the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth for the mesh vertices to be smoothed.

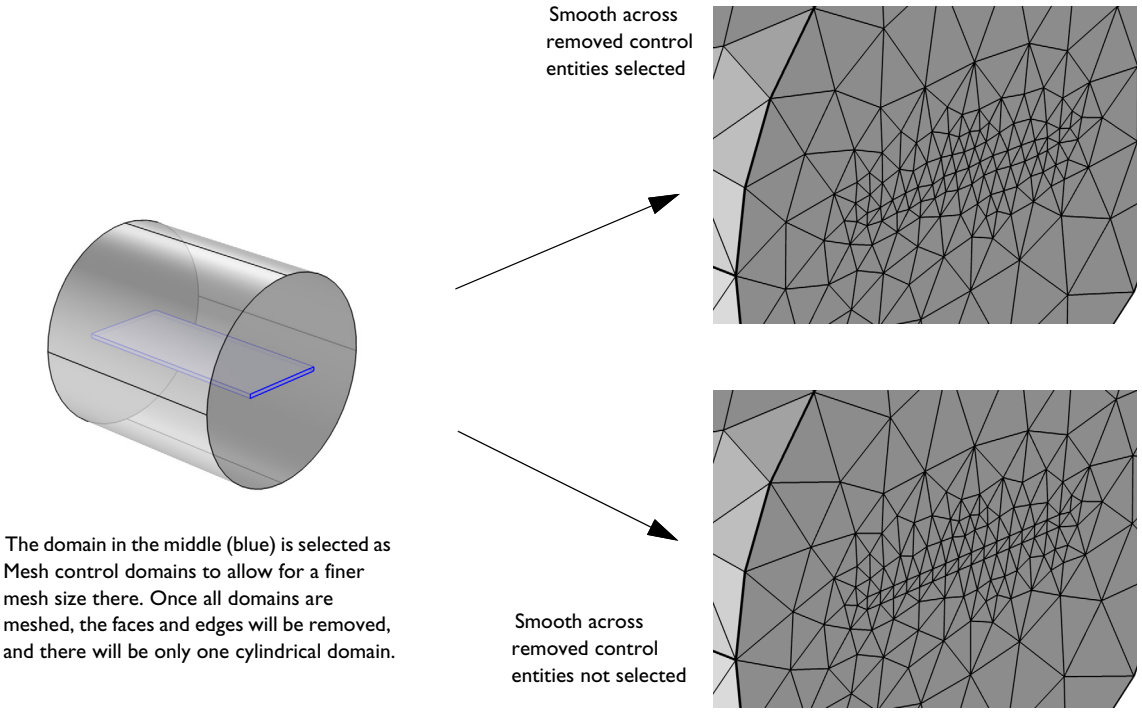

Figure 8-59: Comparing meshes where Smooth across removed control entities has been used vs. not used. With the Smooth across removed control entities checkbox selected, the mesher adjusts the sizes of the mesh elements to get a smoother transition from large to small elements by moving the mesh vertices. Clear the checkbox to not adjust the mesh.

TESSELLATION

From the **Method** list, choose the Delaunay tessellation method to use for creating a tetrahedral mesh:

- Select **Automatic** (the default) to make the mesh generator determine the best algorithm to use for each domain.
- Select **Delaunay** to use a version of the Delaunay algorithm that under some conditions can modify the boundary mesh to simplify the meshing.
- Select **Delaunay (legacy version)** to use the Delaunay algorithm available in earlier versions of COMSOL Multiphysics. This is also the method that will be used if you open a model created in COMSOL Multiphysics 5.1 or earlier.

ELEMENT QUALITY OPTIMIZATION

In this section, you can control how much effort COMSOL Multiphysics puts into optimizing the minimum element quality and tuning the optimization for certain situations. Use the Mesh Statistics to see the full statistics of your mesh. All optimization is done on the volume elements while keeping the surface mesh fixed.

From the **Optimization level** list, choose one of the following levels:

- **Basic** (the default), which makes basic optimizations aiming at a minimal element quality of 0.2.
- **Medium**, which makes more optimization and aims at a minimal element quality of 0.35. Meshing with medium level will take longer time than with the Basic level.
- **High**, which attempts all available optimization operations. If the quality of the mesh is low, meshing with this setting can take a significant amount of time.

As an example, refer to the tutorial *Adjusting the Element Size for the Unstructured Mesh Generator* and compare the amount of mesh elements plotted for qualskewness < 0.2 (see Figure 8-60). In this tutorial, the Maximum element growth rate is high which means that the element size can grow fast from the small elements on the boundaries into the domain. This results in fewer domain elements, but also more elements of less good quality. Increasing the **Optimization level** from **Basic** (image 2 below) to **High** (image 3 below) increases both the minimum and average quality. Compare this to lowering the Maximum element growth rate (image 4), which gives about the same minimum and average quality, but results in more elements in total.

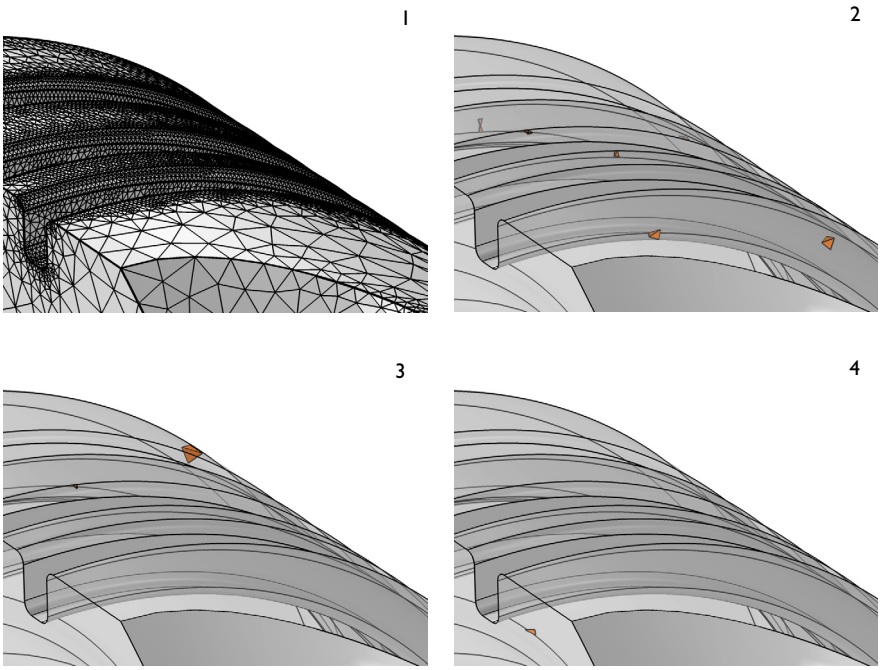

Figure 8-60: Comparing the meshes built with different Optimization level settings and compared to a mesh with finer size settings. 1. The mesh of the piston. 2. A plot of the mesh built with Optimization lever: Basic. 3. Mesh built with Optimization level: High. Optimizing the mesh influences the elements some distance away, which is why new elements might appear. 4. A mesh built with lowered Maximum element growth rate on the domain. About the same quality as (3), but this mesh has three times as many elements.

There are additional settings under **Accept lower element quality to** that you can use if you can accept a lower mesh element quality. A Physics-Controlled Mesh will typically ensure that the mesh is good with respect to the physics at hand and is recommended. For user-controlled meshing sequences, wave and CFD problems are examples of computations that can be sensitive to too large and too small elements and might require changed settings.

- If the computation is sensitive to too large mesh elements, you can select the **Avoid elements that are too large** checkbox. For each mesh element, there is a desired element size (h), specified by the mesh size parameters, and if the element is larger than that, COMSOL Multiphysics tries to make it smaller. The cost for this option is longer meshing time and a lower element quality. If you evaluate the maximum of h on a sufficiently large mesh of uniform size, this value is typically decreased by 10 percent if you have selected this option.
- Select the **Avoid elements that are too small** checkbox to optimize the mesh so that the diameter of the inscribed sphere of each element is maximized while still trying to respect the desired local element size. Optimizing this

parameter can improve performance when solving problems using the discontinuous Galerkin method. Refer to the section The Time-Explicit Algorithms for more information.

- The **Avoid inverted curved elements** checkbox is selected by default. This setting makes the optimization try to reduce the number of mesh elements that become inverted when they are curved. The cost of this optimization is longer meshing time, often a slightly higher number of mesh elements, and a lower element quality.

- Corner Refinement

Free Triangular

Use **Free Triangular** ( ) to create an unstructured triangular mesh on boundaries in 3D and domains in 2D, as shown in Figure 8-61. The **Free Triangular** operation can also be used to remesh faces of imported surface meshes in 3D.

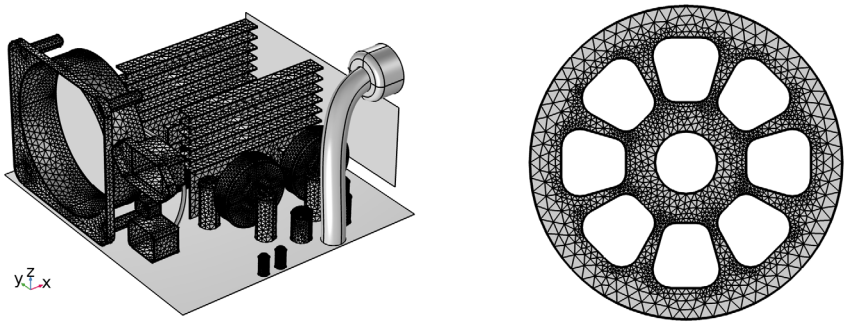

Figure 8-61: Use Free Triangular to create unstructured triangle meshes on faces in 3D (left) and on domains in 2D (right).

You can control the number, size, distribution, and refinement of elements by using Size, Size Expression, Distribution, and Corner Refinement subnodes (only **Size** and **Distribution** subnodes are available for Finalizing the Mesh).

For a mesh that defines its own geometric model, use **Free Triangular** to remesh one or several faces. The operation separates the selected boundaries from the mesh, creates a geometry from the separated mesh, meshes the geometry, and then copies the new generated mesh onto the original imported mesh. This operation has the following practical implications:

- External edges of the selection are kept unchanged, while internal edges are remeshed.
- Before generating a geometry, the mesh is simplified according to the settings in the Mesh Preprocessing section below.
- If remeshing fails, the error message might be referring to a problem in generating geometry from the mesh.

Only surface meshes with first-order elements can be remeshed. Clear the **Import domain elements** checkbox in the mesh **Import** node to import only boundary elements. Select checkbox **Import as linear elements** to ignore second-order mesh data. See Importing Meshes for more information.

See The Mesh Node to learn more about meshes that define their own geometric model.

To add a **Free Triangular** node, select one or several boundaries (3D) or domains (2D) in the **Graphics**, then choose one of the following:

- Right-click in the **Graphics** window and select **Free Triangular** ( ) from The Graphics Context Menu.
- In The Mesh Toolbar, choose **Free Triangular** from the **More Generators** ( ) menu (3D components and parts) or click the **Free Triangular** ( ) button (2D).
- Right-click a **Mesh** node and choose **Free Triangular** ( ). For 3D components and parts, this is selected from the **More Generators** menu.

Then enter the properties for the triangular meshing operation using the following sections:

ENTITY SELECTION

Define the boundaries (3D) or domains (2D) where you want to create an unstructured triangular mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify unstructured triangular mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to create an unstructured triangular mesh in the entire geometry.

In 2D and 2D Axial symmetry, for the options **Entire geometry** and **Remaining**, the operation will mesh all remaining entities, even those that are not adjacent to a domain.

- Choose **Boundary** (3D) or **Domain** (2D) to specify the geometric entities for which you want to create an unstructured triangular mesh. Choose **Manual** in the **Selection** list to select the boundaries or domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All boundaries** (3D) or **All domains** (2D) to select all entities.

For imported meshes in 3D, the available options in the **Geometry entity level** list are **Manual** and **All boundaries**.

SCALE GEOMETRY

To scale the geometry during the meshing operation, change the x-scale, y-scale, and z-scale in 3D to positive real numbers, as shown in Figure 8-62. If any of the scale factors are not equal to one (1), the software scales the geometry in those directions before meshing. After meshing, it restores the geometry and mesh to fit the original size.

The scale factors make it possible to generate meshes that are anisotropic, and is one alternative to use if the mesh generator creates many elements due to a thin geometry or large aspect ratios in the geometry (compare the first and last mesh in Figure 8-62). Compare this to changing the **Resolution of narrow region** parameter in a mesh Size attribute to only affect the mesh size in narrow regions. In 3D, consider using the Collapse Face Regions or Remove Details to remove narrow regions, if these are not important to the simulation at hand.

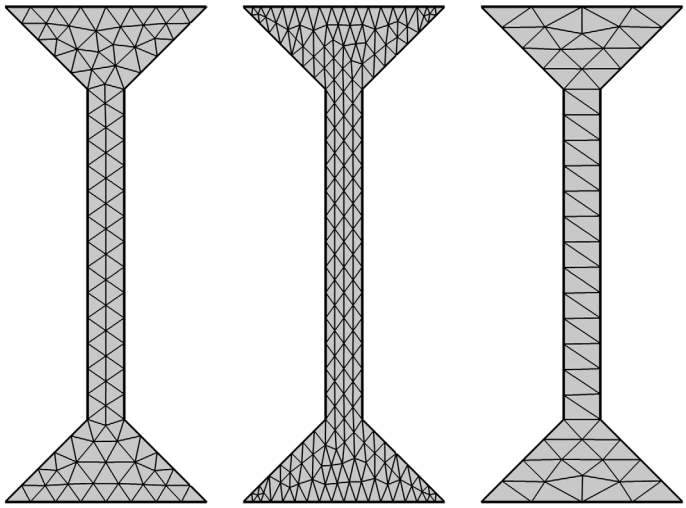

Figure 8-62: Three hourglass shaped geometries meshed with triangular meshes where the mesh in the narrow region can be more or less resolved by scaling the geometry in the background. The first geometry (left) is not scaled. The geometry in the middle is scaled with a factor 2 in the x direction. The last geometry (right) is scaled with a factor 0.5 in the x direction before meshing it and restoring it to its original size. Note that the scaling influences the whole domain, not only the narrow region in the middle.

NARROW DOMAIN REGIONS

Select the checkbox **Resolve narrow domain regions** to allow the element size to be smaller close to narrow domain regions, as shown in Figure 8-63. The surface mesh will be the same as if the Free Tetrahedral operation had been built in the adjacent domain. Clear the checkbox to generate a triangular mesh without accounting for narrow

domain regions. The checkbox is selected by default for meshes that define their own geometric models, such as imported meshes, and is cleared by default for meshes that are conforming with geometry.

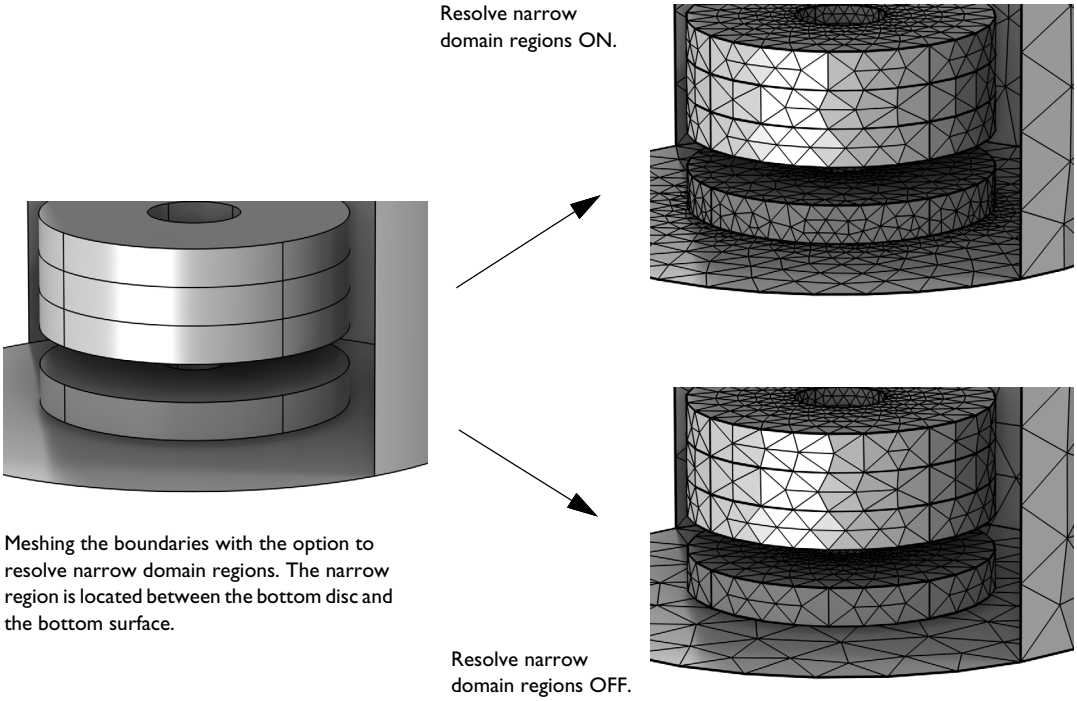

Figure 8-63: Meshing the boundaries using the option Resolve narrow domain regions. Turning on the option resolves the surface mesh as if a tetrahedral mesh was created in the narrow region (upper right).

CONTROL ENTITIES

!	This section is not available for meshes that define their own geometric model.

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed Controlling the Mesh Size Using Mesh Control Entities. You can specify the number of smoothing iterations in

the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth for the mesh vertices to be smoothed.

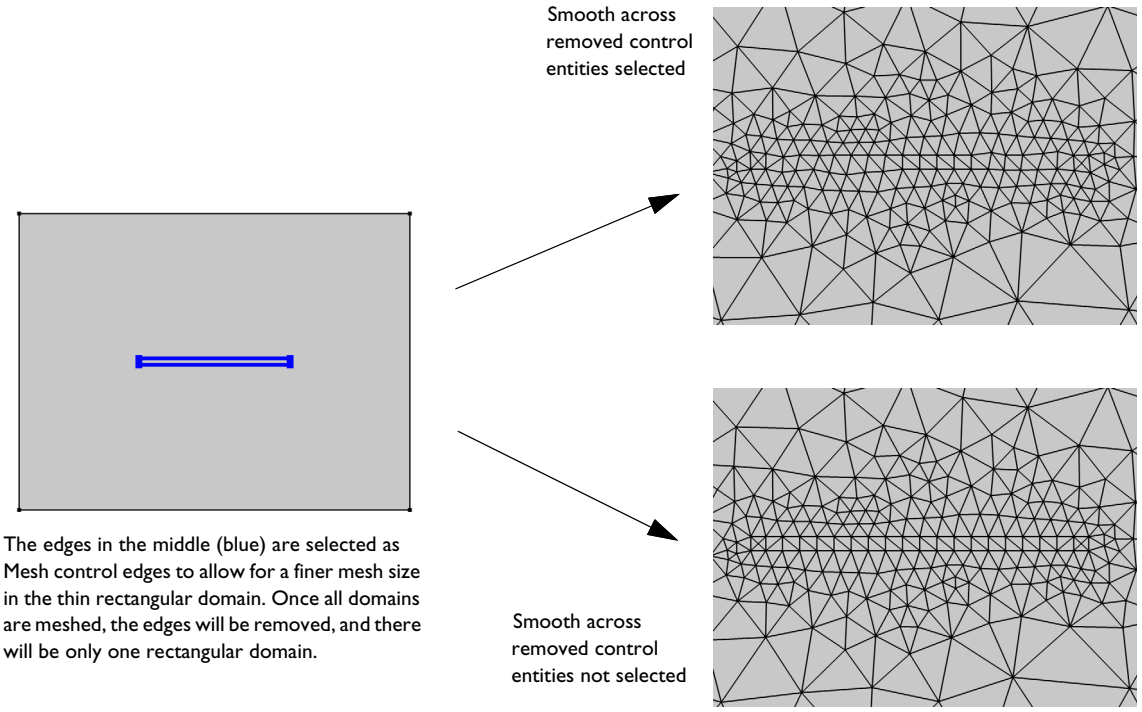

Figure 8-64: Comparing meshes where Smooth across removed control entities has been used vs. not used. With Smooth across removed control entities checkbox selected, the mesher adjusts the sizes of the triangles to get a smoother transition from large to small elements.

TESSELLATION

Here you can specify the triangulation method used when creating the triangular mesh. Select **Automatic** (default) to let the software use the method that is best suited for the geometry. Select **Delaunay** to use a method based on a Delaunay algorithm. This results in a mesh with more irregular structure. Select **Advancing front** to use a method based on an advancing front algorithm. This results in a mesh with more regular structure.

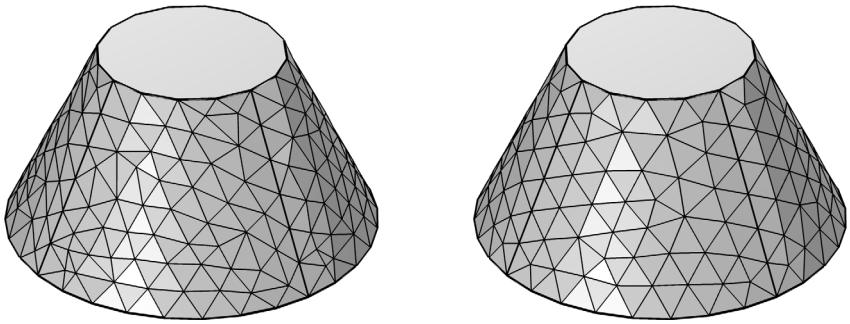

Figure 8-65: A cone meshed with a triangular mesh using different triangulation methods. The image to the left shows a mesh generated using the Delaunay method. The image to the right shows a mesh generated with the Advancing front.

MESH PREPROCESSING

This section is only available for meshes that define their own geometric model. Refer to the section Remeshing Imported Meshes for more information and related tutorials.

You can optionally simplify the mesh when remeshing faces in an imported mesh. The simplification can remove small defects typically present in mesh data from measurements, such as tomography, and it can speed up the process by removing unnecessary elements. The **Simplify mesh** checkbox is selected by default to enable simplification.

The **Relative simplification tolerance** (default value: 0.01) is relative to the dimensions of the entire geometry and specifies a global limit for how much the mesh can be modified. The **Defect removal factor** (default value: 1) is relative to the local feature size, as estimated by the algorithm, and is combined with the global limit to produce a limit for how much the mesh can be modified at a certain location. If the mesh contains many defects that you want to remove, you could try to increase the value of the **Defect removal factor**. If the mesh describes the desired geometry with high accuracy, you might want to decrease this factor instead.

- Corner Refinement
- Remeshing Imported Meshes

Free Quad

Use **Free Quad** ( ) to generate an unstructured quadrilateral mesh on boundaries in 3D and domains in 2D, as shown in Figure 8-66. The operation can also be used to remesh faces of imported surface meshes in 3D.

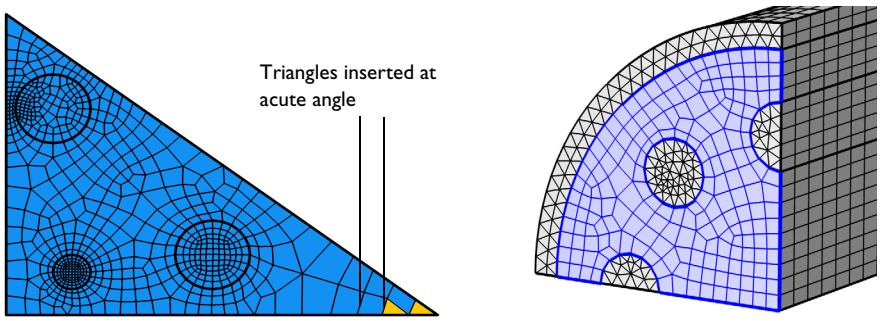

Figure 8-66: An unstructured quad mesh in a 2D geometry with four domains (left). The Free Quad mesher inserts triangles (yellow) at acute angles to avoid too skewed quad elements. This image also shows how the size of the elements grows from small in narrow regions to larger some distance away. The quad mesh on the face in the 3D geometry (colored in blue to the right) is swept together with the triangular face mesh (gray) on adjacent faces, resulting in a mixed prism and hexahedral mesh. The default face meshing method for Swept *is to create an unstructured quad mesh.*

The quadrilateral mesh generator does not strictly create only quadrilateral elements. In places of the geometry where it judges it as necessary, it can also create triangular elements, as shown in Figure 8-66.

You can control the number, size, distribution, and refinement of elements by using Distribution, Size Expression, Size, and Corner Refinement subnodes (only **Size** and **Distribution** subnodes are available for Finalizing the Mesh).

For meshes that define their own geometric model, use **Free Quad** to remesh one or several faces. The operation separates the selected boundaries from the mesh, creates geometry from the separated mesh, meshes the geometry, and then copies the new generated mesh onto the original mesh. This operation has the following practical implications:

- External edges of the selection are kept unchanged, while internal edges are remeshed.
- Before generating geometry, the mesh is simplified according to the settings in the Mesh Preprocessing section below.
- If remeshing fails, the error message might be referring to a problem in generating geometry from the mesh.

Only surface meshes with first-order elements can be remeshed. Clear the **Import domain elements** checkbox in the mesh **Import** node to import only boundary elements. Select checkbox **Import as linear elements** to ignore second-order mesh data. See Importing Meshes for more information.

See The Mesh Node to learn more about meshes that define their own geometric model.

To add a **Free Quad** ( ) node, select boundaries (3D) or domains (2D) in the **Graphics**, then choose one of the following:

- Right-click in the **Graphics** window and select **Free Quad** ( ) from The Graphics Context Menu.

- In The Mesh Toolbar, choose **Free Quad** ( ) from the **More Generators** ( ) menu (3D components and parts) or click the **Free Quad** ( ) button (2D).
- Right-click a **Mesh** node and choose **Free Quad** ( ). For 3D components and parts, this is selected from the **More Generators** menu.

Then enter the properties for the quadrilateral meshing operation using the following sections:

ENTITY SELECTION

Define the boundaries (3D) or domains (2D) where you want to create an unstructured quad mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify unstructured quad mesh for remaining, unmeshed faces (3D) or domains (2D).
- Choose **Entire geometry** to create an unstructured quad mesh in the entire geometry.

In 2D and 2D Axial symmetry, for the options **Entire geometry** and **Remaining**, the operation will mesh all remaining entities, even those that are not adjacent to a domain.

- Choose **Boundary** (3D) or **Domain** (2D) to specify the geometric entities for which you want to create an unstructured quad mesh. Choose **Manual** in the **Selection** list to select the boundaries or domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All boundaries** (3D) or **All domains** (2D) to select all entities.

For imported meshes in 3D, the available options in the **Geometry entity level** list are **Manual** and **All boundaries**.

SCALE GEOMETRY

To scale the geometry during the meshing operation, change the x-scale, y-scale, and z-scale in 3D to positive real numbers. If any of the scale factors are not equal to one, the software scales the geometry in those directions before meshing; after meshing, it restores the geometry and mesh to fit the original size, as shown in Figure 8-67.

The scale factors make it possible to generate meshes that are anisotropic. They are also useful if the mesh generator creates many elements due to a thin geometry or due to large aspect ratios in the geometry (compare the first and

last meshes in Figure 8-68). Compare this to changing the **Resolution of narrow region** parameter in a mesh Size attribute to only affect the mesh size in narrow regions.

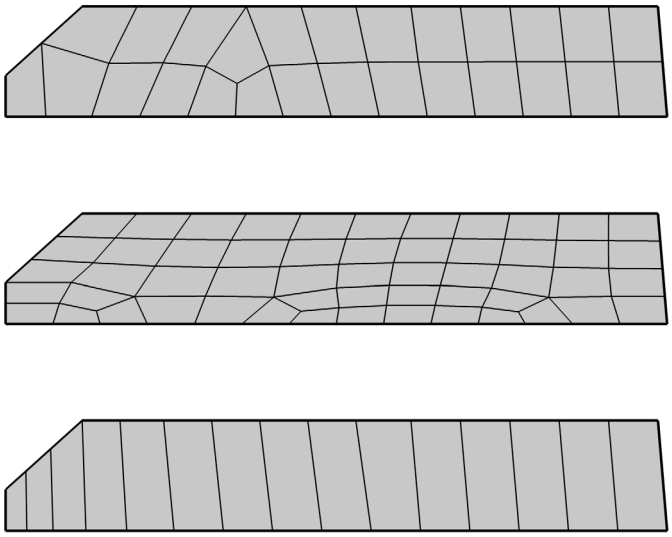

Figure 8-67: Three copies of the same geometry, where the quad mesh is more or less resolved in the y direction by scaling the geometry in the background before it is meshed. The top geometry is not scaled. The one in the middle is scaled with a factor 2 in the y direction. The geometry at the bottom is scaled with a factor 0.5 in the y direction.

CONTROL ENTITIES

!	This section is not available for meshes that define their own geometric model.

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed Controlling the Mesh Size Using Mesh Control Entities. You can specify the number of smoothing iterations in

the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth for the mesh vertices to be smoothed.

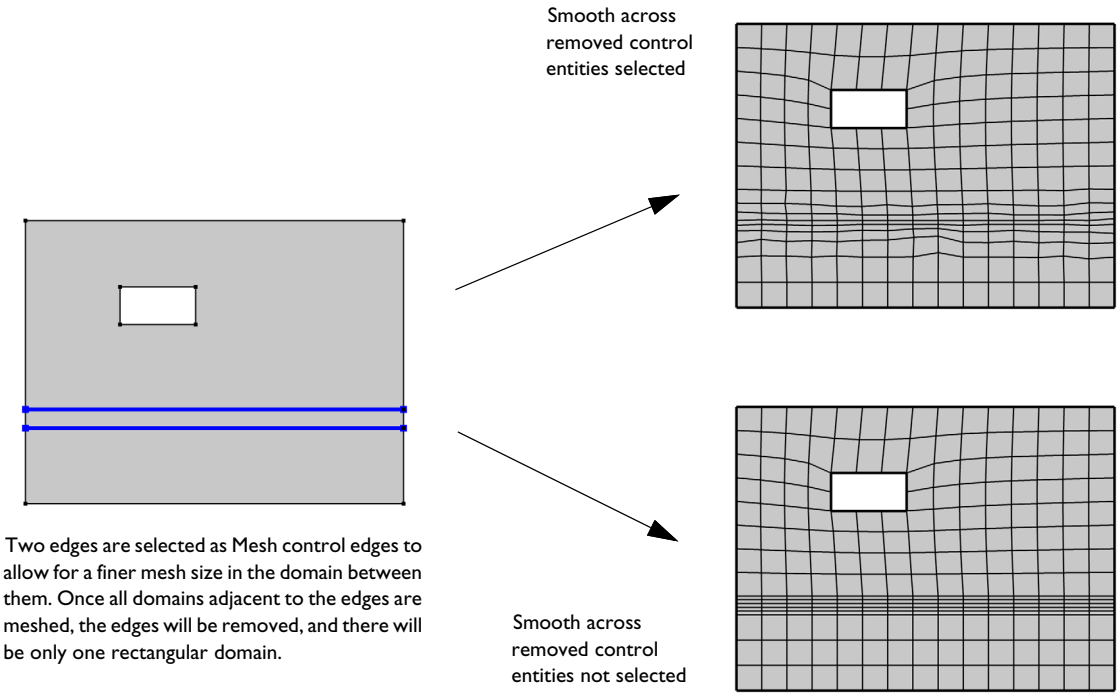

Figure 8-68: Comparing meshes where Smooth across removed control entities has been used vs. not used. The two edges (highlighted in blue in left image) adjacent to the domain in the middle are designated as Mesh Control Edges. *A finer distribution is set between the edges and when all domains are meshed, the edges are removed, leaving only one rectangular domain. With the Smooth across removed control entities checkbox selected (upper right image), the mesher adjusts the sizes of the quad elements to get a smoother transition from large to small elements. Clear the checkbox to not adjust the mesh (lower right image).*

TESSELLATION

From the **Method** list, choose the tessellation method to use for generating an unstructured quadrilateral mesh:

- Select **Automatic** (the default) to make the mesh generator determine the best algorithm to use for each domain.
- Select any of the legacy versions to use a specific version of the algorithm.

MESH PREPROCESSING

!	This section is only available for meshes that define their own geometric models. Refer to the section Remeshing Imported Meshes for more information and related tutorials.

You can optionally simplify the mesh when remeshing faces in an imported mesh. The simplification can remove small defects typically present in mesh data from measurements, such as tomography, and it can speed up the process by removing unnecessary elements. The **Simplify mesh** checkbox is selected by default to enable simplification.

The **Relative simplification tolerance** (default value: 0.01) is relative to the dimensions of the entire geometry and specifies a global limit for how much the mesh can be modified. The **Defect removal factor** (default value: 1) is relative to the local feature size, as estimated by the algorithm, and is combined with the global limit to produce a limit for how much the mesh can be modified at a certain location. If the mesh contains many defects that you want

to remove, you could try to increase the value of the **Defect removal factor**. If the mesh describes the desired geometry with high accuracy, you might want to decrease this factor instead.

Identical Mesh

Use **Identical Mesh** ( ) to ensure that pairs of boundaries or edges get the same mesh, as shown in Figure 8-69.This attribute is useful when applying periodic boundary conditions and other types of symmetry conditions that require identical meshes.

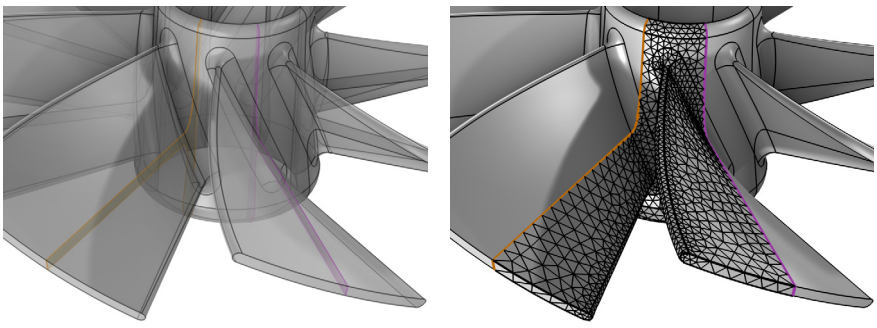

Figure 8-69: One section of an impeller is meshed with the Identical Mesh attribute applied on the boundaries.The volume mesh of the section can then be copied to the other sections of the impeller.

The mesh size field is synchronized over the pairs to ensure that an identical mesh is built on the selected entities. The smallest size on each position along the faces or edges takes precedence over a larger size, as shown for the exterior boundaries of the highlighted domain in Figure 8-70.

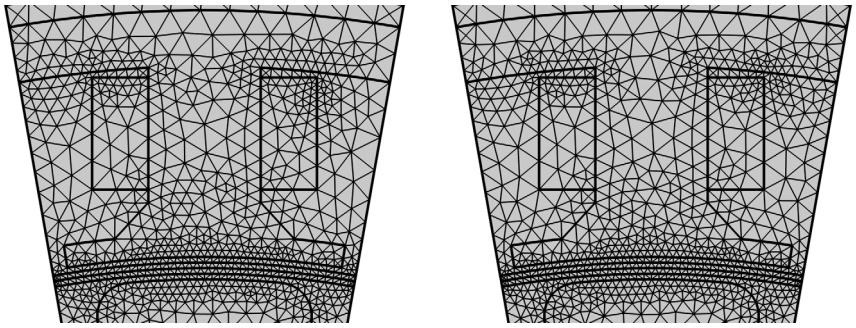

Figure 8-70: Meshes built without (left) and with (right) Identical Mesh applied on the periodic boundaries on the left and right hand side of the domains. Right: The size field is synchronized between the entity pairs for each position.

For meshes conforming with geometry, **Identical Mesh** can only be added as a global attribute to ensure that the identity mapping is kept through the meshing sequence. The domains can be meshed directly after applying an **Identical Mesh** attribute.

	Compare this with using the copy operations, where the entities needs to be meshed before the mesh can be copied. The copy operations copies the mesh using a rigid body transformation with a scale factor which allows for slightly different shapes on source and destination, but it does not guarantee an identical mesh.

The identical mesh specification defined by a local attribute will be used in subsequent operations if the entities it is applied to are not modified. However, it is still recommended to remesh the boundaries with applied **Identical Mesh** as late as possible in the meshing sequence.

	• Global vs. Local Attributes • For more information about meshes that define their own geometric model, see The Mesh Node.

Use Edge Map, One-Point Map, or Two-Point Map to control how to map the entities from one group to the other.

Operations Considering Identical Mesh Specifications

The following operations take the Identical Mesh specifications into consideration when they are built:

- Boundary Layers
- Edge
- Free Tetrahedral
- Free Triangular
- Free Quad
- Remesh Faces
- Swept (for source and destination faces)

Requirements

To be able to use the **Identical Mesh** attribute, the following criteria must be fulfilled:

- The number of entities of the two entity groups must be equal.
- For faces, the number of adjacent edges of the two face groups must be equal.
- It should be possible to transfer the mesh from the entities of one group to the other using a single rigid body transformation.

Premeshed entities

When an entity is premeshed (and is not included in the current operation), the identical relation preserves the identical mesh by effectively copying the mesh from the meshed entity to the entity to be meshed. On the other hand, if an entity is not meshed and not included in the current operation, any sizing attribute or distribution assigned to that entity is ignored. For example, take the two periodic boundaries in Figure 8-69 and assume that boundary 1 and boundary 2 are specified to have identical mesh, the Size on boundary 1 (yellow in Figure 8-71) is set to Fine, and we have the following sequences of operations:

Generate mesh on boundary 1 (yellow) using a Free Triangular operation and after that mesh boundary 2 (magenta). Both boundaries get the same fine mesh.

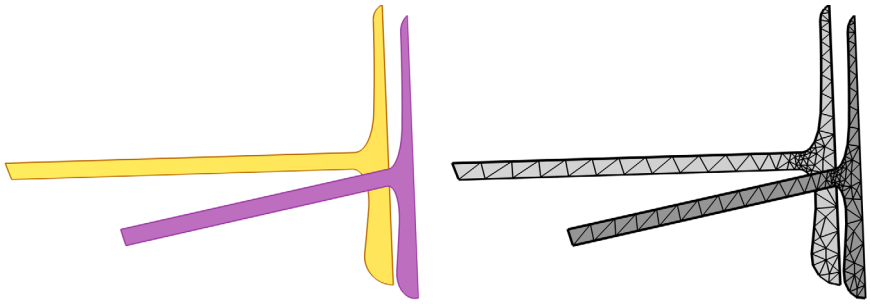

Figure 8-71: Two boundaries are assigned to have identical mesh. The yellow boundary with a finer size setting is meshed first.

You will get the same result if you mesh boundary 1 and boundary 2 in the same Free Tetrahedral or Free Triangular operation, as seen to the left in Figure 8-72. On the other hand, if boundary 2 is meshed first and then boundary 1, then both boundary 1 and boundary 2 get the same normal sized mesh. The sizing attribute on boundary 1 will be ignored, as seen to the right in Figure 8-72.

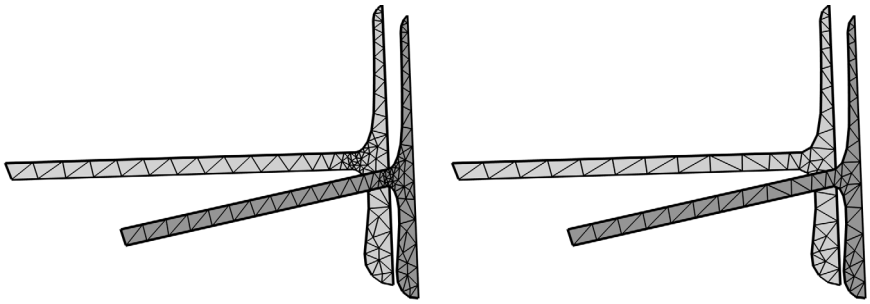

Figure 8-72: Left: Both boundaries are meshed at the same time. Right: Meshing the magenta boundary in Figure 8-71 first. For the left case, the finer size setting is taken into account, while it is not in the right case.

To add **Identical Mesh** ( ) attribute in a mesh conforming with geometry, choose one of the following:

- Right-click a **Mesh** node and select **Identical Mesh** ( ).
- Click **Sizing** ( ) in The Mesh Toolbar and select **Identical Mesh**.

To add **Identical Mesh** ( ) attribute in a mesh that defines its own geometric model, choose one of the following:

- Right-click a mesh operation in the **Model Builder** and select **Identical Mesh** ( ).
- Click on the mesh operation in the **Model Builder** and select **Identical Mesh** from the **More Attributes** ( ) menu in The Mesh Toolbar.

TYPE OF IDENTITY

This section is only visible in 3D. From the **Geometric entity level** list, select to apply the identity on **Boundary** (default) or **Edge** level.

FIRST ENTITY GROUP

To start selecting the entities for the first entity group, click the **Active** button to toggle between turning ON and OFF selections. Select the entities in the mesh from in the **Graphics** window or from the **Selection List** window. If you activate this selection, the **Graphics** window shows the mesh of the source sequence such that you can select entities in this mesh.

SECOND ENTITY GROUP

To start selecting the entities for the second entity group, click the **Active** button to toggle between turning ON and OFF selections. Select the entities in the mesh from in the **Graphics** window or from the **Selection List** window. If you activate this selection, the **Graphics** window shows the mesh of the source sequence such that you can select entities in this mesh.

For a tutorial that uses **Identical Mesh**, see *Permanent Magnet Motor in 3D*: Application Library path **ACDC_Module/Devices,_Motors_and_Generators/pm_motor_3d**.

- Remeshing Imported Meshes
- Edge Map
- One-Point Map
- Two-Point MapCopy
- Copy Edge
- Copy Face

Imprint

Use **Imprint** ( ) to partition faces in a mesh by imprinting faces, edges, or vertices onto them, as seen in Figure 8-73. The mesh elements are partitioned by imprinted edges and vertices.

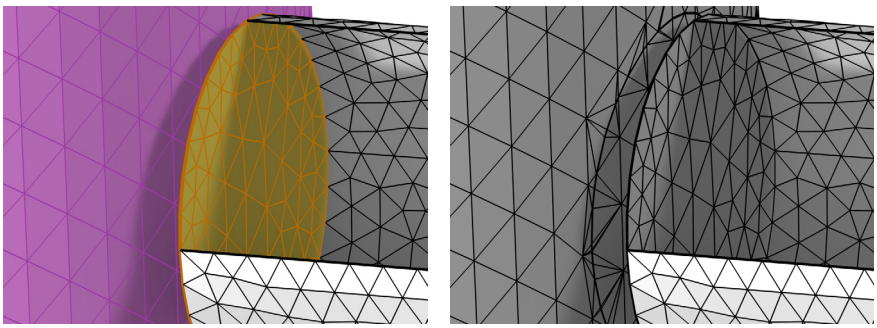

Figure 8-73: Imprinting the circular source face (yellow) onto the larger destination face (magenta) partitions the large boundary into two (right image). One of the cylinder boundaries is hidden for visibility.

	This operation is available for 3D models only.

The operation often generates triangles of bad quality close to imprinted edges. Use Remesh Faces, Free Triangular, Free Quad, Mapped, or Remesh Edges to remesh boundaries and edges. See Remeshing Imported Meshes for more information.

	The source edges or faces must be approximately (locally) in parallel with the destination faces and the distance must be relatively short (in the order of the local mesh size) between source and destination to get a good result. If the distance is larger and you get a distorted result, try setting **Placement of mesh vertices** to **Linear**.

To add an **Imprint** node, select entities to imprint in the **Graphics**, and then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Imprint** ( ) from the **Booleans and Partitions** menu.
- Select **Imprint** ( ) from the **Booleans and Partitions** ( ) menu on The Mesh Toolbar.
- Right-click the **Mesh** node and select **Imprint** ( ) from the **Booleans and Partitions** menu.

	Note that imprinting a mesh can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Imprint** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for **Imprint** using the following sections:

SOURCE

Select the geometric entity level of the source from the **Geometric entity level** list. The possible choices are **Boundary**, **Edge** (the default), or **Point**.

To start selecting the entities to imprint, from the **Selection** list, choose **All edges** (for example) or choose **Manual** to pick the entities from the **Graphics** window. Click the **Active** button to toggle between turning ON and OFF

selections. Select the entities to imprint in the mesh from in the **Graphics** window. If you activate this selection, the **Graphics** window shows the mesh of the source sequence such that you can select entities in this mesh.

Select the **Group adjacent edges** checkbox to automatically extend an edge selection to neighboring edges that seem to be part of the loop. If you clear this checkbox, each edge can be selected or deselected manually. This option is only available when **Geometric entity level** is set to **Edge**.

DESTINATION FACES

This section is similar to the **Source Entities** section above, but you use it to define the boundaries on which you want to imprint the source entities.

Select **Destination** (default) from the **Imprint on** list to imprint the source faces on the destination faces. Select **Destination and Source** to also imprint the destination faces on the source faces. This option is only available when **Geometric entity level** is set to **Boundary** in the **Source** section.

IMPRINT

Use the **Maximum distance** setting to control the maximum distance to bridge when imprinting entities of a mesh. Choose **Relative** to enter a value in the **Relative distance** field. This value is relative to the length of the longest side of the mesh's bounding box. Select **Absolute** to specify a value in the **Absolute distance** field. When the operation is built with the setting **Automatic** (the default), the value in the **Absolute distance** field is automatically updated to correspond to the actually used distance. The automatic tolerance is based on the size of the bounding box of the mesh.

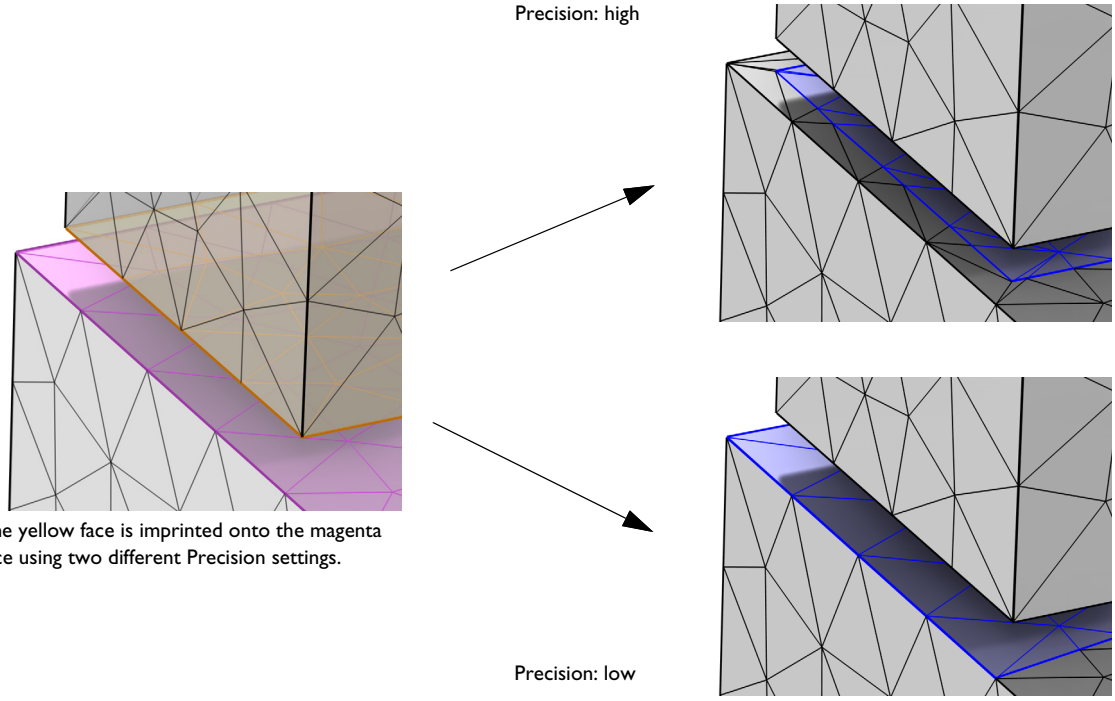
Use the **Placement of mesh vertices** setting to specify if the mesh vertices of the entities to be removed will be placed on the **Curved** (default) or **Linear** representation of the destination faces.

ENTITY MATCHING

This section is only available when the **Geometric Entity Level** in **Source** is set to **Boundary**.

Use the **Precision** field or slider to specify the accuracy of the imprint, as shown in Figure 8-74. A low precision will give a sloppier matching, meaning that regions of entities with approximately the same shape will be matched

without imprinting, while high precision gives a more accurate imprint but also means that small entities and details can appear.



The yellow face is imprinted onto the magenta face using two different Precision settings.

Figure 8-74: Imprinting a face onto another using two different Precision settings: high and low. The resulting face is highlighted in blue.

- Merge Entities
- Free Triangular
- Remesh Faces
- Remeshing Imported Meshes

Intersect with Line

Use **Intersect with Line** ( ) to intersect the elements of an imported mesh with a straight line, as shown in Figure 8-75. The selected geometric entities are partitioned by the line. A selection of domains will also lead to a partitioning of adjacent boundaries.

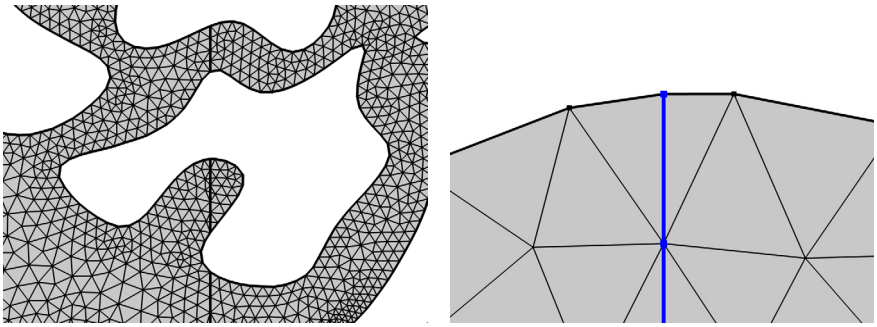


Figure 8-75: Partitioning the domain of an imported 2D mesh using the Intersect with Line operation (left). Zooming in on one of the intersections with the curved boundary (right) to show that the placement of the point is done on the curved representation of the boundary.

Use boundary selections only when there are no adjacent domains. For a selection of only boundaries, an error is given if the line intersects domains adjacent to the selection.

	This operation is available for 2D models only.

To add a **Intersect with Line** ( ) node, select domains in the **Graphics**, and then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Intersect with Line** ( ) from the **Booleans and Partitions** menu.
- Select **Intersect with Line** ( ) from the **Booleans and Partitions** ( ) menu on The Mesh Toolbar.
- Right-click the **Mesh** node and select **Intersect with Line** ( ) from the **Booleans and Partitions** menu.

	Note that intersecting a mesh can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Intersect with Line** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for **Intersect with Line** using the following sections:

GEOMETRIC ENTITY SELECTION

Define the geometric entities to intersect. From the **Geometric entity level** list: Choose **Entire geometry**, **Domain**, or **Boundary** to specify the domains or boundaries to partition with the line or choose a named selection to refer to a previously defined selection. The option **Entire geometry** selects all domains and boundaries.

POINT

From the **Specify** list, choose **Coordinates** (the default) to specify the positions of a point on the line. Enter values in the corresponding **x** and **y** fields. Alternatively, select **Vertex** to select a vertex.

DIRECTION

From the **Specify** list, choose **Direction vector** (the default) to specify the direction of the line using a vector. Enter values in the corresponding **x** and **y** fields. Alternatively, select **Second point coordinates** or **Second vertex** to let the line and its direction be defined by two points. For **Second point coordinates**, specify the coordinates in the corresponding **x** and **y** fields. For **Second vertex**, select a vertex.

VERTEX

Click the **Active** button to toggle between turning ON and OFF the vertex selection. To add a vertex to the selection, click on a vertex in the **Graphics** window or add one using the **Selection List**.

CLEANUP

The intersection of mesh elements can result in short mesh edges, relatively small mesh elements, and elements of poor element quality. To improve the quality of the mesh, cleanup is done by snapping mesh vertices. Mesh vertices on the intersected edges can be moved (snapped) to the line to ensure a straight intersection when cleanup is performed. To decrease the amount of snapping performed, lower the **Repair tolerance**.

Mesh vertices are snapped to the intersection line if both of the following apply:

- The mesh vertices are located within a distance, specified by the **Repair tolerance**, to the intersection line.
- The resulting mesh elements will not become inverted after snapping.

Use the **Repair tolerance** list to control the snapping distance by choosing **Automatic** (the default), **Relative**, or **Absolute**. Choose **Relative** to enter a value in the **Relative tolerance** field. This value is relative to the length of the longest side of the mesh bounding box. Select **Absolute** to specify a value in the **Absolute tolerance** field. When the operation is built with either of the settings **Automatic** or **Relative**, the values in the **Relative tolerance** (for **Automatic** only) and **Absolute tolerance** fields are automatically updated to be an average of the distances the mesh vertices were actually moved.

To ensure a straight intersection when cleanup is performed, mesh vertices on the intersected edges can be moved (snapped) to the line. This means that previously straight edges can become nonlinear after intersected with a line. Lower the **Repair tolerance** to respect the shape more closely.

Use the **Placement of mesh vertices** setting to specify if the new mesh vertices on the intersecting edges will be placed using a **Curved** (default) or **Linear** representation. See Figure 8-76.

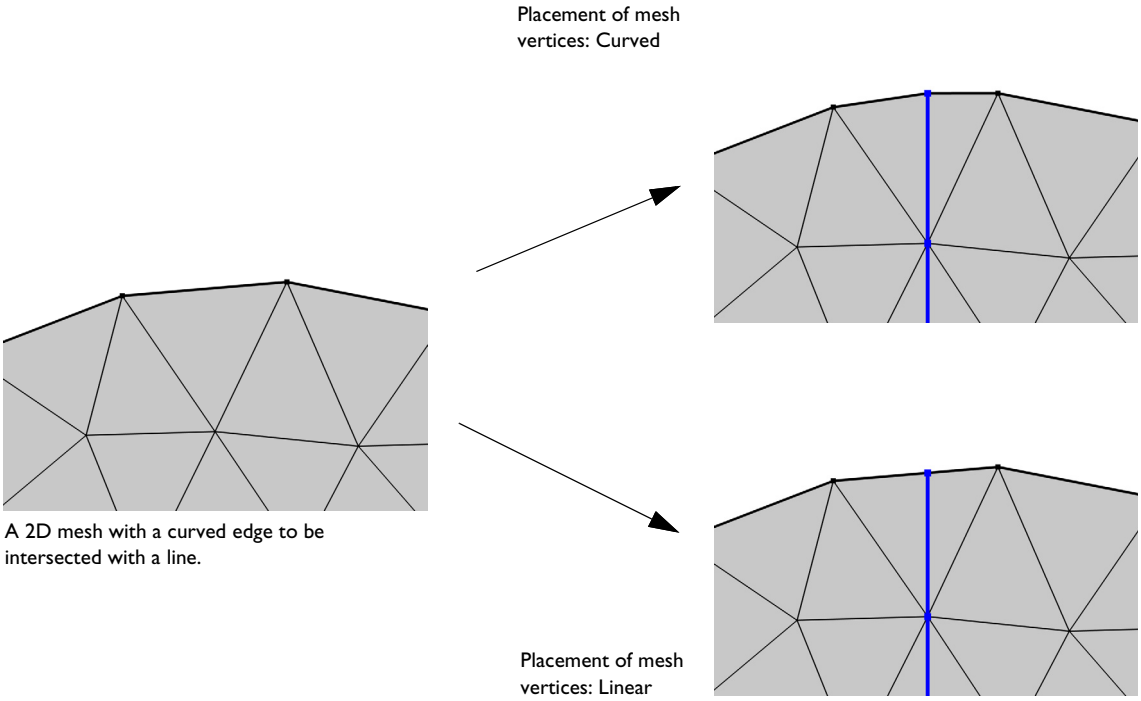

Figure 8-76: The mesh vertices on the intersection edge is placed on either a curved representation (upper right) or a linear representation (lower right).

SELECTIONS OF RESULTING ENTITIES

Select the **Intersection edges**, **Entities above**, and/or **Entities below** checkboxes to create predefined selections in subsequent nodes in the mesh sequence. To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), select the **Show in physics** (**Show outside part** if in a mesh part) checkbox or choose an option from the **Show in physics** (**Show outside part** if in a mesh part) list: **All levels**, **Domain selection**, **Boundary selection**, or **Point selection**. To keep the selection local to the mesh sequence/part, choose **Off**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

- Remesh Domains
- Intersect with Plane
- Partition with Ball
- Partition with Box
- Partition with Cylinder
- Partition by Expression
- Union

Intersect with Plane

Use **Intersect with Plane** ( ) to intersect the elements of an imported mesh with one or several parallel planes. The selected geometric entities are partitioned by the planes, as seen in Figure 8-77. A selection of domains will also lead to a partitioning of adjacent boundaries and edges. Closed regions formed by the edges in the intersection plane will be filled with meshed faces by default (see Intersections for more information).

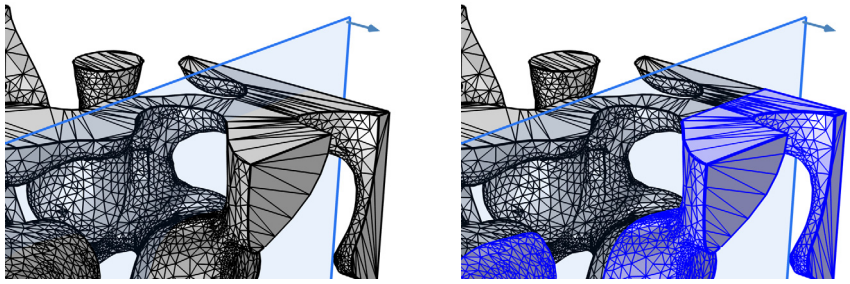

Figure 8-77: Intersecting an imported STL mesh with a plane (light blue) to partition the boundaries along the plane (highlighted blue in right image).

This operation is available for 3D models only.

To add an **Intersect with Plane** ( ) node, select the entities to intersect in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Intersect with Plane** ( ) from the **Booleans and Partitions** menu.
- Click **Booleans and Partitions** ( ) in The Mesh Toolbar and select **Intersect with Plane** ( ).
- Right-click the **Mesh** node and select **Intersect with Plane** ( ) from the **Booleans and Partitions** menu.

Note that intersecting a mesh can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Intersect with Plane** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for the **Intersect with Plane** node using the following sections:

GEOMETRIC ENTITY SELECTION

Define the geometric entities to intersect. From the **Geometric entity level list**: Choose **Entire geometry**, **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges to partition with the plane or choose a named

selection to refer to a previously defined selection. Only unmeshed domains are supported. The option **Entire geometry** selects all boundaries and edges.

The intersection of meshed domains is not supported. It is possible to build the operation as long as the specified planes do not intersect any meshed domain. To remove a domain mesh while keeping the boundary mesh, add a Delete Entities operation, add the domains to delete, and select the checkbox **Keep as unmeshed domains**. To later restore the domain mesh, add a Free Tetrahedral operation.

PLANE DEFINITION

Plane Type

The layout of the **Plane Definition** section depends on the selection in the **Plane type** list, where you select how to define the plane. Choose one of the following types:

- Quick (the default)
- Face parallel
- Edge parallel
- Normal vector
- Vertices
- Coordinates

Quick

In the **Plane** list, select one of the global coordinate planes *xy*, *yz*, *zx*, *yx*, *zy*, or *xz*, denoting the first and second axes of the plane's local coordinate system. Specify an offset using one of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance from the coordinate plane in the third axis' direction using the **z-coordinate**, **x-coordinate**, or **y-coordinate** field (default value: 0; that is, no offset).
- **Through vertex** to define the position of the plane by selecting a vertex. The plane's position then contains that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset Vertex** selections.

Face parallel

Select a planar face in the **Graphics** window that is parallel to the plane you want to create. The list below shows the selected face. Click the **Active** button to toggle between turning ON and OFF the **Planar Face** selections. Specify an offset using one of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance in the **Offset in normal direction** field. Default value: 0; that is, no offset. Enter a value to offset the plane along the normal of the planar face. The normal direction is indicated in the **Graphics** window, showing arrows in the corners of the visualization of the plane.
- **Through vertex** to define the position of the plane by selecting a vertex. The plane's position then includes the position of that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset Vertex** selections.

To reverse the orientation of the plane, select the **Reverse normal direction** checkbox.

Edge parallel

Select a planar edge (that is not straight) in the **Graphics** window that is parallel to the plane you want to create. The list below then shows the selected edge. Click the **Active** button to toggle between turning ON and OFF the **Planar Curved Edge** selections.

Specify an offset using one of the following settings in the **Offset type** list:

- **Distance** (the default) to define the distance in the **Offset in normal direction** field. Default value: 0; that is, no offset. Enter a value to offset the plane along the normal of the plane containing the edge. The normal direction is indicated in the **Graphics** window, showing arrows in the corners of the visualization of the plane.
- **Through vertex** to define the position of the plane in the third direction by selecting a vertex. The plane's position then includes the position of that vertex. Click the **Active** button to toggle between turning ON and OFF the **Offset Vertex** selections.

To reverse the orientation of the plane, select the **Reverse normal direction** checkbox.

Normal vector

Use this plane type to orient the plane with a prescribed normal vector.

Under **Normal vector**, in the **x**, **y**, and **z** fields (SI unit: m), enter the components of the normal vector.

Under **Point on plane**, from the **Specify** list, choose **Coordinates** (the default) or **Vertex**. For **Coordinates**, enter the coordinates for a point on the plane in the **x**, **y**, and **z** fields (SI unit: m). For **Vertex**, select a vertex in the geometry, or if available, use a user-defined vertex selection.

Vertices

In each of the lists **First vertex**, **Second vertex**, and **Third vertex**, select a vertex by first clicking the corresponding **Active** button and then selecting a vertex in the **Graphics** window. This creates a plane parallel to a plane through the three vertices.

Specify an offset in the **Offset in normal direction** field (default value: 0; that is, no offset). The normal direction is indicated in the **Graphics** window, showing arrows in the corners of the visualization of the plane. Reverse the orientation of the plane by selecting the **Reverse normal direction** checkbox.

Coordinates

This choice creates a plane through the three points with the given coordinates.

INTERSECTIONS

Select the **Additional parallel planes** checkbox to add several planes which will be parallel to the one specified above. Enter the desired plane offsets in the **Distances** field (using comma- or space-separated numbers), specifying the distances between each additional plane and the original plane. Both positive and negative values are allowed. Alternatively, use the **Range** button ( ) to create an array of values. The orientation of the first plane determines the orientation of generated faces and on what side additional planes are placed. Reverse the offset direction by selecting the **Reverse direction** checkbox (the positive direction is the normal direction of the first plane).

Use the **Create intersection faces** option to fill closed regions formed by the edges in the intersection plane (default ON). This results in planar faces meshed with an unstructured triangular mesh. For a domain selection, faces will only be created inside the selected domains. A warning that no faces could be created might be expected if only one boundary has been selected. To get rid of the warning, clear the **Create intersection faces** checkbox.

Creation of intersection faces is not supported for assembly pair boundaries and other entities that are geometrically coinciding but nonadjacent.

CLEANUP

Intersection of boundary and edge elements can result in short mesh edges, relatively small elements, and elements of poor element quality. To improve the quality of the mesh, cleanup is done by snapping mesh vertices and collapsing short mesh edges. Mesh vertices on the intersected faces and edges can be moved (snapped) to the plane

to ensure a planar intersection when cleanup is performed. To decrease the amount of snapping performed, lower the **Repair tolerance**.

Mesh vertices are snapped to the intersection plane if both of the following apply:

- The mesh vertices are located within a distance, specified by the **Repair tolerance**, to the intersection plane.
- The resulting mesh elements will not become inverted after snapping.

Use the **Repair tolerance** list to control the snapping distance by choosing **Automatic** (the default), **Relative**, or **Absolute**. Choose **Relative** to enter a value in the **Relative tolerance** field. This value is relative to the length of the longest side of the mesh bounding box. Select **Absolute** to specify a value in the **Absolute tolerance** field. When the operation is built with either of the settings **Automatic** or **Relative**, the values in the **Relative tolerance** (for **Automatic** only) and **Absolute tolerance** fields are automatically updated to be an average of the distances the mesh vertices were actually moved.

To ensure a planar intersection when cleanup is performed, mesh vertices on the intersected faces and edges can be moved (snapped) to the plane. This means that previously planar faces can become nonplanar after intersected with a plane. Lower the **Repair tolerance** to respect the shape more closely.

Use the **Placement of mesh vertices** setting to specify if the new mesh vertices on the intersection edge will be placed using a **Curved** (default) or **Linear** representation. See Figure 8-76.

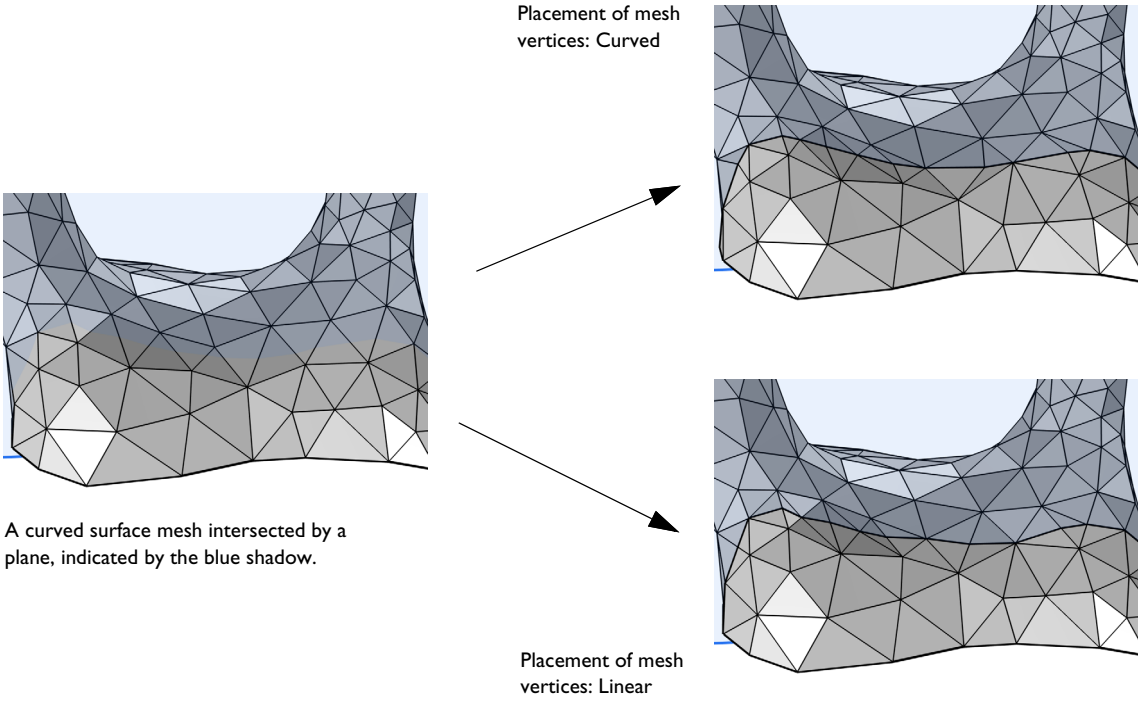

Figure 8-78: The new mesh vertices on the intersection edge are placed on either a curved representation (upper right) or a linear representation (lower right).

Select the **Cleanup of resulting mesh** checkbox to allow short mesh edges to be removed. Mesh edges shorter than the specified value in the **Repair tolerance** field will be collapsed as long as this does not result in an invalid mesh.

SELECTIONS OF RESULTING ENTITIES

Select all or some of the **Intersection Faces**, **Intersection edges**, **Entities above**, and **Entities below** checkboxes to create predefined selections in subsequent nodes in the mesh sequence. To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), select the **Show in physics** (**Show outside part** if in a mesh part) checkbox or choose an option from the **Show in physics** (**Show outside part** if in a mesh part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge Selection** or **Point selection**. To keep the selection local to the mesh sequence or mesh part, choose **Off**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

	STL Import 1 — Repairing and Combining STL Files: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes**

	• Remesh Faces • Free Triangular • Intersect with Line • Partition with Ball • Partition with Box • Partition with Cylinder • Partition by Expression • Union

Join Entities

Use **Join Entities** ( ) to join adjacent geometric entities in a mesh, as shown in Figure 8-79.

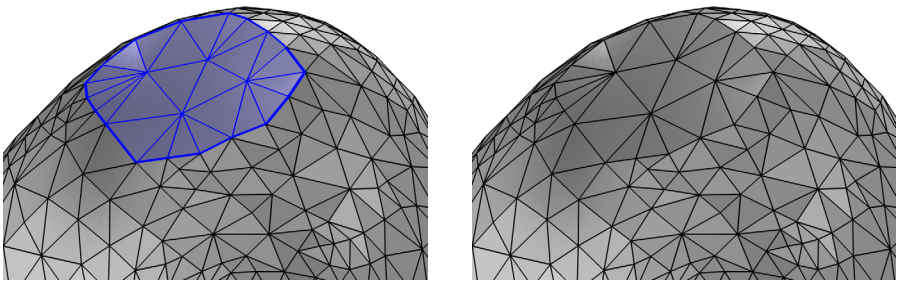

Figure 8-79: Using the Join Entities operation to join the blue and gray boundaries of this mesh (left image). The right image shows the resulting mesh with one boundary.

To add a **Join Entities** ( ) node, select the domains, boundaries, or edges to join in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window and select **Join Entities** from The Graphics Context Menu.

- In The Mesh Toolbar click the **Join Entities** ( ) button.
- Right-click a 2D or 3D **Mesh** node and select **Join Entities** ( ).

Note that joining entities can modify the number of geometric entities in the mesh. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Join Entities** node is added to this new sequence. For more information, see The Mesh Node.

Then use the following sections to specify the geometric entities to join:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to join. You choose the geometric entity level from the **Geometric entity level** list: Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to join or choose a named selection to refer to a previously defined selection. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

ADJACENT ENTITIES

Select the **Join adjacent lower dimensional entities** checkbox to also join the adjacent entities of lower dimensions (boundaries and edges for joined domains, for example).

Mapped

Use **Mapped** ( ) to generate a structured quadrilateral mesh on boundaries in 3D and domains in 2D, as shown in Figure 8-80. The operation can also be used to remesh meshes that define their own geometric model, such as imported meshes in 2D and 3D.

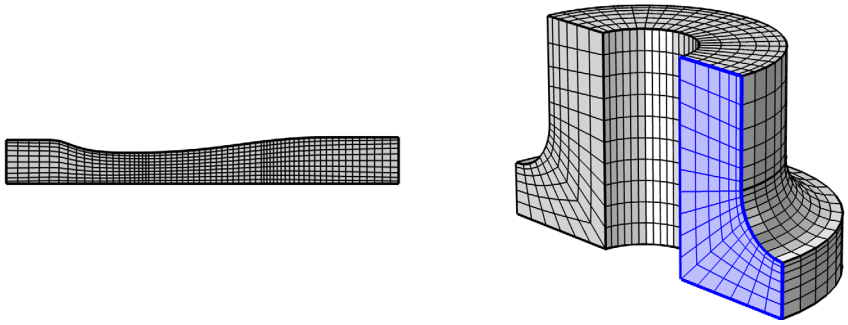

Figure 8-80: A mapped mesh in a 2D domain of a flow duct (left). The image on the right-hand side shows a mapped mesh on an L-shaped cross-section face (highlighted in blue) of a part of a shaft. The mapped mesh is swept through the 3D domain to arrive at a hexahedral volume mesh, using a Swept *operation.*

You can control the number, size, and distribution of elements using Size (only the Maximum element size parameter is used) and Distribution subnodes.

For a mesh that defines its own geometric model, use **Mapped** to remesh one or several faces. The mesh vertices are placed on a curved surface approximation of the input mesh.

Only surface meshes with first-order elements can be remeshed. Clear the **Import domain elements** checkbox in the mesh **Import** node to import only boundary elements. Select checkbox **Import as linear elements** to ignore second-order mesh data. See Importing Meshes for more information.

See The Mesh Node to learn more about meshes that define their own geometric model.

To create a mapped quadrilateral mesh for each domain (boundaries in 3D), the mapped mesher maps a regular grid defined on a logical unit square onto each domain. The mapping method is based on transfinite interpolation. The settings in the **Size** and **Distribution** nodes used by a **Mapped** node determine the density of the logical meshes. For the mapping technique to work, the opposite sides of each logical unit square must be discretized by the same number of edge elements.

By default, the relationship between the four sides of the logical unit square and the boundaries around a domain is based on a criterion related to the sharpest angle between boundaries. If you want to control this relationship, right-click the **Mapped** node to add an Edge Groups subnode.

2D Mapped Mesh Geometry

For the 2D mapped meshing technique to work properly, the geometry must be reasonably regular. The following conditions must be satisfied:

- Each domain must be bounded by at least four boundary segments.
- Each domain must be bounded by only one connected boundary component (that is, no holes are allowed).
- The domains must not contain isolated or embedded vertices or boundary segments.
- The shape of each domain must not differ significantly from a rectangle.

For a geometry that does not initially meet these criteria, it is usually possible to modify it so that a mapped mesh is generated, for example, by partitioning it into simpler domains, as shown in Figure 8-81. Consider using Mesh Control Operations to hide the added edges and points from the physics view.

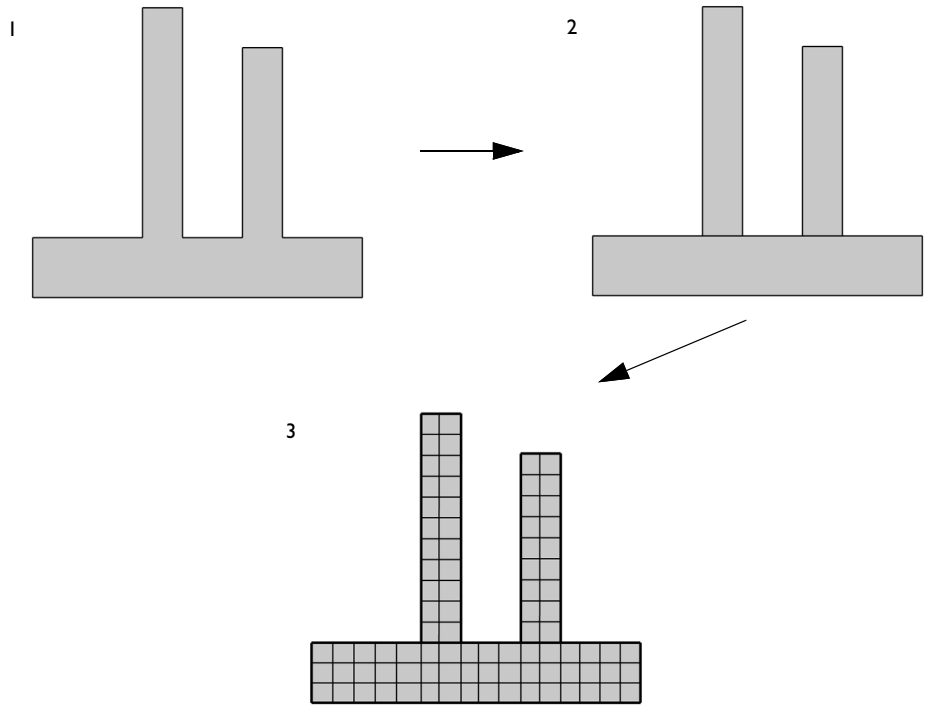

Figure 8-81: Partitioning a domain into smaller rectangular domains in order to build a mapped mesh. 1.Original domain where a mapped quad mesh cannot be created. 2. Partition the domain into three rectangular domains. 3. Resulting mapped mesh in the partitioned geometry.

To add a **Mapped** ( ) node, select boundaries (3D) or domains (2D) in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window and select **Mapped** ( ) from The Graphics Context Menu.
- From tThe Mesh Toolbar, choose **Mapped** from the **More Generators** menu ( ) (3D components) or click the **Mapped** ( ) button (2D components).
- In 2D, right-click a **Mesh** node and choose **Mapped** ( ). For 3D models, this is selected from the **More Generators** menu ( ) menu.

Then enter the properties for the mapped meshing operation using the following sections:

ENTITY SELECTION

Define the boundaries (3D) or domains (2D) where you want to create a mapped quad mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to specify mapped quad mesh for remaining, unmeshed domains.
- Choose **Entire geometry** to create a mapped quad mesh in the entire geometry.
- Choose **Boundary** (3D) or **Domain** (2D) to specify the geometric entities for which you want to create a mesh. Choose **Manual** from the **Selection** list to select the boundaries or domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All boundaries** (3D) or **All domains** (2D) to select all boundaries or all domains.

CONTROL ENTITIES

!	This section is not available for meshes that define their own geometric model.

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed Controlling the Mesh Size Using Mesh Control Entities. You can specify the number of smoothing iterations in

the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth for the mesh vertices to be smoothed.

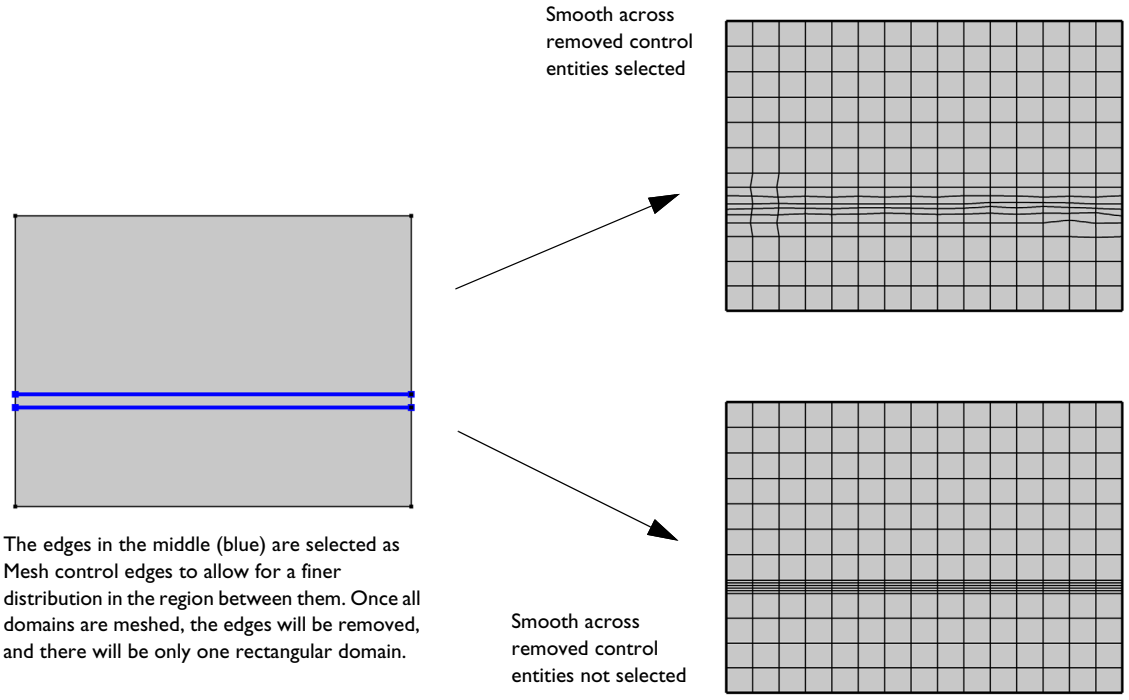

Figure 8-82: Comparing meshes where Smooth across removed control entities has been used vs. not used. The two edges (highlighted in blue in left image) adjacent to the domain in the middle are designated as Mesh Control Edges. *A finer distribution is set between the edges and when all domains are meshed, the edges are removed, leaving only one large rectangular domain. With the Smooth across removed control entities checkbox selected (upper right image), the mesher adjusts the sizes of the quad elements to get a smoother transition from large to small elements. Clear the checkbox to not adjust the mesh (lower right image).*

REDUCE ELEMENT SKEWNESS

Select the **Adjust edge mesh** checkbox (cleared by default) to allow the mapped mesher to adjust the mesh on edges that are not already meshed and where no explicit distribution is applied in order to reduce the element skewness (see Figure 8-83 below).

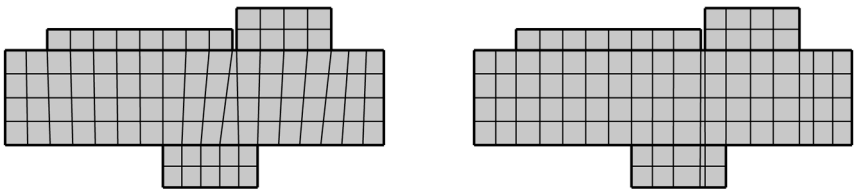

Figure 8-83: Images showing the effect of the Adjust edge mesh setting. The default mapped mesh (left) has some skewed elements. Turning on the Adjust edge mesh setting results in quads with angles closer to 90 degrees (image to the right).

ADVANCED SETTINGS

This section is available for 3D models only.

This section is not available for meshes that define their own geometric model.

In this section you can choose between two different interpolation methods in the **Interpolation method** list. This specifies how the mapped meshing operation determines the positions of the interior mesh vertices. Select **Automatic** (default) to let the mapped meshing operation determine a suitable interpolation method automatically. In many cases, the interpolation methods give the same result. If you select **Transfinite in 2D**, the positions of the interior mesh vertices are determined by transfinite interpolation in the 2D parameter space of the corresponding surface. This method works best for faces with smooth surface parameterization. If you select **Transfinite in 3D**, transfinite interpolation is done in 3D to determine these positions. This method works best if the shape of the exterior edges represent the shape of the surface in a good way.

Merge Entities

Use **Merge Entities** ( ) to merge entities of a 3D mesh, as shown in Figure 8-84. It is possible to merge boundaries, edges, and points by specifying entities to keep and the entities to remove. Depending on the specified maximum distance, only parts of the entities are merged, similar to the geometry operation Collapse Face Regions.

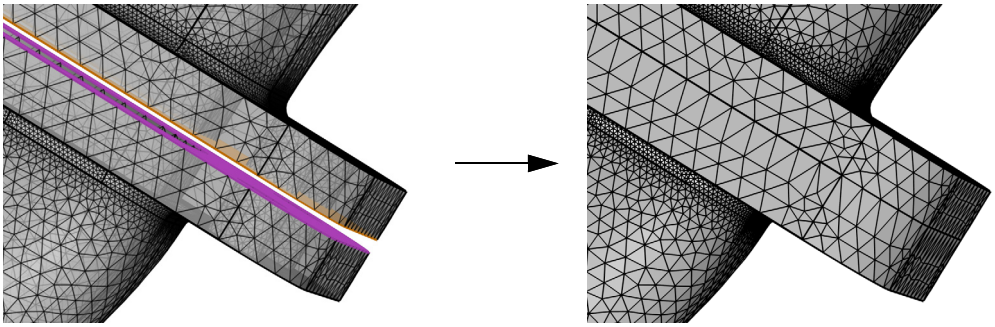

Figure 8-84: Merging two boundaries of two disconnected components in a mesh by specifying the boundary to keep (yellow) and the one to remove (magenta). The image to the right shows the result after the faces have been merged.

	This operation is supported in 3D models only.

	For a more automated operation to collapse small entities of a mesh, use Collapse Entities.

	If the mesh is conforming to a geometry, consider using Remove Details or any of the Virtual Geometry Operations to remove entities or to collapse narrow face regions already in the geometry.

To add a **Merge Entities** ( ) node, select one or several edges or boundaries in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu. Select **Merge Entities** ( ) from the **Cleanup and Repair** menu.
- In The Mesh Toolbar, choose **Merge Entities** from the **Cleanup and Repair** menu ( ).
- Right-click the **Mesh** node and choose **Merge Entities** ( ) from the **Cleanup and Repair** menu.

Enter the properties for **Merge Entities** using the following sections:

TYPE OF SELECTION

Select the dimension of the entities to merge using the **Geometric entity level** setting. The options are **Boundary** (default), **Edge**, and **Point**.

Use the option **Pairing of entities to keep and remove** to choose how to pair the entities to merge. Select **Automatic** (default) to enter all entities in the **Geometric Entity Selection** and let the operation choose which entities to keep

and which entities to remove. Select **Manual** to enter the entities to keep and remove in the **Entities to Keep** and **Entities to Remove**, respectively.

	You can inspect the automatically chosen entities to keep and remove by first building the operation with the **Automatic** setting and then switching to **Manual**.

GEOMETRIC ENTITY SELECTION

This section is visible if the option **Pairing of entities to keep and remove** is set to **Automatic**.

Click the **Active** button to toggle between turning ON and OFF selections. Select all the entities to merge, for example by clicking in the **Graphics** window.

ENTITIES TO KEEP

This section is visible if the option **Pairing of entities to keep and remove** is set to **Manual**.

Click the **Active** button to toggle between turning ON and OFF selections. Select the entities to keep, for example by clicking in the **Graphics** window.

Click the **Swap Entities to Keep and Remove** button ( ) to swap the entities in the selection to keep above and the entities in the selection to remove below.

ENTITIES TO REMOVE

This section is visible if the option **Pairing of entities to keep and remove** is set to **Manual**.

Click the **Active** button to toggle between turning ON and OFF selections. Select the entities to remove, for example by clicking in the **Graphics** window.

MERGE

Use the **Maximum distance** setting to control the maximum distance to bridge when merging entities of the mesh, as shown in Figure 8-85.

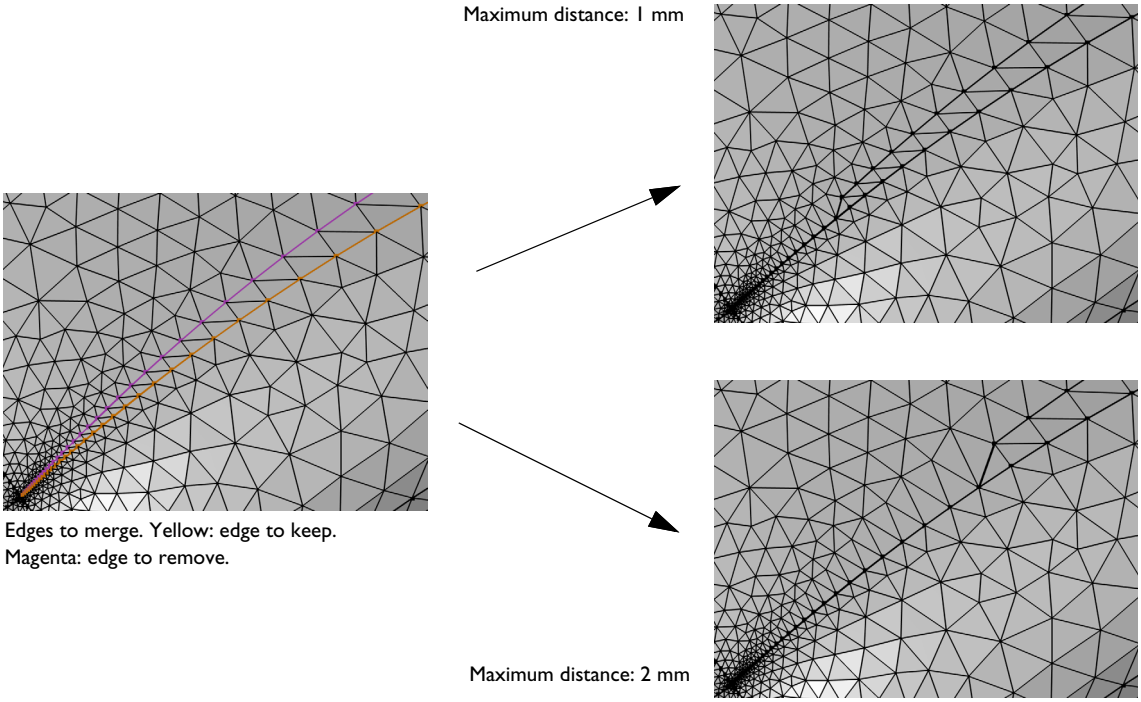

Figure 8-85: Merging two edges using different Maximum distance values. A larger value of the Maximum distance collapses a larger portion of the narrow face region.

Choose **Relative** to enter a value in the **Relative distance** field. This value is relative to the length of the longest side of the mesh's bounding box. Select **Absolute** to specify a value in the **Absolute distance** field. When the operation is built with the setting **Automatic** (the default), the value in the **Absolute distance** field is automatically updated to correspond to the actually used distance. The automatic tolerance is based on the size of the bounding box of the mesh.

Use the **Placement of mesh vertices** setting to specify if the mesh vertices of the entities to be removed will be placed on the **Curved** (default) or **Linear** representation of the entities to keep, as shown in Figure 8-86.

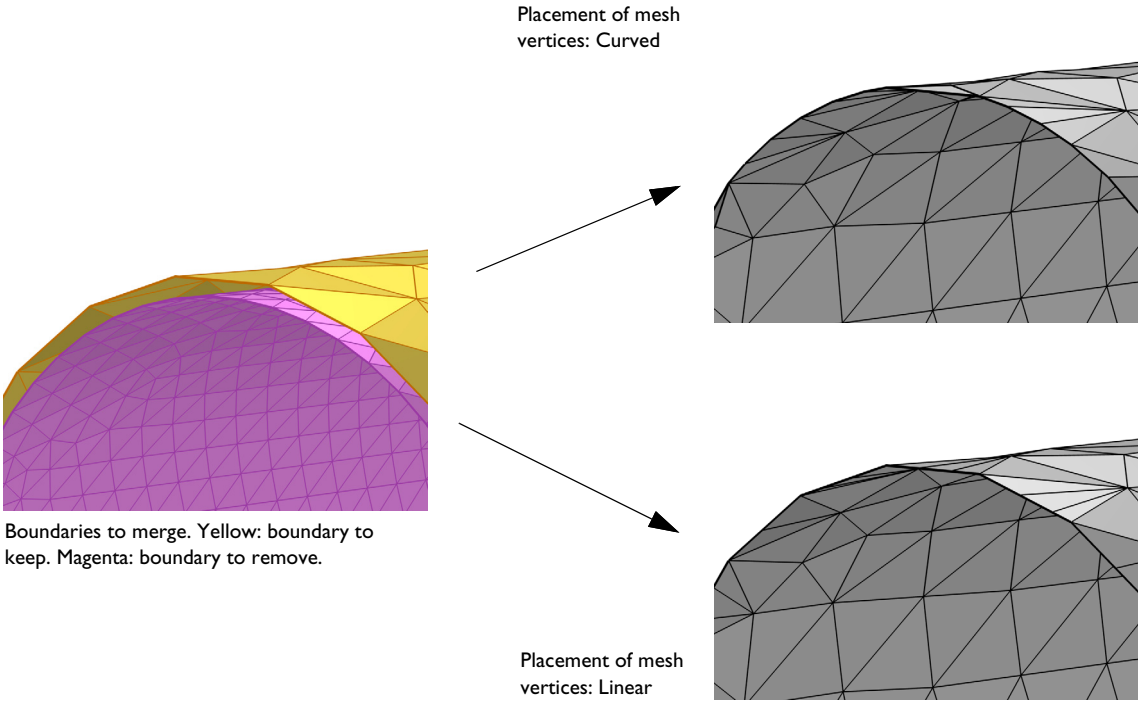

Figure 8-86: The mesh vertices of the boundary to remove is placed on the edge of the boundary to keep in either a curved representation (upper right) or a linear representation (lower right).

Use the **Deformation propagation** field (or slider) to determine how much of the deformation on the remove side is propagated further into the side to remove. A low value will only move the mesh vertices closest to the entity to remove while a high value will shift the whole connected component toward the keep side.

ENTITY MATCHING

Use the **Method** setting to specify the way to match a determined pair of entities to keep and remove. The method **Make imprints** means that the keep entities make an imprint on the remove entities and, symmetrically, the remove entities make an imprint on the keep entities. Then, only the overlapping imprints are merged.

Use the **Precision** field or slider to specify the accuracy of the imprint. A low precision will give a sloppier matching, meaning that regions of entities with approximately the same shape will be matched without imprinting, while high precision gives a more accurate imprint but also means that small entities and details can appear.

The method **One-to-one** forces the entities on the remove side to be matched with the keep side without any imprints. This is useful when the shape is approximately the same and you want to match them exactly. Note that if the entities have too different shape, the merge will generally not be successful with this option.

- Free Triangular
- Remeshing Imported Meshes
- Imprint

One-Point Map

Use the **One-Point Map** ( ) attribute to specify the orientation of the source mesh on the destination for a Copy, Copy Face, Copy Domain, or an Identical Mesh node. Using this node, the source mesh of the copy operation is transformed so that the source point of the **One-Point Map** node is mapped onto the destination point with the specified orientation, as shown in Figure 8-87.

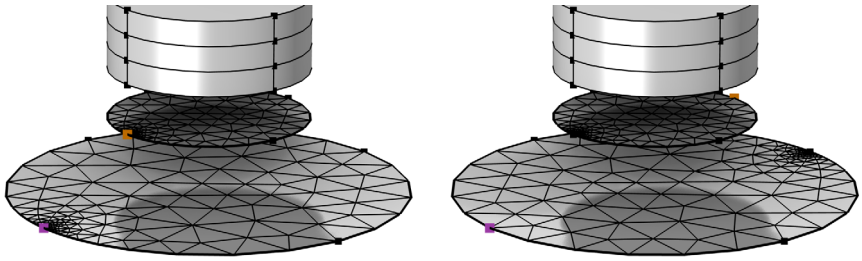

Figure 8-87: Specifying two different selections for a One-Point Map node when copying the mesh from the smaller circle (yellow source point) to the larger circle (magenta destination point).

To add **One-Point Map** node, choose one of the following:

- Right-click the Copy, Copy Face, Copy Domain, or an Identical Mesh node and select **One-Point Map** ( ) from The Model Builder Context Menu.
- When a **Copy Face**, **Copy Domain**, or **Identical Mesh** node is selected in the **Model Builder** tree, click **More Attributes** ( ) in the **Mesh** toolbar and select **One-Point Map** ( ).

Then enter the properties using the following sections:

POINT SELECTION

Click the **Active** button to toggle between turning ON and OFF selections.

- Activate the **Point on source** list and select the point that you want to define as source point in the **Graphics** window.
- Activate the **Point on destination** list and select the point that you want to define as destination point in the **Graphics** window.

- Copy
- Copy Face
- Copy Domain
- Edge Map
- Two-Point Map
- Identical Mesh

Partition with Ball

Use **Partition with Ball** ( ) to partition geometric entities of a mesh by creating at least one new geometric entity for the elements enclosed in the specified ball, as seen in Figure 8-88.

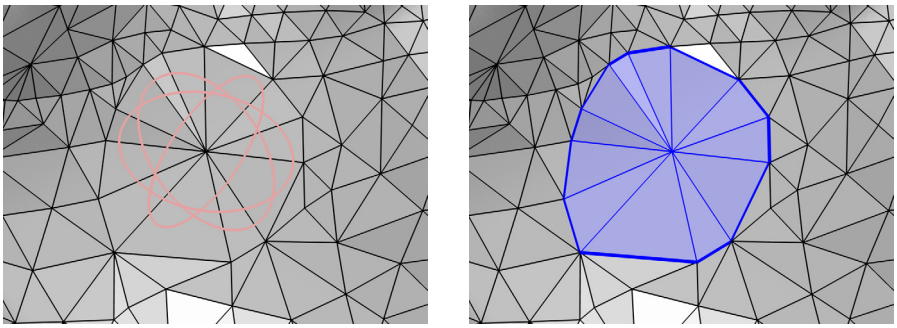

Figure 8-88: Using a Partition with Ball operation (left) to define a boundary (right) on which a boundary condition can be applied.

Note that partitioning a mesh can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Partition with Ball** node is added to this new sequence. For more information, see The Mesh Node.

To add a **Partition with Ball** ( ) node, select one or several entities in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu. Select **Partition with Ball** ( ) from the **Booleans and Partitions** menu.
- Click **Booleans and Partitions** ( ) on The Mesh Toolbar and select **Partition with Ball**.
- Right-click the **Mesh** node and select **Partition with Ball** ( ) from the **Booleans and Partitions menu**.

Enter the properties for the **Partition with Ball** node using the following sections:

Then use the following sections to specify the geometric entities to partition, the properties of the ball, and the condition for division:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to partition. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to divide all geometric entities according to the specified ball.
- Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to partition or choose a named selection to refer to a previously defined selection. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

BALL CENTER

Specify the center of the ball in the **x**, **y**, and **z** (only in 3D) fields (SI unit: m).

BALL RADIUS

Specify the radius of the ball in the **Radius** field (SI unit: m). The default radius is 1.

CONDITION

Use the **Include element if ball contains** list to select the condition for which the element is enclosed in the specified ball. Choose **All vertices** to consider an element to be enclosed in the specified ball if all element vertices are located inside, or choose **Some vertex** to consider it enclosed if at least one element vertex is located inside the ball.

SELECTIONS OF RESULTING ENTITIES

Select one or both of the **Entities inside** and **Entities outside** checkboxes to create predefined selections in subsequent nodes in the mesh sequence. To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show outside part** if in a mesh part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection** or **Point selection**. To keep the selection local to the mesh sequence or mesh part, choose **Off**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

- Partition with Cylinder
- Partition by Expression
- Union
- Detect Faces

Partition with Box

Use **Partition with Box** ( ) to partition geometric entities of a mesh by creating at least one new geometric entity for the elements enclosed in the specified box, as shown in Figure 8-89.

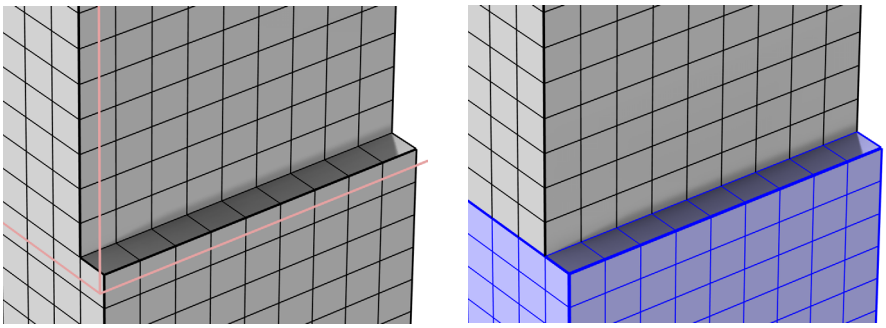

Figure 8-89: Using a Partition with Box node (left) to define two domains in the imported hex mesh (right).

To add a **Partition with Box** ( ) node, select one or several entities in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu. Select **Partition with Box** ( ) from the **Booleans and Partitions** menu.
- Click **Booleans and Partitions** ( ) on The Mesh Toolbar and select **Partition with Box**.
- Right-click the **Mesh** node and select **Partition with Box** ( ) from the **Booleans and Partitions menu**.

Enter the properties for the **Partition with Box** node using the following sections:

Note that partitioning a mesh can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Partition with Box** node is added to this new sequence. For more information, see The Mesh Node.

Then use the following sections to specify the geometric entities to partition, the properties of the box, and the condition for division:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to partition. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to divide all geometric entities according to the specified box.
- Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to partition or choose a named selection to refer to a previously defined selection. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

BOX LIMITS

Specify the limits of the box in the **x minimum**, **x maximum**, **y minimum**, **y maximum**, **z minimum** (3D only), and **z maximum** (3D only) fields.

CONDITION

Use the **Include element if box contains** list to select the condition for which an element is enclosed in the specified box. Choose **All vertices** to consider an element to be enclosed in the specified box if all element vertices are inside, or choose **Some vertex** to consider it enclosed if at least one element vertex is inside the box, as shown in Figure 8-90.

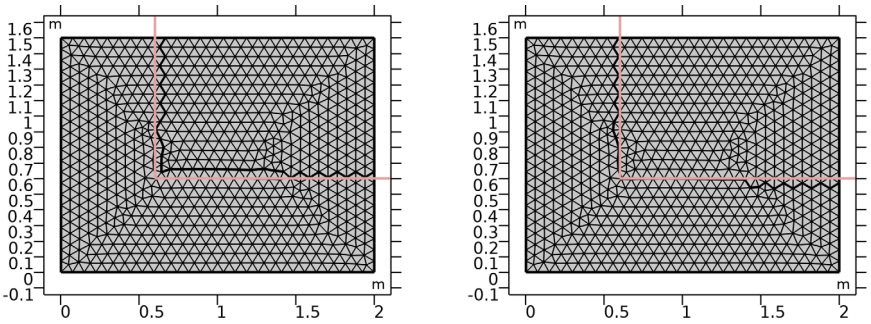

Figure 8-90: Partitioning a mesh of a rectangle with x and y minimum set to `0.6` *(pink lines) using different condition settings. The left image shows the result with Include element if box contains is set to All vertices. The right image shows the result with the condition set to Some vertex. The created edges follows the existing mesh edges.*

SELECTIONS OF RESULTING ENTITIES

Select one or both of the **Entities inside** and **Entities outside** checkboxes to create predefined selections in subsequent nodes in the mesh sequence. To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show outside part** if in a mesh part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection** or **Point selection**. To keep the selection local to the mesh sequence or mesh part, choose **Off**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree.

From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

Partition with Cylinder

Use **Partition with Cylinder** ( ) to partition geometric entities of a mesh by creating at least one new geometric entity for the elements enclosed in the specified cylinder.

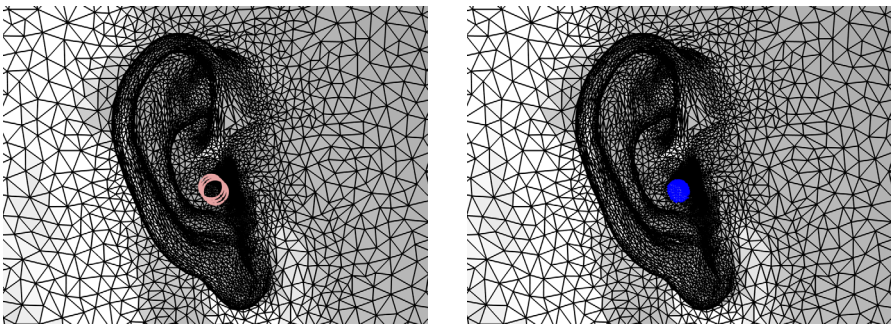

Figure 8-91: Using a Partition with Cylinder operation (pink edges) to define a boundary (highlighted blue) for the entrance to the ear canal on which to assign a Normal velocity boundary condition.

To add a **Partition with Cylinder** ( ) node, select one or several entities in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Partition with Cylinder** ( ) from the **Booleans and Partitions** menu.
- Click **Booleans and Partitions** ( ) on The Mesh Toolbar and select **Partition with Cylinder**.
- Right-click the **Mesh** node and select **Partition with Cylinder** ( ) from the **Booleans and Partitions menu**.

Enter the properties for **Partition with Cylinder** using the following sections:

Note that partitioning a mesh can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Partition with Cylinder** node is added to this new sequence. For more information, see The Mesh Node.

Then use the following sections to specify the geometric entities to partition, the properties of the cylinder, and the condition for division:

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to partition. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to divide all geometric entities according to the specified cylinder.
- Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to partition or choose a named selection to refer to a previously defined selection. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

SIZE AND SHAPE

Specify the radius of the cylinder in the field ***r*** and the positions of the upper and lower boundary circles in the **Top distance** and **Bottom distance** fields, respectively.

POSITION

Specify the position of cylinder in the **x**, **y**, and **z** fields.

AXIS

Use **Axis type** to set the direction of the cylinder axis. Choose **x-axis**, **y-axis**, or **z-axis** to let the cylinder axis coincide with one of the coordinate axes. It is also possible to customize the cylinder axis by choosing **Cartesian** or **Spherical** and using **x**, **y**, and **z**, or **theta** and **phi**, respectively.

CONDITION

Use the **Include element if cylinder contains** list to select the condition for an element to be enclosed in the specified cylinder. Choose **All vertices** to consider an element to be enclosed in the specified cylinder if all element vertices are inside, or choose **Some vertex** to consider it enclosed if at least one element vertex is inside the cylinder.

SELECTIONS OF RESULTING ENTITIES

Select one or both of the **Entities inside** and **Entities outside** checkboxes to create predefined selections in subsequent nodes in the mesh sequence. To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show outside part** if in a mesh part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection** or **Point selection**. To keep the selection local to the mesh sequence or mesh part, choose **Off**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

- Create Edges
- Intersect with Line
- Intersect with Plane
- Partition with Ball
- Partition with Box
- Partition by Expression
- Union
- Detect Faces

Partition by Expression

Use **Partition by Expression** ( ) to partition geometric entities of a mesh by creating at least one new geometric entity for the elements that fulfill the specified logical expression, as shown in Figure 8-92.

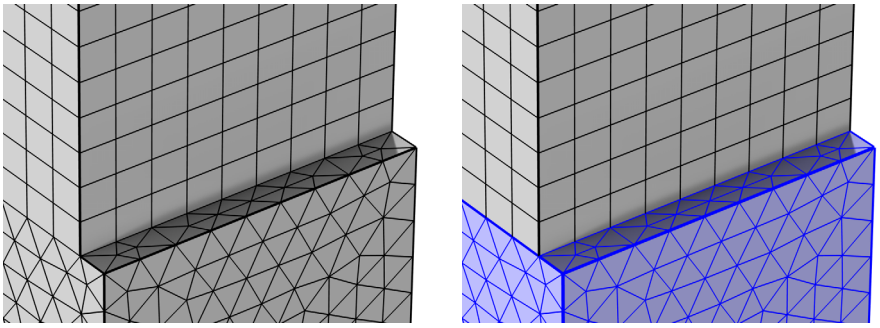

Figure 8-92: An imported mesh with hexahedral, tetrahedral, and prism elements in one single domain (left). Using a Partition by Expression with the Logical expression `ishex` *to define one domain for the hexahedral elements and one domain for the rest (right).*

To add a **Partition by Expression** node, select one or several entities in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu. Select **Partition by Expression** ( ) from the **Booleans and Partitions** menu.
- Click **Booleans and Partitions** ( ) on The Mesh Toolbar and select **Partition by Expression**.
- Right-click the **Mesh** node and select **Partition by Expression** ( ) from the **Booleans and Partitions menu**.

Enter the properties for **Partition by Expression** using the following sections:

Note that partitioning a mesh can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Partition with Expression** node is added to this new sequence. For more information, see The Mesh Node.

Then use the sections below to specify the geometric entities to partition, the logical expression, and the condition for division.

GEOMETRIC ENTITY SELECTION

Define the geometric entities that you want to partition. You choose the geometric entity level from the **Geometric entity level** list:

- Choose **Entire geometry** to divide all geometric entities according to the specified cylinder.
- Choose **Domain**, **Boundary**, or **Edge** to specify the domains, boundaries, or edges, respectively, that you want to partition or choose a named selection to refer to a previously defined selection. Use **All domains**, **All boundaries**, or **All edges** to select all entities of the specified dimension.

EXPRESSION

Enter a logical expression using `x`, `y`, or `z` (3D only); the mesh size `h` and mesh quality `qual*` (see Mesh Element Quality); Unary, Binary, and List Operators and Their Precedence Rules; and Mathematical and Numerical Constants in the **Logical expression** field. For instance, the expression `(x*x+y*y)<1` defines a ball partition in 2D and an infinite cylinder division in 3D. You can also use the Boolean variables `istri`, `isquad`, `istet`, `ispyr`, `isprism`, or `ishex` in the expression in order to partition the mesh according to the respective element type (triangular, quadrilateral, tetrahedral, pyramid, prism, or hexahedral, respectively). For instance, the expression `istet` makes a separate domain for each connected set of tetrahedra, while the expression `ispyr || ishex` makes a separate domain for each connected set of elements containing pyramids or hexahedra. You can also use the `meshelement` variable to partition the mesh. For example, if you know that elements 1 to 10 are a separate domain, write `meshelement<=10` to partition this as a separate domain.

By default, the expression is set to 1, not inducing any split of geometric entities.

CONDITION

Use the **Include element if expression is fulfilled for** list to select the condition for which the logical expression is fulfilled for an element. Choose **All vertices** to make an element satisfy the expression if it is true for all element vertices, or choose **Some vertex** if it is true for at least one element vertex.

SELECTIONS OF RESULTING ENTITIES

Select one or both of the **Entities fulfilling expression** and **Entities not fulfilling expression** checkboxes to create predefined selections in subsequent nodes in the mesh sequence. To also make the selections available in all applicable selection lists outside the mesh sequence or mesh part (in physics and materials settings, for example), choose an option from the **Show in physics** (**Show outside part** if in a mesh part) list: **All levels**, **Domain selection**, **Boundary selection**, **Edge selection** or **Point selection**. To keep the selection local to the mesh sequence or mesh part, choose **Off**. The default is **Domain selection**, which is suitable for use with materials and physics defined in domains. For use with a boundary condition, for example, choose **Boundary selection**. These selections do not appear as separate selection nodes in the model tree. From the **Color** list, choose a color for highlighting the resulting objects selection. See Selection Colors and Creating Named Selections in the Mesh Sequence.

- Intersect with Line
- Intersect with Plane

- Union
- Detect Faces

Reference

Use **Reference** ( ) to refer to another meshing sequence. Building a **Reference** node runs the operation nodes of the referenced sequence. If you have a Scale node before a **Reference** node, or as a subnode to a **Reference** node, you can create a finer or coarser version of the mesh generated by the referenced sequence.

To add a **Reference** node, choose one of the following:

- In The Mesh Toolbar from the **Modify** ( ) menu, select **Reference** ( ).
- Right-click a **Mesh** node and select **Reference** in the **Modifying Operations** submenu.

Then use the following section to specify the sequence to reference:

REFERENCE

Select the meshing sequence to reference.

It is possible to *expand* a reference (that is, replacing the reference with a copy of the referred sequence). If the reference node has a **Scale** subnode, the attribute nodes in the expanded sequence are scaled accordingly. In some cases, such scaling of attributes cannot be done explicitly, and additional scale nodes are created instead.

To expand a reference, right-click **Reference** node and select **Expand** ( ).

Refine

Use **Refine** ( ) to refine a mesh by splitting elements by either splitting the longest side of an element, or by inserting centerpoints, as seen in Figure 8-93.

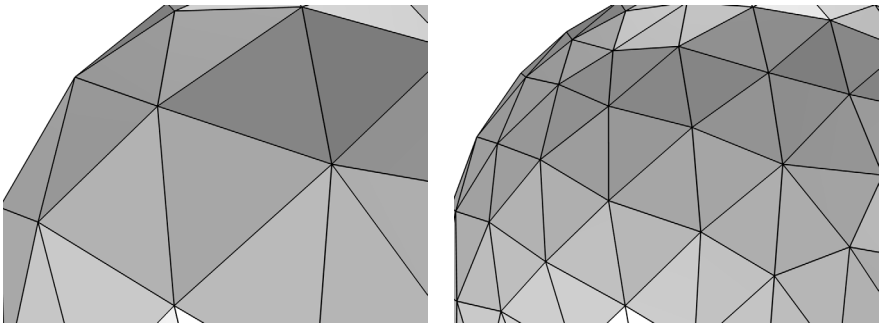

Figure 8-93: A tetrahedral mesh (left) is refined once using the method Regular refinement (right).

To add a **Refine** ( ) node, select one or several entities in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu. Select **Refine** ( ) from the **Modifying Operations** menu.
- Click **Modify** ( ) on The Mesh Toolbar and select **Refine**.
- Right-click the **Mesh** node and select **Refine** ( ) from the **Modifying Operations** menu.

Then use the following sections to specify the parts of the mesh to refine and the method used to refine the elements:

DOMAIN SELECTION

Define the domains where you want to refine the mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to refine the entire mesh.
- Choose **Domain**, **Boundary** (2D and 3D), or **Edge** (3D only) to specify the domains, boundaries, or edges for which you want to refine the mesh. Choose **Manual** from the **Selection** list to select the domains, boundaries, or edges in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains**, **All boundaries**, or **All edges** to select all domains, all boundaries, or all edges, respectively.

REFINE OPTIONS

Refinement Method

From the **Refinement method** list, select **Regular refinement** or **Split longest side**. The regular refinement method bisects each edge of the element. The result is (with one exception) 2^(element dimension) new elements of the same type. For example, a triangle is split into four triangles; a prism element is split into eight prisms. The pyramid element is the exception: It is split into six pyramids and four tetrahedra. The longest side refinement method bisects the longest edge of each element. This method is generally not suitable for nonsimplex meshes because the refinement destroys the structured nature of such meshes; if you bisect one edge of a regular quad element, you get a triangle and a rather skewed quad element. For 1D elements, these methods are equivalent. For 1D models, this option is excluded.

Number of Refinements

Choose the number of consecutive mesh refinements from the **Number of refinements** list (the default is one refinement).

If you want to control the refinement by an element size expression rather than a fixed factor, you can use the **Adapt** node (see Adapt).

FACE REPRESENTATION

Specify which representation to use for the refinement. The setting only affects how mesh vertices are placed on curved faces.

The **Face representation** setting is only available for 3D meshes that define their own geometric model. A typical example is a mesh imported from file.

Select:

- **Linear** to place new or moved mesh vertices on the input mesh. The resulting mesh will keep the shape of the input mesh to a great extent, as seen in the upper right image in Figure 8-94.
- **Curved** to place new or moved mesh vertices on a curved surface approximation of the input mesh. On curved faces where the mesh has been refined, the resulting mesh will typically be smoother than the input mesh, as seen in the lower right image in Figure 8-94.

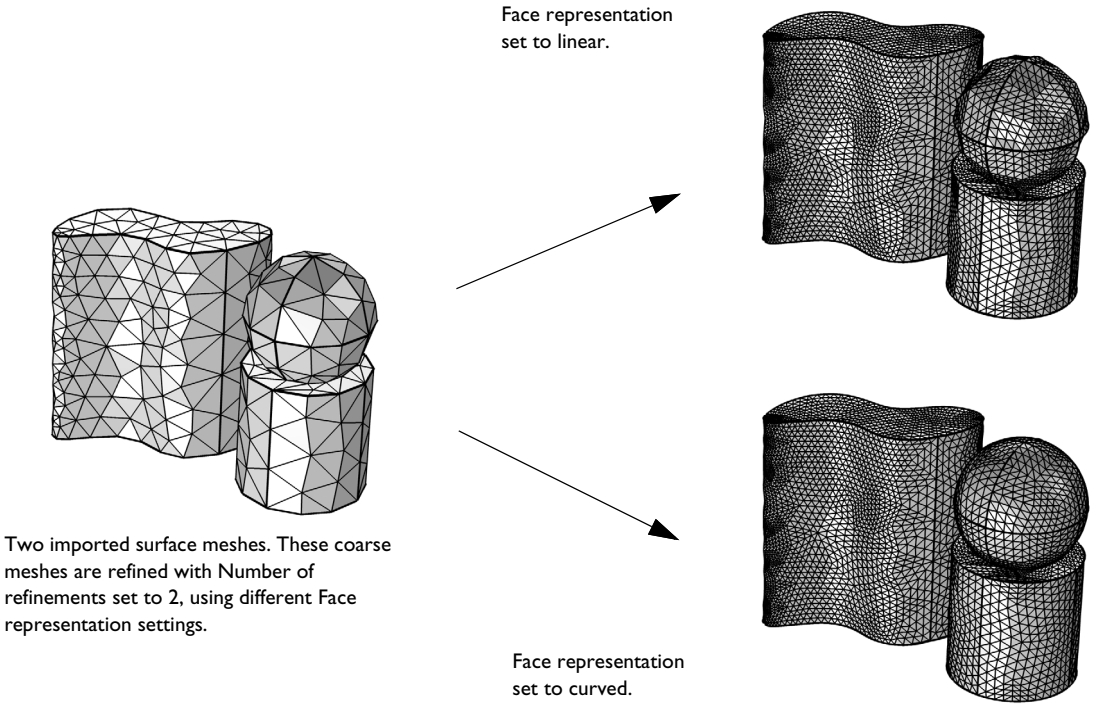

Figure 8-94: Two imported surface meshes (left) are refined using the Refine operation. Set the Face representation to Linear to keep the shape of the input mesh (upper right). Use the setting Curved to get a smoother mesh as a curved approximation of the surfaces is used when placing the new mesh vertices. (lower right).

REFINE ELEMENTS IN BOX

Check **Specify bounding box** to refine the mesh only within a box. If you refine the mesh only on certain domains, the mesh is refined only in the intersection between the box and the domains.

Specify the box either by entering the coordinates of the lower-left corner and upper-right corner of the box or click **Draw box** to interactively specify the box (only available in 2D).

- Adapt
- Modifying the Element Size Using Refine and Adapt

Remesh Domains

Use **Remesh Domains** ( ) to modify the mesh in 2D domains, as seen in Figure 8-95. This operation is supported for meshes that define their own geometric models, such as imported meshes.

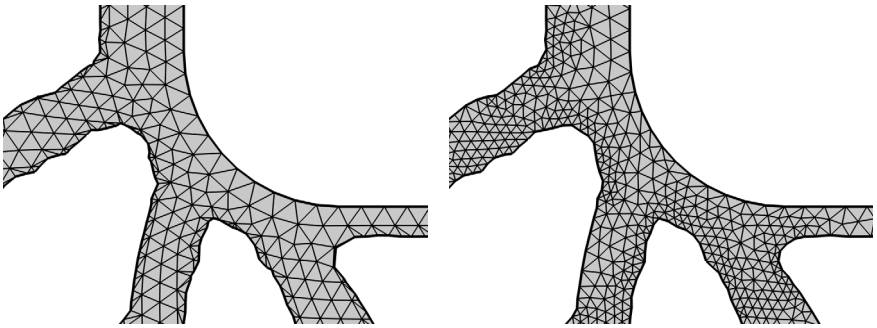

Figure 8-95: The filter dataset of a topology optimization imported and remeshed to improve the quality of the mesh for a verification study.

This operation is available for 2D models only.

The attributes Corner Refinement, Distribution, and Size control the element size on boundaries and edges. The **Remesh Faces** operation also remeshes the adjacent edges and may therefore modify the mesh on adjacent domains. Use the Fixed Mesh attribute to keep the edge mesh on adjacent boundaries fixed when remeshing. Use the Identical Mesh attribute to specify groups of boundaries where identical mesh is needed.

To add a **Remesh Domains** node, select one or several domains in the **Graphics**, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Remesh Domains** ( ).
- In The Mesh Toolbar, choose **Remesh Domains** from the **More Generators** ( ) menu.
- Right-click a **Mesh** or **Mesh Part** node and choose **Remesh Domains** ( ).

Then enter the properties for the remeshing operation using the following sections:

DOMAIN SELECTION

Specify the domains that you want to remesh. Use **All domains** to select all domains in the mesh, select **Manual** to specify the domains by clicking in the **Graphics** window or selecting from the **Selection List**, or choose a named selection to refer to a previously defined selection.

- Remeshing Imported Meshes
- Size
- Distribution
- Fixed Mesh
- Identical Mesh
- Boundary Layers
- Modifying the Element Size Using Refine and Adapt

Remesh Edges

Use **Remesh Edges** ( ) to modify the edge mesh (3D) or boundary mesh (2D) of a mesh that defines its own geometric model, such as an imported mesh, as seen in Figure 8-96.

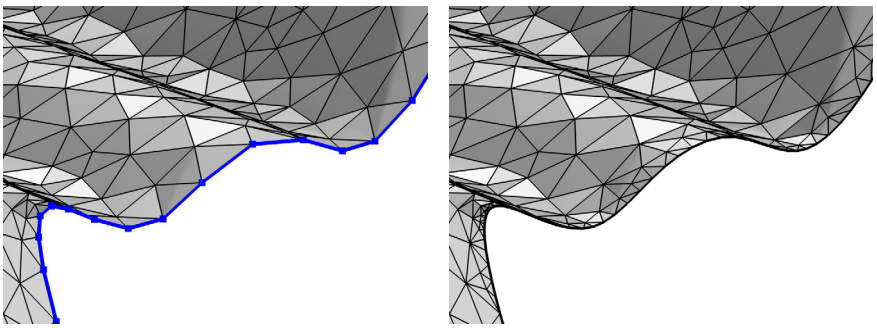

Figure 8-96: Remeshing the edge of an imported mesh (left) using Remesh Edges (right).

	Remesh Edges modifies the mesh of adjacent faces (3D only) and domains

The attributes Corner Refinement, Distribution, and Size control the element size on edges. Use the Identical Mesh attribute to specify boundaries or edges where identical mesh is needed.

To add a **Remesh Edges** node, select one or several edges (3D) or boundaries (2D) in the **Graphics**, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Remesh Edges** ( ).
- In The Mesh Toolbar, choose **Remesh Edges** from the **More Generators** ( ) menu.
- Right-click a **Mesh** or **Mesh Part** node and choose **Remesh Edges** ( ). In 3D, it is available from the **More Generators** menu.

Then enter the properties for the remeshing operation using the following sections:

ENTITY SELECTION

Specify the edges (3D) or boundaries (2D) that you want to remesh. Use **All edges/All boundaries** to select all entities of that dimension in the mesh, select **Manual** to specify the edges/boundaries by clicking in the **Graphics** window or selecting from the **Selection List**, or choose a named selection to refer to a previously defined selection.

This section is only available in 3D.

Select the **Preserve shape of adjacent faces** checkbox (selected by default) to allow the operation to analyze the shape of adjacent faces to preserve the shape of the faces when remeshing the edges. Clear the checkbox to use a linear representation and only account for the shape of the edge when remeshing it.

- Remeshing Imported Meshes
- Fixed Mesh
- Modifying the Element Size Using Refine and Adapt

Remesh Faces

Use **Remesh Faces** ( )to modify the mesh on boundaries in 3D, as seen in Figure 8-97. Supported for meshes that define their own geometric model, such as imported meshes. After remeshing the faces, use Free Tetrahedral to fill the domains with a tetrahedral mesh.

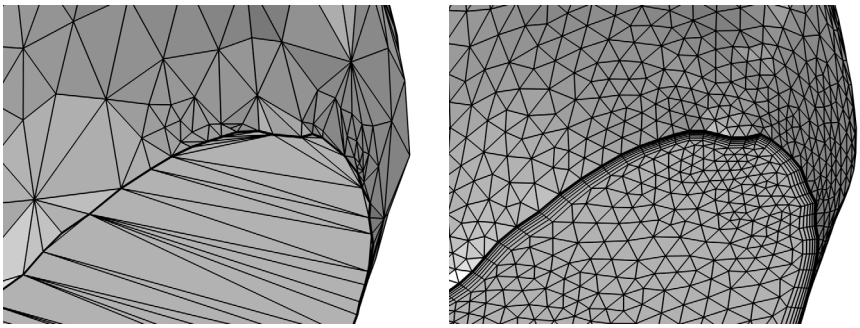

Figure 8-97: Remeshing an imported STL mesh (left) using the Remesh Faces operation (right).

This operation is available for 3D models only.

The **Remesh Faces** operation also remeshes the adjacent edges which will affect the meshes on adjacent faces. If the face is adjacent to a meshed domain, also the adjacent domain mesh will be modified. Since the domain mesh will put constraints on what operations can be done on the mesh, it is typically better to first remove the domain mesh, remesh the faces, and finally mesh the domain again.

To remove domain elements, either clear the **Import domain elements** checkbox in the Import operation or add a **Delete Entities** operation on **Domain** level with the **Keep as unmeshed domains** checkbox selected.

The attributes Corner Refinement, Distribution, and Size control the element size on boundaries and edges. Use the Fixed Mesh attribute to keep the edge mesh on adjacent edges fixed when remeshing. Use the Identical Mesh attribute to specify groups of boundaries or edges where identical mesh is needed.

To add a **Remesh Faces** node, select one or several boundaries in the **Graphics**, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Remesh Faces** ( ).
- In The Mesh Toolbar, choose **Remesh Faces** from the **More Generators** ( ) menu.
- Right-click a **Mesh** or **Mesh Part** node and choose **Remesh Faces** ( ) from the **More Generators** menu.

Then enter the properties for the remeshing operation using the following sections:

BOUNDARY SELECTION

Specify the boundaries that you want to remesh. Use **All boundaries** to select all boundaries in the mesh, select **Manual** to specify the boundaries by clicking in the **Graphics** window or selecting from the **Selection List**, or choose a named selection to refer to a previously defined selection.

NARROW DOMAIN REGIONS

Select the **Resolve narrow domain regions** checkbox (selected by default) to allow the element size to be smaller close to narrow domain regions, as shown in Figure 8-98. This option is useful if the adjacent domain will be filled with a tetrahedral mesh. Clear the checkbox to mesh each boundary without accounting for narrow domain regions. This will give a coarser mesh, as seen in the following image:

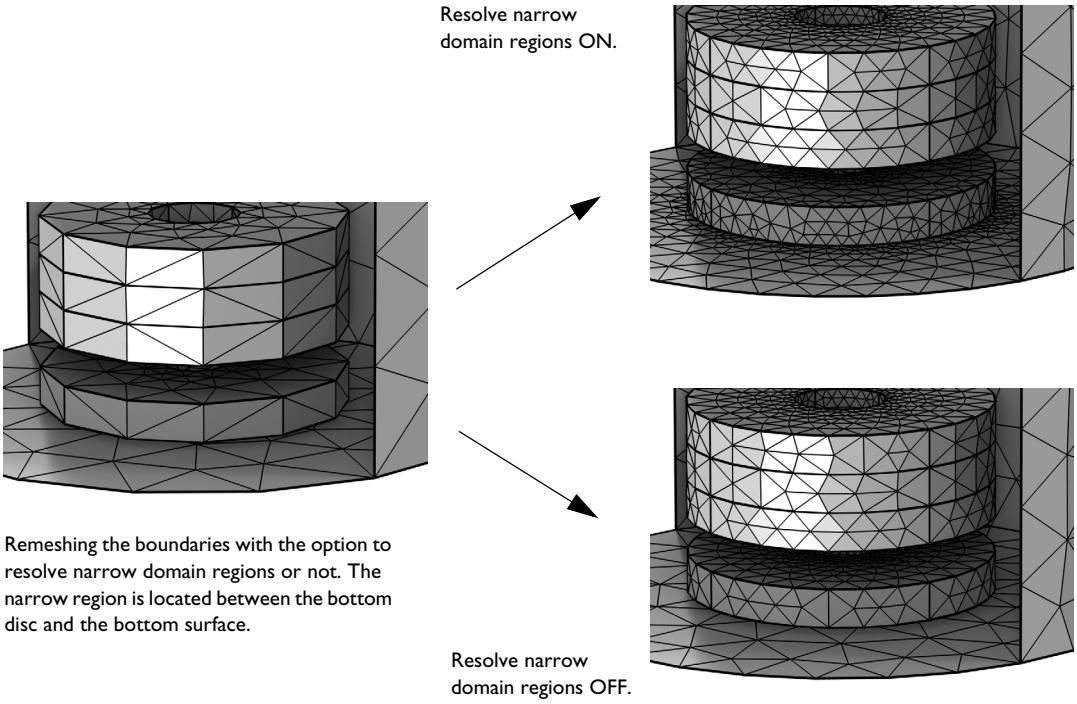

Figure 8-98: Remeshing an imported mesh using the option Resolve narrow domain regions. Turning on the option resolves the surface mesh close to the narrow region (upper right).

FACE REPRESENTATION

Specify which representation to use when remeshing the boundaries. The setting only affects how mesh vertices are placed on curved faces.

- Select **Linear** to place new or moved mesh vertices on the input mesh. The resulting mesh will keep the shape of the input mesh to a great extent.
- Select **Curved** (default) to place new or moved mesh vertices on a curved surface approximation of the input mesh. On curved faces where the mesh has been refined, the resulting mesh will typically be smoother than the input mesh.

- Remeshing Imported Meshes
- Remesh Edges
- Fixed Mesh
- Identical Mesh
- Size
- Distribution
- Corner Refinement

Scale

Use the **Scale** node ( ) to scale the properties of Attributes nodes, as shown in Figure 8-99. It is possible to add **Scale** nodes both as global nodes and as local nodes to Reference nodes. A **Scale** attribute that exists as a global node affects the size of the mesh elements generated by the subsequent operation nodes. A **Scale** attribute that exists as a subnode to a **Reference** node affects the size of the mesh elements generated by the **Reference** node only.

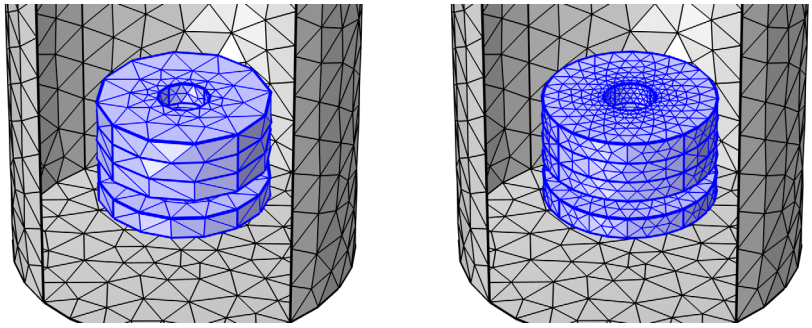

Figure 8-99: Tetrahedral mesh built with the predefined size Normal (left). Scaling the element size on the selected domains (blue) by `0.5`.

Global vs. Local Attributes

If two or more **Scale** nodes exist on the same selection, the resulting scale factor on that selection is the product of the given scale factors.

To add **Scale** ( ) as a global node, choose one of the following:

- Click **Sizing** ( ) in The Mesh Toolbar and select **Scale** ( ).
- Right-click the **Mesh** node and select **Scale** ( ).

To add **Scale** ( ) as a subnode, right-click a Reference node and select **Scale**.

Then use following sections to specify the scaling properties:

GEOMETRIC SCOPE

In this section you define the geometric entities where you want to specify a scale. Choose the level of the geometry from the **Geometric entity level** list.

- Choose **Entire geometry** to specify the scale for the entire geometry.
- Choose **Domain**, **Boundary**, **Edge** (3D), or **Point** (2D and 3D) to specify the domains, boundaries, edges, or points for which you want to refine the mesh. Choose **Manual** from the **Selection** list to select the domains, boundaries, edges, or points in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains**, **All boundaries**, **All edges**, or **All Points** to select all domains, all boundaries, all edges, or all points, respectively.

SCALE

Specify the scale factor in the **Element size scale** field.

A scale factor less than 1 gives smaller (more) elements; a scale greater than 1 gives larger (fewer) elements.

It is not possible to use a coarser mesh size setting on a geometric entity adjacent to a higher dimensional entity with a finer mesh size setting; the finer setting on a geometric entity overrides the coarser setting on its boundary. Therefore a scale factor larger than 1 might have no effect if the dimensional level of the selection is less than the space dimension.

- Global vs. Local Attributes
- Boundary Layer Properties
- Distribution
- Size
- Reference

For tutorials using the **Scale** attribute, see:

- *Magnetic Lens*: Application Library path **ACDC_Module/Electromagnetics_and_Particle_Tracing/magnetic_lens**.
- *Drug Delivery System*: Application Library path **CFD_Module/Multiphase_Flow/drug_delivery_mm**.

Size

Use the **Size** ( ) attribute to specify the size of mesh elements, as shown in Figure 8-100. It is possible to add Size nodes both as global nodes and as local nodes. If there are several **Size** nodes in the sequence with a nonempty selection intersection, the mesher uses properties corresponding to the last Size node in the sequence.

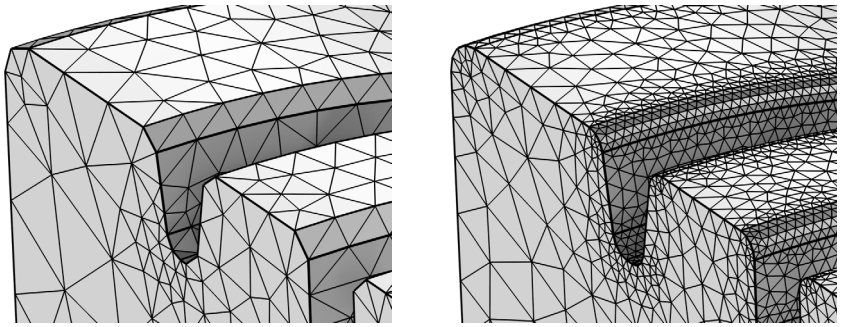

Figure 8-100: Meshing an imported CAD geometry with the predefined size Normal (left). Meshing the same geometry with the predefined size Finer resolves the fillets and other curved boundaries better.

A meshing sequence corresponding to a nonempty geometry contains a Size node at the first position in the sequence. This Size node, referred to as the *default Size node*, is defined for the entire geometry and cannot be removed. To override the mesh size settings defined by this Size node, add another Size node to the sequence.

To add **Size** ( ) as a global node, choose one of the following:

- Right-click a **Mesh** node and select **Size** ( ).
- Click **Sizing** ( ) in The Mesh Toolbar and select **Size**.

To add **Size** ( ) as a local attribute, right-click a mesh operation in the **Model Builder** and select **Size**.

Global vs. Local Attributes

GEOMETRIC ENTITY SELECTION

This section is not available for the default Size node.

In this section you define the geometric entities where you want to specify a size. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to specify the size for the entire geometry.
- Choose **Domain**, **Boundary**, **Edge** (3D), or **Point** (2D and 3D) to specify the domains, boundaries, edges, or points for which you want to refine the mesh. Choose **Manual** from the **Selection** list to select the domains, boundaries, edges, or points in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains**, **All boundaries**, **All edges**, or **All Points** to select all domains, all boundaries, all edges, or all points, respectively.

ELEMENT SIZE

Different types of physics typically require different mesh resolutions. You can use the **Calibrate for** list to adapt the element sizing to a specific physics area or application. The default values of the parameters under **Element Size**

Parameters will be adjusted according to the selected options in the **Calibrate for** and **Predefined** lists. The **Calibrate for** list contains the following options:

- **General physics**
- **Fluid dynamics**
- **Plasma**
- **Semiconductor**
- **Coarse mesh for adaptation**
- **Time-explicit wave propagation**

The default element size is **Predefined** and set as **Normal**. See Controlling the Mesh Size Using Attributes and Predefined Mesh Element Sizes for details about the options. This automatically determines the parameters that you can otherwise customize under **Element Size Parameters**.

Select **Custom** if you want to change the value for any parameters in the **Element Size Parameters** section.

ELEMENT SIZE PARAMETERS

This section is available when **Custom** is selected as the **Element Size**. Specify all element size parameters using numerical values or user-defined parameters.

Except for the default **Size** node, if you select a **Custom** element size above, the checkboxes are automatically added next to each field. Click to select a checkbox to activate, and edit, the corresponding parameter.

The following parameters control the mesh element size (the parameters where you define a size use the geometry's length unit). Defaults vary based on whether it is a default node or not. Edit the default values as required for the following fields:

- **Maximum element size**: Use this parameter to limit the allowed element size, for example, if you want to limit the maximum element size to a fraction of the wavelength to make sure that the wave propagation is fully resolved. By using a parametric sweep to vary the maximum element size, you can solve the model using meshes with different mesh density to study how it affects the solution.
- **Minimum element size**: Use this parameter to specify the minimum allowed element size. You can use this value to, for example, prevent the generation of many elements around small curved parts of the geometry. If some details of the geometry are smaller than the minimum element size, the mesh will contain elements of a smaller size in order to resolve the geometry. This parameter is not available in 1D.
- **Maximum element growth rate**: Use this parameter to determine the maximum rate at which the element size can grow from a region with small elements to a region with larger elements. The value must be greater or equal to one. For example, with a maximum element growth rate of 1.5, the element size can grow by at most 50% (approximately) from one element to another.
- **Curvature factor**. Use this parameter to determine the size of boundary elements compared to the curvature of the geometric boundary (that is, the ratio between the boundary element size and the curvature radius). The curvature radius multiplied by the *curvature factor*, which must be a positive scalar, gives the maximum allowed element size along the boundary. A smaller curvature factor gives a finer mesh along curved boundaries. This parameter is not available in 1D.
- **Resolution of narrow regions**: Use this parameter to control the number of layers of elements that are created in narrow regions (approximately). The value must be a nonnegative scalar. A higher value gives a finer mesh in

narrow regions. If the value of this parameter is less than one, the mesh generator might create elements that are anisotropic in size in narrow regions.

There is no guarantee that all mesh elements in the generated mesh strictly fulfill the size constraints given by the specified element size parameters.

It is not possible to use a coarser mesh size setting on a geometric entity adjacent to a higher dimensional entity with a finer mesh size setting; the finer setting on a geometric entity overrides the coarser setting on its boundary. A warning is given when coarser settings are overridden.

For a tutorial about adjusting the mesh size, see

- *Adjusting the Element Size for the Unstructured Mesh Generator*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/piston_mesh**.
- *Using Meshing Sequences*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/meshing_sequence**.

- Meshing Operations and Attributes
- Free Tetrahedral
- Free Triangular
- Free Quad

Size Expression

Use the **Size Expression** (a=) attribute to specify the size of mesh elements as an expression evaluated on a grid (as shown in Figure 8-101), a computed solution, or a temporary solution corresponding to the initial value of a study step.

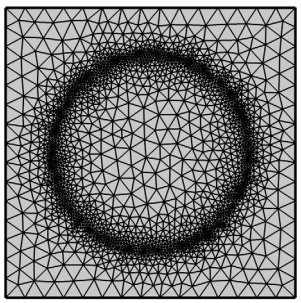

Figure 8-101: The Size Expression max(abs(sqrt(x^2+y^2)-0.05), 0.002) evaluated on a grid.

It is possible to add a **Size Expression** node both as a global node and as a local node. Free Triangular, Free Tetrahedral, and Free Quad operations that follow below the **Size Expression** node in the meshing sequence take the size expression into account.

For some types of adaptation and error estimation in the study settings (using mesh initialization), the adaptive solver add a **Size Expression** node to the meshing sequences that represent the adaptive mesh generation, but you

can also add a **Size Expression** node to set up a mesh size expression of your choice. Right-click a **Mesh** node to add a **Size Expression** node from the context menu.

Only one **Size Expression** node per meshing sequence is supported.

To add **Size Expression** ( ) as a global node, choose one of the following:

- Right-click a **Mesh** node and select **Size Expression** ( ).
- In The Mesh Toolbar, click **Sizing** ( ) and select **Size Expression** ( ).

To add **Size Expression** ( ) as a local attribute, right-click a mesh operation and select **Size Expression**.

Global vs. Local Attributes

Enter the properties for **Size Expression** using the following sections:

GEOMETRIC ENTITY SELECTION

In this section you define the geometric entities where you want to specify a size expression. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Entire geometry** to specify the size expression for the entire geometry.
- Choose **Domain**, **Boundary**, **Edge** (3D), or **Point** (2D and 3D) to specify the domains, boundaries, edges, or points for which you want to refine the mesh. Choose **Manual** from the **Selection** list to select the domains, boundaries, edges, or points in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains**, **All boundaries**, **All edges**, or **All Points** to select all domains, all boundaries, all edges, or all points, respectively.

ELEMENT SIZE EXPRESSION

From the **Evaluate on** list, choose **Grid** (the default), **Solution,** or **Initial expression** to specify whether the evaluation is done on a grid, a solution, or an expression evaluated using initial values.

Evaluation on a Grid

Use the **Size expression** field to enter an expression for the absolute element size as a function of x, y, and z (depending on the space dimension). You can also use parameters and global functions, variables, and materials in the expression, but no features from the component are available. The actual size used in a coordinate is the minimum of the specified size expression and the result of the other size parameters (such as the maximum element size and the curvature factor), but this minimum is cut off by the specified minimum element size on a given entity, which acts as a lower bound. If the expression evaluates to something smaller than the minimum element size, you get a warning that the value was cut off.

The **Size expression** field uses the unit system defined by the component. The evaluated value of the expression is interpreted as a length in the geometry's unit system.

Size expressions that can be evaluated on boundaries only cannot be used for geometries with domains, even if they are applied only on the boundary.

To control the grid, you can specify the **Grid type**, which can be **Resolution**, where you specify the number of isotropic cells per dimension in the grid in the **Number of cells per dimension** field (which only accepts positive integer constant values), or **Cell size**, where you specify the side length of a grid cell in the **Side length** field.

Evaluation on a Solution

From the **Solution** list, select the solution to use for evaluation.

From the **Solution selection** list, select which solution to use for evaluate error estimates:

- Select **Use last** to use the last solution.
- Select **Use first** to use the first solution.
- Select **All** (the default for Eigenvalue studies) to use all solutions from that study.
- Select **Manual** to use a specific solution number that you specify as solution indices in the **Index** field.

In the **Weights** field (only available when **Solution selection** is **Manual** or **All**), enter weights as a space-separated list of positive (relative) weights so that the error estimate is a weighted sum of the error estimates for the various solutions (eigenmodes). The default value is 1, which means that all the weight is put on the first solution (eigenmode). That is, any omitted weight components are treated as zero weight.

From the **Type of expression** list, choose **Error indicator** (the default) or **Absolute size**.

Error Indicator

If you select **Error indicator**, the following settings appear:

The **Error expression** list, where you can add expressions for the error, for example, in terms of the dependent variables (including the variables for error estimation). You can use any expression, including field variables and their derivatives, defined in the domain. Use the **Active** column to control which error expressions that are active by selecting or clearing the corresponding checkbox.

The **Error order** column is available when **Element selection** is set to **Rough global minimum** and forms an array of h-exponents for the decrease of the error expression. This array has the same indexing as the error expression's indexing (for an error expression with two expressions, such as `errexpr1`, `errexpr2`, and error orders = 2, 3, it means that `errexpr1` = $O(h^2)$ and `errexpr2` = $O(h^3)$). When the adaptation method is used, these numbers are filled in automatically based on the **Residual order** and **Error estimate** settings (on the adaptation study). The shape functions can also influence this order. Note that these order numbers need to be positive to generate additional elements (element growth).

Use the **Move Up** (↑), **Move Down** (↓), **Add** (+)and **Delete** ( ) buttons as needed. If you use several expressions, such as one for each solution component, the error expressions are added to form the sum of all of them. Or right-click a table cell and select **Move Up**, **Move Down**, **Add**, or **Delete**.

In 2D, use the **Refinement method** list to control how to refine mesh elements. Select:

- **Longest** to make the solver refine only the longest edge of an element.
- **Regular** to make the solver refine elements in a regular pattern.

Use the **Element selection** list to specify how the element refinement vector is determined from the error expression. Select:

- **Rough global minimum** to minimize the L_2 norm of the error by refining a fraction of the elements with the largest error in such a way that the total number of elements increases roughly by a factor greater than 1 specified in the accompanying **Element growth rate** field. The default value is 1.7, which means that the number of elements increases by roughly 70%.

- **Fraction of worst error** to refine elements whose local error indicator is larger than a given fraction of the largest local error indicator. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the fraction contains the elements with more than 50% of the largest local error.
- **Fraction of elements** to refine a given fraction of the elements. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the solver refines about 50% of the elements with the largest local error indicator.

Absolute Size

If you select **Absolute size**, the following setting appears:

In the **Size expression** field, type an expression for the element size (in terms of variables defined by the solution).

The **Size expression** field uses the unit system defined by the component. The evaluated value of the expression is interpreted as a length in the geometry's unit system.

Size expressions that can be evaluated on boundaries only cannot be used for geometries with domains, even if they are applied only on the boundary.

Evaluation Using an Initial Expression

With this option, you can use a size expression that contains variable values in physics, material data, and settings made in the study (such as a frequency), with the same evaluation as you get when running **Get Initial Value for Step** on a study step. A typical application could be to adapt the mesh size to a (nonconstant) wavelength.

From the **Mesh** list, select a mesh (on the same geometry as the **Size Expression** node) on which the interpolation is done. If **Automatic** (the default) is chosen, a mesh will be created automatically.

From the **Study step** list, choose a study step (for which **Get Initial Value for Step** will be run). If you choose **None** (the default), an empty study is created. The mesh that was specified above is used in the referenced or empty study step that you choose. These actions take place in a copy of the model and are therefore not visible in the **Model Builder** tree.

Use the **Size expression** field to enter an expression for the absolute element size as a function of x, y, and z (depending on the space dimension). You can also use variables and materials from the physics, parameters, and global functions and materials in the expression. The actual size used in a coordinate is the minimum of the specified size expression and the result of the other size parameters (such as the maximum element size and the curvature factor), but this minimum is cut off by the specified minimum element size on a given entity, which acts as a lower bound. If the expression evaluates to something smaller than the minimum element size, you get a warning that the value was cut off.

The **Size expression** field uses the unit system defined by the component. The evaluated value of the expression is interpreted as a length in the geometry's unit system.

Size expressions that can be evaluated on boundaries only cannot be used for geometries with domains, even if they are applied only on the boundary.

The following settings are available under **External changes**:

There is a caching scheme that caches various data required to compute the mesh size field. If you have changed something in the model, which has not been picked up by the code and thus invalidated the cache, you can clear the cache by clicking **Reevaluate with Updated Model**.

The selection in the **Update when parameter is changed** list provides the possibility to have the cache cleared whenever the values of the selected parameter are changed.

SMOOTHING

In this section, you can control the amount of smoothing of the mesh size expression. The **Maximum size field growth rate** (default: 1.4) controls how fast the size field can grow. It is a factor that must be larger than 1.0. Use a higher value to make the mesh coarser closer to areas with a small mesh size, which results in fewer mesh elements.

- Global vs. Local Attributes
- Size
- Distribution
- Boundary Layers

For a tutorial using **Size Expression**, see

- *Transient Gaussian Explosion*: Application Library path **Acoustics_Module/Tutorials,_Pressure_Acoustics/gaussian_explosion**.

Swept

Use **Swept** ( ) to generate a swept mesh on a domain in 3D by sweeping the mesh from the source faces along the domain to the opposite destination faces, as shown in Figure 8-102. A swept mesh is an example of a semistructured mesh since it is structured in the sweep direction and can be either structured or unstructured orthogonally to the direction of the sweep. A swept mesh is typically a hexahedral mesh (hex mesh) or a prism mesh.

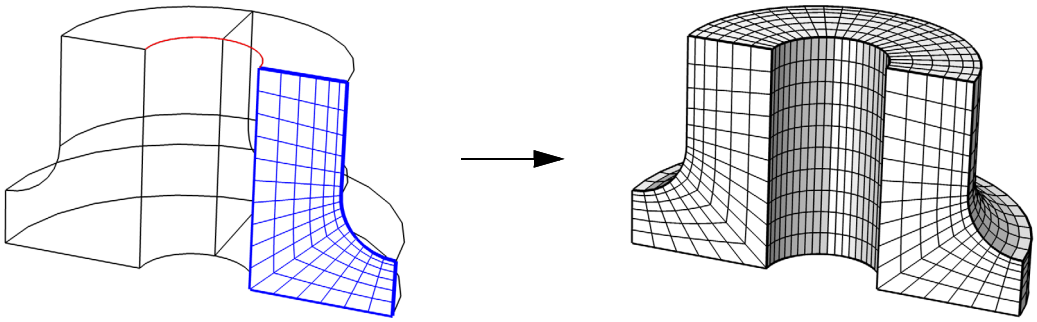

Figure 8-102: Generation of a hexahedral mesh. A mapped mesh is built on the source face, highlighted in blue. This mesh is swept along the circular linking edges (highlighted in red), resulting in a hexahedral mesh, as shown to the right.

See the Learning Center resource *Using Swept Meshes for Model Geometries* for more examples and animations: https://www.comsol.com/support/learning-center/article/48941/152

The **Swept** operation is available both for meshing sequences that generate mesh for a geometry and for meshes that define their own geometric model.

See The Mesh Node for more information about meshes that define their own geometric models.

You can control the number, size, and distribution of elements using the Size and Distribution subnodes. The **Swept** operation only reads properties from **Size** nodes defined on the entire geometry or on the domain level and **Distribution** nodes defined on the domain level.

Classifications

Each face about a domain that is to be operated on by the swept mesher is classified as either a *source face*, a *destination face*, or a *linking face*. The linking faces are the faces connecting the source and destination faces, as shown in Figure 8-103.

The *linking edges* are the edges, or the chains of edges, that are approximately tangent to the sweep direction. The *section edges* are the edges, or chains of edges, that are approximately perpendicular to the sweep direction.

A *section* is a face component bounded by two loops of section edges.

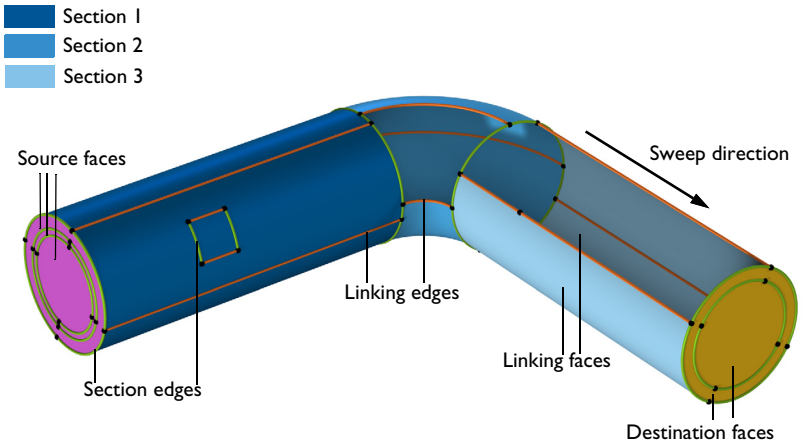

Figure 8-103: Classification of the boundaries and edges about a domain used for swept meshing. The sections are depicted by the three shades of blue. If the number of faces differ on source and destination, the source will always have the larger number of faces. Two faces are hidden to show the inside of the domain.

Requirements

For the sweeping technique to work, the geometry must satisfy these criteria:

- Each domain must not contain holes or isolated faces except if they penetrate both source and destination (see Figure 8-104).

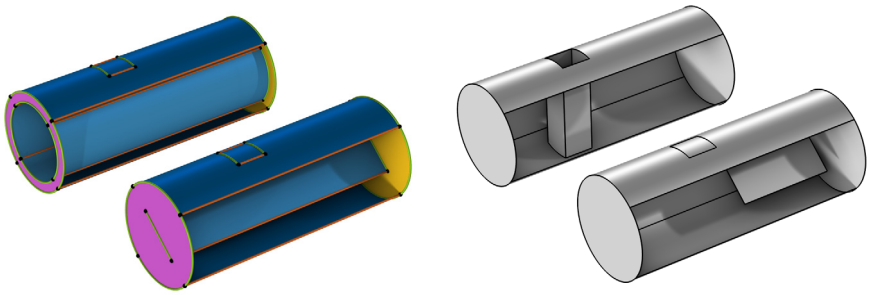

Figure 8-104: Domains containing holes and isolated faces. Left: the domains are sweepable because the hole and face penetrate both source and destination. Right: the geometries do not fulfill the criteria but can be swept meshed if partitioned into smaller domains (see Figure 8-107).

Also, the domains must not contain void regions. The exceptions are solid shell domains with a geometrical thickness that have a one-to-one mapping between the source and destination entities, as seen in Figure 8-105.

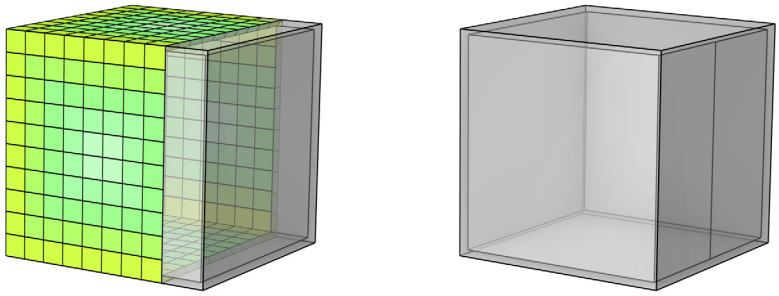

Figure 8-105: Left: A swept mesh in a thin domain with a void region inside the inner faces. Some elements have been filtered out for visibility. Right: The thin domain cannot be swept as there are fewer outer boundaries than inner.

- For each domain, the source and destination must be connected face components.

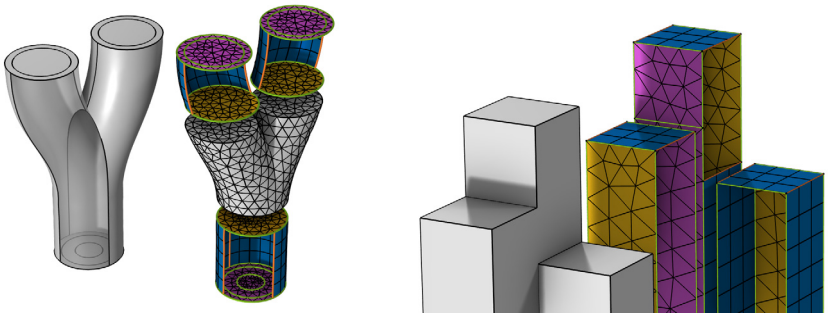

Figure 8-106: The domains to the left in both images cannot be swept meshed due to the disconnected face components on the top. By partitioning the geometry, most or all domains can be swept meshed (exploded view of resulting domains with some faces hidden in the foreground).

- Each destination face must correspond to one or more source faces (see Figure 8-103 and Figure 8-106).

- Each source face must correspond to precisely one destination face or a subset of it (see Figure 8-103 and Figure 8-106). If needed, use a Cross Section operation to make an imprint of the source faces on the destination.
- Coincident source and destination faces are allowed, as when sweeping the mesh a full revolution around an axis.
- Each edge of a linking face must be either a linking edge or a section edge.
- There must be at least two chains of linking edges connecting the two loops of section edges of each section.

Even if the original geometry does not fulfill the above criteria, it is sometimes possible to partition the geometry in order to obtain domains where a swept mesh can be created, as shown in Figure 8-106 and Figure 8-107.

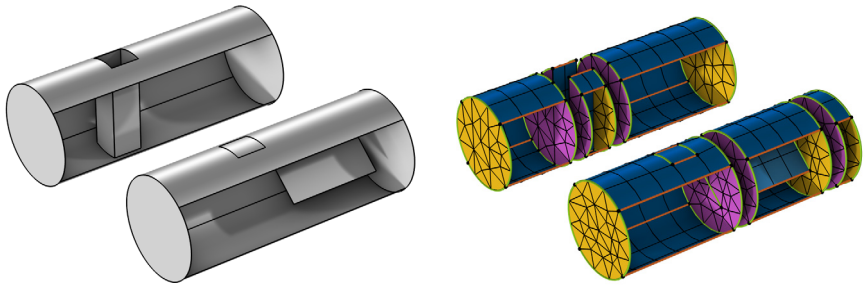

Figure 8-107: Left: Domains where a swept mesh cannot be created due to holes and isolated faces that do not penetrate source and destination (some faces are hidden). Right: Partitioning the domains results in smaller, sweepable domains (exploded view of the domains).

If any of the faces about a domain is meshed prior to the sweeping operation, the following must be fulfilled:

- If the source and destination faces are meshed, these meshes must match.
- If any of the linking faces are meshed, these must be meshed with structured quad meshes in such a way that one direction in the grid is aligned with the linking edges and the other direction is aligned with the section edges.

To add a **Swept** node, select the domains to sweep or the boundaries to use as source faces in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window and select **Swept** ( ) from The Graphics Context Menu.
- In The Mesh Toolbar, click the **Swept** ( ) button.
- Right-click a 3D **Mesh** node and select **Swept** ( ).

DOMAIN SELECTION

Specify the domains where you want a swept mesh. Choose the level of the geometry from the **Geometric entity level** list:

- Choose **Remaining** to generate a swept mesh for the remaining, unmeshed domains.
- Choose **Entire geometry** to specify swept mesh for the entire geometry.
- Choose **Domain** to specify the domains for which you want a swept mesh. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains** to select all domains.

SOURCE FACES

Click the **Activate Selection** button to toggle between turning ON and OFF selections.

In most cases the swept mesher can automatically identify source and destination faces from the geometry. To specify the source faces, activate the **Source Faces** list and select the faces defining the source of the sweep operation in the **Graphics** window.

Click the **Swap Source and Destination** button (↕) to swap the faces in the source list above and the faces in the destination list in the **Destination Faces** section below.

DESTINATION FACES

To specify the destination faces, activate the **Destination Faces** list and select the faces defining the destination of the sweep operation in the **Graphics** window.

SWEEP METHOD

Face Meshing Method

In the **Face meshing method** list, you can specify how unmeshed source faces are automatically meshed by the Swept operation. For meshes defining their own geometric model, select the **Remesh source faces** checkbox (selected by default) to remesh the source faces using the selected method:

- Select **Automatic (prefer hexahedra)** to let the algorithm select a suitable face meshing method (default). It tries to generate a quadrilateral mesh and switches to triangular if it fails or if the element quality becomes to low. The source faces are allowed to have different element types, which means that the resulting mesh can contain a mixture of hexahedral and prism elements, also in the same domain.
- Select **Quadrilateral (generate hexahedra)** to generate a surface mesh with quadrilateral elements.
- Select **Triangular (generate prisms)** to generate a surface mesh with triangular elements.
- Select any of the legacy versions to generate a surface mesh with quadrilateral elements using an algorithm used in earlier versions of the software.

Sweeping Path

Use the **Swept path calculation** list if you want to specify the shape of the sweep path:

- The default, **Automatic**, means that the sweeping algorithm automatically tries to determine if the sweep path is straight or circular; otherwise, a general approach is used.
- **Sweep following straight lines** means that all interior mesh vertices are located on straight lines between the corresponding source and destination points.
- **Sweep following circular arcs** means that all interior mesh vertices are located on circular arcs between the corresponding source and destination points, as shown in Figure 8-102.
- **Sweep using interpolation** means that the positions of the interior mesh vertices are determined by a general interpolation procedure, as shown in Figure 8-108.

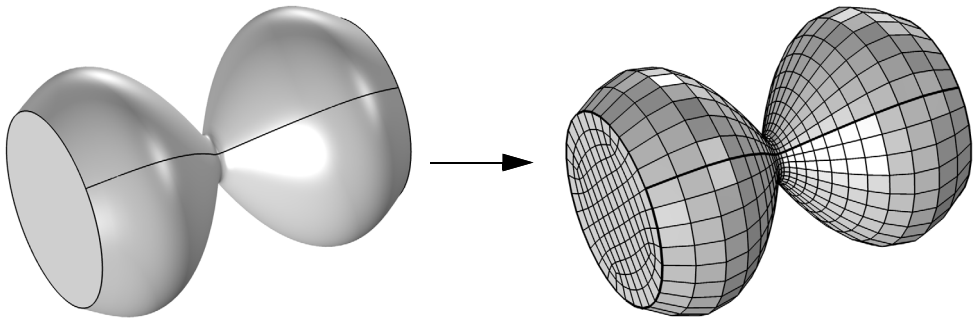

Figure 8-108: An hourglass-shaped geometry in which an unstructured quad mesh is swept using a general interpolation procedure.

Destination Mesh

Use the **Destination mesh generation** list if you want to specify the method to be used for transferring the source mesh to the destination:

- The default, **Determine suitable method**, means that the algorithm automatically tries to determine a suitable method for creating the destination mesh.
- **Use a rigid transformation** when the source and destination have the same shape, up to a scaling factor.
- **Morph source onto destination** when the source and destination have different shape. For example, when going from a circular to a rectangular cross-section, or going from a planar source face to a curved destination face.
- **Project source mesh onto destination** means that the destination mesh is created from the source mesh by a projection technique. This is useful when the source and destination faces are close to each other and have different shape.

CONTROL ENTITIES

Select the **Smooth across removed control entities** checkbox to smooth the transition in element size across removed control entities. When selected, the mesher adjusts the sizes of the mesh elements to get a smoother transition from large to small elements by adjusting the locations of the mesh vertices on the entity that is removed. Clear the checkbox to not adjust the mesh. You can specify the number of smoothing iterations in the **Number of iterations** field. In the **Maximum element depth to process** field you can specify the maximum element depth for the mesh vertices to be smoothed.

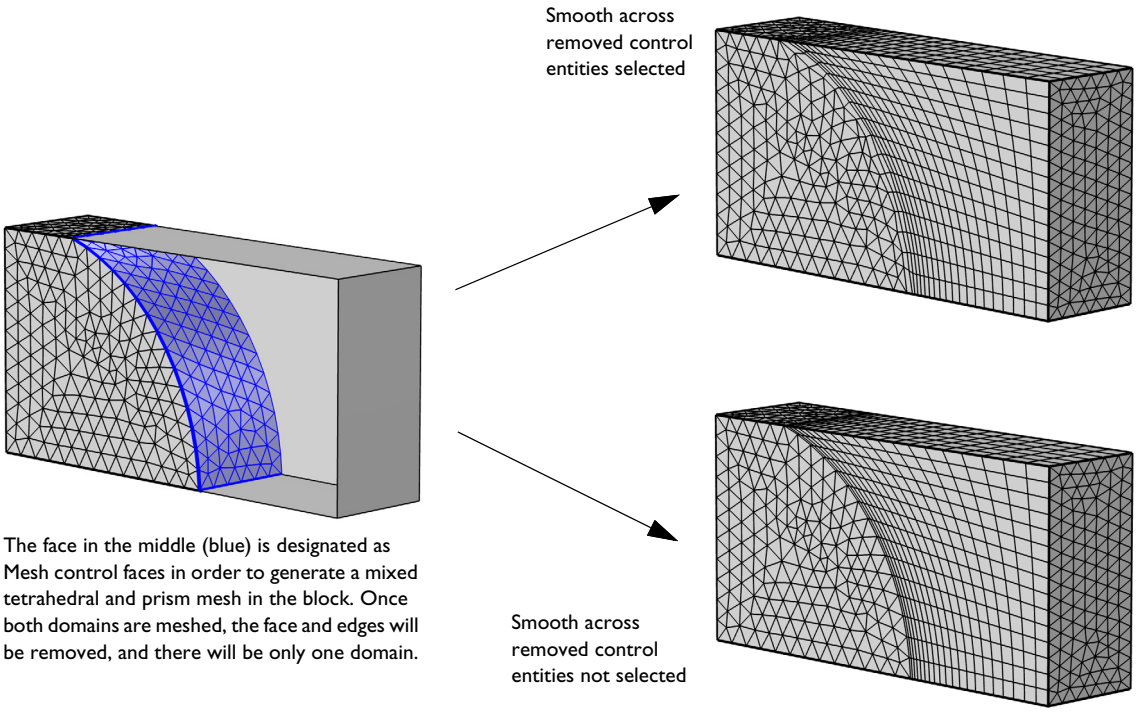

Figure 8-109: Comparing meshes where Smooth across removed control entities has been used vs. not used.

LINKING FACES

You can choose between two different interpolation methods for the linking faces in the **Interpolation method for linking faces** list. This specifies how the mapped mesher, which is used by the swept mesher for the linking faces, determines the positions of the interior mesh vertices. For more information on the different options see Mapped.

For examples of how to build swept meshes, see:

Transform

Use the **Transform** ( ) attribute to position, rotate, or scale an imported mesh. The positioning is done by specifying a point in the source and a position to match with the point. After that, any specified rotation or scaling

is applied, and, lastly, if an additional displacement is specified, it is added to the translation. With the default settings, the imported mesh is not transformed.

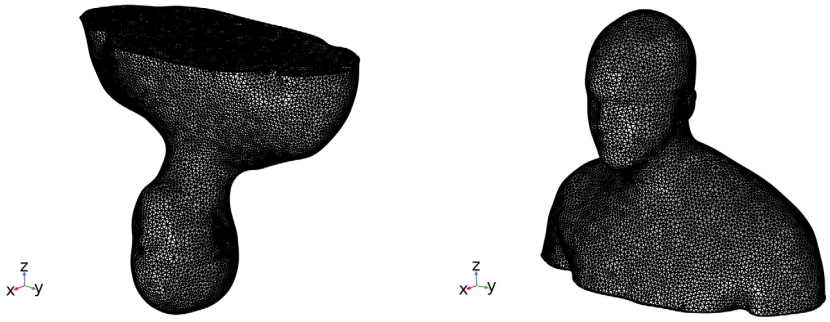

Figure 8-110: Mirroring the mesh of a head and torso in the xy-plane using a Transform attribute.

Transform is an attribute that acts on the **Import** node only.

No associativity update is done for geometric entity numbers. It is recommended to add **Transform** attributes directly, before adding more operations to the meshing sequence.

To add a **Transform** attribute, right-click the **Import** node and select **Transform** ( ). Then use the sections below to specify the displacement, rotation angle, and scale factor for the transformation.

POSITION IN SOURCE

Control how the imported mesh is positioned relative to the coordinates in the file by matching a predefined point in the file with the position specified in the **Position to Match** section. From the **Base** list choose:

- **Origin** (default) to position the origin in the file.
- **Corner** to position the minimum coordinate of the imported mesh's bounding box.
- **Center** to position the center of the imported mesh's bounding box.
- **Bottom** to position the center in x and y, but minimum z-coordinate of the imported mesh's bounding box. For 2D: position the center in the x-coordinate and minimum in the y-coordinate of the imported mesh's bounding box.
- **Top** to position the center in x and y, maximum in z-coordinate of the imported mesh's bounding box. For 2D: position the center in the x-coordinate and maximum in the y-coordinate of the imported mesh's bounding box.

POSITION TO MATCH

Control if the imported mesh is positioned relative to the origin or to a specified existing vertex. Specify the **Anchor** point as **Origin** (default) or **Vertex**. For the option **Vertex**, specify a mesh vertex in the associated **Anchor Vertex** section. The mesh is translated so that the specified **Base** point is moved to the position to match.

DISPLACEMENT

Offset the imported mesh by entering **x**, **y**, and **z** (3D) values for the displacement. The displacement is applied after the **Base** and **Anchor** points have been matched.

	The positioning of imported meshes is supported for static positioning only. To parameterize the geometry and move objects around in a parametric sweep, use the option of Creating Geometry from Mesh to apply the parameterization in the geometry sequence.

AXIS (3D ONLY)

The mesh is rotated so that the *z*-axis in the source mesh is rotated to the specified axis. Any specified rotation is performed around this axis (after the *z*-axis has been rotated to match this axis). Select **Axis type** as **z-axis** (default), **x-axis**, **y-axis**, **Cartesian**, or **Spherical**.

ROTATION ANGLE

Specify a rotation of the mesh around the origin (as specified by the **Base** point, but before the offset or translation to the anchor vertex is applied). If you want another center of rotation, you can use several **Transform** attributes in a sequence to first move the rotation center to the origin and then move it back.

SCALE

Scale the mesh with an isotropic or anisotropic scale. Select **Isotropic** (default) or **Anisotropic** from the **Scaling** list and enter values for the scaling. Enter a negative scale to mirror the mesh. The scale is applied prior to any translation or rotation; the point specified in **Position in Source** is used as center point.

	Using an anisotropic scaling with zero scale effectively projects the mesh onto a coordinate plane. In general, this leads to degenerated elements and self-intersections, but it is a useful way to project a curved surface mesh onto a plane.

	Importing Meshes

	• See *STL Import 1 — Repairing and Combining STL Files*: Application Library path **COMSOL_Multiphysics/Meshing_Tutorials/stl_1_repair_imported_meshes** • See *Head and Torso HRTF Computation*: Application Library path **Acoustics_Module/Tutorials,_Pressure_Acoustics/head_torso_hrtf**

Two-Point Map

Use the **Two-Point Map** ( ) attribute to specify the orientation of the source mesh on the destination for a Copy, Copy Face, Copy Domain, or an Identical Mesh node. Using this node, the source mesh of the copy operation is

transformed so that the source points of the **Two-Point Map** node are mapped onto the destination points with the specified orientation, as shown in Figure 8-111.

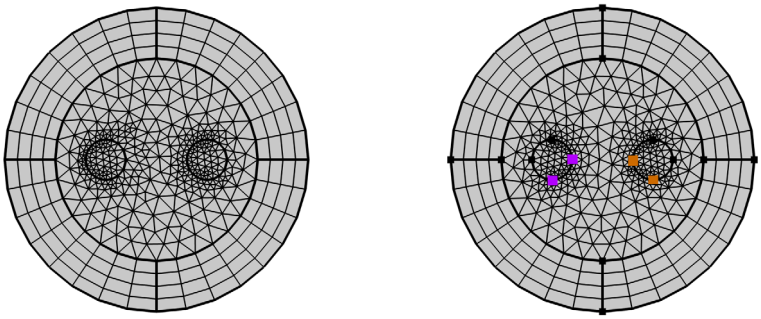

Figure 8-111: The left image shows the resulting mesh after copying the triangle mesh on the right circle to the left. The right image shows the resulting mesh with an Edge Map applied, generating a mirrored mesh on the circles. The yellow points specify the points on the source that is mapped onto the magenta points on the destination.

To add a **Two-Point Map** ( ) node as a subnode to a Copy, Copy Face, Copy Domain, or an Identical Mesh node, choose one of the following:,

- Right-click the operation in the **Model Builder** and select **Two-Point Map** ( ) from its context menu.
- Select the operation node in the **Model Builder**, click **More Attributes** ( ) on The Mesh Toolbar, and select **Two-Point Map**.

Then enter the properties using the following sections:

SOURCE POINTS

Click the **Active** button to toggle between turning ON and OFF selections.

- Activate the **First point on source** list and select the point that you want to define as first source point in the **Graphics** window.
- Activate the **Second point on source** list and select the point that you want to define as second source point in the **Graphics** window.

DESTINATION POINTS

Activate the **First point on destination** list and select the point that you want to define as first destination point in the **Graphics** window.

Activate the **Second point on destination** list and select the point that you want to define as second destination point in the **Graphics** window.

- Copy
- Copy Domain
- Copy Face
- Edge Map
- One-Point Map
- Identical Mesh

Union

Use **Union** ( ) to unite surface meshes in 3D. The operation introduces mesh edges if mesh elements intersect, thereby intersecting existing mesh elements. It also partitions geometric entities accordingly by, for example, introducing geometry edges where mesh faces intersect, as shown in Figure 8-112. If the surface meshes contain unmeshed domains, the domain information is updated to account for overlap domains.

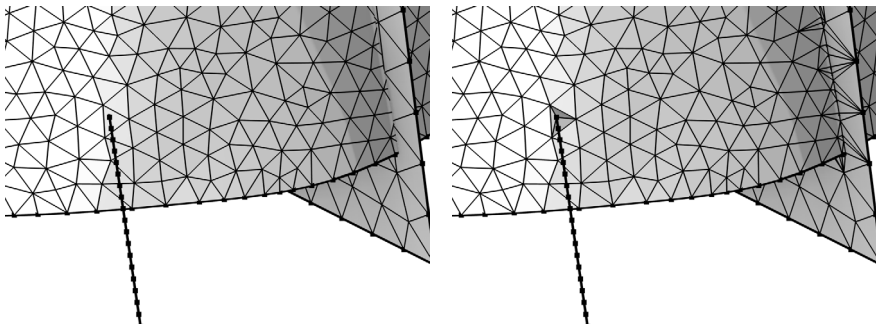

Figure 8-112: Imported surface and edge meshes (left) that are united using the Union operation (right).

This operation is available for 3D models only.

The operation often generates triangles of bad quality close to intersection edges. Use Free Triangular or Free Quad to remesh boundaries. See Remeshing Imported Meshes for more information.

The **Union** operation partitions existing faces in order to avoid self-intersecting faces. When this happens, an **Information** node is added with information about additional faces.

To add a **Union** ( ) node, select entities to unite in the **Graphics** window, then choose one of the following:

- Right-click in the **Graphics** window to open The Graphics Context Menu and select **Union** ( ) from the **Booleans and Partitions** menu.
- Select **Union** ( ) from the **Booleans and Partitions** menu ( ) on The Mesh Toolbar.
- Right-click the **Mesh** node and select **Union** ( ) from the **Booleans and Partitions** menu.

Note that uniting meshes can modify the number of geometric entities. Thus when you are adding this operation to a meshing sequence that is conforming with the component's geometry, a new meshing sequence that is defining its own geometric model is automatically created, and the **Union** node is added to this new sequence. For more information, see The Mesh Node.

Enter the properties for **Union** ( ) using the following sections:

DIMENSION

Define the geometric entities to intersect. From the **Geometric entity level** list:

- Choose **Entire geometry** (default) to unite all available entities.

- Select **Domain** to unite domains. Choose **Manual** in the **Selection** list to select the domains in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All domains** to select all domains. Only unmeshed domains can be selected.

To remove domain elements while keeping the boundary mesh either

- Clear the **Import domain elements** checkbox in the **Settings** window of the **Import** node, or
- Add a Delete Entities operation, add the domains to delete, and select the **Keep as unmeshed domains** checkbox.

To later restore the domain mesh, add and build a Free Tetrahedral operation.

- Select **Boundary** to unite boundaries. Choose **Manual** in the **Selection** list to select the boundaries in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All boundaries** to select all boundaries.
- Choose **Edge** to unite isolated edges. Choose **Manual** in the **Selection** list to select the edge in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All edges** to select all edges.
- Select **Mixed dimensions** to specify a mixture of entities to unite.

GEOMETRIC ENTITY SELECTION

Click the **Activate Selection** for the entity selections of interest to start adding entities. The selections support unmeshed domains, any boundary, isolated edges, and isolated points.

CLEANUP

Intersection of boundary and edge elements can result in short mesh edges, relatively small elements, and elements of poor element quality. To improve the quality of the mesh, cleanup is done by snapping mesh vertices and collapsing short mesh edges. Lower the **Repair tolerance** to decrease the amount of snapping performed.

The **Union** operation can be used to clean up a mesh of very bad quality even if nothing needs to be united. It can, for example, be useful for a mesh imported from a Filter dataset.

Use the **Repair tolerance** list to control the snapping distance when intersecting faces and for cleanup of the mesh. Choose **Relative** to enter a value in the **Relative tolerance** field. This value is relative to the length of the longest side of the mesh bounding box. Select **Absolute** (the default) to specify a value in the **Absolute tolerance** field. When the operation is built with either of the settings **Automatic** or **Relative**, the values in the **Relative tolerance** (for **Automatic** only) and **Absolute tolerance** fields are automatically updated to correspond to the actually used tolerance. The automatic tolerance is based both on the size of the bounding box and of the average size of mesh elements in the selection.

Use the **Placement of mesh vertices** setting to specify if the mesh vertices will be placed on the **Curved** (default) or **Linear** representation of intersection edges. See Figure 8-113.

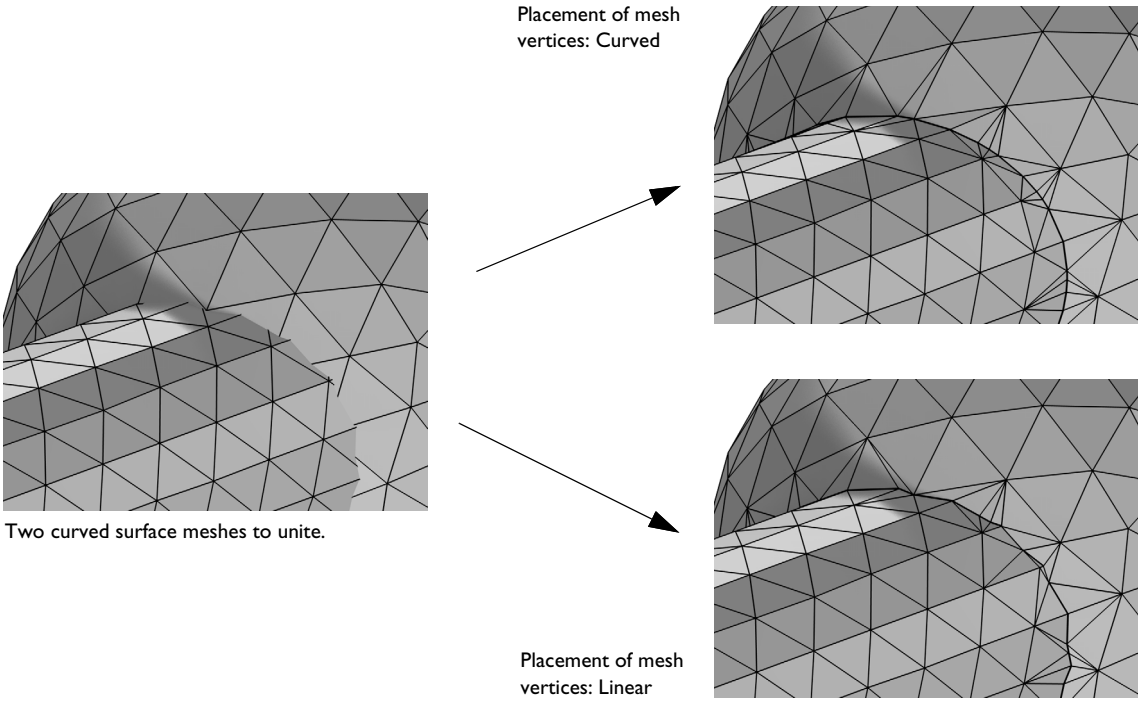

Figure 8-113: The mesh vertices on the intersection edge are placed using either a curved representation (upper right) or a linear representation (lower right).

Select the **Cleanup of resulting mesh** checkbox to control if cleanup is performed.

- Create Domains
- Delete Entities
- Remeshing Imported Meshes
- Remesh Faces
- Free Triangular
- Free Tetrahedral
- Intersect with Line
- Intersect with Plane

Vertex

Use **Vertex** ( ) to mesh points in 1D, 2D, and 3D. The operation is useful when meshing isolated vertices, as shown in Figure 8-114.

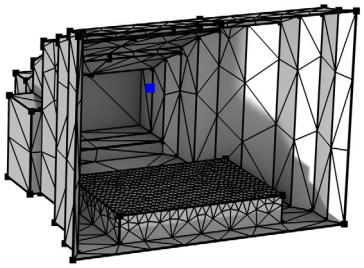

Figure 8-114: Meshing the isolated point (blue) using the Vertex operation. For this ray acoustics simulation, only the boundaries and the isolated vertex need a mesh.

Isolated vertices are automatically meshed if a Free Tetrahedral, Free Triangular, Free Quad, or Edge operation is built with **Geometric entity level** set to **Remaining** or **Entire Geometry**. For the Mapped operation, isolated vertices are automatically meshed if **Geometric entity level** is set to **Remaining**.

To add a **Vertex** ( ) node, select one or several points in the **Graphics**, then choose one of the following:

- Right-click in the **Graphics** window, and select **Vertex** ( ) from The Graphics Context Menu.
- In The Mesh Toolbar, choose **Vertex** from the **More Generators** ( ) menu (3D or 2D components) or click **Vertex** ( ) (1D components).
- Right-click the **Mesh** node and choose **Vertex** ( ) (under **More Generators** in 3D).

Then enter the properties using the following sections:

ENTITY SELECTION

To define the points where you want a create a mesh, first choose the level of the geometric entities from the **Geometric entity level** list:

- Choose **Entire geometry** to generate a vertex mesh for the entire geometry.
- Choose **Remaining** to specify a vertex mesh for the remaining, unmeshed vertices.
- Choose **Point** (3D and 2D) or **Boundary** (1D) to specify the points for which you want to create a mesh. Choose **Manual** in the **Selection** list to select the points in the **Graphics** window, choose a named selection to refer to a previously defined selection, or choose **All points** (3D and 2D) or **All boundaries** (1D) to select all points.

For a tutorial using the **Vertex** operation, see

Small Concert Hall Acoustics: Application Library path **Acoustics_Module/Building_and_Room_Acoustics/small_concert_hall**.

Materials

This chapter includes information about how to work with materials in models and describes the material databases included with COMSOL Multiphysics® and the add-on modules.

In this chapter:

- Materials Overview
- Working with Materials
- Material Properties Reference
- User-Defined Materials and Libraries
- Using Functions in Materials
- Working with External Materials
- Module-Specific Material Libraries

Materials Overview

About Materials and Material Properties

MATERIALS

In COMSOL Multiphysics models, you can add one or more *materials*, which are named collections of *material properties*. Each such material is represented by a **Material** node ( ). Each material includes a number of physical properties with the values or functions (for temperature-dependent material properties, for example) that describe the material.

When you add a material from a material database or the Material Library, the **Model Builder** node label is copied from the library — for example, **Copper** or **Air**. When you add a **Blank Material**, the default node label is **Material** followed by a number. At any time press F2 to rename a node. The **Settings** window is always called **Material**, irrespective of the current node label. Also see The Settings Window for Material.

MATERIAL PROPERTIES AND PROPERTY GROUPS

The material properties are organized in material *property groups*, which appear as subnodes under the **Material** node in the **Model Builder**:

- The **Basic** property group contains common material properties that can generally be measured and are meaningful without any context.
- User-defined groups may contain a subset of the same quantities.
- Each predefined property group contains one or more material properties that are only meaningful together and in the context of a particular material model.
- The material property values are outputs of the material, which can be constant values or functions of *model inputs* (physical quantities like temperature and pressure). In principle, the physics interfaces first ask a material which inputs it requires to compute its output properties, then ask the material to compute property values given values of the model inputs — for example, thermal conductivity (output) as function of temperature (input). See About Model Inputs.
- Each property group can also define a set of local properties and functions that can be used together with model inputs in output property expressions. This makes it possible to, for example, create generic materials for certain classes of some type of material and use the local properties to parameterize the material.

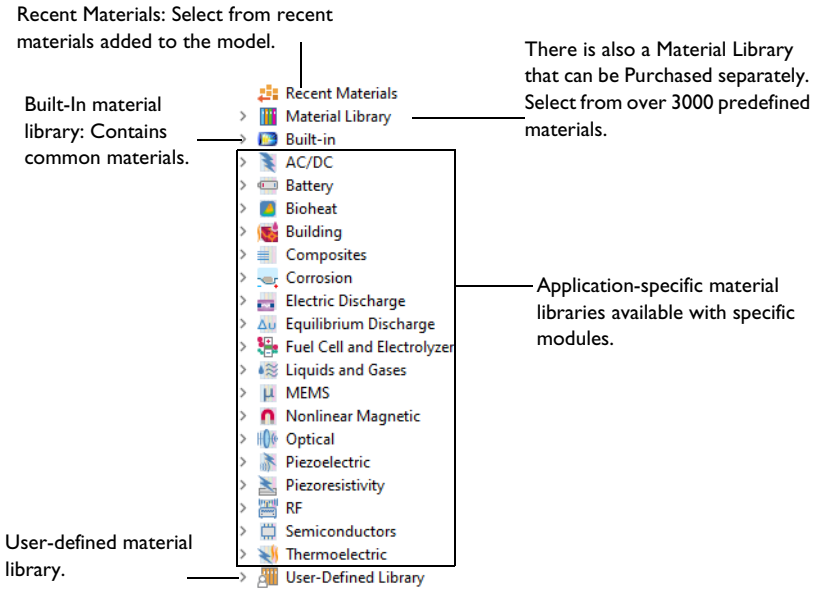

Figure 9-1: Use the Material Browser to select predefined materials in all applications.

All COMSOL Multiphysics modules have predefined material data available in collections of materials — material libraries (databases) — to build models. The most extensive material data is contained in the separately purchased Material Library, but all modules contain commonly used or module-specific collections of materials. For example, the Built-in material library is available to all users, but the MEMS material library is included with the MEMS Module and Structural Mechanics Module. You can also create custom materials and material libraries by researching and entering material properties.

The **Material Browser** window provides access to all material libraries (including the Material Library). The following material libraries are available in the Material Browser (some require additional module licenses):

- *Recent Materials*: From the **Recent Materials** folder ( ), select from a list of recently used materials with the most recent at the top. This folder is available after the first time a material is added to a Component node.
- *Material Library*: An optional add-on library, the **Material Library**, contains data for over 2500 materials and 20,000 property functions.
- *Built-in*: Included with COMSOL Multiphysics, the **Built-in** library contains common materials with primarily electrical, structural, and thermal properties. The materials in this library can be considered as examples of common materials with typical values for their material properties. The *Air* and *Water, liquid* materials use the same temperature- and pressure-dependent property values as the corresponding values in the Liquids and Gases Material Library. Nimonic is a registered trademark of Huntington Alloys Corporation.
- *AC/DC*: Included in the AC/DC Module, the **AC/DC** library has electric properties for some magnetic and conductive materials.
- *Battery*: Included in the Battery Design Module, the **Battery** library includes properties for electrolytes and electrode reactions for certain battery chemistries.
- *Bioheat*: Included in the Heat Transfer Module, the **Bioheat** library includes properties for several biological tissues such as bone, fat, human and porcine liver, lung, muscle, myocardium, prostate, and skin.
- *Building*: Included in the Heat Transfer Module, the **Building** library includes hygroscopic and thermal properties for several materials used for structure, sheathing, thermal insulation, and vapor barriers in buildings.

- *Composites*: Included in the Structural Mechanics Module and MEMS Module, the **Composites** library includes fiber constituents, matrix constituents, and laminae for modeling of composite materials.
- *Corrosion*: Included in the Corrosion Module, the **Corrosion** library includes polarization data for several different metals and alloys in various electrolytes.
- *Electric Discharge*: Included in the Electric Discharge Module.
- *Equilibrium Discharge*: Included in the Plasma Module and Electric Discharge Module.
- *Fuel Cell and Electrolyzer*: Included in the Fuel Cell & Electrolyzer Module, the **Fuel Cell and Electrolyzer** library includes properties for electrolytes for some common cell chemistries contains electrolyte properties, such as properties for alkaline, molten carbonate, polymer, and solid oxide electrolytes.
- *Liquids and Gases*: Included in the Acoustics Module, CFD Module, Battery Design Module, Chemical Reaction Engineering Module, Heat Transfer Module, MEMS Module, Microfluidics Module, Pipe Flow Module, and Subsurface Flow Module, the **Liquids and Gases** library includes transport properties and surface tension data for liquid/gas and liquid/liquid interfaces.
- *MEMS*: Included in the MEMS Module and Structural Mechanics Module, the **MEMS** library has properties for MEMS materials: metals, semiconductors, insulators, and polymers.
- *Nonlinear Magnetic*: Included in the AC/DC Module and the RF Module, the **Nonlinear Magnetic** library has properties, such as nonlinear magnetization curves, for a large set of ferromagnetic alloys like various types of steel.
- *Optical*: Included with the Ray Optics Module and Wave Optics Module, the **Optical** library contains frequency-dependent refractive index properties for organic and inorganic materials, glasses, and other materials such as semiconductors.
- *Piezoelectric*: Included in the Acoustics Module, MEMS Module, and Structural Mechanics Module, the **Piezoelectric** library has properties for piezoelectric materials.
- *Piezoresistivity*: Included in the MEMS Module, the **Piezoresistivity** library has properties for piezoresistive materials, including p-type and n-type silicon materials.
- *RF*: Included in the RF Module, the **RF** library includes material properties for substrate materials to assist in modeling RF, microwave, and millimeter-wave circuit boards.
- *Semiconductors*: Included in the Semiconductor Module, the **Semiconductors** library contains silicon, germanium, gallium arsenide, $Al_xGa_{1-x}As$, gallium nitride (wurtzite and zincblende structures), gallium phosphide, gallium antimonide, indium arsenide, indium phosphide, and indium antimonide materials for use with this module.
- *Thermoelectric*: Included with the Heat Transfer Module and contains bismuth telluride and lead telluride materials for use with the Thermoelectric Effect interface.
- *User-Defined Library*: The **User-Defined Library** folder ( ) is where user-defined material libraries are created. When you have created a new library, it also displays in the **Material Browser**.

The material databases shipped with COMSOL Multiphysics are read-only. This includes the Material Library and any materials shipped with the optional modules.

In addition, when your license includes the Metal Processing Module and you have added a space-dependent physics interface from that module, you can right-click the global **Materials** node and choose **Import Materials** or

Import Materials From to import material properties for steel quenching from JMatPro® as an XML-file. For more information, see the documentation for the Metal Processing Module.

- Creating a New Material Library and Adding and Editing Materials

About Using Materials in COMSOL Multiphysics

USING THE MATERIALS IN THE PHYSICS SETTINGS

The physics setup in a model is determined by a combination of settings in the **Materials** and physics nodes. When the first material is added to a Component node, COMSOL Multiphysics automatically assigns that material to all domains in the geometry (or all boundaries or edges if the Component only contains surfaces or edges). Different geometric entities can have different materials. The following example uses the *heat_sink.mph* model file contained in the Heat Transfer Module and CFD Module Application Libraries.

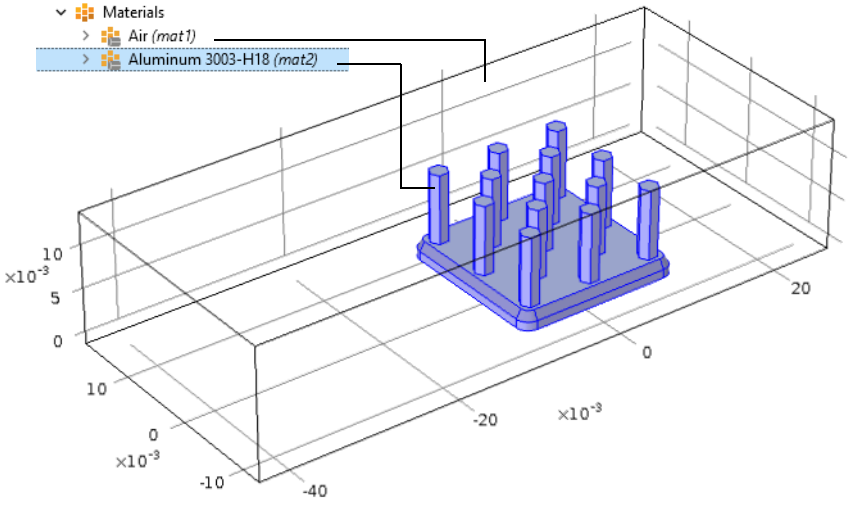

Figure 9-2: Assigning materials to a heat sink model. Air is assigned as the material to the box surrounding the heat sink, and aluminum to the heat sink itself.

If a geometry consists of a heat sink in a container, **Air** can be assigned as the material in the container surrounding the heat sink and **Aluminum** as the heat sink material itself (see Figure 9-2). The **Conjugate Heat Transfer** interface, selected during model setup, uses a **Fluid** model to simulate nonisothermal flow, with heat transfer by convection and conduction, in the box surrounding the heat sink, and a **Heat Transfer in Solids** model to simulate heat conduction in the heat sink. The **Heat Transfer in Solids 1** settings use the material properties associated to the **Aluminum 3003-H18** materials node, and the **Fluid 1** settings define the flow using the **Air** material properties. The other nodes under **Conjugate Heat Transfer** define the initial and boundary conditions.

All physics node properties automatically use the correct material properties from the **Material** nodes when the default **From material** setting is used. This means that one node can be used to define the physics across several domains with different materials; the COMSOL Multiphysics software then uses the material properties from the different materials to define the physics in each domain.

The Settings Window for Material

There are also some physics nodes where you can explicitly select a material from which material properties are retrieved (for example, the **Settings** window for **Fluid Properties** for two-phase flow modeling). The default setting is then typically to use the **Domain material** on each domain (that is, the materials defined on the same domains as the physics that uses the material data). In addition to the **Domain material**, you can select any other material that is present in the Component, regardless of its selection. The selected material's properties are then applied to all domains in the feature's selection.

EVALUATING AND PLOTTING MATERIAL PROPERTIES

You can access the material properties for evaluation and plotting like other variables in a model using the following variable naming conventions and namespaces:

- To access a material property throughout the model (across several materials) and not just in a specific material, use the special material namespace `root.material`. For example, `root.material.rho` is the density ρ as defined by the materials in each domain in the geometry. For plotting, you can type the expression `material.rho` to create a plot that shows the density of all materials. This shorthand syntax is available for materials in the Basic (with the tag `def`) material property group, but you can also access the density in the Basic material property group namespace as `material.def.rho`.
- For an anisotropic property such as the electric conductivity, its values are available as `material.def.sigma11`, `material.def.sigma12`, and so on. If such a property is set as isotropic for some material, `material.def.sigma_iso` represents that isotropic value.
- For properties in property groups other than the Basic group, the full namespace must be used, including the property group name. For example, to access the initial yield stress `sigmags` for elastoplastic materials in the Elastoplastic Material Model property group, use `material.ElastoplasticModel.sigmags`.

If you use a temperature-dependent material, each material contribution asks for a special model input. For example, `rho(T)` in a material `mat1` asks for `root.mat1.def.T`, and you need to define this variable (`T`) manually — if the temperature is not available as a dependent variable — to make the density variable work.

- To access a material property from a specific material, you need to know the names for the material and the property group. Typically, for the first material (Material 1) the name is `mat1` and most properties reside in the default **Basic** property group with the name `def`. The variable names appear in the **Variable** column in the table under **Output properties** in the **Settings** window for the property group; for example, `Cp` for the heat capacity at constant pressure. The syntax for referencing the heat capacity at constant pressure in Material 1 is then `mat1.def.Cp`. Some properties are anisotropic tensors, and each of the components can be accessed, such as `mat1.def.k11`, `mat1.def.k12`, and so on, for the thermal conductivity. The numbers 1, 2, and 3 denote the first, second, and third direction, respectively, in the active coordinate system. In the general case, you can define a 3-by-3 tensor, for example, k_{ij} in the order k_{11}, k_{21}, k_{31}, k_{12}, k_{22}, k_{32}, k_{13}, k_{23}, and k_{33}. For material properties that are functions, call these with input arguments such as `mat1.def.rho(pA,T)` where `pA` and `T` are numerical values or variables representing the absolute pressure and the temperature, respectively. Functions can be plotted directly from the function nodes' **Settings** window by first specifying suitable ranges for the input arguments. If a possibly anisotropic property is defined as isotropic, you can access its value as `mat1.def.k_iso`, for example.
- Material Link nodes define all properties of the current source material in the Material Link's namespace. For example, for the node **Material Link 1 (matlnk1)**, the density of the currently selected source material is available as `matlnk1.def.rho`.
- Material Switch nodes define variables similarly to Material Link nodes. For example, during a material sweep over the children of **Switch 1 (sw1)**, you can access the density of the material used in the current sweep step as `sw1.def.rho`.

- Many physics interfaces also define variables for the material properties that they use. For example, `solid.rho` is the density in the Solid Mechanics interface and is equal to the density in a material when it is used in the domains where the Solid Mechanics interface is active. If you define the density in the Solid Mechanics interface using another value, `solid.rho` represents that value and not the density of the material. If you use the density from the material everywhere in the model, `solid.rho` and `material.rho` are identical.
- To see the domain groups (that is, groups of domains with equal material settings), the variable `root.material.domain` — and, for lower-dimensional entities when applicable, `root.material.boundary`, `root.material.edge`, and `root.material.point` — is available and evaluates to unique integer values for each domain group.

For all property groups except the Basic group, changing the name in the **Name** field also changes the tag, which is what is used in the namespace for accessing material properties.

THE MATERIAL TYPE SECTION

The **Material type** setting, available on some physics node **Settings** windows, decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Nonsolid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

The Settings Window for Material

Working with Materials

The Material Browser Window

The **Material Browser** window ( ) contains a number of databases with a broad collection of elastic, solid mechanics, electromagnetic, fluid, chemical, thermal, piezoelectric, piezoresistive, and semiconductor properties of materials. The number of material databases depends on which COMSOL products your license includes. See About the Material Libraries for information about available material databases. Use the Material Browser to find predefined materials and add them to the Model Builder, or create a custom material library.

Win

To open the **Material Browser** :

- In the **Materials** toolbar, click **Browse Materials**.
- Right-click the **Materials** node ( ), and then select **Browse Materials**.
- From the **Home** toolbar, select **Windows** > **Material Browser**.

Mac

Linux

To open the **Material Browser** :

- In the **Model Toolbar**, click **Browse Materials**.
- Right-click the **Materials** node ( ), and then select **Browse Materials**.
- Select **Windows** > **Material Browser**.

The **Material Browser** is similar to The Add Material Window but it includes detailed property information about each material. From this window you can also create a new material library and import a material library. See Adding Materials to a Component for information about adding materials to your model's components (geometries). Click **Done** ( ) to close the **Material Browser** and add the materials in the **Added to model** list to the model. Click **Cancel** ( ), press Escape, or click in the main toolbar to exit the **Material Browser** without adding any materials.

Right-click a material library in the **Material Browser** and choose **Reload Selected** ( ) to clear all cached data for that library and force the COMSOL Multiphysics software to reload the content from the file system. This operation is useful, for example, if the library is a user-defined library that has been edited since the COMSOL Multiphysics session started and needs to be reloaded to display the latest contents.

You can browse all of the available material databases or search for specific materials. There is also a **Recent Materials** folder where you find the most recently used materials. **Search** a specific material by name (or, primarily for the Material Library product, by UNS, DIN, WNr, JIS, ASTM, AISI, SAE, AMS, or AFNOR number, which are listed in the Material Browser when available).

When browsing the material databases, in particular the **Material Library**, some materials include additional information — UNS, DIN, or other material identification number, composition, and orientation or other variations.

As in Figure 9-3, the following information is included in the window to the right of the material tree. Navigate in the material tree and click a material to display the information.

Material availability is based on the type of COMSOL Multiphysics license. For example, if you have the MEMS Module, you have the **Built-In**, **Liquids and Gases**, **MEMS**, and **Piezoelectric** material libraries.

PROPERTIES

While browsing the databases, predefined material properties for the selected material are listed in a table in the columns **Property**, **Expression**, **Unit**, and the **Property group** to which the material property belongs. If **Property group** is empty, the material property is a **Basic** property.

Under **Property reference**, for the materials in the Material Library product and any other materials where property information has been added, reference information or other information about a material's properties appears when you click a property above.

INPUTS

For some materials, predefined function inputs are listed in a table in the columns **Input**, **Variable**, and **Unit**. Inputs appear for material properties defined using functions that require the input. Typical inputs are temperature and pressure, for temperature- and pressure-dependent material properties, respectively.

CREATE A NEW MATERIAL LIBRARY OR IMPORT A MATERIAL LIBRARY

Click the **New Material Library** button ( ) to open the **New Material Library** dialog. You can also right-click a material and select **Add to New Library** ( ) to create a new material library and add that material to the new library. Go to Creating a New Material Library and Adding and Editing Materials.

Click the **Import Material Library** button ( ) to open the **Choose Material Library** dialog. You can also click the downward-pointing arrow to the right of the Import Material Library button and choose **Import Material From** ( ) to open the fullscreen **Select Material** window and choose the material from a database. Go to Importing a Material Library.

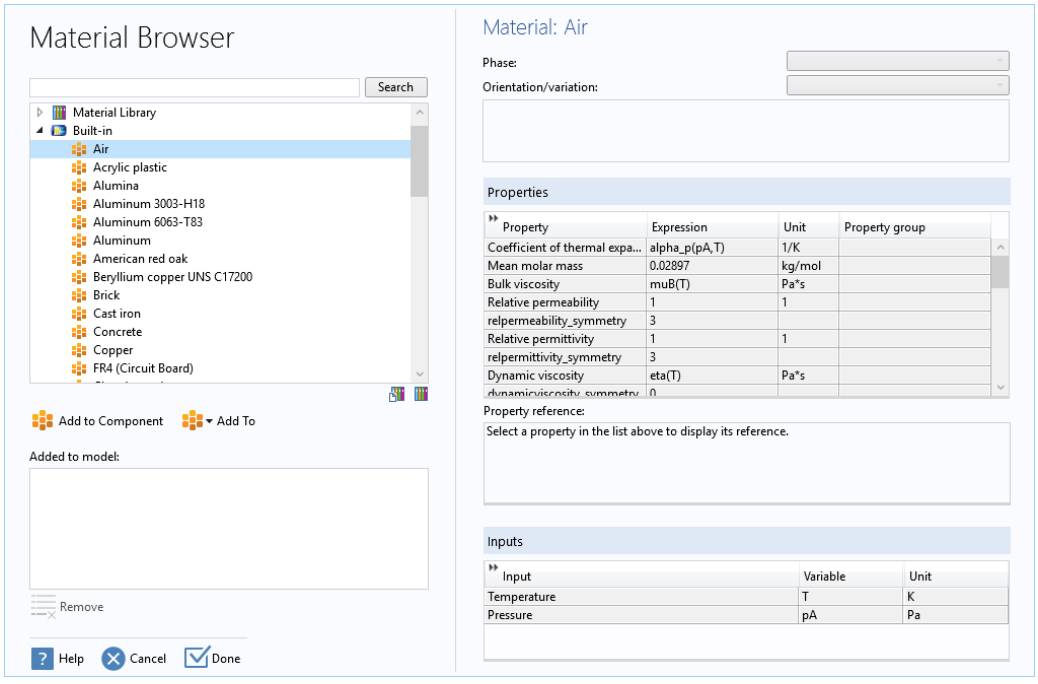

Figure 9-3: The Material Browser details a material's properties after selection. In this example, the properties of Air, selected from the Built-In library, are listed to the right of the Material Browser folders.

The Add Material Window

The **Add Material** window is similar to The Material Browser Window. It has the same material libraries available but does not include the detailed properties about each material. The number of material libraries depends on which COMSOL Multiphysics products your license includes. See About the Material Libraries for information about available material databases. This window is a quick way to add materials to models.

To open the **Add Material** window :

- From the **Materials** toolbar, click **Add Material**.
- Right-click the **Materials** node ( ) and select **Add Material from Library**.

As in Figure 9-4, you can browse all the available material databases or search for specific materials. There is also a **Recent Materials** folder where you find the most recently used materials. **Search** a specific material by name or material numbers such as a UNS number or DIN number, for materials that have such material numbers defined.

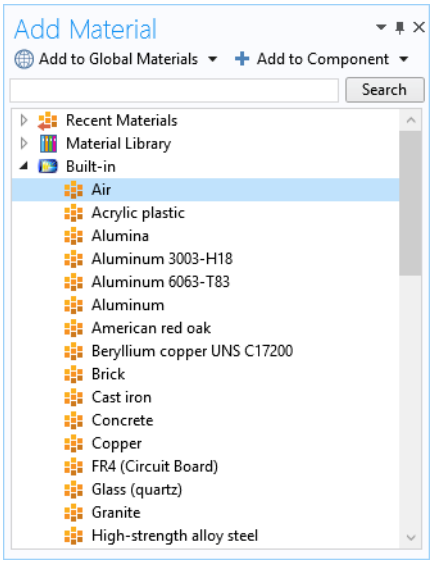

Figure 9-4: The Add Material window. In this example, Air is selected from the Built-In library and can be added to the Material node in the local Component or as a global material in the Model Builder.

Adding Materials to a Component

You can add materials to Component nodes using either the **Add Material** or **Material Browser** windows. In either window, use the **Search** field to find materials by name or material number. Or click any of the folders and subfolders to locate and add a specific material. For example, from the left column, click **Built-In** and in the right column, click **Air**. To add a material to the current component, click the **Add to Component** button, right-click the material and choose **Add to Component**, or, in the **Add Material** window, press Enter. In the **Add Material** window you can also add a material to global **Materials** list and to the current selection. In the **Material Browser** window, you can also add the material to the global **Materials** list and to an existing user-defined or new material library.

Using the Add Material Window

1 Open the **Add Material** window (see The Add Material Window).

2 In the **Add Material** window, select a material by phase (liquid, vapor, gas, or solid) and orientation/variation, when available.

3 Click the **Add to Global Materials** or **Add to Component** buttons, or right-click the material and select the same options from the context menu. If there is more than one **Component** node in the model tree, add the material to the applicable geometry.

- Click the **Add to Global Materials** button to add it under the global **Materials** node.
- Click the **Add to Component** button to add the material to the active component in the **Model Builder** and then make it an active material in the domains (or other geometric entities) where it is selected. You can also select any of the components in the model to add it to its **Materials** node, or select **Add to Switch 1**, for example, to add it under a **Switch** node for materials under the global **Materials** node. Right-click the **Material** node to rename it, for example, using the name of the material it represents.

Using the Material Browser Window

1 Open the **Material Browser** window (see The Material Browser Window).

2 In the **Material Browser**, select options from the **Phase** and **Orientation/variation** lists, when available included for some materials in the Material Library product, for example). In this window you can review the material **Properties** and **Input** sections.

3 Click the **Add to Component** button ( ) under the list of materials to add the selected material to the current model component. Alternatively, click the **Add To** button ( ) to add the material to the global **Materials** node (choose **Global Materials**), to any available model component, or to an existing or new user-defined material library. You can also right-click the selected material node to add that material to a model component or user-defined material library. Materials that you have selected to add to any of the model components appear in the **Added to model** list.

4 Click **Done** ( ) to add the materials to the model tree in the **Model Builder** and close the **Material Browser**. If it is the first material in that model component, the material in the **Model Builder** becomes the default material; otherwise, the material is initially not used anywhere but becomes the active material in the domains (or other geometric entities) that you pick to add to that material's selection list.

Merging a Material Into Another Material

You can merge a material into another material. The other material, into which that material is merged, then inherits all material properties from the material that you merge. If both materials include the same material properties, then the values of those material properties in the material that you merge into another material are used in the other, remaining material. The **Material** node for the node that you merge into another material is removed from the model tree. To merge a material, do the following steps:

1 Right-click the **Material** node for the material that you want to merge into another material in the model.

2 From the **Merge Into** context menu, choose one of the materials in the same folder (under **Global Materials**, or under **Materials** in a **Component**), or choose a material from another folder.

3 The material is then merged into the material that you selected from the **Merge Into** menu. The material property values from this **Material** node is then used in the other material, and the original material property values are overwritten if both materials included some common material properties. This **Material** node is removed.

You can also use the **Merge Into** menu ( ) in the **Materials** toolbar.

Importing and Exporting Materials

You can import and export materials to and from your COMSOL Multiphysics models. The **Materials** toolbar include **Import Materials** and **Export Materials** buttons. You can also right-click one of the following nodes in the Model Builder and choose **Import Materials**, **Import Materials From**, or **Export Materials**:

- The **Materials** node under **Global Definitions**.
- The **Materials** node under **Definitions** in a component.
- Any node group under those branches.

The selected node determines where the imported materials will go or what materials to export into a new XML-file.

To import materials first select one of these nodes, then click the **Import Materials** button or choose it from a context menu. An **Import Materials** dialog appears that displays the content of the selected file. Select the materials to import and then click **OK** to import them to the model. You can also choose **Import Materials From**, which opens the **Select Model** fullscreen window for choosing a materials file from a database.

Some types of materials can only be imported to either **Global Definitions** or **Definitions**. Importing such a materials to the wrong branch is not allowed, so they are therefore ignored in the import. A message will appear when this happens.

To export materials, click the **Export Materials** button or choose it from a context menu. In the **Export Materials** dialog that appears, choose the file location and enter a name for the XML-file to export materials to. Click **OK** when you are done to export the materials in the chosen file.

MATERIAL IMPORT AND EXPORT FORMATS

COMSOL can import materials from the following formats:

- MPH files.
- Model XML-file format.
- A special XML-file format (JmatPro XML) for metal processing.

There are no special extension for the supported XML-file formats, and they expect the `.xml` extension. The COMSOL Multiphysics software detects the actual format automatically by looking at the first part of the file.

For materials export, COMSOL Multiphysics only supports explicit export to the Model XML-file format. You can export materials on the MPH-file format by just saving a model, which can contain materials only.

For more information about the XML-file format, see Materials in *The COMSOL File Formats* chapter in the *COMSOL Multiphysics Programming Reference Manual*.

To see how a material is stored in the Model XML-file format, you can export it from the COMSOL Desktop and then open the resulting XML-file to see the XML content for the exported materials.

Materials

Use the nodes under **Materials** ( ) to add predefined or user-defined materials, including layered materials and porous materials, to specify material properties using model inputs, functions, values, and expressions as needed, or to create a custom material library. Also see Material Link, Switch for Materials, Working with External Materials,

About the Material Libraries, Layered Material, Layered Material Link, Layered Material Stack, Single Layer Materials, Porous Material, and Topology Link.

You can right-click the **Materials** node and select **Add Material from Library** to add a material using The Add Material Window or select Browse Materials to open The Material Browser Window for more thorough information about the available materials in the material libraries. You can also select **Blank Material** to add a Material node with no predefined material properties.

MATERIAL OVERVIEW

This section provides an overview of the materials in the Component node and where they are used. You can also add materials under **Global Definitions**. To access such global materials in a model component, use a Material Link.

The **Material** column lists the current materials in the Component using the materials' node labels from the model tree according to the settings defined in Displaying Node Names, Tags, and Types in the Model Builder.

The **Selection** column lists the geometric entities selected for the material (the domains, boundaries, or edges where the material is defined).

ERRORS RELATING TO THE MATERIAL NODES

If a material property in a physics interface takes its value from a material and no material is defined for the same geometric selection, a stop sign (STOP) displays in the leftmost column and the **Material** column contains **Entities needing a material**. The **Selection** column contains the geometric entities in which a material definition is missing. The Materials node also indicates when there is a material error (see Figure 9-5). For example, if some property is deleted but needed in a part of the geometry, then the icon indicates where the error is located.

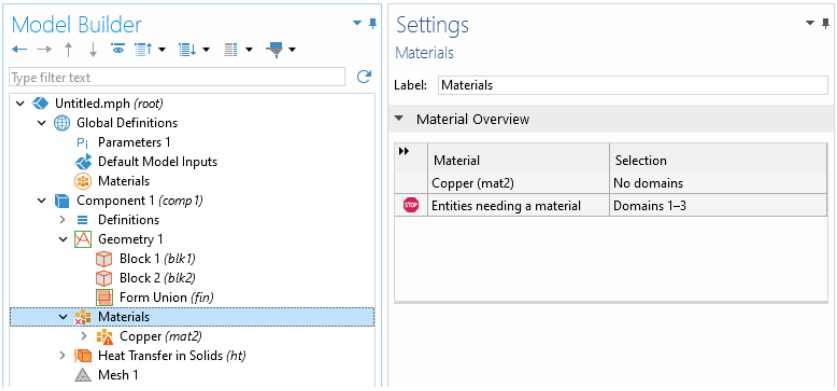

Figure 9-5: An example of a Materials node error.

Grouping of Materials for User-Defined Material Libraries

When creating materials for a user-defined material library, you can add **Group** nodes to create folders in the material library or to define a phase or a phase and orientation in the **Material Library Settings** section.

This structure will appear in the **Material Browser** window as folders and materials with a selection of phase or orientation/variation when you have saved the materials with their settings and group structure as an MPH-file and then imported that file as a user-defined material library.

When you add grouping for the phase and for an orientation or variation, use the **Label** in the **Group** node for the name of the material, such as `Material name`. For any subgroups or **Material** nodes for the phase, use `Material name [Phase]` as the **Label** for those nodes. For **Material** nodes under those phase groups, use `Material name [Phase, Orientation/variation]` as the **Label** to make the material appear with those phase and orientation or variation names (in brackets) as options in the **Phase** and **Orientation/variation** lists in the **Material Browser**.

Select the **Material Library Settings** checkbox in the **Show More Options** dialog to display this section for material under **Global Definitions**.

From the **Group type** list, choose one of the following options:

- **Library folder** (the default), to use the **Group** node's label as a library folder for organizing the material library into groups of material.
- **Phase**, to use the group for defining variations of a material with different material phases and possibly also orientation or variation. You define those properties in the **Material** subnodes' **Material Library Settings** sections.
- **Phase and orientation**, to use the group for materials with a certain phase and different orientation or variation. You define the orientation or variation in the **Material** subnodes' **Material Library Settings** sections. From the **Phase** list, choose **Custom**, **Solid**, **Liquid**, or **Gas** to define the phase of the materials in this group.

The Settings Window for Material

The **Settings** window for **Material** ( ) summarizes the predefined or user-defined material properties for a material. This is where you can add or change material properties to fit your model and assign the material to all types of geometric entities: domains (most common), boundaries, edges (3D models only), or points. Also see Material Link and Switch for Materials.

After adding a material (see The Add Material Window and The Material Browser Window), click the Material node (for example, **Material 1** or **Copper**) in the **Model Builder**. The **Settings** window for **Material** opens.

A standard **Material** node in the global component can turn into a layered material by adding a **Shell** property group. After that, it can be linked by a Layered Material Link

In the **Label** field, enter a suitable label for the material. If you defined global materials for a user-defined material library, the label becomes the name of the material. See also **Material Library Settings** below. You can also use the **Name** field to change the identifier. This setting also changes the tag and therefore makes it possible to control the scope of variables and functions that the material defines.

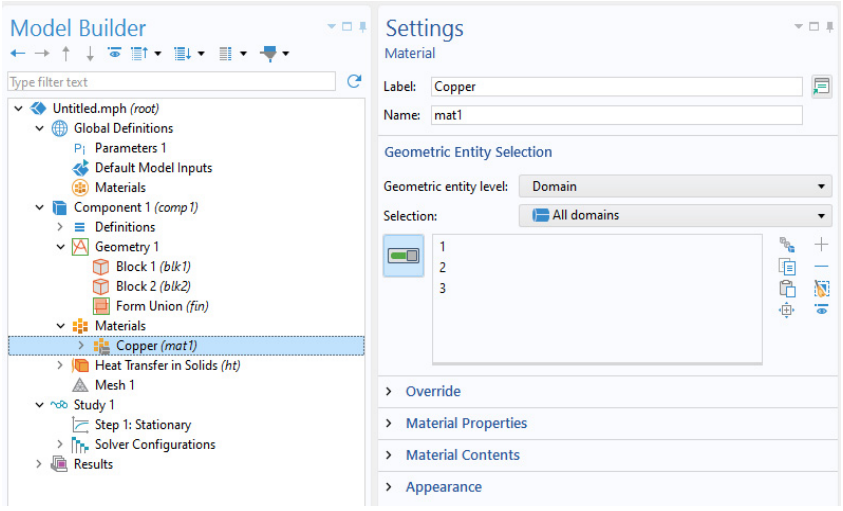

Figure 9-6: Click the Copper node to open the Settings window for Material for the node.

GEOMETRIC ENTITY SELECTION

This section is available for materials in a component. Assign the material to some or all entities on a specific **Geometric entity level** — **Domain**, **Boundary**, **Edge** (3D only), or **Point** — on the geometry in the **Graphics** window (the geometry in the model). The icon for the Material node indicates the geometry level. For a 3D component, for example, the following icon overlays represent the domain, boundary, edge, and point level, respectively: , , , and .

	By default, the first material in the Component is active in all domains (or all boundaries or edges if the Component only contains surfaces or edges). By assigning other materials to some or all domains, the first material is overridden and remains active only in domains where no other material, added below it in the **Materials** branch, is active.

	If the Component contains features on different geometric entity levels, such as solid mechanics in domains coupled to beams on edges, and the features use the same material, you need to add two Material nodes with the same material, one defined in the domains, and the other defined on the edges.

OVERRIDE

This section, available for materials in a component, shows if the material, in some or all parts of the geometry where it is active, is overridden by another material added underneath it in the Materials branch, or if it overrides another material above it.

The **Overridden by** list shows the names of the materials that override this material. The **Selection** list in the **Geometric Entity** section displays **(overridden)** for the geometric entities in which this material is overridden.

The **Overrides** list shows the names of the materials that this material overrides.

	• Physics Exclusive and Contributing Node Types • Physics and Variables Selection • Physics Node Status

ORIENTATION AND POSITION

	This section only appears in **Material** nodes that are single layer material. See Single Layer Materials.

Select a **Coordinate system** defining the principal directions of the laminate. Only **Boundary System** coordinate systems can be selected.

Choose a **Position** — **Midplane on boundary**, **Downside on boundary**, **Upside on boundary**, or **User defined**. This controls the possible offset of the material from the geometrical boundary on which the mesh exists (the *reference surface*). For **User defined**, enter a value for the **Relative midplane offset**. The value 1 corresponds to **Downside on boundary**, and the value –1 corresponds to **Upside on boundary**. Values may be outside the range –1 to 1, in which case the reference surface is outside the laminate.

The **Position** setting is only used by physics features where the physical behavior depends of the actual location, such as structural shells.

By clicking the **Layer Cross Section Preview** ( ) button, you get a preview plot of the single layer material, including the location of the reference surface. This plot looks similar to Figure 9-12, but there is only a single layer. You can also click the downward pointing arrow to choose **Layer Cross Section Preview** ( ) button or **Create Layer Cross Section Preview** ( ) button, which adds the preview plot as a new plot group under **Results**.

MATERIAL PROPERTIES

You can add material properties to the material if they are not already included. To do so, browse the available material property categories (**Basic Properties**, **Acoustics**, and so on), and select a material property or a collection of material properties in one of the property groups or material models that appear under the main level of material property categories. Right-click the material property or property group and select **Add to Material**, or click the **Add to Material** button (+) to add the material property or group of properties to the material.

	Review the properties listed in the **Material Contents** table before adding new material properties.

For example, under **Acoustics** > **Viscous Model** select **Bulk viscosity (muB)** and right-click to **Add to Material** or click the **Add to Material** button (+). If you add a material model like the **Viscous Model** with more than one property, all of its material properties are added to the **Material Contents** table. In this example, a **Viscous model** node is added to the **Model Builder** and its associated properties are added to the **Material Contents** table.

	To delete a property group, right-click the property group node (in the **Model Builder**) and select **Delete** ( ). The **Basic** property group cannot be deleted.

A Note About Adding Basic Material Properties

Material properties can be added to the **Basic** group or to any **User-Defined Property Group** from two locations — the **Settings** windows for **Material** and **Property Group**.

- When material properties are added from the **Basic** node's or a user-defined group node's **Settings** window for **Property Group**, they are listed under **Output Properties** and **Model Inputs** in that **Settings** window.
- When material properties are added from the **Settings** window for **Material**, the available material properties are listed under **Material Properties** and are added to the list under **Material Contents** with the property group listed. The list under **Material Contents** also contains material properties added from a subnode with a **Settings** window for **Property Group**.

Material Type

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Nonsolid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame and for which no unique material reference configuration can be defined.

Simply put, **Solid** materials associate material properties with specific pieces of the material, and the properties follow the material as it moves around. In particular, a solid material may be inherently anisotropic, meaning that its axes rotate together with the material. The **Nonsolid** choice, in contrast, applies typically to liquids and gases whose properties are associated with fixed points in space and insensitive to local rotation of the material. Such materials are inherently isotropic when studied in isolation but can exhibit anisotropy induced by external fields. In practice, this means that any anisotropic tensor properties in a nonsolid material must be functions of some external vector field.

MATERIAL CONTENTS

This section lists all of the material properties that are defined for the material or required by the physics in the model. The table lists the **Property**, **Variable**, **Value**, and **Unit** for the material property as well as the **Property group** to which the material property belongs. The **Property group** corresponds to the subnodes in the **Model Builder** with the same name. If required, edit the values or expression for the property's **Value**.

The left column provides visual cues about the status of each property:

- A stop sign ( ) indicates that an entry in the **Value** column is required. It means that the material property is required by a physics feature in the model but is undefined. When you enter a value in the **Value** column, the material property is added to its property group.
- A warning sign ( ) indicates that the material property has been added to the material but is still undefined. An entry is only required if the material property is to be used in the model.
- A check mark ( ) indicates that the property has a **Value** and is currently being used in the physics of the model.
- A synchronize symbol ( ) indicates that the property is computed and synchronized using the given values for other material properties from which it can be computed.
- Properties with no indication in the left column are defined but not currently used by any physics in the model.

You can change the value for any property that is not synchronized by editing its value directly in the **Value** column, or, for a selected property, click the **Edit** button ( ) or right-click and choose **Edit** to enter a value in the window that opens. If the property can be anisotropic, you can choose to enter the values in one of these forms: **Isotropic**, **Diagonal**, **Symmetric**, or **Full**. The **Variable** column lists the variable names corresponding to the degree of anisotropy. For example, for a symmetric electric conductivity, it contains **{sigma11, sigma12, sigma22, sigma13, sigma23, sigma33}; sigmaij = sigmaji**. For an isotropic electric conductivity, it contains **sigma_iso; sigmaii = sigma_iso, sigmaij = 0**, where `sigma_iso` is the name of the variable for the isotropic electric conductivity (available as, for example, `mat1.def.sigma_iso`).

If a material has properties that are defined using synchronization rules, the row for that property in the table will be disabled. To break the synchronization and add a value for this property, select the disabled row in table and click the **Break Synchronization** button ( ) in the toolbar underneath the table. The material model will then be added automatically, and the values of the parameters in the material model will be set to the expression used by the synchronization. It is then also possible to edit the expression for the property.

You can right-click any defined material property in the table and choose **Go to Requesting Node**; the focus in the model tree then moves to the node that requested that material property. If there are more than one node that requests that material property, a **Go to Requesting Node** dialog appears, where you can choose which of those nodes to go to. Also, for nodes such as **Material Link** and **Layered Material Link**, you can right-click any defined material property and choose **Go to Source** to move to the material node that is the source of that material property.

MATERIAL LIBRARY SETTINGS

Select the **Material Library Settings** checkbox in the **Show More Options** dialog to display this section for **Material** nodes under **Global Definitions**.

In this section, you can define properties for materials in a user-defined material library to create a set of materials with varying material phase and orientation or variation.

Click the **Update the Label** button ( ) to update the label, which becomes the name of the material in the user-defined material library.

From the **Phase** list, choose **Custom**, **Solid**, **Liquid**, or **Gas** to define the material's phase. This setting is not available if the parent **Group** node has its **Group type** set to **Phase and orientation**, in which case the phase is defined in that **Group** node's settings.

In the **Orientation/variation** field, enter some orientation or variation that represent this material.

Under **Material information**, it is possible to add material information such as a DIN or SAE number or using a custom title with some information. The type or title appears in the **Title** column. All entries appear with their information in the **Text** column. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons to rearrange the material information in the table, and click the **Add** (+) button to add more material information.

Click the **Edit Material Information** ( ) button to edit the content of the selected row. You can only add one table row for each type except **Custom**. The following material identification types are available from the **Type** list:

- **DIN**: The Deutsche Industrie Norm (DIN), a German standard.
- **UNS**: The unified numbering system (UNS) is an alloy designation system widely accepted in North America.
- **WNr**: The Werkstoffnummer (WNr) is a German material numbering system.
- **ISO/EN/DIN**: Numbering common to the ISO (International Organization for Standardization), EN (European Standards or Euronorm), and DIN.
- **JIS**: The Japanese Industrial Standards (JIS), a Japanese standard.
- **ASTM**: ASTM International, an international standards organization.
- **AISI**: Designations for materials from the American Iron and Steel Institute (AISI).
- **SAE**: Designations for materials from the Society of Automotive Engineers (SAE).
- **AMS**: SAE aerospace material specifications (AMS).
- **AFNOR**: Association Française de Normalisation (AFNOR) is a Paris-based standards organization and a member body for France at the International Organization for Standardization.
- **Custom** (the default): Add any custom material information type. For **Custom**, also add a **Title** for the information type.

For all entries, add the desired text in the **Information** field.

Click **OK** to save the edits. This material information then appears above the **Properties** table when you select the material from a library in the **Material Browser** window, and you can search using, for example, a material identification number.

APPEARANCE

The settings in this section, available for materials in a component, make it possible to control or change the default appearance of a material in the Graphics window when working in the materials or physics parts of the model tree.

In 3D components, the material is rendered including color and texture when **Scene Light** is active. In 2D models and in 3D components, when **Scene Light** is turned off, only a change of color is visible.

The **Material type** list provides quick settings approximating the appearance of a number of materials — **Air**, **Aluminum**, **Brick**, **Concrete**, **Copper**, **Glass**, **Gold**, **Iron**, **Lead**, **Magnesium**, **Oil**, **Plastic**, **Rock**, **Soil**, **Steel**, **Titanium**, **Water**, **Wood**, and many more. You can also choose **Default geometry material** and **Default plot material**, which can be useful to, for example, use in surface plots in apps to show something that looks like a geometry.Select **Custom** to make further adjustments of the specific settings for colors, texture, reflectance, and so on. The default custom settings are inherited from the material selected last from the **Material type** list. If you have chosen a family other than

Custom, click the **Customize** button to define a custom material. For **Plastic**, **Default plot material**, and some other materials, a separate **Color** list is available for adding a color (default: white). For **Default geometry material** the color is taken from the color theme.

Specular Color, Diffuse Color, and Ambient Color

For each of these properties, select a standard color from the list: **Black**, **Blue**, **Cyan**, **Gray**, **Green**, **Magenta**, **Red**, **White**, or **Yellow**, or choose **Custom** button to define a custom color from the color palette that becomes available underneath the list of colors.

The combination of **Specular color**, **Diffuse color**, and **Ambient color** gives a 3D object its overall color:

- **Specular color** is the color of the light of a specular reflection (specular reflection is the type of reflection that is characteristic of light reflected from a shiny surface).
- **Diffuse color** represents the true color of an object; it is perceived as the color of the object itself rather than a reflection of the light. The diffuse color gets darker as the surface points away from the light (shading). As with Ambient color, if there is a texture, this is multiplied by the colors in the texture, otherwise it is as if it has a white texture.
- **Ambient color** is the color of all the light that surrounds an object; it is the color seen when an object is in low light. This color is what the object reflects when illuminated by ambient light rather than direct light. Ambient color creates the effect of having light hit the object equally from all directions. As with Diffuse color, if there is a texture, this is multiplied by the colors in the texture; otherwise, it is as if it has a white texture.

For examples of specular, diffuse, and ambient light, which are related to these definitions, see About the 3D View Light Sources and Attributes.

Custom Basis for Brush Lines

Select the **Custom basis for brush lines** checkbox to define a custom coordinate basis for the brush lines. The default values for the brush line axes represent the global Cartesian coordinate system. Specify other x, y, and z coordinates for the **Origin** and the **xm-axis** if desired. To specify other coordinates for the **ym-axis**, first select the **Specify ym-axis** checkbox.

Normal Mapping

Select the **Normal mapping** checkbox to add normal vector noise and brush lines. Normal mapping is a texture that disturbs the normals when calculating lighting on the surface (also called bump mapping). This causes the surface to look rough and textured. The default **Normal vector noise scale** and **Normal vector noise frequency** are taken from the material. You can choose the type from the **Noise type** list: **White noise** (a uniform distribution) or **Simplex noise**.

Enter other values as needed, or click to clear the **Normal mapping** checkbox.

- The **Normal vector noise scale** is the power of the noise texture. A high value creates a stronger texture of the surface. A value between 0–1 is suitable.
- The **Normal vector noise frequency** is the size of the noise disturbances. A small value creates smaller features on the texture. A value between 0–10 is suitable.
- Add brush lines if desired by choosing an option from the **Brush lines** list: **No brush lines** (the default), **Brush lines orthogonal to xm-axis**, **Brush lines orthogonal to ym-axis**, **Brush lines orthogonal to zm-axis**, **Brush lines along xm-axis**, **Brush lines along ym-axis**, **Brush lines along zm-axis**, **Brush lines around xm-axis**, **Brush lines around ym-axis**, **Brush lines around zm-axis**, or **Brush lines around origin**.

The "m" in **xm**, **ym**, and **zm** above represents that the coordinates are with respect to the material basis (custom basis).

Additional Color

Select the **Additional color** checkbox if you want to blend the appearance with an additional color that is added on the surface using noise. The settings are similar to those for the normal mapping above, but you can also choose the color to add from the **Color** list and choose a **Color blend** between 0 and 1. The **Noise color** is a parameter that affects the appearance of the added color.

Opacity

The default **Opacity** is 1.

Lighting Model

The default **Lighting model** — **Blinn-Phong** or **Cook-Torrance** — is based on the material. Select **Simple** instead as needed; it has no additional settings.

The different lighting models provide a set of techniques used to calculate the reflection of light from surfaces to create the appropriate shading. For example, a specular highlight is the bright spot of light that appears on shiny objects when illuminated. Specular highlights are important in 3D computer graphics because they provide a strong visual cue for the shape of an object and its location with respect to light sources in the scene.

For **Blinn-Phong**, the default **Specular exponent** is 64. The specular exponent determines the size of the specular highlight. Typical values for this property range from 1 to 500, with normal objects having values in the range 5 to 20. This model is particularly useful for representing shiny materials.

For **Cook-Torrance**, the default settings are taken from the material. The Cook–Torrance lighting model accounts for wavelength and color shifting and is a general model for rough surfaces. It is targeted at metals and plastics, although it can also represent many other materials, and it includes the following settings.

- The **Reflectance at normal incidence** value is the amount of incoming light from the normal direction (of the surface) that is reflected.
- The **Surface roughness** is a value that describes microreflectance on the surface. Higher values create a rougher look of the surface with fewer highlights.
- The **Anisotropy** is a value that defines the anisotropic specular highlighting. You can use it to give an effect that could be the result of machining or polishing in a certain direction. Select the **Flip anisotropy** checkbox to flip that apparent direction. Also, enter the direction of the anisotropy axis as a vector with three components in the **Anisotropy axis** field.
- The **Metallic** parameter is a value that affects how metallic the material appears to be. A less metallic material reflects less of the environment. A nonmetallic material cannot reflect the environment
- The **Pearl** parameter is an artificial effect that mimics the colors of a pearl.
- The **Diffuse wrap** value gives an artificial effect that you can use to emulate subsurface scattering.
- The **Clear coat** parameter is an artificial effect that makes surfaces that are parallel to the view direction more white. It also adds specular highlighting and reduces the effect on the environment reflections from the normal mapping.
- The **Reflectance** value is an additional setting that affects how much of the environment that is reflected.

You can enter these values in the respective text fields; alternatively, use the sliders underneath each text field to adjust those values between 0 and 1. If you use the sliders, the material appearance is updated directly.

Property Groups

The **Settings** window for **Property Group** nodes ( ) is where output properties and model inputs are added, local properties are defined, and expressions for material properties are entered in a specific property group such as **Basic**. The property groups are subnodes to a material node. The **Settings** window for **Property Group** is displayed when

you click the property group node (for example, **Basic**) under the material node (typically with the material's name — **Aluminum**, for example) in the **Model Builder**.

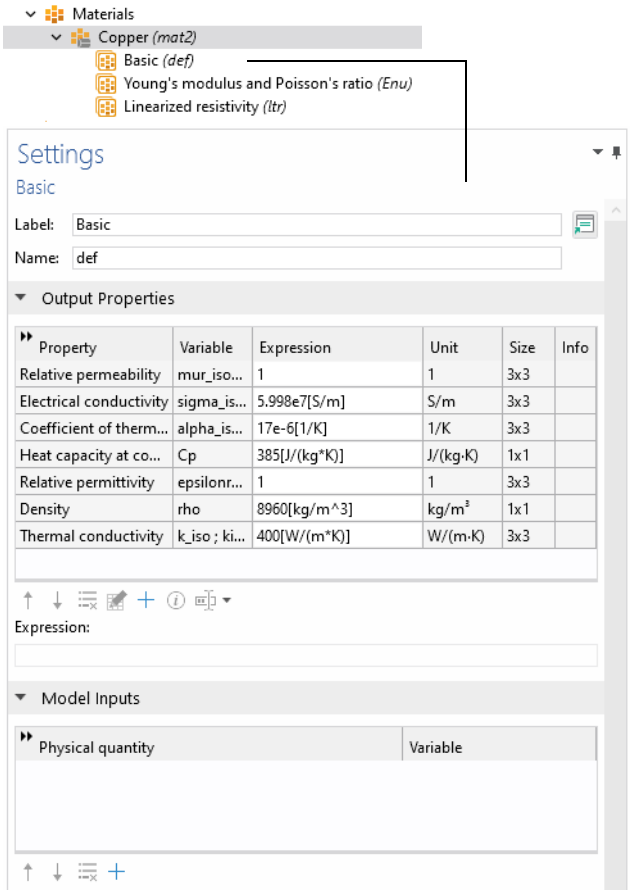

Figure 9-7: An example of a Basic Settings window for Property Group.

A property group under a material creates the following variables:

TABLE 9-1: VARIABLES GENERATED FROM A PROPERTY GROUP.

TYPE	VARIABLE NAME	SCOPE	SELECTION	EXAMPLE
Basic property	Variable name of physical quantity	`root.material`	Material selection	`root.material.rho`
		`root.<comp>.<mat>.<group>`	Global selection	`root.comp1.mat1.def.rho`
Output property	Property name	`root.material.group`	Material selection	`root.material.linzRes.alpha`
		`root.<comp>.<mat>.<group>`	Global selection	`root.comp1.mat1.linzRes.alpha`

In the **Label** field, enter a suitable label for the property group if needed. You can also use the **Name** field to change the identifier. This setting also changes the tag — except for the Basic property group, where it is always `def` — and therefore makes it possible to control the scope of variables and functions that the property group defines. You can, for example, make the identifier shorter.

OUTPUT PROPERTIES

The predefined material properties in the property group appear in a table in the **Output Properties** section.

It is only possible to add, move, and delete output properties from the **Basic** material properties and with user-defined property groups.

Click the **Add** button (+) to add another output property, which you choose from one of the available physical quantities in the **Physical Quantity** dialog that opens.

If required, edit the expressions in the list's **Expression** column. Edit directly in the table or in the **Expression** field underneath the table. You can insert predefined expressions by clicking the **Insert Expression** button ( ) or clicking Ctrl+Space and then choosing an expression from the list of predefined expressions. You can also click the **Edit** button ( ), which opens a dialog for easier specification of orthotropic and anisotropic material properties (tensors), when applicable. Select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** when entering the data in the material property's dialog. In the **Expression** column, use a syntax with curly braces such as `{k11, k21, k31, k12, k22, k32, k13, k23, k33}` to enter anisotropic material properties for a 3-by-3 tensor k_{ij} in the order k_{11}, k_{21}, k_{31}, k_{12}, k_{22}, k_{32}, k_{13}, k_{23}, and k_{33}. 1, 2, and 3 represent the first, second, and third direction in the active coordinate system. In many cases (for example, when entering the elasticity matrix for structural mechanics), the matrix must for physical reasons be symmetric. The upper diagonal part of the matrix you enter will then be mirrored when forming the actual constitutive matrix, and the lower diagonal part is ignored.

The **Variable** column lists the variable names depending on the type of anisotropy. For an isotropic k, `k_iso` represents its single scalar value.

The **Unit** and **Size** columns provide information about the unit and size of the output property. The size is 1x1 for a scalar value such as density and 3x3 for a tensor (matrix) quantity such as electric conductivity.

If desired, you can add information about the property, such as references for its value or expression. To do so, click the **Edit/Show Property Information** button ( ) and enter the property information in the dialog that opens and then click **OK**. When information is available for a property, an information symbol ( ) appears in the **Info** column.

Use the **Move up** (↑), **Move down** (↓), and **Delete** ( ) buttons to organize the table as needed.

MODEL INPUTS

The model inputs are physical quantities, such as temperature, that are used as inputs in the expressions that define the output properties (for example, to describe a temperature-dependent physical quantity). For example, adding **Temperature** as a model input with the variable name `T` makes it possible to use an expression for the heat capacity at constant pressure C_p, such as `300[J/(kg*K)]*T[1/K]`, which works regardless of the name of the actual dependent variable for temperature in the model that uses the temperature-dependent material. Without the model input, the expression above only works with a temperature variable called `T`.

Click the **Add** button (+) to add another model input, which you choose from one of the available physical quantities in the **Physical Quantity** dialog that opens.

Use the **Move up** (↑), **Move down** (↓), and **Delete** ( ) buttons to organize the table as needed.

LOCAL PROPERTIES

Here you can enter a user-defined property by entering its variable name in the **Name** column and its corresponding **Expression** and organizing the table as needed. You can also enter a **Description**, which appears in the **Property** column in the **Material Contents** section of the parent **Material** node. In that node, the **Name** entered here appears in the **Variable** column. These local properties are useful for parameterizing functions that describe material properties if they contain inputs other than those that are model inputs (such as temperature and pressure). For

example, a local property can be a reference value at a certain temperature. Use the **Move up** (↑), **Move down** (↓), and **Delete** ( ) buttons to organize the tables as needed.

	You can use local properties to parameterize a material (for example, to create a generic "template" material for a particular symmetry class of anisotropic materials). You can then adjust the local property values for each instance of the material.

About Automatic Adding of Property Groups to a Material

Material property groups are automatically added to the material node in the **Model Builder**. You can also add additional predefined property groups or create a **User-Defined Property Group** (in the **Materials** toolbar, click **User-defined Property Group** ( ) or right-click the **Material** node). The available properties are collected in property groups according to the physical context.

Each property group has a **Settings** window for **Property Group**. When a **Model Builder** node is clicked (for example, **Basic**), the **Settings** window for **Property Group** displays specific information about that property group. The physical properties for all property groups are summarized in a **Material Contents** table in the **Settings** window for the parent **Material** node.

Material Link

Add a **Material Link** node ( ) under a **Materials** node in a model component to add a link to a material that you have added under the global **Materials** node ( ) and use it as a material in that component's geometry. To add it, right-click the **Materials** node and choose **Material Link** from the **More Materials** submenu. The **Material Link** node's **Settings** window is similar to the **Settings** window for a material node (see The Settings Window for Material), with the exception that there is no **Material Properties** sections. Instead, it includes the following section:

LINK SETTINGS

From the **Material** list, select the global material that you want to link to:

- Any global material node, to use that material in the component.
- Any **Switch** node, if you want to run a material sweep.
- **None**, to not link to any global material.

Click the **Go to Material** button ( ) to move to the selected material node. Click the **Add Material from Library** button (+) to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

Switch for Materials

Use the **Material Switch** node ( ) to switch between materials during a solver sweep. You add the materials as subnodes under the **Material Switch** node. Right-click to add a **Blank Material** or select **Add Material from Library** to select materials from the libraries in the **Add Material** window. You can also add a **Layered Material** or a **Single Layer Material**.

The switch for materials essentially acts as a switch statement in a programming language; that is, it dynamically selects one of its underlying branches depending on a parameter that can be controlled from the solvers, using a Material Sweep study. The parameter name is constructed based on the tag of the Material Switch node, using the special namespace `matsw`. For example, the parameter controlling a Switch node on the global level will typically be `matsw.sw1`, while for a component-level Switch it will be `matsw.comp1.sw1`.

During a material sweep, the sweep parameter takes consecutive integer values, starting from one, indicating which material under the switch that should currently provide material properties. You can use the parameter name in conditional expressions to control also other aspects of the model. Conversely, it is possible to control a material Switch also by manually defining the full switch parameter name in a **Parameters** node. You can then choose the parameter to sweep over in a standard **Parametric Sweep** node or assign it different (integer) values in different parameter **Case** nodes and sweep using a *Parameter switch* sweep.

The **Material Switch** node's **Settings** window contains the following sections:

MATERIAL CONTENTS

This section lists all of the material properties that are defined for the material or required by the physics in the model on domains where the **Switch** node is the active domain material. The table lists the **Property**, **Name**, **Value**, and **Unit** for the material property as well as the **Property group** to which the material property belongs. The **Property group** corresponds to the subnodes in the **Model Builder** with the same name. If required, edit the values or expression for the property's **Value**.

The list includes properties that are defined by any of the materials under the **Switch** node. The left column provides visual cues about the status of each property:

- A stop sign ( ) indicates that some subnode is missing a required **Value**. That is, the material property is required by a physics feature in the model but is not defined for all switch cases.
- A warning sign ( ) indicates that the material property has been added to some material subnode but is still undefined.
- A check mark ( ) indicates that the property has a **Value** in all subnodes and is currently being used in the physics of the model.

APPEARANCE

The settings in this section make it possible to control or change the default appearance of the material switch in the Graphics window when working in the materials or physics parts of the model tree. See The Settings Window for Material for more information.

Layered Material

In the **Layered Material** node ( ), you can specify the properties of a multilayer laminate. It is used when defining the properties of the following features:

- The Layered Shell interface (requires the Composite Materials Module).
- **Linear Elastic Material, Layered** in the Shell or Membrane interface (requires the Composite Materials Module).
- **Hyperelastic Material, Layered** in the Shell interface (requires the Composite Materials Module).
- **Piezoelectric Material, Layered** in the Shell interface (requires the Composite Materials Module).
- **Thin Layer** in the Heat Transfer in Solids interface.
- The Heat Transfer in Shells interface (requires the Heat Transfer Module).
- The Electric Currents, Layered Shell interface (requires the AC/DC Module).

A **Layered Material** node can be present in two locations in the Model Builder:

- The most common place is under **Global Definitions** > **Materials**. When you reference a layered material from a physics interface, you do it indirectly through either a Layered Material Link or a Layered Material Link (Subnode) under **Materials** in the current component.
- It can also be a subnode under a Layered Material Stack node in a component.

LAYER DEFINITION

In this table you specify the properties of each layer.

Click the **Add** button (+) to add another table row. Use the **Move up** (↑), **Move down** (↓), and **Delete** ( ) buttons to organize the table as needed. To completely reset the table to its default state, you can use the **Reset to Default** button ( ).

Conceptually, the layers are ordered from bottom to top of the laminate. Enter the following data in the table:

Layer

Here you can assign a name to the layer for future reference. The default is a sequential numbering: Layer 1, Layer 2, and so on.

Material

Select any available material. If the **Layered Material** node is located under **Global Definitions**, the list contains only global materials. If the **Layered Material** node is used as a subnode to a **Layered Material Stack**, also materials defined under **Materials** in the component are available.

When you have a certain row in the table selected, you can access three shortcuts:

- Click the **Blank Material** ( ) button to add a new blank material under global materials. The material is referenced in current row of the **Material** column.
- Click the **Add Material from Library** ( ) button to add a new material under global materials from Material Libraries. The material is referenced in current row of the **Material** column.
- Click the **Go to Material** ( ) button to jump to the definition of the material selected on the current row.

When you add a new row to the table, the same material as on the previous row is selected. This means that if you have many, not adjacent, layers with the same material, it is more efficient to initially add all layers with that same material. Then you can go back and change the material for some layers. Alternatively, you can reorder the layers using the **Move up** (↑) and **Move down** (↓) buttons.

Rotation

If the material in the layer is orthotropic or anisotropic, enter the angle in degrees (positive counterclockwise) from the first principal axis of the laminate to the first principal axis of the layer. Even for an isotropic material, the orientation can matter for result presentation, since it affects the interpretation of for example stress tensor components.

Thickness

Enter the thickness of the layer (default unit: m). The thickness can be numeric value or a scalar parameter.

Mesh Elements

In the physics interfaces, the layered materials are handled through the concept of a virtual *extra dimension*. For a layered material defined on a boundary, you can think of that as an extra coordinate in the normal direction. Enter the number of elements that you want in the extra dimension for the layer.

INTERFACE PROPERTY

In some physics features, not only the layers themselves but also the interfaces between them are important. In such a case, you can assign materials to the interfaces in this table. The number of interfaces is one more than the number of layers because the free top and bottom surfaces of the laminate are also considered as interfaces.

In most cases, you do not need to enter anything in this section.

Interface

This is the interface name, for future reference. As a default, the interface name is constructed from the names of the two adjacent layers. For the top and bottom interfaces, the labels “up” and “down” are used for the two exterior sides.

You can rename the interfaces. This is, however, seldom needed.

Position

This column shows the location of the interface. The distance is counted from the bottom of the laminate. The column is for information only, and cannot be modified.

Material

Select the material of the interface. You only need to assign materials to the interfaces that are explicitly referenced by physics features. The default is to take the material **From layer**. The interface material properties are then computed from the adjacent layers’ material properties.

Figure 9-8 shows an example of the settings for a layered material. The layer names have been entered manually, whereas the interfaces have retained their default names.

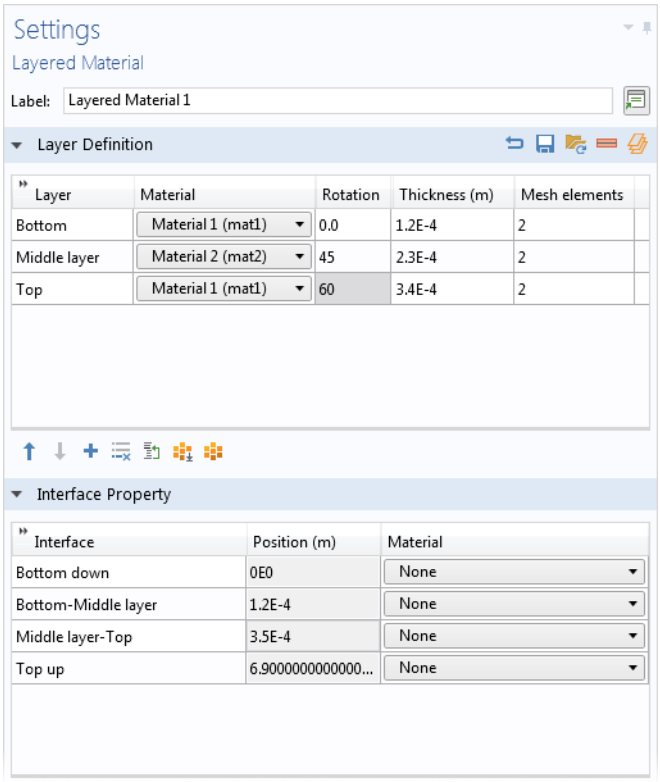

Figure 9-8: Settings for a material with three layers.

You can save the laminate definition to a text file by clicking the **Save Layers to File** ( ) button. For the example above, the text file has the following contents:

```
Bottom mat1 0.0 1.2E-4 2
"Middle layer" mat2 45 2.3E-4 2
Top mat1 60 3.4E-4 2
```

To load a text file on this format, click the **Load Layers from File** ( ) button. For complex laminates, it may be easier to start by creating the text file representation in a text editor, than to enter the data in the GUI.

	When loading a file, the second column containing the material tag is ignored. The reason is that there is no way to ascertain that a material tag like '`mat2`' would point to the same material in another context. You can even load a file where that column is absent.

You have two options for visualizing the laminate defined in the **Layered Material** node. To see the thickness of each layer, click the **Layer Cross Section Preview** ( ) button. This will give a plot like the one shown in Figure 9-9.

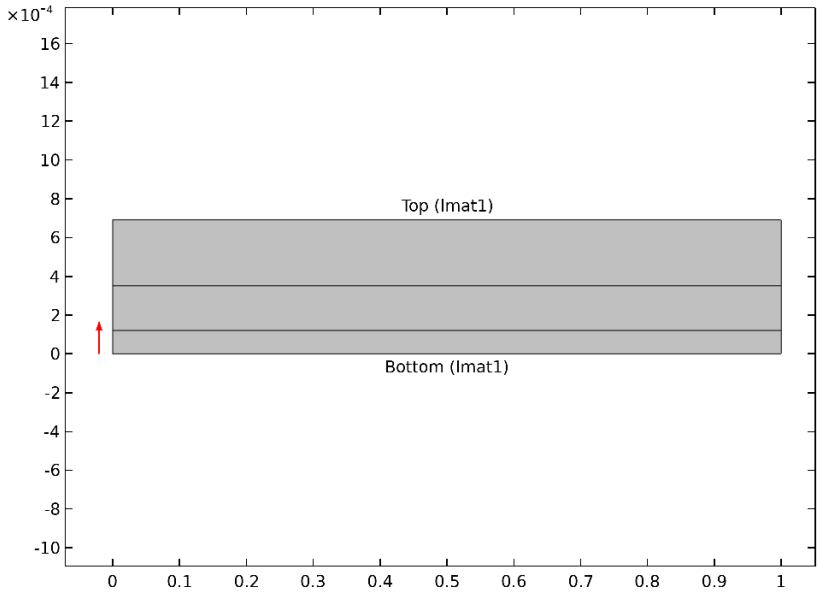

Figure 9-9: The layer cross section plot for a material with three layers.

You can also click the downward pointing arrow to choose **Layer Cross Section Preview** ( ) or **Create Layer Cross Section Preview** ( ), which adds the preview plot as a new plot group under **Results**. By clicking the **Layer Cross Section Preview** ( ) button, you get a preview plot of the single layer material, including the location of the reference surface. This plot looks similar to Figure 9-12, but there is only a single layer.

To visualize the layer orientations, click the **Layer Stack Preview** ( ) button. In Figure 9-10, an example of such a plot is shown. The x-axis corresponds to the principal laminate direction, and the stripes indicate the principal direction of each layer. You can also click the downward pointing arrow to choose **Layer Stack Preview** ( ) or

Create Layer Stack Preview ( ), which adds the preview plot as a new plot group under **Results**. Click the **Create Layer Stack Plot** button ( ) to add the preview of the layer stack as a new plot group under **Results**.

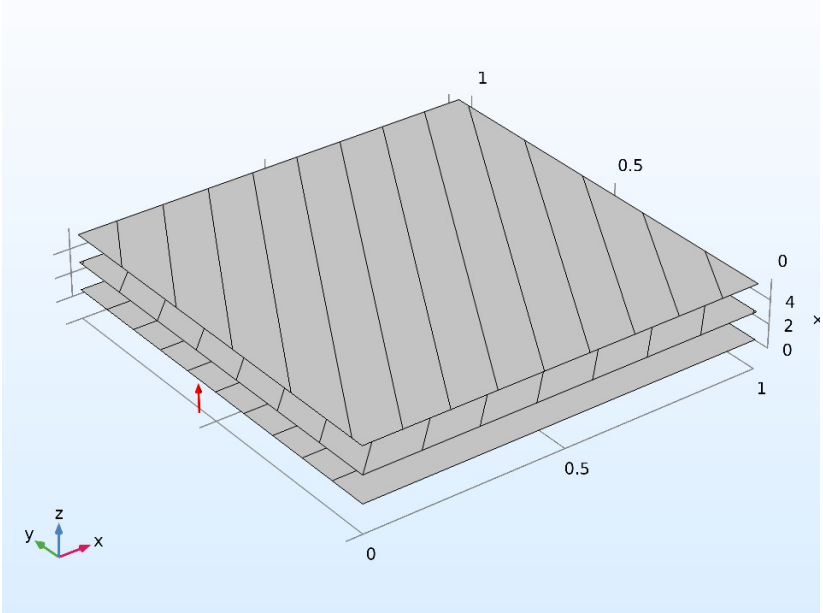

Figure 9-10: The layer stack preview plot for a material with three layers.

PREVIEW PLOT SETTINGS

In this section, you can fine-tune the display in the preview plots.

In the **Distance between the orientation lines** text field, you can enter a value for the spacing of the stripes showing the orientation of the principal orientation of the layer. The layer itself is always drawn as a square with the unity side length. If you clear the corresponding checkbox, no orientation lines are drawn.

The value of the **Thickness-to-width ratio** is used by both types of preview plots.

- In a layer stack preview plot, it controls the height of the stack in the z direction. For laminates with many layers, you may need to increase this value.
- In the layer cross section preview plot, it controls the height in the y direction. The width is always unity.

Clear the **Shows labels in cross section plot** checkbox to remove the text labels showing layer names and materials.

Layered Material Link

The **Layered Material Link** node ( ) provides a bridge from a Layered Material, located under **Global Definitions**, to a physics feature residing in a component. A physics feature designed to work with layered materials cannot directly reference a **Layered Material**. The **Layered Material Link** node is located in the **Layers** submenu under a **Materials** node.

LAYERED MATERIAL SETTINGS

Select a layered material from the **Material** list. You can also select a Switch for Materials.

By clicking the **Go to Material** ( ) button, you can jump to the settings for the selected material.

Click the **Add Layered Material** button (+) to add another **Layered Material** or a **Switch**. The added material then becomes the one selected in the **Material** list.

From the **Transform** list, choose one of the following options:

- **None** (the default), for no transformation.
- **Symmetric** or **Antisymmetric**, to create a symmetric or antisymmetric layered material when the information of layers of one side of the midplane is supplied. Choose which side to mirror in from the **Mirror in** list: **Upside** (the default) or **Downside**. Upside means that the symmetry layers are on the top of the original layers. The symmetry line is the top-side boundary. Downside means that the symmetry layers are on the bottom of the original layers. The symmetry line is the bottom-side boundary. Select the **Merge middle layers** checkbox to merge the two middle layers into one to create an odd symmetric layer.
- **Repeated**, to create a number of repeating stacks, which you enter in the **Number of repeats** field (default: 1).

Select the **Scale** checkbox to scale the layered material's thickness with a factor (default: 1).The scale can be a numerical value, a parameter, or an expression. Such an expression can, for example, be a function of the coordinates so that a surface with variable thickness can be described.

If a single layer in a laminate has a variable thickness, you can define that layer in either a separate **Layered Material** or in a **Single Layer Material**.

- When using a **Layered Material**, apply the scaling expression in a **Layered Material Link**, and then use a **Layered Material Stack** to build the complete laminate.
- When using a **Single Layer Material** with an expression for the thickness, use a **Layered Material Stack** to build the complete laminate.

If you have defined a layer with a scaling factor, it appears in the preview window with a darker color than a nonscaled layer.

The preview is not shown in the base geometry space, so it will not show any geometrical dependency.

The labels of the newly created layers include a suffix to distinguish them from the original layers:

- **(sym)** for the symmetric layers.
- **(asym)** for the antisymmetric layers.
- **(repX)** for the repeated layers (number *X*).

Click the **Layer Cross Section Preview** button ( ) to plot a preview of the layer cross section including the transformation (see the following plot for an example).

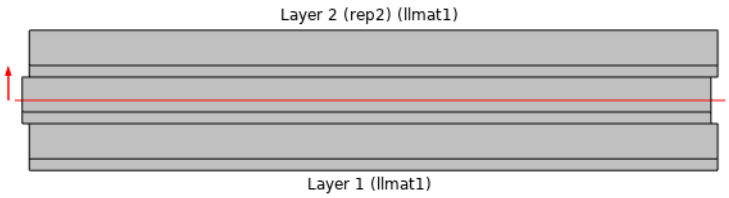

Figure 9-11: A repeat laminated stacks with 2 times repeated layers.

You can also click the downward pointing arrow to choose **Layer Cross Section Preview** ( ) or **Create Layer Cross Section Preview** ( ), which adds the preview plot as a new plot group under **Results**.

Click the **Layer Stack Preview** button ( ) to get a preview of the stack with the transformation.

ORIENTATION AND POSITION

Select a **Coordinate system** defining the principal directions of the laminate. The orientation of each layer, given in the **Layered Material** node, is a rotation from the first coordinate axis of this coordinate system. Only **Boundary System** coordinate systems can be selected.

Choose a **Position** — **Midplane on boundary**, **Down side on boundary**, **Up side on boundary**, or **User defined**. This controls the possible offset of the layered material from the geometrical boundary on which the mesh exists (the *reference surface*). For **User defined**, enter a value for the **Relative midplane offset**. The value 1 corresponds to **Down side on boundary**, and the value –1 corresponds to **Up side on boundary**. Values can be outside the range –1 to 1, in which case the reference surface is outside the laminate.

The **Position** setting is only used by physics features where the physical behavior depends of the actual location, such as structural shells.

By clicking the **Layer Cross Section Preview** ( ) button, you get a preview plot of the layered material, including the location of the reference surface (Figure 9-12). The height of the laminate in the plot is controlled by the value of the **Thickness-to-width ratio** specified in the **Preview Plot Settings** for the selected layered material. You can also click the downward pointing arrow to choose **Layer Cross Section Preview** ( ) or **Create Layer Cross Section Preview** ( ), which adds the preview plot as a new plot group under **Results**.

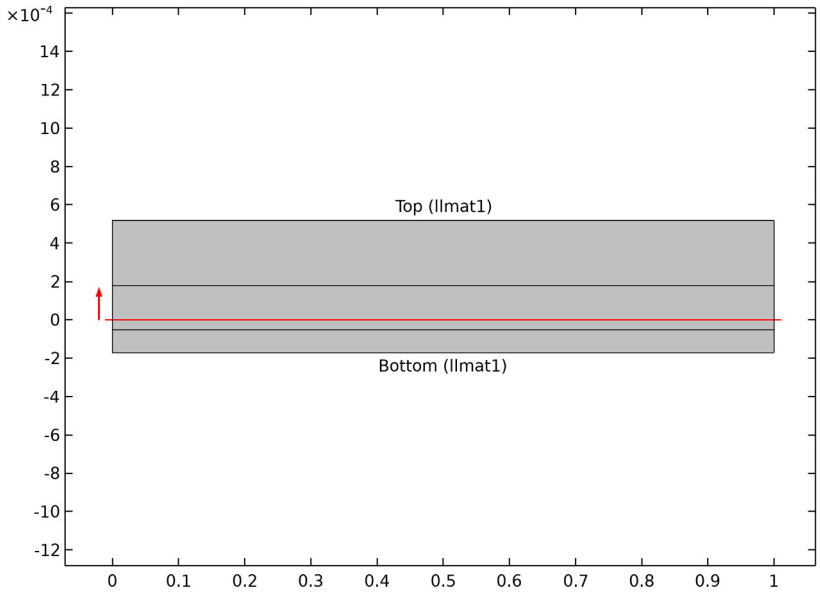

Figure 9-12: Layer cross section preview plot with relative offset set to 0.5.

NONLAYERED MATERIAL SETTINGS

In some cases, a single standard material definition is needed on the same boundary as a layered material. This can, for example, be the case if two different physics interfaces are active on the same boundary, but only one of them supports a layered material definition. You can select any nonlayered material from the **Material** list. The default settings is **Same as layered material**, which means that the nonlayered material properties are computed as an average value of the layer's material properties. This selection is completely analogous to using a Material Link.

You cannot use an ordinary **Material** or **Material Link** with the same selection as the **Layered Material Link**. These nodes override each other.

By clicking the **Go to Material** ( ) button, you can jump to the settings for the selected material.

Click the **Add Material from Library** button (+) to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

PREVIEW PLOT SETTINGS

In this section, you can fine-tune the display in the preview plot.

The value of the **Thickness-to-width ratio** controls the height in the *y* direction. The width is always unity.

Deselect the **Shows labels in cross-section plot** checkbox to remove the text labels showing layer names and materials.

MATERIAL CONTENTS

See the documentation for Material Contents for the **Material** node.

The **Value** column will usually contain the string `Layer`, indicating that the actual value is layer dependent.

APPEARANCE

See the documentation for Appearance for the **Material** node.

Layered Material Stack

In the **Layered Material Stack** node ( ), you can compose a new layered material by stacking other layered materials (including Material nodes that define single-layer materials) on top of each other. There are three main reasons why you may want to do this:

- The layup is repetitive, say with the same four layers repeated five times. Rather than defining twenty layers in a **Layered Material** node, you define four, and then add this definition five times in a **Layered Material Stack**.
- There are layer drop-offs, that is some layers are not present everywhere in the structure. Then, it is efficient to create only subsets of the laminate in **Layered Material** nodes, and use a number of **Layered Material Stack** nodes to combine them into different configurations.
- Two **Layered Material Stack** nodes can have parts of their definitions linked to the same **Layered Material** node. When a transition through a continuity feature is used, the corresponding layers in two laminates defined as stacks can be connected automatically.

Ply modeling can be achieved from the selection of substack materials. By using different selections on each stack member, you can create ply-based selections. From the ply-based selections, a set of the product selections, called zone-based selections, can be deduced and displayed in a **Stack Zone Definition** section (see below).

The **Layered Material Stack** node is located in the Layers submenu under a Materials node. To compose the stack, you add subnodes to the **Layered Material Stack**. These subnodes can be either a Layered Material or a Layered Material Link (Subnode). You can add any number of subnodes, and mix the two types. The order of the subnodes determines the ordering of the layers in the final laminate.

The interface between the two **Layered Material Stack** nodes takes the interface material from the first **Layered Material Stack** node and ignores the interface material of the second **Layered Material Stack** node.

LAYERED MATERIAL SETTINGS

From the **Transform** list, choose one of the following options:

- **None** (the default), for no transformation.

- **Symmetric** or **Antisymmetric**, to create a symmetric or antisymmetric layered material when the information of layers of one side of the midplane is supplied. Choose which side to mirror in from the **Mirror in** list: **Upside** (the default) or **Downside**. Upside means that the symmetry layers are on the top of the original layers. The symmetry line is the top-side boundary. Downside means that the symmetry layers are on the bottom of the original layers. The symmetry line is the bottom-side boundary. Select the **Merge middle layers** checkbox to merge the two middle layers into one to create an odd symmetric layer.
- **Repeated**, to create a number of repeating stacks, which you enter in the **Number of repeats** field (default: 1).

Select the **Scale** checkbox to scale the layered material's thickness with a factor (default: 1). If you have defined a layer with a scaling factor, it appears in the preview window with a darker color than a nonscaled layer.

The preview is not shown in the base geometry space, so it will not show any geometrical dependency.

The labels of the newly created layers include a suffix to distinguish them from the original layers:

- **(sym)** for the symmetric layers.
- **(asym)** for the antisymmetric layers.
- **(repX)** for the repeated layers (number *X*).

Click the **Layer Cross Section Preview** button (to plot a preview of the layer cross section including the transformation. You can also click the downward pointing arrow to choose **Layer Cross Section Preview** ( ) or **Create Layer Cross Section Preview** ( ), which adds the preview plot as a new plot group under **Results**. Click the **Layer Stack Preview** button ( ) to get a preview of the stack with the transformation. Click the **Create Layer Stack Plot** button ( ) to add the preview of the layer stack as a new plot group under **Results**.

A combination of transformations can be made by defining the transformations for both the **Layered Material Stack** node and a **Layered Material Link** subnode.

ORIENTATION AND POSITION

Select a **Coordinate system** defining the principal directions of the laminate. The orientation of each layer, given in the **Layered Material** node, is a rotation from the first coordinate axis of this coordinate system. Only **Boundary System** coordinate systems can be selected.

Choose a **Position** — **Midplane on boundary**, **Down side on boundary**, **Up side on boundary**, or **User defined**. This controls the possible offset of the layered material from the geometrical boundary on which the mesh exists (the *reference surface*). For **User defined**, enter a value for the **Relative midplane offset**. The value 1 corresponds to **Down side on boundary**, and the value –1 corresponds to **Up side on boundary**. Values may be outside the range –1 to 1, in which case the reference surface is outside the laminate. If you use ply modeling, these additional positions are available: **Midplane of stack member on boundary**, **Downside of stack member on boundary**, **Upside of stack member on boundary**. If you choose one of those positions, also choose a member of the ply stack from the **Stack member** list. Also, with one of those positions, the **Automatic alignment when the selected stack member is not available** checkbox is selected by default. The stack members (in zones that do not have the selected stack member) will then be aligned with the stack members in the zone that have the selected stack member. Clear it if you do not want that automatic alignment.

The **Position** setting is only used by physics features where the physical behavior depends of the actual location, such as structural shells.

By clicking the **Layer Cross Section Preview** ( ) button, you get a preview plot of the stacked layered material, including the location of the reference surface. In Figure 9-13, a laminate composed of three stacked layered materials, each consisting of three layers is shown. Note that there is a slight indentation, used for emphasizing the transition from one part of the stack to the next.

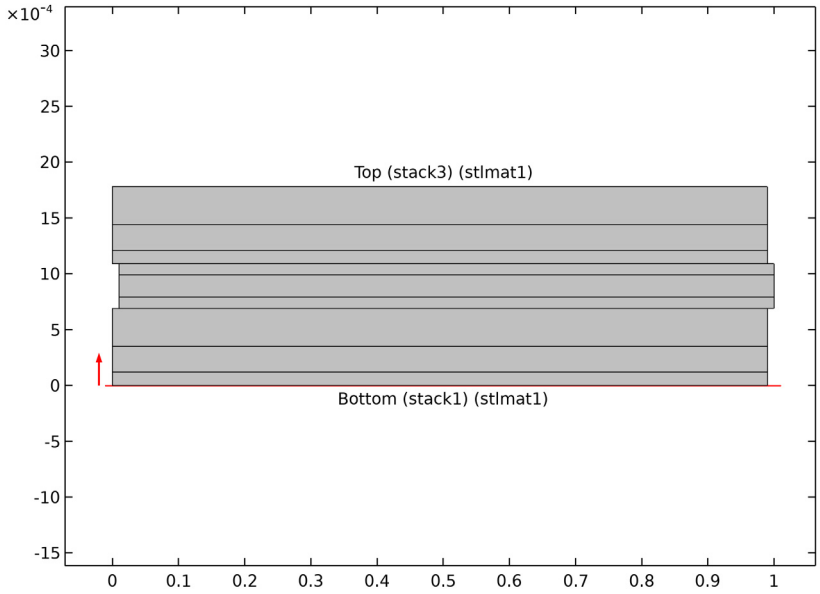

Figure 9-13: Layer cross section preview plot with relative offset set to Down side on boundary.

You can also click the downward pointing arrow to choose **Layer Cross Section Preview** ( ) or **Create Layer Cross Section Preview** ( ), which adds the preview plot as a new plot group under **Results**.

STACK ZONE DEFINITION

This section is available if there are multiple zones. It then lists the names of the zones, the stack members for each zone, and the boundary selections for each zone.

NONLAYERED MATERIAL SETTINGS

In some cases, a single standard material definition is needed on the same boundary as a layered material. This can for example be the case if two different physics interfaces are active on the same boundary, but only one of them supports a layered material definition. You can select any nonlayered material from the **Material** list. The default settings is **Same as layered material**, which means that the nonlayered material properties are computed as an average value of the layer's material properties. This selection is completely analogous to using a Material Link.

You cannot use an ordinary **Material** or **Material Link** with the same selection as the **Layered Material Stack**. These nodes override each other.

By clicking the **Go to Material** ( ) button, you can jump to the settings for the selected material.

Click the **Add Material from Library** button ( ) to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

PREVIEW PLOT SETTINGS

In this section, you can fine-tune the display in the preview plot.

The value of the **Thickness-to-width ratio** controls the height in the *y* direction. The width is always unity.

Deselect the **Shows labels in cross-section plot** checkbox to remove the text labels showing layer names and materials.

MATERIAL CONTENTS

See the documentation for Material Contents for the **Material** node.

The **Value** column will usually contain the string `Layer`, indicating that the actual value is layer dependent.

APPEARANCE

See the documentation for Appearance for the **Material** node.

Layered Material Link (Subnode)

The **Layered Material Link** subnode ( ) is used for referencing a Layered Material from a Layered Material Stack node. You can add any number of **Layered Material Link** subnodes under a **Layered Material Stack** node.

LINK SETTINGS

Select a layered material from the **Material** list.

By clicking the **Go to Material** ( ) button you can jump to the settings for the selected material.

Click the **Add Layered Material** button (+) to add another **Layered Material** or a **Switch**. The added material then becomes the one selected in the **Material** list.

From the **Transform** list, choose one of the following options:

- **None** (the default), for no transform.
- **Symmetric** or **Antisymmetric**, to create a symmetric or antisymmetric layered material when the information of layers of one side of the midplane is supplied. Choose which side to mirror in from the **Mirror in** list: **Upside** (the default) or **Downside**. Upside means that the symmetry layers are on the top of the original layers. The symmetry line is the top-side boundary. Downside means that the symmetry layers are on the bottom of the original layers. The symmetry line is the bottom-side boundary. Select the **Merge middle layers** checkbox to merge the two middle layers into one to create an odd symmetric layer.
- **Repeated**, to create a number of repeating stacks, which you enter in the **Number of repeats** field (default: 1).

Select the **Scale** checkbox to scale the layered material's thickness with a factor (default: 1). The scale can be a numerical value, a parameter, or an expression. Such an expression can, for example, be a function of the coordinates so that a surface with variable thickness can be described.

If a single layer in a laminate has a variable thickness, you can define that layer in either a separate **Layered Material** or in a **Single Layer Material**.

- When using a **Layered Material**, apply the scaling expression in a **Layered Material Link**, and then use a **Layered Material Stack** to build the complete laminate.
- When using a **Single Layer Material** with an expression for the thickness, use a **Layered Material Stack** to build the complete laminate.

If you have defined a layer with a scaling factor, it appears in the preview window with a darker color than a nonscaled layer.

	The preview is not shown in the base geometry space, so it will not show any geometrical dependency.

The labels of the newly created layers include a suffix to distinguish them from the original layers:

- **(sym)** for the symmetric layers.
- **(asym)** for the antisymmetric layers.
- **(repX)** for the repeated layers (number X).

Click the **Layer Cross Section Preview** button ( ) to plot a preview of the layer cross section including the transform. You can also click the downward pointing arrow to choose **Layer Cross Section Preview** ( ) or **Create Layer Cross Section Preview** ( ), which adds the preview plot as a new plot group under **Results**. Click the **Layer Stack Preview** button ( ) to get a preview of the stack with the transform. Click the **Create Layer Stack Plot** button ( ) to add the preview of the stack with the transform as a new plot group under **Results**.

Single Layer Materials

To add a single-layer material, choose **Single Layer Material** ( ) from the global **Materials** node's context menu or the **Layers** submenu on the context menu of a **Materials** node in a component. Then, a **Material** node is created with some additional settings (see The Settings Window for Material) and a **Shell** property group (see Shell Geometric Properties) with a default thickness of 10^{-4} m. You can also switch an **Material** node into a single-layer material by adding a **Shell** property group and define a thickness, and it can also turn into a single-layer material when you specify a value for the requested thickness in the **Material Contents** table, which appears when a layered shell feature requests the material properties from a standard material. The thickness for a single-layer material can be defined as a numerical value, a parameter, or an expression. Such an expression can, for example, be a function of the coordinates so that a surface with variable thickness can be described.

	If a single layer in a laminate has a variable thickness, you can define that layer in either a separate **Layered Material** or in a **Single Layer Material**. • When using a **Layered Material**, apply the scaling expression in a **Layered Material Link**, and then use a **Layered Material Stack** to build the complete laminate. • When using a **Single Layer Material** with an expression for the thickness, use a **Layered Material Stack** to build the complete laminate.

Single-layer materials provide a quick way to define data for a nonlayered material to be used in physics feature designed for layered materials. Using a single-layer material is equivalent to defining a **Layered Material** with only one layer and then referencing it through a **Layered Material Link**. A single-layer material can be linked by a Layered Material Link, and it can also be a stack member of a Layered Material Stack or a switch member of a Switch for Materials.

Porous Material

Add a **Porous Material** node ( ) under a **Materials** node in a model component to add a definition of a porous material. In the settings for this node you can define the porosity of the porous material, or you can right-click the

Porous Material node to add Fluid, Solid, Pellet, and Immobile Fluid subnodes as required and define the porous material properties in those subnodes.

POROSITY

If you have not added any subnode for defining the porous material, enter a value or expression between 0 and 1 in the ε_p field. Otherwise, depending on the added subnodes, the corresponding expression for the porosity of the porous material appears here under **Volume fractions of immobile phases**.

PHASE-SPECIFIC PROPERTIES

Physics features that support porous media request properties per phase present. These properties are listed in the **Phase-Specific Properties** table. All phase-specific properties need to be specified in a corresponding subnode to the **Porous Material** node (as a **Solid**, **Liquid**, or **Pellet** subnode). The list can contain multiple entries of the same kind, such as the density of the fluid and the density of the solid. When a subnode is missing, a red stop symbol appears in the table, and the **Add Required Phase Nodes** button ( ) is active. Click that button to create the missing subnodes. You then need to go to the created subnodes and define all requested properties there.

Right-click a row in the Property and Phase columns to choose **Go to Requesting Node** to move to the physics node that requested the property, or choose **Go to Source** to move to the subnode that is the source for the property, when applicable.

Click any column header to sort the list alphabetically according to the content in that column. You can use this to, for example, list the properties according to their phase.

HOMOGENIZED MATERIAL

From the **Material** list, choose the material to represent the homogenized material: **Locally defined** (the default), or select any other material that you have added. Click the **Go to Material** button ( ) to move to the selected material's node. Click the **Add Material from Library** button (+) to add a material from the **Add Material to Pellet** window. You can also click the downward arrow next to the button and choose **Blank Material** to add a new blank material. In both cases, the added material becomes selected in the **Material** list.

HOMOGENIZED PROPERTIES

When physics features that do not support porous media take properties **From material**, and the domain material is a porous material, then properties are shown in the **Homogenized Properties** table. Here, there is only one set of properties and not one per phase. The properties are to be thought of as homogenized in some manner. The material is porous, but for the one-phase interface, homogenized properties are used. In this manner you can, for example, add a Solid Mechanics interface to a model of porous media and model the structural mechanics part as usual. When the **Material** in the **Homogenized Material** section is **Locally defined**, enter values or expressions for the properties in the **Value** column.

APPEARANCE

For the **Appearance** settings, see Appearance.

Fluid

Right-click a **Porous Material** node to add a **Fluid** subnode ( ) to define properties of a fluid phase in the porous medium.

FLUID PROPERTIES

From the **Material** list, choose the material to represent the fluid: **Locally defined** (the default), or select any other material that you have added. Click the **Go to Material** button ( ) to move to the selected material's node. Click the **Add Material from Library** button (+) to add a material from the **Add Material to Pellet** window. You can also

click the downward arrow next to the button and choose **Blank Material** to add a new blank material. In both cases, the added material becomes selected in the **Material** list.

MATERIAL PROPERTIES

This section is only available if you have selected **Locally defined** from the **Material** list in the **Fluid Properties** section. You can then choose material properties that you want to add for the fluid from the list and then click the **Add to Material** button (+) to add those properties to the table in the **Material Contents** section below.

MATERIAL CONTENTS

This section contains a table with the material properties for the fluid, which typically consist of the porosity and the material properties from the chosen material for the fluid. When the **Material** in the **Fluid Properties** section is **Locally defined**, enter values or expressions for the properties in the **Value** column. You can also click the **Edit** button ( ) below the table to enter the property values.

Solid

Right-click a **Porous Material** node to add a **Solid** subnode ( ) to define properties of a solid phase in the porous medium.

SOLID PROPERTIES

From the **Material** list, choose the material to represent the solid: **Locally defined** (the default), or select any other material that you have added. Click the **Go to Material** button ( ) to move to the selected material's node. Click the **Add Material from Library** button (+ to add a material from the **Add Material to Pellet** window. You can also click the downward arrow next to the button and choose **Blank Material** to add a new blank material. In both cases, the added material becomes selected in the **Material** list.

For the **Volume fraction** of the solid, enter a value between 0 and 1 in the θ_s field.

MATERIAL PROPERTIES

This section is only available if you have selected **Locally defined** from the **Material** list in the **Solid Properties** section. You can then choose material properties that you want to add for the solid from the list and then click the **Add to Material** button (+) to add those properties to the table in the **Material Contents** section below.

MATERIAL CONTENTS

This section contains a table with the material properties for the solid, which typically consist of the porosity and the material properties from the chosen material for the solid. When the **Material** in the **Solid Properties** section is **Locally defined**, enter values or expressions for the properties in the **Value** column. You can also click the **Edit** button ( ) below the table to enter the property values.

Pellet

Right-click a **Porous Material** node to add a **Pellet** subnode ( ) to define properties of a pellet phase in the porous medium. The **Pellet** subnode provides the properties for a certain type of pellets that the solid part of the porous material consists of. A porous material can include pellets of different types. For example, the pellets might be a mix of 30% spherical pellets with a certain diameter, 20% spherical pellets with another diameter, and 50% of a third type of pellet that is cylindrical instead of spherical. Those 100% together form the solid phase in the "pellet bed".

A **Pellet** node provides the geometrical properties for pellets and material properties for the solid phase in the pellet, such as density and heat capacity. The material properties for the fluid phase should be defined in a Fluid subnode.

When a **Porous Material** node is used in the physics, then all pellet types will exist at each point in the geometry. Therefore, the plural form, **Pellets** as a subnode to the **Packed Bed** node, used in the Chemical Reaction Engineering

Module to model packed bed reactors with catalytic pellets. Also, **Pellets** as a subnode to the **Porous Medium** node can be used to model the local temperature field within pellets when using a Heat Transfer in Porous Media interface.

PELLET PROPERTIES

From the **Material** list, choose the material to represent the pellet: **Locally defined** (the default), or select any other material that you have added. Click the **Go to Material** button ( ) to move to the selected material's node. Click the **Add Material from Library** button (+) to add a material from the **Add Material to Pellet** window. You can also click the downward arrow next to the button and choose **Blank Material** to add a new blank material. In both cases, the added material becomes selected in the **Material** list.

From the **Shape** list, define the shape of the pellet: **Sphere** (the default), **Cylinder**, **Flake**, or **User defined**:

- For **Sphere**, further specify a **Diameter** $d_{\mathrm{pe,s}}$ (SI unit: m), where the default value is 1 mm. The effective diameter $d_{\mathrm{pe,eff}}$ is then equal to $d_{\mathrm{pe,s}}$.
- For **Cylinder**, further specify a **Diameter** $d_{\mathrm{pe,c}}$ (SI unit: m), where the default value is 1 mm.The effective diameter $d_{\mathrm{pe,eff}}$ is then equal to $\frac{3d_{\mathrm{pe,c}}}{2}$.
- For **Flake**, define a **Thickness** $w_{\mathrm{pe,f}}$ (SI unit: m), where the default value is 1 mm, in a similar way. The effective diameter $d_{\mathrm{pe,eff}}$ is then equal to $3w_{\mathrm{pe,f}}$.
- For **User defined**, specify the **Pellet surface** A_{pe} (SI unit: m^2) and **Pellet volume** V_{pe} (SI unit: m^3). The default values are 1 m^2 and 1 m^3, respectively. The effective diameter $d_{\mathrm{pe,eff}}$ is then equal to $\frac{6V_{\mathrm{pe}}}{A_{\mathrm{pe}}}$

Also specify a **Porosity** $\varepsilon_{\mathrm{pe}}$ as a relative number between 0 and 1 (default: 0.1). This is the microscale porosity of the inside of an individual pellet.

If you define a second **Pellet** subnode, the **Pellet Bed Properties** section below is not available. Instead, specify a **Bed volume fraction**, a relative number between 0 and 1. Only the first **Pellet** subnode can define the pellet bed porosity. For additional **Pellet** subnodes, you instead specify the volume fraction relative to the other pellet types.

PELLET BED PROPERTIES

In this section you specify the porosity of the pellet bed. From the **Porosity** list, choose **User defined** (the default) or **From densities**. With **User defined**, add a value for the porosity ε_{p} as a relative number between 0 and 1 (default: 0.26, representing perfectly packed spheres). With **From densities**, the porosity is defined as $1 - \rho_{\mathrm{b}}/\rho_{\mathrm{pe}}$, where you define the density of the packed bed, ρ_{b}, in the **Density** field (default: 800 $\mathrm{kg/m}^3$).

MESH

In this section you specify the properties of the mesh for the extra dimension that each **Pellet** subnode defines so that both the species concentration and the temperature can be computed locally in the pellet.

For the mesh distribution, choose **Linear**, **Cubic root sequence** (the default), or **Square root sequence** from the **Distribution** list. Also, specify the **Number of elements** (default: 6).

Click the **Extra Dimension Mesh Preview** button ( ) in the **Mesh** section toolbar to get a plot of the extra dimension mesh in a separate plot window, showing the mesh distribution and direction.

MATERIAL PROPERTIES

This section is only available if you have selected **Locally defined** from the **Material** list in the **Pellet Properties** section. You can then choose material properties that you want to add for the pellet from the list and then click the **Add to Material** button (+) to add those properties to the table in the **Material Contents** section below.

MATERIAL CONTENTS

The table in this section contains the material properties for the pellet material. When the **Material** in the **Pellet Properties** section is **Locally defined**, enter values or expressions for the properties in the **Value** column. You can also click the **Edit** button ( ) below the table to enter the property values.

Immobile Fluid

Right-click a **Porous Material** node to add a **Immobile Fluid** subnode ( ) to define properties of an immobile fluid phase in the porous medium.

IMMOBILE FLUID PROPERTIES

From the **Material** list, choose the material to represent the immobile fluid: **Locally defined** (the default), or select any other material that you have added. Click the **Go to Material** button ( ) to move to the selected material's node. Click the **Add Material from Library** button (+) to add a material from the **Add Material to Pellet** window. You can also click the downward arrow next to the button and choose **Blank Material** to add a new blank material. In both cases, the added material becomes selected in the **Material** list.

For the immobile fluid's **Volume fraction**, enter a value between 0 and 1 in the θ_{imf} field.

MATERIAL PROPERTIES

This section is only available if you have selected **Locally defined** from the **Material** list in the **Immobile Fluid Properties** section. You can then choose material properties that you want to add for the immobile fluid from the list and then click the **Add to Material** button (+) to add those properties to the table in the **Material Contents** section below.

MATERIAL CONTENTS

This section contains a table with the material properties for the immobile fluid, which typically consist of the porosity and the material properties from the chosen material for the immobile fluid. When the **Material** in the **Immobile Fluid Properties** section is **Locally defined**, enter values or expressions for the properties in the **Value** column. You can also click the **Edit** button ( ) below the table to enter the property values.

Topology Link

Add a **Topology Link** node ( ) under a **Materials** node in a model component to add material based on a material that you have added under the global **Materials** node ( ) and **Density Model** use( ) that you have added under the component **Definitions** node ( ). To add it, right-click the **Materials** node and choose **Topology Link** from the **More Materials** submenu.

The **Topology Link** will be added automatically, if one of the topology optimization study steps is chosen in the model wizard.

LINK SETTINGS

From the **Material** list, select the global material that you want to link to:

- Any global material node, to use that material in the component.
- Any **Switch** node, if you want to run a material sweep.
- **None**, to not link to any global material.

From the **Topology source** list, select the **Density Model**, which should modify the material. The Density model will scale the Young's modulus with the *penalized material volume factor* (`dtopo#.theta_p`), and the density with the *output material volume factor* (`dtopo#.theta`).

Multiphase Material

Add a **Multiphase Material** node ( ) under a **Materials** node in a model component to define a material composed of two or more immiscible phases. Instead of resolving the exact position in space of each phase, they are approximated by their volume fraction, and the effective properties of the material are obtained from a set of mixing rules.

The material properties of each phase are defined on their respective Phase (Subnode) subnode.

FRACTIONS

The **Volume fraction definition** can either be **Locally defined** or controlled from a physics interface providing volume fractions, such as the **Level Set**, **Phase Field**, **Ternary Phase Field**, and **Phase Transport** interfaces. The default is **Locally defined**. When the volume fractions are defined locally, they can be specified as user inputs in each Phase (Subnode) subnode or in the phases table described below. The Multiphase Material feature will automatically constrain each volume fraction to be between 0 and 1.

Use the **Constrained phase** setting to control which phase that does not have an explicit definition of its volume fraction but instead gets the remaining volume fraction as 1 minus the sum of fractions from the other phases. The default is **First phase**.

PHASES

The **Phases** table displays a summary of all of the phases in the material, the source of their material properties, and their volume fraction expression. See Phase (Subnode) for more information.

MATERIAL CONTENTS

The material properties in the multiphase material are defined by a mixing rule that depends on the volume fractions and one or more material properties of each phase.

The material content table contains the mixing rules for the material properties for the multiphase material. The mixing rule for a specific material property can be edited in a separate window. To open this window, right-click the row containing the material property and select **Edit Mixing Rule** ( ). You can also select a row and click the **Edit Mixing Rule** button ( ) under the table. The **Edit Mixing Rule** button ( ) cannot be used if more than one row are selected or if no row is selected. See The Edit Mixing Rule Dialog for more information on selecting mixing rules.

When the **Mixing rule** for a material property is set to **From homogenized properties**, enter values or expressions for the properties in the **Homogenized Properties** section.

HOMOGENIZED MATERIAL

From the **Material** list, choose the material to represent the homogenized material properties: **Locally defined** (the default), or select any other material that you have added. Click the **Go to Material** button ( ) to move to the selected material's node. Click the **Add Material from Library** button ( ) to add a material from the **Add Material from Library** window. You can also click the downward arrow next to the button and choose **Blank Material** to add a new blank material. In both cases, the added material becomes selected in the **Material** list.

HOMOGENIZED PROPERTIES

Material properties that use **From homogenized properties** instead of a specific mixing rule are shown in the **Homogenized Properties** table. The properties are to be thought of as homogenized in some matter other than through the available mixing rules. When the **Material** in the **Homogenized Material** section is **Locally defined**, enter values or expressions for the properties in the **Value** column. You can also click the **Edit** button ( ) below the table to enter the property values.

APPEARANCE

For the **Appearance** settings, see Appearance.

Effective Material

Add an **Effective Material** node ( ) under a **Materials** node in a model component to define a material composed of two or more immiscible constituents. Instead of resolving the exact position in space of each constituent, they are approximated by their volume fraction, and the effective properties of the material are obtained from a set of mixing rules.

The **Effective Material** node is similar to the Multiphase Material node, with the exception that it contains Constituent (Subnode) instead of **Phases** and that it includes special mixing rules for composite materials.

Phase (Subnode)

Right-click a **Multiphase Material** node to add a **Phase** subnode ( ) to define properties of a phase in the material.

The **Phase** node's **Settings** window is similar to the **Settings** window for a material node (see The Settings Window for Material), with the exception that it includes **Volume Fraction** and **Link Settings** sections:

VOLUME FRACTIONS

When the phase material is selected as the constrained phase in the parent multiphase material, its volume fraction is defined as one minus the sum of volume fractions of the other phases. If the current phase is not the constrained phase, enter a value or expression between 0 and 1 in the **Volume fraction** V_f field.

LINK SETTINGS

From the **Material** list, select the material that you want to link to:

- **Locally defined** (the default). In this case, the **Material Properties** section will be available (see The Settings Window for Material).
- Any global material node.
- Any material in the component, except the parent multiphase material.

Click the **Go to Material** button ( ) to move to the selected material node. Click the **Add Material from Library** button (+) to add a global material from the material libraries or a new blank global material. The added material then becomes the one selected in the **Material** list.

Constituent (Subnode)

Right-click an **Effective Material** node to add a **Constituent** subnode ( ) to define properties of a constituent in the material.

The **Constituent** subnode's **Settings** window is identical to the **Settings** window for a **Phase** subnode (see Phase (Subnode)).

The Edit Mixing Rule Dialog

The **Edit Mixing Rule** dialog is used to control the mixing rules in the **Material Contents** table of a Multiphase Material or Effective Material.

To open the **Edit Mixing Rule** dialog:

- Right-click the desired row in the **Materials Contents** table and select **Edit Mixing Rule** ( ).
- Select a row and click the **Edit Mixing Rule** button ( ) under the table. The button is not active if more than one row are selected or if no row is selected.

If there are several material properties in the table, you can step through the table without closing the dialog using the **Previous Row (Discard Changes)** ( ), **Previous Row (Store Changes)** ( ), **Next Row (Discard Changes)** ( ), and **Next Row (Store Changes)** ( ) toolbar buttons. The current row of the is identified by the **Property Group** and **Parameter** fields.

The Multiphase Material and Effective Material features support several different mixing rules, which you choose from the **Mixing rule** list. Some of the rules are only available for specific material parameters. The mixing rules for composites are exclusive of the Effective Material, and the Krieger-type viscosity is only available for the Multiphase Material. See the sections below for more information about the mixing rules.

BASIC MIXING RULES

The basic mixing rules are available to all material properties.

Volume Average

The volume average mixing rule uses an arithmetic mean weighted by the volume fractions,

$$X = \sum_{i=1}^{n} V_{f,i} X_i \tag{9-1}$$

where n is the number of phases, $V_{f,i}$ is the volume fraction of phase i, X is the effective material property, and X_i is the material property of phase i.

Mass Average

The mass average mixing rule uses an arithmetic mean weighted by the mass fractions,

$$X = \sum_{i=1}^{n} w_i X_i \tag{9-2}$$

where w_i is the mass fraction of phase i,

$$w_i = \frac{V_{f,i}\rho_i}{\rho} \tag{9-3}$$

Here, ρ is the effective density and ρ_i is the density of phase i.

The mass average mixing rule is not available for density.

Harmonic Volume Average

The harmonic volume average mixing rule uses a harmonic mean weighted by the volume fractions,

$$X = \left(\sum_{i=1}^{n} \frac{V_{f,i}}{X_i} \right)^{-1} \tag{9-4}$$

Harmonic Mass Average

The harmonic mass average mixing rule uses a harmonic mean weighted by the mass fractions,

$$X = \left(\sum_{i=1}^{n} \frac{w_i}{X_i} \right)^{-1} \tag{9-5}$$

The harmonic mass average mixing rule is not available for density.

Power Law

The power law mixing rule uses a power law distribution,

$$X = \prod_{i=1}^{n} X_i^{V_{f,i}} \tag{9-6}$$

Heaviside Function

The Heaviside Function mixing rule uses an arithmetic mean weighted by a smooth step function of the volume fraction:

$$X = \sum_{i=1}^{n} f_{hs,i} X_i \tag{9-7}$$

$$f_{hs,i \neq c} = \mathrm{H}\left(V_{f,i} - 0{,}5, \frac{l_{\mathrm{mix}}}{2} \right)$$

$$f_{hs,c} = 1 - \sum_{i \neq c}^{n} f_{hs,i}$$

where $f_{hs,i}$ is the fraction used for phase i, $f_{hs,c}$ is the fraction corresponding to the constrained phase, and l_{mix} is a user-defined **mixing parameter** (default: 0.8) defining the size of the transition zone between phases for the smooth Heaviside function H.

MIXING RULES FOR COMPOSITE MATERIALS

The effective structural material properties of composites depend on the material properties of the constituents and their geometric arrangements. These can be approximated either analytically or numerically. The numerical approach is applicable to a broader range of geometrical configurations, but is more complicated to use. The Effective Material includes a list of analytical approaches that are simple and handy, aimed at cases where an orthotropic fiber acts as reinforcement of an isotropic matrix. These methods are taken from Ref. 1, Ref. 2, and Ref. 3.

In this section, the properties of the fiber reinforcements are denoted by subscript f, while properties of the matrix are denoted by m. The mixing rules for composites are only available to a specific set of material properties. These rules should be used together with a Volume Averaged mixing rule for density.

Voigt–Reuss Model

The Voigt–Reuss model, also known as Rule of Mixtures, is an analytical method to compute homogenized material properties of composites. This method works well for cases where continuous orthotropic fibers are embedded in the isotropic matrix.

TABLE 9-2: EFFECTIVE PROPERTIES FOR THE VOIGT–REUSS MODEL.

		k_{33}	$\frac{k_{f33}k_m}{k_m V_{f,f}+k_{f33}V_{f,m}}$
Electric conductivity, σ	Basic	σ_{11}	$\sigma_{f11}V_{f,f}+\sigma_m V_{f,m}$
		σ_{22}	$\frac{\sigma_{f22}\sigma_m}{\sigma_m V_{f,f}+\sigma_{f22}V_{f,m}}$
		σ_{33}	$\frac{\sigma_{f33}\sigma_m}{\sigma_m V_{f,f}+\sigma_{f33}V_{f,m}}$

Modified Voigt–Reuss Model

The Voigt–Reuss model provides results in the longitudinal directions that are in good agreement with experiments, but not in the transverse directions. The modified Voigt–Reuss model, or modified rule of mixture, provides corrections in the transverse direction. The following correction factors are used:

$$\eta_f = \frac{E_{f11}V_{f,f} + \left(\left(1 - \nu_{f12}^2 \frac{E_{f22}}{E_{f11}}\right)E_m + \nu_m \nu_{f12} E_{f22}\right)V_{f,m}}{E_{f11}V_{f,f} + E_m V_{f,m}} \tag{9-8}$$

$$\eta_m = \frac{E_m V_{f,m} + ((1 - \nu_m^2)E_{f11} + \nu_m \nu_{f12} E_m)V_{f,f}}{E_{f11}V_{f,f} + E_m V_{f,m}} \tag{9-9}$$

$$\eta_g = 0{,}6 \tag{9-10}$$

TABLE 9-3: EFFECTIVE PROPERTIES FOR THE MODIFIED VOIGT–REUSS MODEL.

Halpin–Tsai Model

The Halpin–Tsai model is a semi-empirical method to computed homogenized properties of composites based on self-consistent micromechanics as well as experimental curve fitting. This method works well for continuous orthotropic fibers or discontinuous orthotropic fibers embedded in the isotropic matrix, including short fibers.

The Halpin–Tsai model includes empirical factors ζ for the components of the elastic modulus and are a measure of the reinforcement that depends on fiber geometry. Some typical values for the orthotropic Young's modulus are depicted in the table value. The value of ζ for the components of G is typically 1.

TABLE 9-5: TYPICAL VALUES OF ζ FOR YOUNG'S MODULUS E.

COMPONENT	ζ FOR DISCONTINUOUS FIBERS	ζ FOR CONTINUOUS FIBERS
E_{11}	$2\dfrac{l_{11}}{t_{33}}$	∞
E_{22}	$2\dfrac{w_{11}}{t_{33}}$	0

In the table above, l_{11} is the fiber length in the 11 direction, w_{22} is the fiber width in the 22 direction, and t_{33} is the fiber thickness in the 33 direction.

The effective material properties are given by:

TABLE 9-6: EFFECTIVE PROPERTIES FOR HALPIN–TSAI MODEL.

Halpin–Tsai–Nielsen Model

The Halpin–Tsai–Nielsen model extends the Halpin–Tsai model by accounting for the maximum packing fraction of the reinforcement, ϕ_{max} (default 0.82). Typical values of the maximum packing factor are listed in Table 9-7.

TABLE 9-7: MAXIMUM PACKING FACTORS.

FIBER ARRANGEMENT	ϕ_{max}
Square array of fibers	0.785
Hexagonal array of fibers	0.907
Other arrangements	0.82

The Halpin–Tsai–Nielsen model introduces an auxiliary variable,

$$\Psi = 1 + \left(\frac{1 - \phi_{\max}}{\phi_{\max}^2} \right) V_{f,f} \tag{9-11}$$

and the effective properties are given by Table 9-8.

TABLE 9-8: EFFECTIVE PROPERTIES FOR THE HALPIN–TSAI–NIELSEN MODEL.

		G_{23}	$G_m \frac{1+\varsigma_{G,23}\eta_{G,23}V_{f,f}}{1-\eta_{G,23}\Phi V_{f,f}}$ $\eta_{G,23} = \frac{\frac{G_{f23}}{G_m}-1}{\frac{G_{f23}}{G_m}+\varsigma_{G,23}}$
		G_{13}	$G_m \frac{1+\varsigma_{G,13}\eta_{G,13}V_{f,f}}{1-\eta_{G,13}\Phi V_{f,f}}$ $\eta_{G,13} = \frac{\frac{G_{f13}}{G_m}-1}{\frac{G_{f13}}{G_m}+\varsigma_{G,13}}$
Poisson's ratio, ν	Orthotropic	ν_{12}	$\nu_{f12}V_{f,f}+\nu_m V_{f,m}$
		ν_{23}	$\nu_{f23}V_{f,f}+\nu_m V_{f,m}$
		ν_{13}	$\nu_{f13}V_{f,f}+\nu_m V_{f,m}$

Hashin–Rosen Model

The Hashin–Rosen model is based on a composite cylinder assemblage (CCA). In order to compute homogenized material properties, additional properties are computed first.

The bulk modulus of fiber, K_f, and matrix, K_m, under longitudinal strain are

$$K_{f,11} = \frac{E_{f,11}}{2(1-2\nu_{f,12})(1+\nu_{f,12})} \tag{9-12}$$

$$K_m = \frac{E_m}{2(1-2\nu_m)(1+\nu_m)} \tag{9-13}$$

The bulk modulus of the composite K under longitudinal strain is

$$K = \frac{K_m(K_{f,11} + G_m)V_{f,m} + K_{f,11}(K_m + G_m)V_{f,f}}{(K_{f,11} + G_m)V_{f,m} + (K_m + G_m)V_{f,f}} \tag{9-14}$$

In this model, the effective shear modulus of the composite G_{23} is approximated from the quadratic equation

$$A\left(\frac{G_{23}}{G_m}\right)^2 + 2B\left(\frac{G_{23}}{G_m}\right) + C = 0 \tag{9-15}$$

where

$$A = 3V_{f,f}V_{f,m}\left(\frac{G_{23}}{G_m} - 1\right)\left(\frac{G_{23}}{G_m} + \eta_f\right) \tag{9-16}$$

$$+\left(\frac{G_{23}}{G_m}\eta_m + \eta_f\eta_m - \left(\frac{G_{23}}{G_m}\eta_m - \eta_f\right)V_{f,f}^3\right)\left(\left(\frac{G_{23}}{G_m} - 1\right)V_{f,f}\eta_m - \left(\frac{G_{23}}{G_m} + 1\right)\right)$$

$$B = -3V_{f,f}V_{f,m}\left(\frac{G_{23}}{G_m} - 1\right)\left(\frac{G_{23}}{G_m} + \eta_f\right) \tag{9-17}$$

$$+\frac{V_{f,f}}{2}(\eta_m + 1)\left(\frac{G_{23}}{G_m} - 1\right)\left(\frac{G_{23}}{G_m} + \eta_f - \left(\frac{G_{23}}{G_m}\eta_m - \eta_f\right)V_{f,f}^3\right)$$

$$+\frac{1}{2}\left(\frac{G_{23}}{G_m}\eta_m - \left(\frac{G_{23}}{G_m} - 1\right)V_{f,f} + 1\right)\left((\eta_f + 1)\left(\frac{G_{23}}{G_m} + \eta_f\right) - 2\left(\frac{G_{23}}{G_m}\eta_m - \eta_f\right)V_{f,f}^3\right)$$

$$C = -3V_{f,f}V_{f,m}\left(\frac{G_{23}}{G_m} - 1\right)\left(\frac{G_{23}}{G_m} + \eta_f\right) \tag{9-18}$$

$$+\left(\frac{G_{23}}{G_m}\eta_m + \left(\frac{G_{23}}{G_m} - 1\right)V_{f,f} + 1\right)\left(\frac{G_{23}}{G_m} + \eta_f + \left(\frac{G_{23}}{G_m}\eta_m - \eta_f\right)V_{f,f}^3\right)$$

and

$$\eta_m = 3 - \nu_m$$

$$\eta_f = 3 - \nu_{f,23}$$

The effective material properties are then given by Table 9-9.

TABLE 9-9: EFFECTIVE PROPERTIES FOR HASHIN–ROSEN MODEL.

		ν_{13}	$\nu_{f13}V_{f,f} + \nu_m V_{f,m} + \dfrac{V_{f,f}V_{f,m}(\nu_{f,13} - \nu_m)\left(\frac{1}{K_m} - \frac{1}{K_f}\right)}{\frac{V_{f,f}}{K_m} + \frac{1}{G_m} + \frac{V_{f,m}}{K_f}}$

OTHER MIXING RULES IN THE MULTIPHASE MATERIAL

Krieger-Type Viscosity

The effective dynamic viscosity μ in suspensions may be modeled using the Krieger-type model as

$$\mu = \mu_1\left(1 - \frac{V_{f,2}}{V_{f,\max}}\right)^{-2,5V_{f,max}} \tag{9-19}$$

When **Krieger type** viscosity is selected, enter a value or expression for the **Maximum packing concentration** $V_{f,\max}$ (dimensionless). The default is 0.62.

The Krieger type mixing rule is available only for the dynamic viscosity parameter in the basic property group.

Material Properties Reference

The material properties for the predefined materials are accessible from most physics interfaces. Using this information, either create a material property group or define a completely new material.

In the **Basic** > **Property Group** window, you can add **Output Properties** under the **Quantities** subsection. You can also add **Model Inputs** to, for example, create a temperature-dependent material property.

About Model Inputs

Model inputs is a special type of parameter in physics features or physics properties where you can choose from a list of announced variables (typically field quantities such as temperature, concentration, or electric field, where vector fields have three components). Model inputs can also be used as an input to a **Property Group** under a material to represent, for example, a temperature-dependent material property. If the property group specifies that it supports one or more model inputs, any physics feature that uses the group's material will display those model input lists in the **Model Inputs** section of the physics node's **Settings** window. Any physical quantity in COMSOL Multiphysics can be used as a model input.

Model inputs are always available as default model inputs. See Default Model Inputs.

All physical quantities that can act as model inputs declare and define common variables that are always available (for example, `minput.T` for the temperature T).

To define the absolute pressure for heat transfer, see the settings for the Fluid node.

To define the absolute pressure for a Fluid Flow interface, see the settings for the Fluid Properties node (described for the Laminar Flow interface).

If you have a license for a Nonisothermal Flow interface, see that documentation for further information.

Model Inputs and Multiphysics Couplings

About the Output Material Properties

Some of these material groups are only used by physics interfaces in the add-on modules and detailed information is in the applicable documentation.

This section describes all available property groups and the material properties that they contain. These material properties can be added to models from two **Settings** windows: the **Material** node's window and its subnodes' **Property Group** windows.

The **Basic** group contains over 25 basic properties for use with all materials.

Materials

BASIC MATERIAL PROPERTIES

These common material properties belong to the **Basic** property group.

- When this information is accessed from the **Basic** > **Property Group** window, it is listed under **Quantities** > **Output Properties** and **Variable** is listed in the table.
- When this information is accessed from the **Material** window, it is listed under **Material Properties** > **Basic Properties** and **Name** is listed in the table under **Material Contents**.

TABLE 9-10: BASIC MATERIAL PROPERTIES.

Water content	w_c	kg/m^3
Young's modulus	E	Pa

The coefficient of thermal expansion (CTE) and the resistivity temperature coefficient have the SI unit 1/K. COMSOL Multiphysics translates this into the Fahrenheit temperature unit using an offset. This translation means that you do not get the expected results.

Use caution when a model uses the coefficient of thermal expansion or the resistivity temperature coefficient and the unit system's temperature is not kelvin.

Specific gas constant	Rs	J/(kg·K)

Shell Geometric Properties

The **Shell** material property group is used in connection with layered materials (it is, for example, added when you add a **Material** node by choosing **Single Layer Material** from the **Layers** submenu on the **Materials** node's context menu). This property group contains geometric properties for the definition of a layer in the **Layer Definition** section.

TABLE 9-17: SHELL PROPERTIES.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
SHELL		
Thickness	lth	m
Rotation	lrot	deg
Mesh elements	lne	1

Magnetostrictive Models

These material property groups are used for various magnetostrictive material models in the AC/DC Module.

TABLE 9-18: MAGNETOSTRICTIVE MODELS MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
MAGNETOSTRICTIVE		
Saturation magnetization	Ms	A/m
Initial magnetic susceptibility	chi	1
Saturation magnetostriction	lambdas	1
Magnetostriction constants	lambda100	1
Magnetostriction constants	lambda111	1
STRAIN-MAGNETIZATION FORM	This material node is only available with the AC/DC Module.	
Compliance matrix	sH (6-by-6 matrix)	1/Pa
Loss factor for compliance matrix sH	eta_sH (6-by-6 matrix)	1
Piezomagnetic coupling matrix	dHT (3-by-6 matrix)	m/A
Relative permeability	murT (3-by-3 matrix)	1
STRESS-MAGNETIZATION FORM	This material node is only available with the AC/DC Module.	
Elasticity matrix	cH (6-by-6 matrix)	Pa
Loss factor for elasticity matrix cH	eta_cH (6-by-6 matrix)	1
Piezomagnetic coupling matrix	eHS (3-by-6 matrix)	T
Relative permeability	murS (3-by-3 matrix)	1

Optical Models

These material property groups appear in optical materials and are used by the Ray Optics Module and Wave Optics Module.

TABLE 9-19: OPTICAL MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
ATTENUATION COEFFICIENT		
Attenuation coefficient	alpha1	1/m
CAUCHY		
Cauchy dispersion coefficients	{ODcca1, ODcca2, ODcca3, ODcca4, ODcca5, ODcca6}	1
Reference temperature	Trefcca	K
Reference pressure	Prefcca	Pa
CONRADY		
Conrady dispersion coefficients	{ODcra1, ODcra2, ODcra3}	1
Reference temperature	Trefcra	K
Reference pressure	Prefcra	Pa
HERZBERGER		
Herzberger dispersion coefficients	{ODhza1, ODhza2, ODhza3, ODhza4, ODhza5}	1
Reference temperature	Trefhza	K
Reference pressure	Prefhza	Pa
INTERNAL TRANSMITTANCE, 2 MM SAMPLE THICKNESS		
Internal transmittance, 2 mm sample thickness	taui2	1
INTERNAL TRANSMITTANCE, 5 MM SAMPLE THICKNESS		
Internal transmittance, 5 mm sample thickness	taui5	1
INTERNAL TRANSMITTANCE, 10 MM SAMPLE THICKNESS		
Internal transmittance, 10 mm sample thickness	taui10	1
INTERNAL TRANSMITTANCE, 25 MM SAMPLE THICKNESS		
Internal transmittance, 25 mm sample thickness	taui25	1
SCHOTT		
Schott dispersion coefficients	{ODsca1, ODsca2, ODsca3, ODsca4, ODsca5, ODsca6}	1
Reference temperature	Trefsca	K
Reference pressure	Prefsca	Pa
SCHOTT EXTENDED		
Schott extended dispersion coefficients	{ODscb1, ODscb2, ODscb3, ODscb4, ODscb5, ODscb6, ODscb7, ODscb8, ODscb9}	1
Reference temperature	Trefscb	K

TABLE 9-19: OPTICAL MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
Reference pressure	Prefscb	Pa
SCHOTT THERMO-OPTIC		
Schott thermo-optic dispersion coefficients	{TOsco1, TOsco2, TOsco3, TOsco4, TOsco5, TOsco6}	1
Reference temperature	Trefsco	K
SELLMEIER		
Sellmeier dispersion coefficients	{ODsma1, ODsma2, ODsma3, ODsma4, ODsma5, ODsma6}	1
Reference temperature	Trefsma	K
Reference pressure	Prefsma	Pa
SELLMEIER MODIFIED, TYPE 1		
Sellmeier modified, type 1 dispersion coefficients	{ODsmb1, ODsmb2, ODsmb3, ODsmb4, ODsmb5, ODsmb6}	1
Reference temperature	Trefsmb	K
Reference pressure	Prefsmb	Pa
SELLMEIER MODIFIED, TYPE 2		
Sellmeier modified, type 2 dispersion coefficients	{ODsmc1, ODsmc2, ODsmc3, ODsmc4, ODsmc5, ODsmc6}	1
Reference temperature	Trefsmc	K
Reference pressure	Prefsmc	Pa
TEMPERATURE-DEPENDENT SELLMEIER		
Temperature-dependent Sellmeier dispersion coefficients	{ODtds1, ODtds2, , ODtds30}	1

Piezoelectric Models

These material property groups for piezoelectric materials are used by the Acoustics Module, MEMS Module, or Structural Mechanics Module.

TABLE 9-20: PIEZOELECTRIC MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
STRAIN-CHARGE FORM		
Compliance matrix	sE	1/Pa
Coupling matrix	dET	C/N
Loss factor for compliance matrix	sE	1
Loss factor for coupling matrix	d	1
Loss factor for electric permittivity	εT	1
Relative permittivity	epsilonrT	1
STRESS-CHARGE FORM		
Coupling matrix	eES	C/m^2
Elasticity matrix	cE	Pa

TABLE 9-20: PIEZOELECTRIC MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
Loss factor for elasticity matrix	cE	1
Loss factor for coupling matrix	e	1
Loss factor for electric permittivity	εS	1
Relative permittivity	epsilonrS	1

Piezoresistive Models

These material property groups for piezoresistive materials are used by the MEMS Module.

TABLE 9-21: PIEZORESISTIVE MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
ELASTORESISTANCE FORM		
Elastoresistive coupling matrix	ml	Ω·m
PIEZORESISTANCE FORM		
Piezoresistive coupling matrix	Pil	A/m^2

Pyroelectric

This material property group for pyroelectric materials is used by the MEMS Module.

TABLE 9-22: PYROELECTRIC MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
PYROELECTRIC		
Total pyroelectric coefficient	{pET1, pET2, pET3}	$C/(m^2 \cdot K)$

Semiconductor Material Properties

These material property groups for all the material models in semiconductors are used by the Semiconductor Module.

The Property Group, Variable Names, and SI Unit columns are applicable to all materials in the Semiconductor Module. However, the Values and References columns listed in Table 9-23 are specifically for silicon.

Solid Mechanics Material Properties

These material property groups appear for material models in solid mechanics. Most of these properties are used by the Structural Mechanics Module. The property groups of the external material are of a special type that depends on the selected interface type and are not individually documented.

TABLE 9-24: SOLID MECHANICS MATERIALS.

PROPERTY GROUP AND PROPERTY	NAME/VARIABLE	SI UNIT
LINEAR ELASTIC MATERIAL		
ANISOTROPIC		
Elasticity matrix	D	Pa
Loss factor for elasticity matrix D	eta_D	1
ANISOTROPIC, VOIGT NOTATION		
Elasticity matrix, Voigt notation	DV0	Pa
Loss factor for elasticity matrix D, Voigt notation	eta_DVo	1
BULK MODULUS AND SHEAR MODULUS		
Bulk modulus	K	N/m^2
Shear modulus	G	N/m^2
COMPLIANCE		
Compliance matrix	Dinv_iso (6-by-6 matrix)	1/Pa
Loss factor for compliance matrix	eta_Dinv_iso (6-by-6 matrix)	1

Thermal strain	dLi_iso, dLij	1

External Material Properties

The property groups of the external materials are of a special type that depends on the selected interface type and are not individually documented. You can incorporate as many parameters in the call to the external DLL when you add an external material, these parameters will appear in the Material node as material inputs, see Working with External Materials for more information.

Fluid Flow Material Properties: Inelastic Non-Newtonian Material Model

These material property groups for the inelastic non-Newtonian material models (including their associated physical properties) can be added to models from the **Material** window. All inelastic non-Newtonian models property groups are available with Polymer Flow Module. Power Law, Carreau, and Bingham–Papanastasiou property groups are also available with either CFD Module or Microfluidics Module.

TABLE 9-29: INELASTIC NON-NEWTONIAN MATERIAL PROPERTIES.

User-Defined Materials and Libraries

User-defined materials provide the flexibility needed to design your models and experiments using a combination of existing material properties and properties you define yourself. You can also create your own material database (library) to include materials you use often.

	You can also modify and extend existing materials that you load from any of the material libraries. When added to the Component node, the material is a copy of the properties and the material from the library, and you can modify that material's properties in the same way as a user-defined material.

	Materials Toolbar

Importing a Material Library

Material libraries are stored as COMSOL Multiphysics model files (`.mph` file) or as XML files. Any COMSOL model containing materials can be imported as a material library, and conversely a material library stored in the COMSOL Multiphysics model format can be opened and modified in the same way as any other COMSOL Multiphysics model file. The XML format, in contrast, is a simplified text format that can be modified in a text editor or written by some external source of material data.

1 In the **Materials** toolbar, click **Browse Materials** .

2 In the **Material Browser** window's toolbar, click the **Import Material Library** ( ) button. The **Choose Material Library** dialog then opens. You can also click the arrow next to that button and choose **Import Material Library From** ( ) to open the fullscreen **Select Model** window, where you can choose a model from a database to import material libraries from, add a new database, or browse for model files to import material libraries from.

3 Navigate to a material library file on your computer. To the right of **File name**, choose **XML File (.xml)**, to find material libraries stored as XML files.

4 When you have located the file to import, click **Open**.

	An example of an external material library is MatWeb. MatWeb provides a service where you can export technical datasheets from MatWeb's collection in the format for a COMSOL material library. For more information about this service, visit www.matweb.com.

Creating a New Material Library and Adding and Editing Materials

When you first open the **Material Browser**, an empty **User-Defined Library** is available for you to start creating your own library of materials (see Figure 9-1). These steps describe how to create a copy of the existing library, rename it, and then add materials to the empty library.

CREATING A USER-DEFINED MATERIAL LIBRARY

1 In the **Materials** toolbar, click **Browse Materials** .

2 Create the empty material library. There are different ways to do this in the **Material Browser** window:

- Click the **New Material Library** button ( ) under the tree.
- Navigate to the material you want to add — copper, for example. Right-click and select **Add to New Library.**

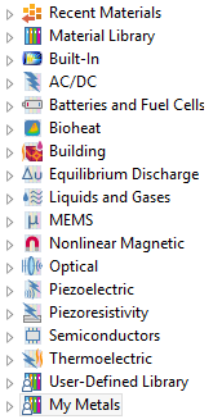
3 In the **New Material Library** dialog, navigate to the folder on the computer where the empty **User-Defined Library** database is located, if desired. The location of the file varies based on your installation. For example, if the installation is on your hard drive:

- The file path on Windows might be similar to `C:\Users\`*`Your_Name`*`\.comsol\v63\materials`.
- On Linux, the file path is typically `~/.comsol/v63/material`.
- On macOS, it is typically `<`*`home folder`*`>/Library/Preferences/COMSOL/v63/material` (if missing, click the Finder's **Go** menu and hold down the Option key to show the `Library` folder). You can also search for the filename `User_Defined_Library.mph`.

4 Choose a filename to name the user-defined material library.

5 Click **Save**. The empty new material library is added to the **Material Browser**.

6 Click **Done** .



ADDING MATERIALS TO A USER-DEFINED MATERIAL LIBRARY

ADDING A PREDEFINED MATERIAL TO THE USER-DEFINED MATERIAL LIBRARY

Add any predefined material to a **Component** node in the **Model Builder**. There are different ways to add the material to the Model Builder as well as to the Material Library.

Using the Material Browser

1 To open the **Material Browser**, right-click the **Materials** node and select **Browse Materials** , or in the **Materials** toolbar, click **Browse Materials** .

2 Right-click the material to add, **Copper** for example, and select **Add to My Metals** (or any other material library available).

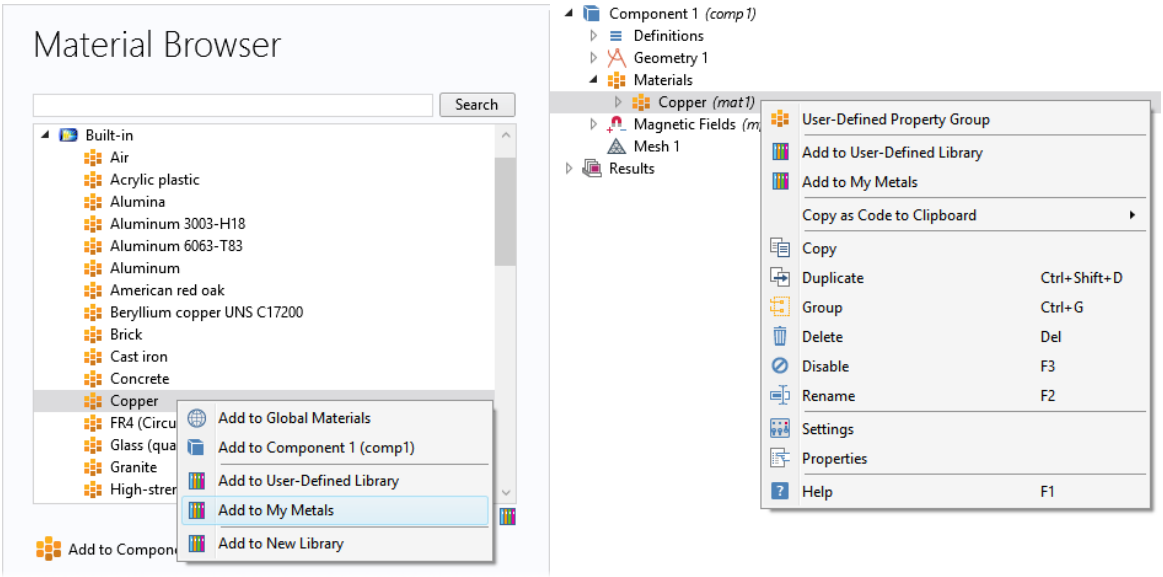


Figure 9-14: Adding a predefined material to a new user-defined library using the Material Browser (left) and after adding a material to the Model Builder (right).

You can also duplicate a material node to start with the defined material properties for that material and then modify some of them to match some similar material that you want to add.

Using the Add Material Window

1 In the **Home** or **Materials** toolbar, click **Add Material** to open the **Add Material** window.

2 Locate the material you want to add, **Copper** for example, and click **Add to Component**.

3 In the **Materials** toolbar, from the **Add to Library** menu, select **Add to** `<material library name>`. Or in the **Model Builder**, right-click **Copper** and choose an option. See Figure 9-14.

Adding a Blank Material to a Material Library

1 In the **Materials** toolbar, click **Blank Material** . An empty **Material** node is added under **Materials** in the **Model Builder**.

2 Add material properties to it as desired to define a new material for the user-defined material library.

3 In the **Materials** toolbar, from the **Add to Library** menu, select **Add to** `<material library name>`. Or in the **Model Builder**, right-click **Material** and choose an option. See Figure 9-14.

4 Right-click the **Material** node to **Rename Selected** material to a more meaningful name.

EDITING MATERIALS IN A USER-DEFINED MATERIAL LIBRARY

To edit materials in a user-defined material library defined as an MPH-file, open the **Material Browser** and click the **Edit** button ( ) below the list of material libraries. The corresponding MPH-file for the user-defined material library then opens. It contains its materials only (under **Global Definitions** > **Materials**). You can edit and modify any aspect of the material in that user-defined library, such as the values of some material properties. When you are done, save the MPH-file for the user-defined material library (under the same name and in the same location) to store the update material library.

REMOVING A USER-DEFINED MATERIAL FROM A MATERIAL LIBRARY

In the **Materials** toolbar, click **Browse Materials** to open the **Material Browser**. Locate the material to remove. Right-click the material and select **Remove Selected** ( ).

Restoring a Deleted User-Defined Library

If the **User-Defined Library** node is deleted in error from the **Material Browser**, you can restore it by following the steps in Creating a New Material Library and Adding and Editing Materials and then add the file to the Material Browser.

Using Functions in Materials

Functions are useful for describing material properties as, for example, functions of temperature or pressure.

Adding a Function to the Material

Material functions are either automatically added to the **Model Builder** sequence (usually with materials from the material library) or functions can be added based on individual requirements.

1 Add a material to the **Component** node (see The Material Browser Window and The Add Material Window).

2 Add an **Analytic** ( ), **Interpolation** ( ), or **Piecewise** ( ) function.

Win	To add an **Analytic** ( ), **Interpolation** ( ), or **Piecewise** ( ) function: • In the **Materials** toolbar, click **Analytic**, **Interpolation**, or **Piecewise**. • Right-click a property group node (for example, **Basic**) and select a function from the **Functions** list.

Mac Linux	To add an **Analytic** ( ), **Interpolation** ( ), or **Piecewise** ( ) function: • Right-click a property group node, for example, **Basic**, and select a function from the **Functions** list. • In the **Materials** contextual toolbar, click **Analytic**, **Interpolation**, or **Piecewise**.

- Select **Analytic** to add an analytic function of one or more input arguments.
- Select **Interpolation** to add an interpolation function that can interpolate from structured data (defined on a grid) or unstructured data (defined on a generic point cloud).
- Select **Piecewise** to add a piecewise function that is useful if a material property has different definitions on different intervals. The intervals must not overlap, and there cannot be any holes between intervals.

	• Defining an Analytic Function • Analytic, Interpolation, and Piecewise

	Once a function is created, you can use it for any property in the same property group.

Defining an Analytic Function

Assume that you want to define the density ρ_1 for a material as a function of pressure and temperature: $\rho_1 = \rho_1(p,T)$. You can name the function `rho1(p,T)` and use the expression `p*0.02897/8.314/T` to define the function.

1 In the **Materials** toolbar, click the **Browse Materials** , **Add Material** , or **Blank Material** button to add a new material to the Component (or use an existing material where density is not defined, or redefine the current expression for the density).

2 Add a **Density** property to the material.

   a In the **Model Builder**, click the **Material** node.

   b In the **Settings** window for **Material**, click to expand the **Material Properties** section. Under **Basic Properties**, right-click **Density** and **Add to Material**.

   A **Density** property is added to the **Basic** property group.

3 In the **Model Builder**, under the material node, right-click **Basic** and select **Functions** > **Analytic**. This adds an **Analytic** subnode ( ) under **Basic**.

4 In the **Settings** window for **Analytic**, enter `rho1` in **Function name**. Replace the default name.

5 Under the **Definition** section:

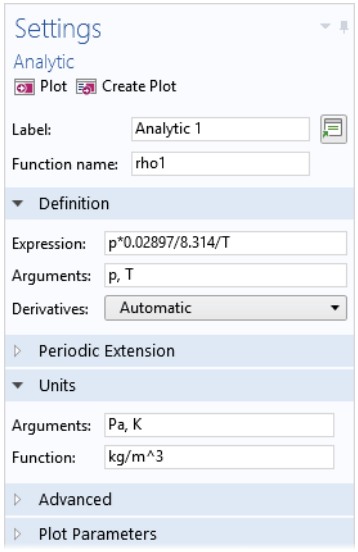
   a In the **Expression** field, enter `p*0.02897/8.314/T`.

   b In the **Arguments** column, enter `p,T`.

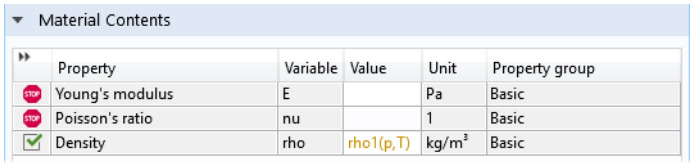
6 Under **Units**:

   a In the **Arguments** field, enter `Pa, K` as the units for the pressure and the temperature, respectively.

   b In the **Function** field, enter `kg/m^3` as the unit for the function's output (density). The function `rho1` can now be used to define the density in your material.



7 Click the **Material** node. In the **Settings** window for **Material**, under **Material Contents**, enter `rho1(p,T)` in the **Value** column (in the **Density** row).



Click the **Basic** node to notice that the **Density** analytic function is defined in the **Settings** window for **Property Group** under **Output Properties**. The expression will be orange if there are no variables `p` and `T` for pressure and temperature, respectively, defined in the component. See Figure 9-15.

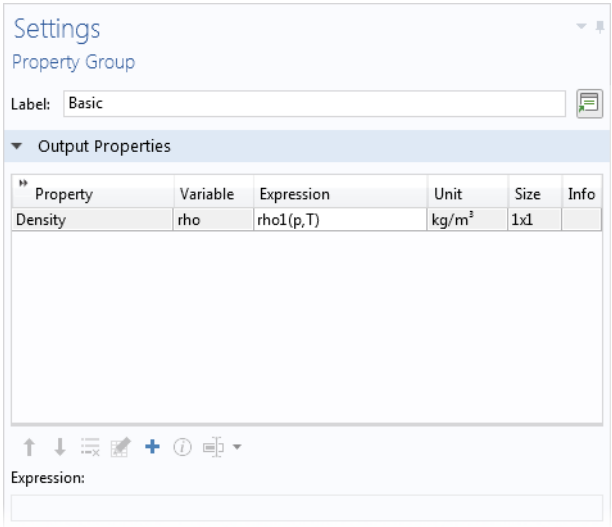


Figure 9-15: A density property is defined using an analytic function.

Working with External Materials

The External Material Model

A general external material model defines a relationship between a number of *input quantities* and a number of *output quantities*, a relationship that may also depend on *model parameters* and stored *states*. From the physics interfaces' point of view, an external material model is a black box, which may implement any relationship between provided input and required output quantities.

The external material model is implemented as a function with a C calling convention, compiled and linked to create a dynamically linked library that can be called from a material feature in COMSOL Multiphysics at runtime. In each solver iteration, current values of the input quantities and model parameters are passed together with previous values of model states as arguments to the external function. The external function is, in return, expected to write new values of model outputs, their partial derivatives with respect to model inputs, as well as updated state values to other preallocated function arguments.

The following sections provide an overview of the external materials framework, as well as details on the built-in interface types and instruction for compiling and linking a shared library.

As a security precaution, running code contained in external libraries is by default not allowed in a new COMSOL installation. Therefore, in order to use external material models, you must open the **Preferences** window, go to the **Security** page, and choose an option to **Allow external libraries**.

Using External Materials in Physics Interfaces

In order for a physics interface to make use of external materials, it must contain one or more features that provide input quantity definitions and make use of returned output quantities in equations and postprocessing expressions. Such features are currently available in the Solid Mechanics; Membrane; Magnetic Fields; and Magnetic Fields, No Currents interfaces.

- Using external materials in Solid Mechanics or Membrane requires a Structural Mechanics Module or MEMS Module license.
- AC/DC interfaces supporting external materials are only available with an AC/DC Module license, except for Magnetic Fields in 2D.

EXTERNAL MATERIAL INTERFACE TYPES

Given that a physics feature requires certain output quantities and defines certain input quantities, there are many possible ways to set up a call to an external function, including declarations of material properties and states. The required interface specification, or *interface type*, is contained in an *external material socket*, which does a number of different things:

- It defines the call syntax for the external material functions; that is, it defines the function name, return type, and the number of arguments with their data types and sizes.
- It defines a mapping between input and output quantity tensor components in the COMSOL Multiphysics variable namespace and positions in external function arguments.
- It defines a mapping between function argument positions and partial derivatives of outputs with respect to inputs.

- It decides which input quantities should be evaluated at the last converged step — rather than at the last iteration — and sets up states for these variables.
- It declares material model state variables and maps them to positions in the function arguments.
- It declares required material properties and maps them to the function arguments.
- It specifies error handling procedures, including error messages for various exit conditions.

The call syntax is in general not fixed for a given socket. Most sockets allow socket parameters to control certain aspects of the socket behavior, including:

- Whether to pass arguments as real or complex numbers.
- Whether to call an initialization function in the external library before the solver is started.
- Whether to call a cleanup function in the external library.
- What user-defined state array names to declare and pass to the external function, as well as the size of each array.
- Whether to add a preallocated string argument of a chosen size to the argument list, to which a detailed error message can be written if the external material function fails in some way.
- Whether to add a number of string arguments at the end of the argument list.

For an external shared library to be compatible with COMSOL Multiphysics, it must follow the conventions specified by some socket. Conversely, when using an existing external library in a multiphysics model, it is important to choose the right **Interface type** and parameters. Failure to do so will result in the external library being called with unexpected arguments, leading to arbitrary behavior.

It is not necessary for a socket to define all output quantities required by a physics feature. The socket and external library may compute only some quantities, while others are left to be specified by property groups under the External Material feature. For example, the built-in General stress-strain relation socket only returns second Piola–Kirchhoff stress as output, while the physics features using this interface type also may require the material density. The density may instead be specified as an expression in the Basic property group.

It is also possible to set the **Interface type** to **None** to select no socket and instead set up the relation between input and output quantities as expressions directly in an external material feature. This behavior is intended mostly for testing and debugging of multiphysics models. Note that no external material function will be called in this case.

Sockets and associated material property groups are identified by an ID tag that must be unique among all COMSOL installations between which files will be shared. In order to avoid conflicts between built-in sockets and future user-developed sockets, a full Java-style naming convention has been adopted. Therefore, for example, the built-in General H(B) relation socket has the unique ID `com.comsol.generalHBRelation` and the associated material property group has tag and name `comcomsolgeneralHBRelation` — that is, a direct concatenation of the ID.

SOLVER ITERATIONS AND STATE UPDATES

This section describes quantities as being evaluated either at the *current* step or at the *previous converged* step. This is related to the iteration pattern of the solvers. The external material functionality is primarily intended for modeling materials with some kind of memory or path dependence (for example, inelastic solid materials or materials exhibiting electromagnetic hysteresis). This means that simulations must be performed in steps over an interval of time or some parameter (which can often be interpreted as a pseudo-time).

Whether a time-dependent or parametric solver is used, taking a step forward requires solving a nonlinear problem, which is typically an iterative procedure. In order for the convergence to be efficient, the modified Newton solver

used needs correct Jacobian information (the Jacobian is sometimes called the *tangential stiffness matrix*), which must be provided by the external material functions in the form of partial derivatives of output argument components with respect to input argument components. When the nonlinear iteration converges, the solution for that time step or parameter step is stored, and the solver moves on to the next step.

The external material functions are typically called in each iteration in the inner nonlinear loop. Arguments that are evaluated at the *current* step are reevaluated at each inner iteration, while arguments defined at the previous converged step retain the value they had when the previous nonlinear iteration converged; that is, the value that was last stored. State variable arguments are passed to the external material function with the same previous converged values in each inner nonlinear iteration. The external material function is expected to overwrite this previous value with a new value corresponding to the current iteration, but this value will only be stored and the states updated when the inner nonlinear iteration converges.

RESULT PRESENTATION

The external material function may also be called during result presentation. In COMSOL Multiphysics, the stored solution consists of the degrees of freedom plus any possible state variables.

As an example, if you have coded your own elastoplastic material model for solid mechanics, you will typically store the plastic strains as states. If you then during result presentation make a plot of the stresses, the material function is called in order to compute the stresses from the displacements and plastic strains. This will happen at a large number of locations in the mesh.

The states are stored at the integration points, so if you request integration point results of the right order, there will be a call to the external material with a consistent already converged state. If the function is well coded, it will then return the stress state after a single iteration.

Often the material function is called from a location that is not an integration point (for example, a mesh node). In that case, the values of the state variables are taken from the closest integration point, while the total strains are computed from the displacement field gradients at the evaluation location. This combination does in general not provide a converged state, so iterations will be needed inside the material function in order to find the stress state. This can have several negative effects:

- The iterations will make the evaluation more expensive.
- The accuracy is decreased, since the state variable values are taken from a neighboring location.
- In the worst case, evaluation in the material function fails completely. What happens in this case depends on how you handle exceptions.

For these reasons it is advantageous, both from a performance and an accuracy point of view, to evaluate results only at the appropriate integration points. In order to ensure that, you can add the gpeval operator to your expressions. Instead of plotting for example `solid.mises`, use an expression like `gpeval(4,solid.mises)`.

Built-in Material Function Interface Types

There are currently six different built-in external material function interface types, or *sockets*, which have many traits in common:

- General Stress-Strain Relation
- General Stress-Deformation Relation
- Inelastic Residual Strain
- Inelastic Residual Deformation
- General B(H) Relation and General H(B) Relation

GENERAL ARGUMENTS FOR THE BUILT-IN MATERIAL FUNCTIONS

These built-in material function interfaces expect the external library to contain at least an evaluation function called `eval`, with a signature following the following pattern:

```
int eval(...,                 // Interface-type-specific arguments
         int *nPar,           // Number of material model parameters, input
         double *par,         // Material model parameters, input
         int *nStates1,       // Size of first state array, input, optional
         double *states1,     // First state array, input/output, optional
         int *nStates2,       // Size of second state array, input, optional
         double *states2, ...  // Second state array, input/output, optional
         char *errMsg,                 // Error message, output, optional
         char *arg1, char *arg2, ...)  // Extra string arguments, optional
```

The user is required to specify an array of material model parameters, called `par`. The number of parameters `nPar` is specified implicitly as the length of the material property array, which must be defined as a property in a property group under the calling **External Material** feature or set in the **Material Contents** table in the **External Material** node's settings. The material property expression list specified in this way is interpreted as a list of model expressions which are evaluated at the points for which external material outputs are requested.

The user may also specify a list of state arrays to be defined at each integration point, as well as the length of each array. The array lengths and values are passed to the external function in consecutive pairs of arguments, here formally called `nStates1`, `states1`, `nStates2`, `states2`, and so on. Note that the state arrays are both input and output: when the function is called, they contain the previous step converged values of the states; on return, they must contain the state values to be stored if the solver decides to proceed to the next step.

The optional `errMsg` argument allows returning a detailed error message if the evaluation must be terminated abnormally, or to pass a warning or log message to be displayed in the solver log. It is a preallocated string of specified size.

The property group which stores the `par` array may also specify another array of *extra function library string arguments*, `arg`, which are passed unevaluated as separate string arguments to the external material function. Note that the number of string arguments passed in this way is not checked.

Initialization and Cleanup

In addition to the `eval` function, the external library may contain functions called `init` and `cleanup`. The initialization function has the following signature:

```
int init(int *nStateArgs,             // Number of user-defined state vectors
         int *nPar,                   // Number of material model parameters
         int *stateArgsSize,          // User-defined state vector sizes
         int *errMsgSize,             // Size of error message output argument
         int *nStringArgs,            // Number of string array arguments
         char *errMsg,                // Error message argument, output, optional
         char *arg1, char *arg2, ...)  // Extra string arguments, optional
```

The first five arguments are always passed. The remaining may or may not be present, depending on settings in the **External Material** node from which the external library is called. If `errMsg` is not present, the `errMsgSize` argument will be negative. The number of extra `char*` arguments at the end of the argument list is given by the `nStringArgs` argument.

The initialization function is called every time a new native representation of the Multiphysics problem is created. In a solver sequence, this point corresponds to the **Compile Equations** node. But native representations may also be

created at other times, for example when showing a default solver. You can rely on the `init` method being called at least once before the solver is started, but it may be called multiple times.

The arguments passed to the `init` method describe the way that the `eval` function will subsequently be called. Implementing the `init` method to check that argument numbers and sizes agree with the implementation in the `eval` function is good practice, and can prevent unexpected program termination caused by reading outside the arguments actually passed.

The `cleanup` function is called when the native representation is discarded. This typically happens when a solution object is overwritten or otherwise discarded, at the latest at program exit. The function has the following signature:

```
int cleanup(char *errMsg,                // Error message argument, output, optional
            char *arg1, char *arg2, ...)  // Extra string arguments, optional
```

The arguments passed are the same as the last arguments to the `init` function, with the same sizes and values.

Note that the cleanup function is called immediately if the `init` function terminates with an error. It must therefore be written in such a way that it is tolerant against missing arguments.

Error Handling, Warnings, and Log Messages

The functions must return an integer values. For the `eval` function, the following return values are defined:

TABLE 9-30: ACCEPTED RETURN VALUES FOR THE EVAL FUNCTION.

RETURN VALUE	MEANING
0	Normal exit
1	Error: "Wrong number of parameters"
2	Error: "Wrong number of states"
-1	Normal exit, but display warning
-2	Normal exit, but display log message if there is an `errMsg` argument
anything else	Unspecified error

For the `init` function, the following return values are defined:

TABLE 9-31: ACCEPTED RETURN VALUES FOR THE INIT FUNCTION.

RETURN VALUE	MEANING
0	Normal exit
1	Error: "Wrong number of parameters"
2	Error: "Wrong number of states"
3	Error: "Wrong number of arguments"
4	Error: "Insufficient error message storage"
-1	Normal exit, but display warning
-2	Normal exit, but display log message if there is an `errMsg` argument
anything else	Unspecified error

For the `cleanup` function, any nonzero return value is reported as "External material cleanup error".

When the return value signals an error, it is also possible to supply an error details string in the optional output argument, `errMsg`. The error message argument, if present, is a preallocated string of a specified size.

You can also use the `errMsg` argument to return a warning or a log message. If the return value is `-1`, the contents of `errMsg` are displayed as a warning in the solver log and in a **Warnings** node under the solver node; when the return value is `-2`, the message is only displayed in the log.

Repeated warning messages are only displayed once. If you want the same warning to display each time the `eval` function returns `-1`, you must make the `errMsg` strings unique, for example by numbering the warnings.

GENERAL STRESS-STRAIN RELATION

The **General stress-strain relation** socket implements a stress-strain relation computing a second Piola–Kirchhoff stress tensor given the current Green-Lagrange strain together with a material property vector and a vector of stored states. The expected external material function signature is:

```
int eval(double *el,           // Green-Lagrange strain, input
         double *Sl,           // Second Piola-Kirchhoff stress, output
         double *Jac,          // Jacobian of stress with respect to strain,output
         int *nPar,            // Number of material model parameters, input
         double *par,          // Material model parameters, input
         int *nStates1,        // Size of first state array, input, optional
         double *states1,      // First state array, input/output, optional
         int *nStates2,        // Size of second state array, input, optional
         double *states2, ...  // Second state array, input/output, optional
         char *errMsg,                 // Error message argument, output, optional
         char *arg1, char *arg2, ...)  // Extra string arguments, optional
```

The `e` and `s` tensors are given in Voigt order; that is, the components in `e` are $\{e_{xx}, e_{yy}, e_{zz}, e_{yz}, e_{xz}, e_{xy}\}$ and similarly for `s`. The Jacobian `Jac` is a 6-by-6 matrix of partial derivatives of components of `s` (rows) with respect to components of `e` (columns); the matrix is stored in row-major order. All components refer to the local material coordinate system. Note that `Jac` in general is nonsymmetric since the three last components of `e` represent strain tensor components, rather than engineering shear ($\gamma_{ij} = 2e_{ij}$). For an explanation of remaining arguments, see General Arguments for the Built-In Material Functions.

GENERAL STRESS-DEFORMATION RELATION

The **General stress-deformation relation** socket implements a stress-deformation relation computing a second Piola–Kirchhoff stress tensor given the current and previous deformation gradient, the current and previous local temperature, the local material coordinate system, a material property vector, plus standard optional arguments. The expected external material function signature is:

```
int eval(double *Fl0ld,          // Deformation gradient at previous step, input
         double *Fl,             // Deformation gradient at current step, input
         double *tempOld,        // Temperature at previous step, input
         double *temp,           // Temperature at current step, input
         double *sysT,           // Local material coordinate system, input
         double *delta,          // Time step / Continuation parameter increment
         double *Sl,             // Second Piola-Kirchhoff stress, output
         double *Jac,            // Jacobian of stress with respect to deformation
                                 // gradient,output
         int *nPar,              // Number of material model parameters, input
         double *par,            // Material model parameters, input
         int *nStates1,          // Size of first state array, input, optional
         double *states1,        // First state array, input/output, optional
         int *nStates2,          // Size of second state array, input, optional
         double *states2, ...    // Second state array, input/output, optional
         char *errMsg,                 // Error message argument, output, optional
         char *arg1, char *arg2, ...)  // Extra string arguments, optional
```

The `Fl0ld` and `Fl` tensors are given as 3-by-3 matrices expanded in row-major order, where the row index refers to global (displacement) directions, and the column index refers to directions in the local material coordinate

system. The coordinate system itself, `sysT`, is passed as a 1-by-9 concatenation of the local system's three covariant base vectors expressed in global material coordinates. The argument `delta` is a scalar reserved for future use.

The output stress tensor, `Sl`, is given in Voigt order; that is, the components in `Sl` are {Sl_{xx}, Sl_{yy}, Sl_{zz}, Sl_{yz}, Sl_{xz}, Sl_{xy}}, where the indices refer to the local material coordinate system. The Jacobian `Jac` is a 6-by-9 matrix of partial derivatives of components of `Sl` (rows) with respect to components of `Fl` (columns); the matrix is stored in row-major order. For an explanation of remaining arguments, see General Arguments for the Built-In Material Functions.

INELASTIC RESIDUAL STRAIN

The **Inelastic Residual Strain** socket implements an update procedure for an additive inelastic contribution to the total Green-Lagrange strain. Total stress and strain at the previous converged step, current total strain, current temperature, a reference temperature, a material property vector, and a vector of stored states are passed as inputs.

```
int eval(double *sOld,          // Second Piola-Kirchhoff stress at previous step, input
         double *eOld,          // Green-Lagrange strain at previous step, input
         double *e,             // Green-Lagrange strain at current step, input
         double *T,             // Temperature, input
         double *Tref,          // Strain reference temperature, input
         double *eInel,         // Inelastic Green-Lagrange strain state, input/output
         double *Jac,           // Jacobian of inelastic strain, output
         int *nPar,             // Number of material model parameters, input
         double *par,           // Material model parameters, input
         int *nStates1,         // Size of first state array, input, optional
         double *states1,       // First state array, input/output, optional
         int *nStates2,         // Size of second state array, input, optional
         double *states2, ...   // Second state array, input/output, optional
         char *errMsg,                  // Error message argument, output, optional
         char *arg1, char *arg2, ...)   // Extra string arguments, optional
```

The `sOld`, `eOld`, `e`, and `eInel` tensors are given in Voigt order (that is, the components in `e` are {e_{xx}, e_{yy}, e_{zz}, e_{yz}, e_{xz}, e_{xy}}) and similarly for the other tensors. The Jacobian `Jac` is a 6-by-6 matrix of partial derivatives of components of `eInel` (rows) with respect to components of `e` (columns); the matrix is stored in row-major order. Note that the primary output quantity `eInel` is declared as states, meaning that the argument on entry contains the previous converged step values. The temperature arguments `T` and `Tref` are standard model inputs, which are specified in the physics feature calling the external material where the Inelastic residual strain socket is selected. For an explanation of remaining arguments, see General Arguments for the Built-In Material Functions.

INELASTIC RESIDUAL DEFORMATION

The **Inelastic Residual Deformation** socket implements an update procedure for an inelastic contribution to the deformation gradient. Total stress and deformation at the previous converged step, current total deformation, current temperature, a reference temperature, plus standard optional arguments are passed as inputs.

```
int eval(double *sOld,          // Second Piola-Kirchhoff stress at previous step, input
         double *FlOld,         // Deformation gradient at previous step, input
         double *Fl,            // Deformation gradient at current step, input
         double *T,             // Temperature, input
         double *Tref,          // Strain reference temperature, input
         double *FlInel,        // Inelastic Green-Lagrange strain state, input/output
         double *Jac,           // Jacobian of inelastic strain, output
         int *nPar,             // Number of material model parameters, input
         double *par,           // Material model parameters, input
         int *nStates1,         // Size of first state array, input, optional
         double *states1,       // First state array, input/output, optional
         int *nStates2,         // Size of second state array, input, optional
         double *states2, ...   // Second state array, input/output, optional
         char *errMsg,                  // Error message argument, output, optional
         char *arg1, char *arg2, ...)   // Extra string arguments, optional
```

The `sOld`, tensor is given in Voigt order (that is, the components in `s` are {s_{xx}, s_{yy}, s_{zz}, s_{yz}, s_{xz}, s_{xy}}). The deformation gradient arguments `FlOld`, `Fl`, and `FlInel` are passed as 3-by-3 matrices expanded in row-major order, where the row index refers to global (displacement) directions, and the column index refers to directions in the local material coordinate system. The Jacobian `Jac` is a 9-by-9 matrix of partial derivatives of components of `FlInel` (rows) with respect to components of `Fl` (columns); the matrix is stored in row-major order. Note that the primary output quantity `FlInel` is declared as states, meaning that the argument on entry contains the previous converged step values. The temperature arguments `T` and `Tref` are standard model inputs, which are specified in the physics feature calling the external material where the Inelastic residual strain socket is selected. For an explanation of remaining arguments, see General Arguments for the Built-In Material Functions.

GENERAL B(H) RELATION AND GENERAL H(B) RELATION

The **General B(H) relation** and **General H(B) relation** sockets implement generalizations of B-H and H-B curves, respectively. The General B(H) relation socket computes an updated magnetic flux density corresponding to an updated magnetic field, given the magnetic field and magnetic flux density at the previous converged step. A material property vector and a vector of stored states are passed as additional input. Typical implementations will use extra states to model hysteresis.

```
int eval(double *oldH,         // Magnetic field at previous step, input
         double *H,            // Magnetic field, input
         double *B,            // Magnetic flux density state, input/output
         double *Jac,          // Jacobian of Bwith respect to H, output
         int *nPar,            // Number of material model parameters, input
         double *par,          // Material model parameters, input
         int *nStates1,        // Size of first state array, input, optional
         double *states1,      // First state array, input/output, optional
         int *nStates2,        // Size of second state array, input, optional
         double *states2, ...  // Second state array, input/output, optional
         char *errMsg,                 // Error message argument, output, optional
         char *arg1, char *arg2, ...)  // Extra string arguments, optional
```

The magnetic fields `oldH` and `H` and the magnetic flux density `B` are passed as arrays of length 3. The Jacobian `Jac` is 3-by-3 matrix of partial derivatives of components of `B` (rows) with respect to components of `H` (columns); the matrix is stored in row-major order. Note that the primary output quantity `B` is declared as states, meaning that the argument on entry contains the previous converged step values. For an explanation of remaining arguments, see General Arguments for the Built-In Material Functions.

For examples showing how to implement and use external materials, see

Library of Utility Functions for Structural Mechanics

When modeling materials for structural mechanics, there are many common operations that you may need, such as

- Computing principal stresses and other eigenvalues
- Matrix inversion
- Converting tensors between matrix and vector representation

A large library of such utility functions which you can call from your external material function is available.

- For a complete list of utility functions and how they are used, see Using External Materials in the *Structural Mechanics User's Guide*.
- For instructions how to include utility functions in your external material library file, see Linking with Utility Functions.

How to Compile and Link an External Material Model

To export functions from the DLL when using Microsoft Visual Studio to compile your library, you must declare the functions as `__declspec(dllexport)`. Therefore, to write a source code that works across platforms, use the following `#define` pattern:

```
#ifdef _MSC_VER
#define EXPORT __declspec(dllexport)
#else
#define EXPORT
#endif

EXPORT <return_type> eval(<arguments>) { }
```

COMPILING AND LINKING

To compile the function into a library, place it in a file (here called `ext.c` as an example) and proceed as follows depending on the platform:

See https://www.comsol.com/system-requirements for information about supported compiler versions.

- 64-bit Windows with Microsoft Visual Studio 2022:
  - Start **Visual Studio 2022** > **Visual Studio Tools** > **VC** > **x64 Native Tools Command Prompt for VS 2022** from the Windows Start menu.
  - `cd` to the directory that contains `ext.c`.
  - `cl /MT /c ext.c`
  - `link /OUT:ext.dll /DLL ext.obj`
- 64-bit Linux with Intel Compiler:
  - `cd` to the directory that contains `ext.c`.
  - `icx -fPIC -c ext.c`
  - `icx -shared -fPIC -o ext.so ext.o -ldl`
- 64-bit Linux ARM64 with GCC:
  - `cd` to the directory that contains `ext.c`.
  - `gcc -fPIC -c ext.c`
  - `gcc -shared -fPIC -o ext.so ext.o -ldl`
- 64-bit macOS (Intel or ARM64) with Clang:
  - `cd` to the directory that contains `ext.c`.
  - `clang -fPIC -c ext.c`
  - `clang -shared -fPIC -o ext.dylib ext.o`

For other compilers, refer to the compiler's documentation for instructions on how to compile and create a shared library.

LINKING WITH UTILITY FUNCTIONS

To use the provided utility functions in your external material function, you need to reference a header file that contains the utility function declarations. Add the following line to your file (again, called `ext.c` as an example):

```
#include "csextutils.h"
```

Proceed as follows, depending on the platform:

- 64-bit Windows with Microsoft Visual Studio 2022:
  - Start **Visual Studio 2022** > **Visual Studio Tools** > **VC** > **x64 Native Tools Command Prompt for VS 2022** from the Windows Start menu.
  - `cd` to the directory that contains `ext.c`
  - `cl /MT /c ext.c /I C:\Program Files\COMSOL\COMSOL63\Multiphysics\data\extmat`
  - `link /OUT:ext.dll /DLL ext.obj C:\Program Files\COMSOL\COMSOL63\Multiphysics\data\extmat\win64\csextutils.lib`
- 64-bit Linux with Intel Compiler:
  - `cd` to the directory that contains `ext.c`
  - `icx -fPIC -c -I/usr/local/comsol63/multiphysics/data/extmat ext.c`
  - `icx -shared -fPIC -o ext.so ext.o -L/usr/local/comsol63/multiphysics/lib/glnxa64 -lcsextutils`
- 64-bit Linux ARM64 with GCC:
  - `cd` to the directory that contains `ext.c`
  - `gcc -fPIC -c ext.c`
  - `gcc -shared -fPIC -o ext.so ext.o -ldl`
- 64-bit macOS (Intel or ARM64) with Clang:
  - `cd` to the directory that contains `ext.c`
  - `clang -fPIC -c -I/Applications/COMSOL63/Multiphysics/data/extmat ext.c`
  - `clang -shared -fPIC -o ext.dylib ext.o -L/Applications/COMSOL63/Multiphysics/lib/maci64 -lcsextutils`

For other compilers, refer to the compiler's documentation for instructions on how to compile and create a shared library.

Known Issues for External Materials

The external materials framework, being a rather recent addition to COMSOL Multiphysics, suffers from a few known issues that may affect usability in some cases:

- There is no unit support: Inputs are passed to the external function in the model's base unit system and outputs are interpreted in the same system.
- Shared libraries containing external material functions are under some circumstances loaded the first time they are used and then never reloaded. To avoid having to repeatedly restart COMSOL Multiphysics while developing an external material function, simply change the name of the linked library each time you make a change to it.
- The way the external functions are called is not fault tolerant in any way. This means that reading or writing outside allocated memory in an external function typically makes the COMSOL Desktop quit unexpectedly.

Exercise caution when coding, and always save your COMSOL model before running it with an external material.

External Material

The **External Material** node ( ) sets up an interface between a physics feature and functions in an external shared library. In addition, it contains most of the functionality of a standard **Material** node, letting you add arbitrary material properties and property groups. Some aspects of a material can be handled by an external library, while others are defined internally in property groups.

	The **External Material** node is only available under the **Global Definitions** > **Materials** node, not under **Materials** inside components. To use property groups under an **External Material** as domain material on geometric entities in a component, use a Material Link node.

	This section focuses on using a material model from an existing external library in your COMSOL Multiphysics model. General information about the external materials framework and how to create your own custom library can be found under Working with External Materials.

To add an external material to a user-defined material library, right-click the **External Material** node and choose **Add to User-Defined Library** ( ).

The **Settings** window for the **External Materials** node contains the following sections:

LIBRARY FOR WINDOWS, 64-BIT

Use this section to define a library for the Windows® operating system. Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. The library must be a DLL (native dynamic library) file.

LIBRARY FOR LINUX, 64-BIT

Use this section to define a library for the Linux® operating system. Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. The library must be a .so (native dynamic library) file.

LIBRARY FOR MACOS, 64-BIT

Use this section to define a library for the macOS operating system. Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. The library must be a .dylib (native dynamic library) file.

LIBRARY FOR MACOS, ARM 64-BIT

Use this section to define a library for the macOS with ARM operating system. Enter a **Library** path and name (the complete network path), or click **Browse** to locate a library to import. The library must be a .dylib (native dynamic library) file.

All libraries must be for a 64-bit architecture.

EXTERNAL MATERIAL MODEL

If the external material DLL is not thread safe, clear the **Thread safe** checkbox. If the DLL is thread safe, several threads can make calls to the DLL at the same time. By clearing the **Thread safe** checkbox, you prevent the DLL from being used by more than one thread at the same time.

Select the appropriate **Interface type** matching your library. The default is **None**; other options may vary between COMSOL installations. The following types are preinstalled:

- **General B(H) relation**
- **General H(B) relation**
- **General stress-deformation relation**
- **General stress-strain relation**
- **Inelastic residual deformation**
- **Inelastic residual strain**
- **Lagrangian interface to PolyUMod**

If the chosen external library contains initialization and cleanup functions and the interface type allows it, select **Call init()** and **Call cleanup()** as appropriate.

If allowed for the chosen interface type and external library, select the **Pass arguments as complex** checkbox to use `complex` rather than `double` as the base type in all numeric array arguments to the external functions.

If required by the chosen interface type, specify a **State base name** for each state array that must be stored at each evaluation point and provide a corresponding array size under **Number of states**. Actual state variables are created by adding the *<matname>*`.state.` namespace as a prefix and appending a state index to the given base names. For example, if for a material with name `extmat1` you request a state array of length 2 with **State base name** `p`, the state values can be accessed during and after a solution as `extmat1.state.p1` and `extmat1.state.p2`.

The maximum total number of arguments in an `eval` function signature is 40. This means that the number of optional arguments, such as pointers to state arrays and error messages, will be limited by the number of required arguments for the specific `eval` function. For example, the maximum number of optional arguments in the **General Stress–Strain Relation** is 35.

If the external library's functions are implemented so as to return error details, select **Return error details** and specify a **Maximum error message length**. A preallocated string of the specified length will then be passed as output argument to all functions.

The **Required input quantities**, **Output quantities**, and **Model states** tables provide an overview of the interface, including which quantities are passed to and from calling physics features, which states are declared, and which component variables are defined by the material feature. Note that all variables are defined in the material's namespace. To directly access, for example, the first axial component of a second Piola–Kirchhoff stress output outside the scope of an **External Material** node with the name `extmat1`, use the variable name `extmat1.output.S11`.

Components of the **Required input quantities** are normally defined by a physics feature calling the external material. When using an external material in equation-based modeling, you can set the inputs up manually by defining the required input components (in the material's namespace) as global variables. For example, if external material `extmat1` requires the temperature T as input, define a global variable called `extmat1.input.T`.

Use the **Init** column in the **Model states** table to specify initial values for all internal states used by the external function. This includes both specific states required by the chosen **Interface type** and numbered states added by this feature.

MATERIAL PROPERTIES

The **Material Properties** section of an external material is identical to the same section in a common **Material** feature. See The Settings Window for Material for more information.

MATERIAL CONTENTS

The **Material Contents** section of an external material is very similar to the same section in a common **Material** feature (see The Settings Window for Material for more information). The only real difference is that the table shows not only defined output properties and properties required by some physics feature, but also parameters required as input to the external material functions. Depending on the selected **Interface type**, these may appear either as individually named parameters or as a single generic, arbitrary-length parameter array. In the latter case, any particular external library typically requires a specific set of properties in a certain order to be specified as an array inside curly brackets. For example, two required parameters can be specified as `{2e11,0.33}`

The table also shows a row for **Extra library function string arguments**, whose value is expected to be an array of single-quoted strings. These strings are stored in a property group in the same way as other parameters. They are passed to the external library's functions as separate string arguments.

Parameters and string arguments required as input to the external library functions are stored in a property group subnode with the same name as the selected **Interface type**.

Module-Specific Material Libraries

- See About the Material Libraries for an overview of the material databases and the modules in which they are included.
- For more information about customizing the material's appearance in the Graphics window, see The Settings Window for Material.

In this section:

- AC/DC Material Library
- Battery Material Library
- Composites Material Library
- Corrosion Material Library
- Bioheat Materials Library
- Building Material Library
- Electric Discharge Material Library
- Equilibrium Discharge Material Library
- Fuel Cell and Electrolyzer Material Library
- Liquids and Gases Material Library
- MEMS Material Library
- Nonlinear Magnetic Material Library
- Optical Material Library
- Piezoelectric Materials Library
- Piezoresistivity Material Library
- RF Materials Library
- Semiconductor Material Library
- Thermoelectric Material Library
- References for the Materials Libraries

AC/DC Material Library

The electromagnetic material properties that can be stored in this material library, available in the AC/DC Module, are:

- Electric conductivity and resistivity
- Relative permittivity
- Relative permeability
- Nonlinear B-H curves
- Refractive index

The database contains electromagnetic and other material properties for these materials:

MATERIALS
Copper
Aluminum

MATERIALS
Soft Iron (without losses)
Soft Iron (with losses)
MuMETAL®
Nonlinear Permanent Magnet
Jiles-Atherton Isotropic Hysteretic Material
Silicon Carbide
Graphite
Graphite Felt
Quartz
FR4 (Circuit Board)

Some properties depend on the magnetic flux density, location, or temperature. The database contains, depending on the material and in addition to the more common material properties, the following properties:

PREDEFINED PROPERTIES
Remnant flux density
Reference temperature
Temperature coefficient
Nonlinear B-H curves
Resistivity at reference temperature

In addition, the AC/DC material database contains material properties for a large number of magnetic materials from Bomatec® in the **Magnetic Materials (Bomatec®)** folder. It also contains a **Hard Magnetic Materials** folder with material properties for a large number of sintered NdFeB grades.

Nonlinear Magnetic Material Library

Battery Material Library

The Battery material library is included with the Battery Design Module and contains the electrode and electrolyte materials listed in Table 9-32 and Table 9-33, respectively. The material property groups (including all associated properties) are listed in Table 9-13.

Literature references are included as property info entries in the Battery Materials library. These can be viewed by clicking the **Edit/Show Property Information** button in the info column in the **Output Properties** section of the **Property Group** subnodes once a **Material** node has been added to the model using **Add Material from Library**. The property references are also shown in the material browser when using **Browse Materials**.

Bioheat Materials Library

The Bioheat materials library contains materials used with the Heat Transfer Module's Bioheat Transfer interface. The properties are given either as a constant value, as a piecewise linear function of the temperature, or as a polynomial approximation function of the temperature that provides a good agreement with the reference, as summarized in the table below. Also see References for the Bioheat Materials Library.

MATERIAL	THERMAL CONDUCTIVITY W/(m·K)	DENSITY kg/m^3	HEAT CAPACITY J/(kg·K)	FREQUENCY FACTOR 1/s	ACTIVATION ENERGY J/mol	REFERENCE

Building Material Library

The Building material library contains hygroscopic and thermal properties for materials used with the Heat Transfer Module's Moisture Transport interface and Heat and Moisture Transport multiphysics interface.

In addition to thermal properties (thermal conductivity, density, and heat capacity), the following hygroscopic properties are provided:

- Effective thermal conductivity (SI Unit: W/(m·K))
- Moisture content (SI Unit: kg/m^3)
- Moisture diffusivity (SI Unit: m^2/s)
- Vapor resistance factor (dimensionless)
- Vapor permeability (SI Unit: s)

Note that for materials intended to be used as vapor barriers, only the vapor resistance factor and vapor permeability are available.

The properties are given either as a constant value, as a piecewise linear function of the temperature or the relative humidity, or as a polynomial approximation function of the temperature or the relative humidity that provides a good agreement with the reference. The table below summarize the materials, their characteristics and their intended use. Also see References for the Building Materials Library.

MATERIAL	USAGE	CHARACTERISTICS	REFERENCE
Concrete	Building structure	-	Ref. 3
Lime silica brick	Building structure	-	Ref. 3
Wood, pine	Studs, panels	Nominal thickness = 10 mm	Ref. 1, Ref. 2
Gypsum board	Interior board	Nominal thickness = 13 mm	Ref. 1, Ref. 2
Glass wool board	Sheathing	Nominal thickness = 30 mm	Ref. 1, Ref. 2
Cellulose board	Sheathing	Nominal thickness = 25 mm	Ref. 1, Ref. 2
Glass wool batt	Thermal insulation	Nominal thickness = 50 mm	Ref. 1, Ref. 2
Cellulose batt	Thermal insulation	Nominal thickness = 50 mm	Ref. 1, Ref. 2
Cellulose (loose)	Thermal insulation	Nominal thickness = 50 mm	Ref. 1, Ref. 2
Plastic coated paper	Vapor/air barrier	-	Ref. 1, Ref. 2
Expanded polystyrene board (EPS)	Thermal insulation, vapor/air barrier	Board from molded blocks conform to norm EN 13163	Ref. 4
Extruded polystyrene board (XPS)	Thermal insulation, vapor/air barrier	Board of thickness < 60mm, without any occluded gas other than air and CO2, conform to norm EN 13164	Ref. 4

Composites Material Library

The Composites material library contains material data for composites, divided into three comprehensive groups of materials: fiber constituents (various types of fibers), matrix constituents (various ceramics and polymers), and laminae (various fiber laminae). It is available with the Structural Mechanics Module and MEMS Module.

Almost all composite material data in the library is based on open literature sources (see Ref. 1–Ref. 8). These references can also be viewed by clicking the **Edit/Show Property Information** button in the info column in the **Output Properties** section of the **Property Group** subnodes once a **Material** node has been added to the model using **Add Material from Library**. The property references are also shown in the material browser when using **Browse Materials**. A few values are taken from other sources on the web, assumed logically, or found analytically.

Corrosion Material Library

The Corrosion material library contains polarization data (local current density versus electrode potential) for a number of different metals in various electrolytes. Equilibrium potentials (potential at zero current density) are also provided.

All corrosion material data in the library is based on open literature sources. These can be viewed by clicking the **Edit/Show Property Information** button in the info column in the **Output Properties** section of the **Property Group** subnodes once a **Material** node has been added to the model using **Add Material from Library**. The property references are also shown in the material browser when using **Browse Materials**.

Polarization curves are typically added as interpolation polynomials, using linear extrapolation and interpolation. Polarization data is added with respect to the same reference electrode as in the scientific literature source. The material node will, however, by definition assume the voltage input from the physics to the material to be versus a Standard Hydrogen Electrode (SHE). Conversion of the potential input versus SHE value to the relevant reference is hence done locally within the Material node before calling the interpolation polynomial function. On the physics side, using another reference electrode than SHE for postprocessing and user-defined equilibrium potentials can be accomplished by the **Physics vs. Materials Reference Electrode Potential** setting on the physics top node. The reference electrode in the original data is stated in the Property Information but also in the descriptions of the local properties defined by the material node, where applicable.

Equilibrium (open circuit) potential data is also provided, defined as the potential for which the current is zero or the magnitude of the current is at its minimum in the experimental polarization curve. Equilibrium potentials are also defined versus the reference in the original data and then converted to equilibrium potentials versus SHE on the Materials node itself.

The equilibrium (open circuit) potential has no impact on the local current density expression defined by the Material node. However, the equilibrium potential could be used by the physics during Primary Current Distribution simulations, the Current Distribution Initialization (primary option) study step, and for calculating electrode reaction heat sources. It should, however, be noted that for polarization data representing the sum of multiple reactions (for example, oxygen reduction plus metal dissolution in many corrosion polarization measurements), there is, in a thermodynamical sense, no well-defined equilibrium for the sum of the reactions, and the equilibrium potential value provided by the Material node should, in this case, not be used for deriving electrochemical heat sources.

Electric Discharge Material Library

The Electric Discharge material library is included with the Electric Discharge Module and contains the materials listed in Table 9-34. The material property groups (including all associated properties) are listed in Table 9-12.

TABLE 9-34: ELECTRIC DISCHARGE MATERIALS DATABASE.

GROUP	MATERIAL	GROUP	MATERIAL	GROUP	MATERIAL
Gases References 1, 2, 3, 4, and 5	Air Br_2 - Bromine CCl_2F_2 - Dichlorodifluoromethane CF_4- Tetrafluoromethane C_2F_6 - Hexafluoroethane C_3F_8 - Octafluoropropane C_4F_{10} - Perfluorobutane Cl_2 - Chlorine CO_2 - Carbon Dioxide H_2O - Water Vapor HCl - Hydrogen Chloride N_2 - Nitrogen NH_3 - Ammonia N_2O - Nitrous Oxide NO - Nitric Oxide O_2 - Oxygen SF_6 - Sulfurhexafluoride	Liquids References 6	Transformer Oil	Solids References 7	Polyethylene

Equilibrium Discharge Material Library

The Equilibrium Discharge material library is included with the Plasma Module and the Electric Discharge Module. It contains the materials listed in Table 9-35. The values are based on data from Ref. 1, using sampling intervals of 500 K instead of 100 K. Note that these values are valid only for a pressure of 1 atm, with minimal deviations allowed, and a temperature range of 500–25 000 K. The material property groups (including all associated properties) are listed in Table 9-15.

TABLE 9-35: EQUILIBRIUM DISCHARGE MATERIALS DATABASE.

MATERIAL
Air (1[atm])
Argon (1[atm])
Helium (1[atm])
Hydrogen (1[atm])
Nitrogen (1[atm])
Oxygen (1[atm])

Fuel Cell and Electrolyzer Material Library

The Fuel Cell and Electrolyzer material library contains electrolyte data for some of the more common fuel cell and electrolyte cell types.

All material data in the library is based on open literature sources. These can be viewed by clicking the **Edit/Show Property Information** button in the info column in the **Output Properties** section of the **Property Group** subnodes

once a **Material** node has been added to the model using **Add Material from Library**. The property references are also shown in the material browser when using **Browse Materials**.

Liquids and Gases Material Library

The Liquids and Gases material library contains thermal and fluid dynamic properties for a set of common liquids and gases. All properties are given as functions of temperature and at atmospheric pressure, except the density, which for gases is also a function of the local pressure. The database also contains surface and interface tensions for a selected set of liquid/gas and liquid/liquid systems. All functions are based on data collected from scientific publications. This material library is included in the Acoustics Module, CFD Module, Chemical Reaction Engineering Module, Heat Transfer Module, MEMS Module, Pipe Flow Module, and Subsurface Flow Module,

TABLE 9-36: LIQUIDS AND GASES MATERIALS.

GROUP	MATERIAL	GROUP	MATERIAL
Gases References 1, 2, 7, and 8	Air Nitrogen Oxygen Carbon dioxide Hydrogen Helium Steam Propane Ethanol vapor Diethyl ether vapor Freon12 vapor SiF4	Liquids References 2, 3, 4, 5, 6, 7, 9, 10, and 11	Engine oil Ethanol Diethyl ether Ethylene glycol Gasoline Glycerol Heptane Mercury Toluene Transformer oil Water R-134A (C2H2F4) R-22 (CHClF2)

MEMS Material Library

The MEMS material library, included in the MEMS Module and Structural Mechanics Module, contains several materials commonly used in MEMS applications. The materials are divided into metals, semiconductors, insulators, and polymers.

The basic structure of the library comes from the book *Microsensors, MEMS, and Smart Devices* (Ref. 1). The material properties come from two primary sources: the *CRC Handbook of Chemistry and Physics* (Ref. 2) and *MacMillan's Chemical and Physical Data* (Ref. 3). Some of the mechanical properties in the library are more MEMS-specific values from *The MEMS Handbook* (Ref. 4), and most of the semiconductor properties are values from Ref. 5. Most of the PDMS material properties are based on Ref. 7, where Young's modulus is based on Ref. 8.

Ref. 6 provides a valuable resource for cross-checking the insulation material properties.

Piezoelectric Materials Library

The Piezoelectric Materials Library contains material property data from the following companies' products:

FERROPERM PIEZOCERAMICS A/S

Pz21, Pz23, Pz24, Pz26, Pz27, Pz29, Pz34, Pz37HD, Pz54, Pz89

The foregoing materials are the property of Ferroperm Piezoceramics A/S. For product information concerning these materials, see https://www.ferropermpiezoceramics.com. For other questions concerning the materials, please contact erling.ringgaard@ctscorp.com.

PI CERAMIC GMBH

PIC144, PIC151, PIC153, PIC181, PIC255, PIC300, PIC700

The foregoing materials are the property of PI Ceramic GmbH. For product information concerning these materials, see https://www.piceramic.com. For other questions concerning the materials, please contact request-pic@pi.ws.

The Piezoelectric materials library, included in the Acoustics Module, MEMS Module, and Structural Mechanics Module, contains the following materials:

MATERIAL
Barium sodium niobate
Barium titanate
Barium titanate (poled)
Lithium niobate
Lithium tantalate
Lead zirconate titanate (PZT-2), (PZT-4), (PZT-4D), (PZT-5A), (PZT-5H), (PZT-5J), (PZT-7A), and (PZT-8)
Quartz LH (1949 IRE), RH (1949 IRE), LH (1978 IEEE), RH (1978 IEEE)
Rochelle salt

MATERIAL
Bismuth germanate
Cadmium sulfide
Gallium arsenide
Tellurium dioxide
Zinc oxide
Zinc sulfide
Ammonium dihydrogen phosphate
Aluminum nitride
Ferroperm Piezoceramics (Pz21), (Pz23), (Pz24), (Pz26), (Pz27), (Pz29), (Pz34), (Pz37HD), (Pz54), (Pz89)
PI Ceramic (PIC144), (PIC151), (PIC153), (PIC181), (PIC255), (PIC300), (PIC700)

All materials define the following material properties needed for piezoelectric modeling:

MATERIAL PROPERTY	DESCRIPTION
c_E	Elasticity matrix
e	Coupling matrix, stress-charge
ε_{rS}	Relative permittivity, stress-charge
s_E	Compliance matrix
d	Coupling matrix, strain-charge
ε_{rT}	Relative permittivity, strain-charge
ρ	Density

With the exception of Ferroperm Piezoceramics A/S data and PI Ceramic GmbH data, the property values are taken from the efunda website: https://www.efunda.com/materials/piezo/material_data/matdata_index.cfm.

Piezoresistivity Material Library

The Piezoresistivity material library is included with the MEMS Module and contains the following materials:

MATERIAL
p-Silicon (single-crystal, lightly doped)
n-Silicon (single-crystal, lightly doped)
p-Silicon (polycrystalline, lightly doped)
n-Silicon (polycrystalline, lightly doped)

All materials define the following material properties needed for modeling the piezoresistance effect:

MATERIAL PROPERTY	DESCRIPTION
D	Elasticity matrix
DVo	Elasticity matrix, Voigt notation
ρ	Density
ε_r	Relative permittivity
σ	Electric conductivity
Π	Piezoresistive coupling matrix
m_l	Elastoresistive coupling matrix

Both the electric conductivity and the piezoresistive or elastoresistive coupling matrix are strong functions of the material dopant density. The material models include appropriate functions, although the piezoresistive and elastoresistive matrices scale only with the conductivity, which is appropriate only at lower dopant densities (below approximately 10^{16} cm^{-3}). The low doping level piezoresistance and elastoresistance values are based on those given in Ref. 1. The conductivity is computed from an empirical functional fit to experimental data given in equation 8 of Ref. 2. Data on the piezoresistance properties of Silicon at higher doping levels is available in Ref. 3 and Ref. 4. Because this data does not include all components of the coupling matrix, it is not included in the material models.

The dopant density must be entered for the material as a model input in the piezoresistive or conductive material node. It can be entered as a constant value or as an expression (for example, a spatially varying function could be used).

Optical Material Library

The Optical material library is included with the Ray Optics Module and the Wave Optics Module. It contains more than 1700 materials, including more than 500 optical glasses from the following optical glass manufacturers:

- CDGM Glass Co., Ltd
- Corning Incorporated
- Ohara Inc.
- Schott AG

For most of these glasses, the refractive index is defined using optical dispersion coefficients to support accurate ray tracing of polychromatic light. Many of these glasses also include tabulated internal transmittance data as a function of wavelength, enabling volumetric light absorption to be predicted, as well as coefficients that describe the temperature dependence of the refractive index. Finally, most optical glasses include additional properties such as density, Young's modulus, Poisson's ratio, thermal conductivity, specific heat capacity, and thermal expansion coefficient, which facilitate coupled structural-thermal-optical performance (STOP) analysis.

For other organic, inorganic, and miscellaneous materials, the properties are based on data from Ref. 1. Here, the material properties are frequency-dependent values for the real and imaginary part of the refractive index.

RF Materials Library

The RF material library is included with the RF Module. It contains a number of substrate materials that assist in modeling RF components. Dielectric properties, like the real part of the relative permittivity and the loss tangent, including the frequency dependence, are included. The materials in this library can assist in modeling RF, microwave, and millimeter-wave circuit boards. The RF material library includes material properties supplied from the following companies:

- Avient Corporation
- Corning Incorporated
- Garlock Sealing Technologies LLC
- Isola Group
- Nanoe
- Rogers Corporation

Some of the materials are the property of Avient Corporation.

Some of the materials are the property of Garlock Sealing Technologies LLC.

Some of the materials are the property of Isola Group.

Some of the materials are the property of Nanoe.

The library also includes laminates and materials from Rogers Corporation. The laminate and materials trademarks are trademarks or registered trademarks of Rogers Corporation and its subsidiaries and joint ventures. All other trademarks are trademarks of their respective companies.

See the *RF Module User's Guide* for more information.

Semiconductor Material Library

The Semiconductor material library is included with the Semiconductor Module and contains the materials listed in Table 9-38. The material property groups (including all associated properties) are listed in Table 9-23.

The Silicon material contains parameters for all material property groups, while the other materials contain only the material parameters in the Semiconductor and Basic material groups.

Table 9-23 also gives the references used for the silicon material properties. The material properties for materials other than Silicon are obtained from Ref. 9 and Ref. 10.

TABLE 9-38: SEMICONDUCTOR MODULE MATERIALS DATABASE.

MATERIAL
Si - Silicon
Ge - Germanium
GaAs - Gallium arsenide
Al(x)Ga(1-x)As - Aluminum gallium arsenide
GaN (Wurtzite) - Gallium nitride
GaN (Zinc Blende) - Gallium nitride
GaP - Gallium phosphide
GaSb - Gallium antimonide
InAs - Indium arsenide
InP - Indium phosphide
InSb - Indium antimonide
C - Diamond
SiC - Silicon Carbide [4H]
SiC - Silicon Carbide [6H]
SiC - Silicon Carbide [3C]

See the *Semiconductor Module User's Guide* for more information.

Thermoelectric Material Library

The Thermoelectric material library is included with the Heat Transfer Module and contains bismuth telluride (Bi_2Te_3) and lead telluride (PbTe) materials for use with the Thermoelectric Effect interface.

The AC/DC Interfaces

This chapter explains the physics interfaces for modeling electromagnetics, which are found under the **AC/DC** branch ( ). It also contains sections about general fundamentals and theory for electric fields.

In this chapter:

- The Electromagnetics Interfaces
- Fundamentals of Electromagnetics
- Theory of Electrostatics
- Theory of Electric Currents
- Theory of Magnetic Fields
- The Electrostatics Interface
- The Electric Currents Interface
- The Magnetic Fields Interface

The Electromagnetics Interfaces

For simulating electromagnetic fields, COMSOL Multiphysics has three physics interfaces.

- Electrostatics
- Electric Currents
- Magnetic Fields

With the first two, you can perform static simulations to solve for electric properties in all space dimensions.

For 2D axisymmetric and 2D geometries, you can use the Magnetic Fields interface to perform magnetostatic simulations. The 3D Magnetic Fields interface is available in the optional AC/DC Module.

This section begins with a brief introduction to electromagnetics and a definition of the electromagnetic quantities. Then it describes each of the physics interfaces in detail.

The optional AC/DC Module contains specialized and extended interfaces for electromagnetic simulations, for example, for computations of inductors and capacitors. The optional RF Module includes interfaces for simulating electromagnetic wave propagation that are especially useful in microwave engineering and photonics.

Fundamentals of Electromagnetics

Maxwell's Equations

The problem of electromagnetic analysis on a macroscopic level is that of solving *Maxwell's equations* subject to certain boundary conditions. Maxwell's equations are a set of equations, written in differential or integral form, stating the relationships between the fundamental electromagnetic quantities. These quantities are:

- Electric field intensity **E**
- Electric displacement field **D**
- Magnetic field intensity **H**
- Magnetic flux density **B**
- Current density **J**
- Electric charge density ρ

For general time-varying fields, Maxwell's equations in the differential form can be written as

$$\begin{aligned} \nabla \cdot \mathbf{D} &= \rho && \text{Gauss' law, electric} \\ \nabla \times \mathbf{E} &= -\frac{\partial \mathbf{B}}{\partial t} && \text{Faraday's law} \\ \nabla \cdot \mathbf{B} &= 0 && \text{Gauss' law, magnetic} \\ \nabla \times \mathbf{H} &= \mathbf{J} + \frac{\partial \mathbf{D}}{\partial t} && \text{Maxwell-Ampère's law} \end{aligned} \tag{10-1}$$

Another fundamental equation, derived from Maxwell's equations, is the *equation of continuity*:

$$\nabla \cdot \mathbf{J} = -\frac{\partial \rho}{\partial t} \tag{10-2}$$

Constitutive Relations

To obtain a closed system, the equations include *constitutive relations* that describe the macroscopic properties of the medium. They are given as

$$\begin{aligned} \mathbf{D} &= \varepsilon_0 \mathbf{E} + \mathbf{P} \\ \mathbf{B} &= \mu_0 (\mathbf{H} + \mathbf{M}) \\ \mathbf{J} &= \sigma \mathbf{E} \end{aligned} \tag{10-3}$$

where ε_0 and μ_0 are the permittivity and permeability of vacuum, and σ is the electric conductivity. The constants ε_0 and μ_0 are available in COMSOL Multiphysics as predefined physical constants. In the SI unit system, ε_0 has an approximate value of $1/(36\pi)\cdot 10^{-9}$ F/m; μ_0 has an approximate value of $4\pi\cdot 10^{-7}$ H/m.

The *electric polarization vector* **P** describes how the material is polarized when an electric field **E** is present. It can be interpreted as the volume density of *electric dipole* moments. **P** is generally a function of **E**. Some materials can have a nonzero **P** when there is no electric field present.

The *magnetization vector* **M** similarly describes how the material is magnetized when a magnetic field **H** is present. It can be interpreted as the volume density of *magnetic dipole* moments. **M** is generally a function of **H**. Permanent magnets, for instance, have a nonzero **M** when there is no magnetic field present.

For linear materials, the polarization is directly proportional to the electric field, $\mathbf{P} = \varepsilon_0\chi_e\mathbf{E}$, where χ_e is the electric susceptibility. Similarly in linear materials, the magnetization is directly proportional to the magnetic field, $\mathbf{M} = \chi_m\mathbf{H}$, where χ_m is the magnetic susceptibility. For such materials, the constitutive relations are:

$$\mathbf{D} = \varepsilon_0(1+\chi_e)\mathbf{E} = \varepsilon_0\varepsilon_r\mathbf{E} = \varepsilon\mathbf{E}$$
$$\mathbf{B} = \mu_0(1+\chi_m)\mathbf{H} = \mu_0\mu_r\mathbf{H} = \mu\mathbf{H}$$

The parameter ε_r is the relative permittivity and μ_r is the relative permeability of the material. Usually these are scalar properties but can, in the general case, be 3-by-3 tensors when the material is anisotropic. The properties ε and μ (without subscripts) are the permittivity and permeability of the material, respectively.

GENERALIZED CONSTITUTIVE RELATIONS

For nonlinear materials, a generalized form of the constitutive relationships is useful. The relationship used for electric fields is $\mathbf{D} = \varepsilon_0\varepsilon_r\mathbf{E} + \mathbf{D}_r$, where $\mathbf{D}_r$ is the *remanent displacement*, which is the displacement when no electric field is present.

Similarly, a generalized form of the constitutive relation for the magnetic field is

$$\mathbf{B} = \mu_0\mu_r\mathbf{H} + \mathbf{B}_r$$

where $\mathbf{B}_r$ is the *remanent magnetic flux density*, which is the magnetic flux density when no magnetic field is present.

For some materials, there is a nonlinear relationship between $\mathbf{B}$ and $\mathbf{H}$ such that

$$\mathbf{B} = f(|\mathbf{H}|)$$

The relation defining the current density is generalized by introducing an externally generated current $\mathbf{J}_e$. The resulting constitutive relation is $\mathbf{J} = \sigma\mathbf{E} + \mathbf{J}_e$.

ENERGY- AND COENERGY-BASED MAGNETIC CONSTITUTIVE RELATIONS

Another general approach to define the constitutive relation of a magnetic material stems from the conservation of magnetic energy density and magnetic coenergy density. For nonlinear magnetic materials without hysteresis, these densities are defined as follows.

$$dW_m = \int_0^{\mathbf{B}} \mathbf{H}\cdot d\mathbf{B}'$$
$$dW'_m = \int_0^{\mathbf{H}} \mathbf{B}\cdot d\mathbf{H}'$$

In this context, the magnetic field $\mathbf{H}$ can be derived from the magnetic flux density $\mathbf{B}$ according to

$$\mathbf{H} = \frac{\partial dW_m}{\partial \mathbf{B}}$$

Equivalently, the magnetic flux density can be derived from the magnetic field as

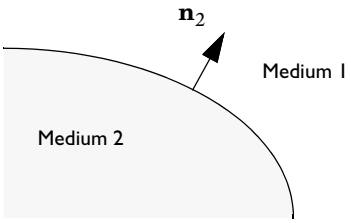
$$\mathbf{B} = \frac{\partial dW'_m}{\partial \mathbf{H}}$$

Boundary Conditions

To get a full description of an electromagnetics problem, boundary conditions must be specified at material interfaces and physical boundaries. At interfaces between two media, the boundary conditions can be expressed mathematically as

$$\begin{aligned} \mathbf{n}_2 \cdot (\mathbf{D}_1 - \mathbf{D}_2) &= \rho_s \\ \mathbf{n}_2 \times (\mathbf{E}_1 - \mathbf{E}_2) &= \mathbf{0} \\ \mathbf{n}_2 \cdot (\mathbf{B}_1 - \mathbf{B}_2) &= 0 \\ \mathbf{n}_2 \times (\mathbf{H}_1 - \mathbf{H}_2) &= \mathbf{J}_s \end{aligned} \tag{10-4}$$

where ρ_s and $\mathbf{J}_s$ denote surface charge density and surface current density, respectively, and $\mathbf{n}_2$ is the outward normal from medium two.



The boundary condition for the current density, derived from Equation 10-4, is expressed as

$$\mathbf{n}_2 \cdot (\mathbf{J}_1 - \mathbf{J}_2) = -\frac{\partial \rho_s}{\partial t}$$

INTERFACE BETWEEN A DIELECTRIC AND A PERFECT CONDUCTOR

A perfect conductor has infinite electric conductivity and thus no internal electric field. Otherwise, it would produce an infinite current density according to the third fundamental constitutive relation. At an interface between a dielectric and a perfect conductor, the boundary conditions for the **E** and **D** fields are simplified. Assume that subscript 1 corresponds to a perfect conductor; then $\mathbf{D}_1 = \mathbf{0}$ and $\mathbf{E}_1 = \mathbf{0}$ in the relationships just given. If it is a time-varying case, then $\mathbf{B}_1 = \mathbf{0}$ and $\mathbf{H}_1 = \mathbf{0}$ as well, as a consequence of Maxwell's equations. The result is the following set of boundary conditions for the fields in the dielectric medium for the time-varying case:

$$\begin{aligned} -\mathbf{n}_2 \cdot \mathbf{D}_2 &= \rho_s \\ -\mathbf{n}_2 \times \mathbf{E}_2 &= 0 \\ -\mathbf{n}_2 \cdot \mathbf{B}_2 &= 0 \\ -\mathbf{n}_2 \times \mathbf{H}_2 &= \mathbf{J}_s \end{aligned} \tag{10-5}$$

Potentials

Under certain circumstances, it can be helpful to formulate the problems in terms of the electric scalar potential V and the magnetic vector potential **A**. They are given by the equalities

$$\begin{aligned} \mathbf{B} &= \nabla \times \mathbf{A} \\ \mathbf{E} &= -\nabla V - \frac{\partial \mathbf{A}}{\partial t} \end{aligned}$$

The defining equation for the magnetic vector potential is a direct consequence of the magnetic Gauss' law. The electric potential results from Faraday's law.

Material Properties

Until now, there has only been a formal introduction of the constitutive relations. These seemingly simple relations can be quite complicated at times. There are four main groups of materials for which they require some consideration. A given material can belong to one or more of these groups.

INHOMOGENEOUS MATERIALS

Inhomogeneous materials are the least complicated. An inhomogeneous medium is one in which the constitutive parameters vary with the space coordinates so that different field properties prevail at different parts of the material structure.

ANISOTROPIC MATERIALS

For anisotropic materials, the field relationships at any point differ for different directions of propagation. This means that a 3-by-3 tensor is necessary to properly define the constitutive relationships. If this tensor is symmetric, the material is often referred to as *reciprocal*. In such cases, rotate the coordinate system such that a diagonal matrix results. If two of the diagonal entries are equal, the material is *uniaxially anisotropic*. If none of the elements have the same value, the material is *biaxially anisotropic* (Ref. 2). Anisotropic parameters are needed, for example, to examine permittivity in crystals (Ref. 2) and when working with conductivity in solenoids.

NONLINEAR MATERIALS

Nonlinearity is the effect of variations in permittivity or permeability with the intensity of the electromagnetic field. Nonlinearity also includes hysteresis effects where not only the current field intensities influence the physical properties of the material, but also the history of the field distribution.

DISPERSIVE MATERIALS

Dispersion describes changes in a wave's velocity with wavelength. In the frequency domain, dispersion is expressed with a frequency dependence of the constitutive relations.

For more information, see Materials, Modeling Anisotropic Materials and Electromagnetic Models.

Frequency Domain

PHASORS

Whenever a problem is time harmonic the fields can be written in the form

$$\mathbf{E}(\mathbf{r},t) = \hat{\mathbf{E}}(\mathbf{r})\cos(\omega t+\phi)$$

Instead of using a cosine function for the time dependence, it is more convenient to use an exponential function, by writing the field as

$$\mathbf{E}(\mathbf{r},t) = \hat{\mathbf{E}}(\mathbf{r})\cos(\omega t+\phi) = \mathrm{Re}(\hat{\mathbf{E}}(\mathbf{r})e^{j\phi}e^{j\omega t}) = \mathrm{Re}(\tilde{\mathbf{E}}(\mathbf{r})e^{j\omega t})$$

The field $\tilde{\mathbf{E}}(\mathbf{r})$ is a *phasor*, which contains amplitude and phase information of the field but is independent of t.

FREQUENCY DOMAIN FORMULATION

With the use of phasors, Maxwell's equations can be formulated in the frequency domain. One of the main advantages is that a time derivative corresponds to a multiplication by $j\omega$:

$$\frac{\partial \mathbf{E}}{\partial t} = \mathrm{Re}(j\omega\tilde{\mathbf{E}}(\mathbf{r})e^{j\omega t})$$

If the fields satisfy a linear time-dependent equation, then the corresponding phasors must satisfy a similar equation in which the time derivatives are replaced by a factor $j\omega$. In this way, linear differential equations are converted to algebraic equations that are much easier to solve.

For sake of simplicity, when writing variables and equations in the frequency domain, the tilde is dropped from the variable denoting the phasor. However, it is important to remember that the field that has been calculated is a phasor and not a physical field. Also note that the phasor $\tilde{\mathbf{E}}(\mathbf{r})$ is visualized in the plot as $\mathrm{Re}(\tilde{\mathbf{E}}(\mathbf{r}))$ by default, which is $\mathbf{E}$ at time $t = 0$. To obtain the solution at a given time, specify a phase factor in all results settings and in the corresponding functions.

The frequency domain formulation is only applicable for equations linear in the fields and for one specific frequency. In general, it cannot be used with materials whose properties depend on the fields themselves. To model such nonlinear materials with the frequency domain formulation, different approaches are required. See Effective Nonlinear Magnetic Constitutive Relations for a formulation that approximates nonlinear magnetic constitutive relations in time-harmonic problems.

SIGN CONVENTION

The time dependency of a time-harmonic field can be written in two ways: $e^{j\omega t}$ or $e^{-j\omega t}$. In COMSOL Multiphysics, the former sign convention $e^{j\omega t}$ is used.

The time-harmonic sign convention dictates the sign convention for some material coefficients in the frequency domain, such as complex permittivity, complex permeability, and complex refractive index. For example, in the dielectric loss model, the complex relative permittivity is defined as

$$\varepsilon_\mathbf{r} = \varepsilon' - j\varepsilon''$$

where ε' and ε'' are two material parameters that are named as the *real part* and *imaginary part* of the relative permittivity, respectively. Inserting the complex relative permittivity in the frequency domain Maxwell–Ampère's law gives

$$\nabla \times \mathbf{H} = j\omega\varepsilon_0\varepsilon'\mathbf{E} + (\omega\varepsilon_0\varepsilon'' + \sigma)\mathbf{E}$$

where the term $\omega\varepsilon_0\varepsilon''$ contributes to energy loss that is indistinguishable from the loss quantified by the electric conductivity σ. With the sign convention used here, a positive material parameter ε'' corresponds to a loss although the imaginary part of the complex number $\varepsilon' - j\varepsilon''$, evaluated as `imag(`$\varepsilon' - j\varepsilon''$`)`, is negative.

Effective Nonlinear Magnetic Constitutive Relations

The effective constitutive relations can be used to approximate the behavior of a nonlinear magnetic material, such as a saturable material, in a (linear) Frequency Domain study.

The approach consists in replacing the nonlinear material with an inhomogeneous linear material — a material described by a magnetic permeability constant in time but which can be space dependent. The local magnetic permeability is chosen using an approximation criterion, such as, for example, that the cycle-average energy stored must be equal to the nonlinear case. As a consequence, the permeability may depend on the amplitude of the magnetic field and the nonlinear solver is invoked during the solution.

The formulation still uses the assumption of harmonic time dependency of the fields (which are still described as phasors): the fields still oscillate at the given frequency; higher-order harmonic effects, or other similar effects due to the nonlinearity, are not accounted for.

Using this constitutive relation provides a better approximation of the behavior of a nonlinear material in the frequency domain than linearizing the material properties, still avoiding the computational cost of a full transient analysis.

Electromagnetic Forces

The Magnetic Field interface contains a predefined domain-level variable for calculating the Lorentz force, which gives the force distribution exerted on a current-carrying conductor placed in magnetic flux density $\mathbf{B}$. The Lorentz force is defined as $\mathbf{F} = \mathbf{J} \times \mathbf{B}$.

The Lorentz force gives very good accuracy for electromagnetic force calculations in conducting domains. For nonconducting domains, use a more general method — integrating the Maxwell stress tensor variables over the boundaries of the object for which to calculate the total force. The Maxwell surface stress tensor is available as a boundary variable.

Theory of Electrostatics

The Electrostatics Interface is available for 3D, 2D in-plane, and 2D axisymmetric components. Applications with electrostatic equations include high-voltage apparatus, electronic devices, and capacitors. The term "statics" is not to be interpreted literally — it is the observation time, or time scale at which the applied excitation changes, that is short compared to the charge relaxation time; also, the electromagnetic wavelength and skin depth are very large compared to the size of the domain of interest.

If you do not know whether to use the Electric Currents or the Electrostatics interface, which both solve for the scalar electric potential V, consider using an explicit charge transport model. See Charge Relaxation Theory.

Charge Relaxation Theory

COMSOL Multiphysics includes physics interfaces for the modeling of static electric fields and currents. Deciding what specific physics interface and study type to select for a particular modeling situation requires a basic understanding of the charge dynamics in conductors.

Physics interfaces for the modeling of dynamic, quasi-static (that is, without including wave propagation effects) electric fields and currents are available with the AC/DC Module and MEMS Module.

The different physics interfaces involving only the scalar electric potential can be interpreted in terms of the charge relaxation process. The fundamental equations involved are *Ohm's law* for the conduction current density

$$\mathbf{J}_c = \sigma\mathbf{E}$$

the *equation of continuity*

$$\frac{\partial\rho}{\partial t} + \nabla\cdot\mathbf{J}_c = 0$$

and *Gauss' law*

$$\nabla\cdot(\varepsilon\mathbf{E}) = \rho$$

By combining these, one can deduce the following differential equation for the space charge density in a homogeneous medium

$$\frac{\partial\rho}{\partial t} + \frac{\sigma}{\varepsilon}\rho = 0$$

This equation has the solution

$$\rho(t) = \rho_0 e^{-t/\tau}$$

where

$$\tau = \frac{\varepsilon}{\sigma}$$

is called the charge relaxation time. For a good conductor like copper, τ is of the order of 10^{-19} s, whereas for a good insulator like silica glass, it is of the order of 10^{3} s. For a pure insulator, it becomes infinite.

When modeling real-world devices, there is not only the *intrinsic time scale* of the charge relaxation time but also an *external time scale* t at which a device is energized or the observation time. It is the relation between the

external time scale and the charge relaxation time that determines what physics interface and study type to use. The results are summarized in Table 10-1 below,

TABLE 10-1: SUITABLE PHYSICS INTERFACE AND STUDY TYPE FOR DIFFERENT TIME-SCALE REGIMES.

CASE	PHYSICS INTERFACE	STUDY TYPE
$\tau >> t$	Electrostatics	Stationary
$\tau << t$	Electric Currents	Stationary
$\tau \sim t$	Electric Currents	Time Dependent or, with the AC/DC Module, MEMS Module, or Semiconductor Module, Frequency Domain

FIRST CASE: $\tau >> T$

If the external time scale is short compared to the charge relaxation time, the charges do not have time to redistribute to any significant degree. Thus the charge distribution can be considered as a given model input. The best approach is to solve the Electrostatics formulation using the electric potential V.

By combining the definition of the potential with Gauss' law, you can derive the classical Poisson's equation. Under static conditions, the electric potential V is defined by the equivalence $\mathbf{E} = -\nabla V$. Using this together with the constitutive relation $\mathbf{D} = \varepsilon_0\mathbf{E} + \mathbf{P}$ between $\mathbf{D}$ and $\mathbf{E}$, you can rewrite Gauss' law as a variant of Poisson's equation

$$-\nabla \cdot (\varepsilon_0 \nabla V - \mathbf{P}) = \rho$$

This equation is used in the Electrostatics interface. It is worth noting that Gauss' law does not require the charge distribution to be static. Thus, provided dynamics are slow enough that induced electric fields can be neglected and hence a scalar electric potential is justified, the formulation can be used also in the Time Dependent study type. That typically involves either prescribing the charge dynamics or coupling a separate formulation for this.

Such separate charge transport formulations can be found in the Electric Discharge Module, the Plasma Module, the Semiconductor Module, and the Chemical Reaction Engineering Module.

SECOND CASE: $\tau << T$

If the external time scale is long compared to the charge relaxation time, the stationary solution to the equation of continuity has been reached. In a stationary coordinate system, a slightly more general form of Ohm's law than above states that

$$\mathbf{J}_c = \sigma\mathbf{E} + \mathbf{J}_e$$

where $\mathbf{J}_e$ is an externally generated current density. The static form of the equation of continuity then reads

$$\nabla \cdot \mathbf{J}_c = -\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = 0$$

To handle current sources, the equation can be generalized to

$$-\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = Q_j$$

This equation is used in the static study type for the Electric Currents interface.

Electrostatics Equations

Under static conditions, the electric potential, V, is defined by the relationship:

$$\mathbf{E} = -\nabla V$$

Combining this equation with the constitutive relationship $\mathbf{D} = \varepsilon_0\mathbf{E} + \mathbf{P}$ between the electric displacement $\mathbf{D}$ and the electric field $\mathbf{E}$, it is possible to represent Gauss' law as the following equation:

$$-\nabla \cdot (\varepsilon_0 \nabla V - \mathbf{P}) = \rho$$

In this equation, the physical constant, ε_0 (SI unit: F/m) is the permittivity of vacuum, $\mathbf{P}$ (SI unit: C/m^2) is the electric polarization vector, and ρ (SI unit: C/m^3) is a space charge density. This equation describes the electrostatic field in dielectric materials.

For in-plane 2D modeling, the Electrostatics interface assumes a symmetry where the electric potential varies only in the x and y directions and is constant in the z direction. This implies that the electric field, $\mathbf{E}$, is tangential to the xy-plane. With this symmetry, the same equation is solved as in the 3D case. The physics interface solves the following equation where d is the thickness in the z direction:

$$-\nabla \cdot d(\varepsilon_0 \nabla V - \mathbf{P}) = \rho$$

The axisymmetric version of the physics interface considers the situation where the fields and geometry are axially symmetric. In this case, the electric potential is constant in the φ direction, which implies that the electric field is tangential to the rz-plane.

The Electrostatics Interface in Time Dependent or Frequency Domain Studies

The Electrostatics Interface can also be solved in a dynamic study (Time Dependent or Frequency Domain). The equation system solved, however, is typically always the one presented in the previous section for the stationary case, in which no transient electromagnetic effects are taken into account. The difference is that the sources of the problem (charge densities, electric potential) are assumed to be time-varying (in a Time Dependent study) or time-harmonic (in a Frequency Domain study).

The support for dynamic studies simplifies the coupling of the Electrostatics interface with other physics interfaces. Using the physics interface in a dynamic study is a valid approximation only if the time-scale (or the frequency) of the study is so slow that transient electromagnetic effects can be neglected; for example, in acoustic or structural problems.

The Electrostatics interface also supports the small-signal analysis study sequence, which can be used when a time-harmonic perturbation is superposed on a static bias charge or voltage.

Theory of Electric Currents

The Electric Currents Interface solves a current conservation problem for the scalar electric potential V and is available for 3D, 2D in-plane, and 2D axisymmetric components. Electrolysis, conductors, and the computation of resistances of grounding plates are examples that involve conductive media with electric conductivities and electric currents. If you are uncertain of whether to use the Electric Currents or the Electrostatics interface, which both solve for the scalar electric potential V, refer to the section on Charge Relaxation Theory.

The Electric Currents Interface assumes that there is only one type of charge carrier. When there are multiple charge carriers, it is often necessary to solve the transport equation for each charge carrier as well as Poisson's equation with the Electrostatics interface.

Electric Currents Equations in Steady State

When handling stationary electric currents in conductive media you must consider the stationary equation of continuity. In a stationary coordinate system, the point form of *Ohm's law* states that:

$$\mathbf{J} = \sigma\mathbf{E} + \mathbf{J}_e$$

where σ is the electric conductivity (SI unit: S/m), and $\mathbf{J}_e$ is an externally generated current density (SI unit: A/m^2). The static form of the equation of continuity then states:

$$\nabla \cdot \mathbf{J} = -\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = 0$$

To handle current sources, you can generalize the equation to:

$$-\nabla \cdot (\sigma \nabla V - \mathbf{J}_e) = Q_j$$

In planar 2D the Electric Currents interface assumes that the model has a symmetry where the electric potential varies only in the x and y directions and is constant in the z direction. This implies that the electric field, $\mathbf{E}$, is tangential to the xy-plane. The Electric Currents interface then solves the following equation, where d is the thickness in the z direction:

$$-\nabla \cdot d(\sigma \nabla V - \mathbf{J}_e) = dQ_j \tag{10-6}$$

In 2D axisymmetry, the Electric Currents interface considers the situation where the fields and geometry are axially symmetric. In this case, the electric potential is constant in the φ direction, which implies that the electric field is tangential to the rz-plane.

Theory of Magnetic Fields

Simulation of magnetic fields is of interest when studying magnets, motors, transformers, and conductors carrying static or alternating currents.

The Magnetic Fields Interface is used for 3D, 2D in-plane, and 2D axisymmetric components. Unless you have a license for the AC/DC Module, only 2D components involving out-of-plane currents and axisymmetric components involving azimuthal currents are supported.

In this section:

- Magnetostatics Equation
- Frequency Domain Equation
- Transient Equation
- Maxwell's Equations (Quasistatic)
- Magnetic and Electric Potentials
- Gauge Transformations
- Selecting a Particular Gauge
- The Gauge and Equation of Continuity for Dynamic Fields
- Time-Harmonic Magnetic Fields

Magnetostatics Equation

To derive the magnetostatic equation, start with Ampère's law for static cases $\nabla \times \mathbf{H} = \mathbf{J}$. The current is

$$\mathbf{J} = \sigma \mathbf{v} \times \mathbf{B} + \mathbf{J}_e$$

where $\mathbf{J}_e$ is an externally generated current density, and $\mathbf{v}$ is the velocity of the conductor.

Using the definitions of magnetic potential, $\mathbf{B} = \nabla \times \mathbf{A}$ and the constitutive relationship, $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$, rewrite Ampère's law as

$$\nabla \times (\mu_0^{-1} \nabla \times \mathbf{A} - \mathbf{M}) - \sigma \mathbf{v} \times (\nabla \times \mathbf{A}) = \mathbf{J}_e$$

which is the equation used in magnetostatics.

Frequency Domain Equation

To derive the time harmonic equation this physics interface solves, start with Ampère's law including displacement currents (then called Maxwell–Ampère's law), as these do not involve any extra computational cost in the frequency domain,

$$\nabla \times \mathbf{H} = \mathbf{J} + \frac{\partial \mathbf{D}}{\partial t} = \sigma \mathbf{E} + \sigma \mathbf{v} \times \mathbf{B} + \mathbf{J}_e + \frac{\partial \mathbf{D}}{\partial t}$$

Now assume time-harmonic fields and use the definitions of the fields,

$$\mathbf{B} = \nabla \times \mathbf{A}$$
$$\mathbf{E} = -j\omega \mathbf{A}$$

and combine them with the constitutive relationships $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$ and $\mathbf{D} = \varepsilon_0 \mathbf{E}$ to rewrite Ampère's law as

$$(j\omega\sigma - \omega^2\varepsilon_0)\mathbf{A} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) = \mathbf{J}_e$$

Transient Equation

The transient equation this physics interface solves is Ampère's law, illustrated here with the constitutive relation $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$.

$$\sigma\frac{\partial \mathbf{A}}{\partial t} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) = \mathbf{J}_\mathrm{e}$$

Maxwell's Equations (Quasistatic)

For cases where currents and electromagnetic fields vary slowly, the induced displacement current can be ignored ($\partial\mathbf{D}/\partial t = 0$). This assumption, referred to as the quasistatic approximation, is widely used in modeling low-frequencies electromagnetics where the dimensions of the structure is small compared to the wavelength. With this approximation, rewrite *Maxwell's equations* (Equation 10-1) in the following manner:

$$\nabla \times \mathbf{H} = \mathbf{J} = \sigma(\mathbf{E} + \mathbf{v} \times \mathbf{B}) + \mathbf{J}_\mathrm{e}$$

$$\nabla \times \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t}$$

$$\nabla \cdot \mathbf{B} = 0$$

$$\nabla \cdot \mathbf{D} = \rho$$

$$\nabla \cdot \mathbf{J} = 0$$

where $\mathbf{J}_\mathrm{e}$ is an externally generated current density and $\mathbf{v}$ is the velocity of the conductor.

Magnetic and Electric Potentials

Using the definitions of the potentials,

$$\mathbf{B} = \nabla \times \mathbf{A}$$

$$\mathbf{E} = -\nabla V - \frac{\partial \mathbf{A}}{\partial t}$$

and the constitutive relation $\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$, Ampère's law can be rewritten as

$$\sigma\frac{\partial \mathbf{A}}{\partial t} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) + \sigma\nabla V = \mathbf{J}_\mathrm{e} \tag{10-7}$$

The equation of continuity, which is obtained by taking the divergence of the above equation, adds the following equation:

$$\nabla \cdot \left(-\sigma\frac{\partial \mathbf{A}}{\partial t} + \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) - \sigma\nabla V + \mathbf{J}_\mathrm{e}\right) = 0 \tag{10-8}$$

Equation 10-7 and Equation 10-8 form a system of equations for the two potentials $\mathbf{A}$ and V.

Gauge Transformations

The electric and magnetic potentials are not uniquely defined from the electric and magnetic fields through

$$\mathbf{E} = -\frac{\partial \mathbf{A}}{\partial t} - \nabla V$$
$$\mathbf{B} = \nabla \times \mathbf{A}$$

Introducing two new potentials

$$\tilde{\mathbf{A}} = \mathbf{A} + \nabla \Psi$$
$$\tilde{V} = V - \frac{\partial \Psi}{\partial t}$$

gives the same electric and magnetic fields:

$$\mathbf{E} = -\frac{\partial \mathbf{A}}{\partial t} - \nabla V = -\frac{\partial (\tilde{\mathbf{A}} - \nabla \Psi)}{\partial t} - \nabla\left(\tilde{V} + \frac{\partial \Psi}{\partial t}\right) = -\frac{\partial \tilde{\mathbf{A}}}{\partial t} - \nabla \tilde{V}$$
$$\mathbf{B} = \nabla \times \mathbf{A} = \nabla \times (\tilde{\mathbf{A}} - \nabla \Psi) = \nabla \times \tilde{\mathbf{A}}$$

The variable transformation of the potentials is called a *gauge transformation*. To obtain a unique solution, choose the gauge — that is, put constraints on Ψ that make the solution unique. Another way of expressing this additional condition is to put a constraint on $\nabla \cdot \mathbf{A}$. A vector field is uniquely defined up to a constant if both $\nabla \cdot \mathbf{A}$ and $\nabla \times \mathbf{A}$ are given. This is called *Helmholtz's theorem*.

One particular gauge is the *Coulomb gauge* given by the constraint: $\nabla \cdot \mathbf{A} = 0$.

Selecting a Particular Gauge

It is important to observe that in the dynamic case, $\mathbf{A}$ and V are coupled via the selected gauge. For a dynamic formulation, it is also possible to select a Ψ such that the scalar electric potential vanishes and only the magnetic vector potential has to be considered. The dynamic formulations (Frequency Domain and Time Dependent study types) of the Magnetic Fields interface are operated in this gauge as it involves only $\mathbf{A}$. In the static limit, $\mathbf{A}$ and V are not coupled via the gauge selection and thus any gauge can be chosen for $\mathbf{A}$ when performing magnetostatic modeling.

The Gauge and Equation of Continuity for Dynamic Fields

After eliminating the electric potential by choosing the appropriate gauge and disregarding the velocity term, the equation of continuity obtained by taking the divergence of Ampère's law reads:

$$\nabla \cdot \left(-\sigma \frac{\partial \mathbf{A}}{\partial t} + \mathbf{J}_e\right) = 0$$

It is clear that unless the electric conductivity is uniform, the particular gauge used to eliminate V cannot be the Coulomb gauge as that would violate the equation of continuity and would thereby also violate Ampère's law.

Time-Harmonic Magnetic Fields

In the time-harmonic case, there is no computational cost for including the displacement current in Ampère's law (then called Maxwell–Ampère's law):

$$\nabla \times \mathbf{H} = \mathbf{J} = \sigma(\mathbf{E} + \mathbf{v} \times \mathbf{B}) + (j\omega \mathbf{D} + \mathbf{J}_e)$$

In the transient case, the inclusion of this term leads to a second-order equation in time, but in the harmonic case there are no such complications. Using the definition of the electric and magnetic potentials, the system of equations becomes:

$$-\nabla \cdot ((j\omega\sigma - \omega^2\varepsilon_0)\mathbf{A} - \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) + (\sigma + j\omega\varepsilon_0)\nabla V - (\mathbf{J}_e + j\omega\mathbf{P})) = 0$$

$$(j\omega\sigma - \omega^2\varepsilon_0)\mathbf{A} + \nabla \times (\mu_0^{-1}\nabla \times \mathbf{A} - \mathbf{M}) - \sigma\mathbf{v} \times (\nabla \times \mathbf{A}) + (\sigma + j\omega\varepsilon_0)\nabla V = \mathbf{J}_e + j\omega\mathbf{P}$$

The constitutive relation $\mathbf{D} = \varepsilon_0\mathbf{E} + \mathbf{P}$ has been used for the electric field.

To obtain a particular gauge that reduces the system of equation, choose $\Psi = -jV/\omega$ in the gauge transformation. This gives:

$$\tilde{\mathbf{A}} = \mathbf{A} - \frac{j}{\omega}\nabla V \qquad \tilde{V} = 0$$

When $\tilde{V}$ vanishes from the equations, only the second one is needed,

$$(j\omega\sigma - \omega^2\varepsilon_0)\tilde{\mathbf{A}} + \nabla \times (\mu_0^{-1}\nabla \times \tilde{\mathbf{A}} - \mathbf{M}) - \sigma\mathbf{v} \times (\nabla \times \tilde{\mathbf{A}}) = \mathbf{J}_e + j\omega\mathbf{P}$$

Working with $\tilde{\mathbf{A}}$ is often the best option when it is possible to specify all source currents as external currents $\mathbf{J}_e$ or as surface currents on boundaries.

The Electrostatics Interface

The **Electrostatics (es)** interface ( ), found under the **AC/DC** > **Electric Fields and Currents** branch when adding a physics interface, is used to compute the electric field, electric displacement field, and potential distributions in dielectrics under conditions where the electric charge distribution is explicitly prescribed. The formulation is stationary except for when it is used together with other physics interfaces. Eigenfrequency, frequency-domain, small-signal analysis, and time-domain modeling are supported in all space dimensions.

The physics interface solves Gauss' law for the electric field using the scalar electric potential as the dependent variable.

Charge Conservation is the main node, which adds the equation for the electric potential and has a Settings window for defining the constitutive relation for the electric displacement field and its associated properties such as the relative permittivity.

When this physics interface is added, these default nodes are also added to the **Model Builder** — **Free Space**, **Zero Charge** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and space charges. You can also right-click **Electrostatics** to select physics features from the context menu.

Physics-Controlled Mesh

The physics-controlled mesh is controlled from the **Mesh** node's **Settings** window (if the **Sequence type** is **Physics-controlled mesh**). There, in the table in the **Physics-Controlled Mesh** section, find the physics interface in the **Contributor** column and select or clear the checkbox in the **Use** column on the same table row for enabling (the default) or disabling contributions from the physics interface to the physics-controlled mesh.

Information from the physics, such as the presence of an infinite elements domain or periodic condition, will be used to automatically set up an appropriate meshing sequence.

!	In the *COMSOL Multiphysics Reference Manual* see the Physics-Controlled Mesh section for more information about how to define the physics-controlled mesh.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `es`.

CROSS-SECTION AREA (1D COMPONENTS)

For 1D components, enter a default value for the **Cross-section area** A (SI unit: m^2). The default value of 1 is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 1D equation identical to the equation used for 3D components. See also Change Cross Section.

THICKNESS (2D COMPONENTS)

For 2D components, enter a default value for the **Out-of-plane thickness** d (SI unit: m). The default value of 1 is typically not representative for a thin dielectric medium, for example. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components. See also Change Thickness (Out-of-Plane).

DEPENDENT VARIABLES

The dependent variable is the **Electric potential** V. You can change its name, which changes both the field name and the variable name. If the new name coincides with the name of another dependent variable in the model, the physics interfaces shares degrees of freedom. The new name must not coincide with the name of a field of another type or with a component name belonging to some other field.

DISCRETIZATION

Select the shape order for the **Electric potential** dependent variable — **Linear**, **Quadratic** (the default), **Cubic**, **Quartic**, or **Quintic**. For more information about the **Discretization** section, see Settings for the Discretization Sections in the *COMSOL Multiphysics Reference Manual*.

	In the *COMSOL Multiphysics Reference Manual*, see Table 2-4 for links to common sections and Table 2-5 to common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

	• Domain, Boundary, Edge, Point, and Pair Nodes for the Electrostatics Interface • Theory of Electrostatics

	Electric Sensor: Application Library path **COMSOL_Multiphysics/Electromagnetics/electric_sensor**

Domain, Boundary, Edge, Point, and Pair Nodes for the Electrostatics Interface

The Electrostatics interface has these domain, boundary, edge, point, and pair nodes available.

ABOUT THE BOUNDARY CONDITIONS

The relevant physics interface condition at interfaces between different media is

$$\mathbf{n}_2 \cdot (\mathbf{D}_1 - \mathbf{D}_2) = \rho_s$$

In the absence of surface charges, this condition is fulfilled by the natural boundary condition

$$\mathbf{n} \cdot [(\varepsilon_0 \nabla V - \mathbf{P})_1 - (\varepsilon_0 \nabla V - \mathbf{P})_2] = -\mathbf{n} \cdot (\mathbf{D}_1 - \mathbf{D}_2) = 0$$

AVAILABLE NODES

These nodes, listed in alphabetical order, are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (Mac or Linux users), or right-click to access the context menu (all users). Also see Table 10-2 for a list of interior and exterior boundary conditions, including edge, point, and pair availability.

In general, to add a node, go to the **Physics** toolbar no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the **Attributes** menu.

- Change Cross Section
- Change Thickness (Out-of-Plane)

- Point Charge
- Point Charge (on Axis)
- Space Charge Density
- Surface Charge Density
- Symmetry Plane (for Electric Field)
- Thin Low Permittivity Gap
- Zero Charge (the default boundary condition)

[1]This feature is available with the Piezoelectricity multiphysics interface.

[2]Requires either the Acoustics Module, MEMS Module, or Structural Mechanics Module.

Table 10-2 lists the interior and exterior boundary conditions available with this physics interface. It also includes edge, point, and pair availability.

TABLE 10-2: INTERIOR AND EXTERIOR BOUNDARY CONDITIONS (INCLUDING EDGE, POINT, AND PAIR AVAILABILITY) FOR THE ELECTROSTATICS INTERFACE.

NODE	INTERIOR	EXTERIOR	ALSO AVAILABLE FOR
Change Cross Section	x	x	pairs
Change Thickness (Out-of-Plane)	x	x	pairs
Electric Displacement Field	x	x	pairs
Electric Potential	x	x	edges, points, and pairs
External Surface Charge Accumulation		x	pairs
Ground	x	x	edges, points, and pairs
Periodic Condition		x	not applicable
Surface Charge Density	x	x	pairs
Symmetry Plane		x	not applicable
Thin Low Permittivity Gap	x		not applicable
Zero Charge (the default)	x	x	pairs

For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node to the model that is valid on the axial symmetry boundaries only. There are also **Line Charge (on Axis)** and **Point Charge (on Axis)** available.

In the *COMSOL Multiphysics Reference Manual*, see Table 2-4 for links to common sections and Table 2-5 to common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Free Space

For electromagnetic modeling, it is quite common for the fields to extend into the environment of the device in question. It is therefore important not only to model the device itself, but also its surroundings. Typically, this is done by adding a box or sphere around the device's geometry.

The default **Free Space** node is used to specify the physical conditions in close proximity to the device — typically in air or vacuum. It adds a **Charge Conservation** governing equation using the **Relative permittivity** constitutive relation with the permittivity ε_r set to one.

The **Free Space** feature provides a canvas on top of which other features can be added to locally specify material properties and excitation forms.

Charge Conservation

The **Charge Conservation** node adds the equations for charge conservation according to Gauss' law for the electric displacement field. It provides an interface for defining the constitutive relation and its associated properties such as the relative permittivity. There are two types of **Charge Conservation** available; **Charge Conservation in Solids** and **Charge Conservation in Fluids**. This distinction decides how materials behave and how material properties are interpreted when the mesh is deformed.

Charge Conservation in Solids applies to materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame).

Charge Conservation in Fluids applies to materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined.

In COMSOL versions **6.2** and earlier, this **Solids/Fluids** distinction was controlled within the **Charge Conservation** node by specifying **Solid/Nonsolid** in the **Material type** setting.

CONSTITUTIVE RELATION D-E

Select a **Dielectric model** to describe the macroscopic properties of the medium (relating the electric displacement $\mathbf{D}$ with the electric field $\mathbf{E}$) and the applicable material properties, such as the relative permittivity. Note that **Charge Conservation in Fluids** uses only **Relative permittivity** or **Polarization**. The other constitutive relations are only accessible in **Charge Conservation in Solids**. Select:

- **Relative permittivity** (the default) to use the constitutive relation $\mathbf{D} = \varepsilon_0\varepsilon_r\mathbf{E}$. Then the default is to take the **Relative permittivity** ε_r (dimensionless) values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** and enter values or expressions in the field or matrix. The default is 1.

- **Polarization** to use the constitutive relation $\mathbf{D} = \varepsilon_0\mathbf{E} + \mathbf{P}$. Then enter the components based on space dimension for the **Polarization** vector $\mathbf{P}$ (SI unit: $\mathrm{C/m^2}$). The defaults are 0 $\mathrm{C/m^2}$.
- **Remanent electric displacement** to use constitutive relation $\mathbf{D} = \varepsilon_0\varepsilon_r\mathbf{E} + \mathbf{D}_r$, where $\mathbf{D}_r$ is the remanent displacement (the displacement when no electric field is present). Then the default is to take the **Relative permittivity** ε_r (dimensionless) values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** and enter values or expressions in the field or matrix. Then enter the components based on space dimension for the **Remanent electric displacement** $\mathbf{D}_r$ (SI unit: $\mathrm{C/m^2}$). The defaults are 0 $\mathrm{C/m^2}$.

Conduction Loss (Time-Harmonic)

This feature requires either the Acoustics Module, or MEMS Module, or Structural Mechanics Module. See the individual documentation for information.

The **Conduction Loss (Time-Harmonic)** subnode to **Charge Conservation** allows you to model possible conductive losses in a dielectric material. The effect is only active in an Eigenfrequency or Frequency Domain study.

CONDUCTION CURRENT

By default, the **Electric conductivity** σ for the media is defined **From material**. You can also select **User defined** or **Linearized resistivity**.

- For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** depending on the characteristics of the electric conductivity, and then enter values or expressions for the **Electric conductivity** σ in the field or matrix.
- For **Linearized resistivity** the default **Reference temperature** T_{ref}, and **Resistivity temperature coefficient** α, and **Reference resistivity** ρ_0 are taken **From material**, which means that the values are taken from the domain (or boundary) material. T is the current temperature, which can be a value that is specified as a model input or the temperature from a heat transfer interface. The definition of the temperature field appears in the **Model Inputs** section.

LOCATION IN USER INTERFACE

Context Menus

Electrostatics > **Charge Conservation** > **Conduction Loss (Time-Harmonic)**

Ribbon

Physics tab with **Charge Conservation** node selected in the model tree:

Attributes > **Conduction Loss (Time-Harmonic)**

Initial Values

The **Initial Values** node adds an initial value for the electric potential V that can serve as an initial condition for a transient simulation or as an initial guess for a nonlinear solver.

INITIAL VALUES

Enter a value or expression for the initial value of the **Electric potential** V (SI unit: V). The default value is 0 V.

Space Charge Density

The **Space Charge Density** node adds a space charge density ρ, which appears on the right-hand side of the equation that the physics interface defines.

SPACE CHARGE DENSITY

Enter a value or expression for the **Space charge density** ρ_v (SI unit: C/m^3). The default is 0 C/m^3.

Zero Charge

The **Zero Charge** node adds the condition that there is zero charge on the boundary so that $\mathbf{n} \cdot \mathbf{D} = 0$. This boundary condition is also applicable at symmetry boundaries where the potential is known to be symmetric with respect to the boundary. This is the default boundary condition at exterior boundaries. At interior boundaries, it means that no displacement field can penetrate the boundary and that the electric potential is discontinuous across the boundary.

Ground

The **Ground** node implements ground (zero potential) as the boundary condition $V = 0$.

Ground means that there is a zero potential on the boundary. This boundary condition is also applicable at symmetry boundaries where the potential is known to be antisymmetric with respect to the boundary.

For some physics interfaces, also select additional **Ground** nodes from the **Edges** (3D components) or **Points** (2D and 3D components) submenus. For 2D axisymmetric components, it can be applied on the Symmetry axis.

BOUNDARY, EDGE, OR POINT SELECTION

⚠	Beware that constraining the potential on edges or points in 3D or on points in 2D usually yields a current outflow that is mesh dependent.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Electric Potential

The **Electric Potential** node provides an electric potential V_0 as the boundary condition $V = V_0$.

Because the electric potential is being solved for in the physics interface, the value of the potential is typically defined at some part of the geometry. For some physics interfaces, also select additional **Electric Potential** nodes from the **Edges** (3D components) or **Points** (2D and 3D components) submenus. For 2D axisymmetric components, it can be applied on the symmetry axis.

BOUNDARY, EDGE, OR POINT SELECTION

⚠	Beware that constraining the potential on edges or points in 3D or on points in 2D usually yields a current outflow that is mesh dependent.

ELECTRIC POTENTIAL

Enter the value or expression for the **Electric potential** V_0 (SI unit: V). The default is 0 V.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Surface Charge Density

The **Surface Charge Density** node provides the following surface-charge boundary condition for exterior boundaries (left) and interior boundaries (right):

$$-\mathbf{n}\cdot\mathbf{D} = \rho_s, \qquad \mathbf{n}\cdot(\mathbf{D}_1 - \mathbf{D}_2) = \rho_s$$

Specify the surface charge density ρ_s at an outer boundary or at an interior boundary between two nonconducting media.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or click **Harmonic Perturbation** in the **Physics** toolbar. For more information, see Harmonic Perturbation — Exclusive and Contributing Nodes.

SURFACE CHARGE DENSITY

Enter the value or expression for the **Surface charge density** ρ_s (SI unit: C/m^2).

External Surface Charge Accumulation

The **External Surface Charge Accumulation** node implements the boundary condition

$$-\mathbf{n}\cdot\mathbf{D} = \rho_s$$

where ρ_s is the solution of the following distributed ODE on the boundary:

$$\frac{d\rho_s}{dt} = \mathbf{n}\cdot\mathbf{J}_i + \mathbf{n}\cdot\mathbf{J}_e$$

where $\mathbf{n}\cdot\mathbf{J}_i$ is the normal component of the total ion current density on the wall and $\mathbf{n}\cdot\mathbf{J}_e$ is the normal component of the total electron current density on the wall, which are feature inputs.

MATERIAL TYPE

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Nonsolid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

EXTERNAL SURFACE CHARGE ACCUMULATION

Enter values or expressions for the **Normal ion current density** $\mathbf{n}\cdot\mathbf{J}_i$ (SI unit: A/m^2) sand the **Normal electron current density** $\mathbf{n}\cdot\mathbf{J}_e$ (SI unit: A/m^2).

Symmetry Plane (for Electric Field)

The **Symmetry Plane** node adds a boundary condition that represents symmetry or antisymmetry in the electric field, depending on which option is chosen.

SYMMETRY TYPE

Choose between **Symmetry** and **Antisymmetry** for the electric field. If **Symmetry** is chosen, the boundary condition is

$$\mathbf{n}\cdot\mathbf{E} = 0$$

which states that the normal component of the electric field is zero. If **Antisymmetry** is chosen, the boundary condition becomes

$$\mathbf{n} \times \mathbf{E} = 0$$

which states that the tangential component of the electric field is zero.

Electric Displacement Field

The **Electric Displacement Field** node adds the following electric-displacement boundary condition:

$$\mathbf{n} \cdot \mathbf{D} = \mathbf{n} \cdot \mathbf{D}_0$$

It specifies the normal component of the electric displacement field at a boundary.

ELECTRIC DISPLACEMENT FIELD

Enter the coordinates of the **Boundary electric displacement field** $\mathbf{D}_0$ (SI unit: $\mathrm{C/m^2}$).

Periodic Condition

The **Periodic Condition** node defines periodicity or antiperiodicity between two boundaries. If required, activate periodic conditions on more than two boundaries, in which case the Periodic Condition tries to identify two separate surfaces that can each consist of several connected boundaries. For more complex geometries, it might be necessary to use the **Destination Selection** section, which you activate by right-clicking the **Periodic Condition** node and select **Manual Destination Selection**. With that section, the boundaries which constitute the source and destination surfaces can be manually specified.

When this feature is used in conjunction with a Sector Symmetry feature on connected boundaries, wherever the sector symmetry boundaries connect with the periodic boundaries, the same periodic condition feature cannot be used on both sides. At least two periodic condition features are required for the model to compute correctly.

BOUNDARY SELECTION

The software usually automatically identifies the boundaries as either source boundaries or destination boundaries, as indicated in the selection list. This works fine for cases like opposing parallel boundaries. In other cases, right-click **Periodic Condition** and select **Manual Destination Selection** to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

When using nonconforming meshes on the source and destination of a periodic boundary pair, for numerical stability, a finer mesh should be applied on the destination side. Use conforming meshes if possible.

DESTINATION SELECTION

This section is available for specifying the destination boundaries, if needed, when the **Manual Destination Selection** option is selected in the context menu for the **Periodic Condition** node. You can only select destination boundaries from the union of all source and destination boundaries.

PERIODIC CONDITION

Select a **Type of periodicity** — **Continuity** (the default), **Antiperiodicity**, or **Floquet periodicity**. Select:

- **Continuity** to make the potential periodic (equal on the source and destination).
- **Antiperiodicity** to make it antiperiodic.
- **Floquet periodicity** (only available with products supporting piezoelectric modeling). Specify the components of the **k-vector for Floquet periodicity** $\mathbf{k}_F$ (SI unit: rad/m).

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

ORIENTATION OF SOURCE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Orientation of Source** section, see Orientation of Source and Destination.

ORIENTATION OF DESTINATION

This section appears if the setting for **Transform to intermediate map** in the **Orientation of Source** section is changed from the default value, **Automatic**, and **Advanced Physics Options** is selected in the **Show More Options** dialog. For information about the **Orientation of Destination** section, see Orientation of Source and Destination.

Thin Low Permittivity Gap

Use the **Thin Low Permittivity Gap** node

$$\mathbf{n} \cdot \mathbf{D}_1 = \frac{\varepsilon_0 \varepsilon_r}{d}(V_1 - V_2)$$

$$\mathbf{n} \cdot \mathbf{D}_2 = \frac{\varepsilon_0 \varepsilon_r}{d}(V_2 - V_1)$$

to model a thin gap of a material with a small permittivity compared to the adjacent domains. The layer has the thickness d and the relative permittivity ε_r. The indices 1 and 2 refer to the two sides of the boundary.

THIN LOW PERMITTIVITY GAP

The default is to take the **Relative permittivity** ε_r (dimensionless) values **From material**. For **User defined**, enter a different value or expression. Enter a **Thickness** d (SI unit: m). The default is 5 mm.

Line Charge

For 3D components, use the **Line Charge** node to specify line charges along the edges of a geometry. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

EDGE SELECTION

⚠	Beware that constraining the potential on edges usually yields a current outflow that is mesh dependent.

LINE CHARGE

Enter a value or expression to apply a **Line charge** Q_L (SI unit: C/m). This source represents electric charge per unit length and the default is 0 C/m.

🔍	Line Charge (on Axis) and Line Charge (Out-of-Plane)

Line Charge (on Axis)

For 2D axisymmetric components, use the **Line Charge (on Axis)** node to specify line charges along the symmetry axis.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or click **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

LINE CHARGE (ON AXIS)

Enter a value or expression to apply a **Line charge** Q_L (SI unit: C/m). This source represents electric charge per unit length and the default is 0 C/m.

🔍	Line Charge and Line Charge (Out-of-Plane)

Line Charge (Out-of-Plane)

For 2D and 2D axisymmetric components, points are selected and this is the same as a line out-of-plane.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

Use the **Line Charge (Out-of-Plane)** node to specify line charges along the points of a geometry for 2D and 2D axisymmetric components.

POINT SELECTION

⚠	Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

LINE CHARGE (OUT-OF-PLANE)

Enter a value or expression to apply a **Line charge** Q_L (SI unit: C/m). This source represents electric charge per unit length and the default is 0 C/m.

🔍	Line Charge and Line Charge (on Axis)

Point Charge

The **Point Charge** node adds a point source to 3D components. The point charge represents an electric displacement field flowing out of the point.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

POINT SELECTION

⚠	Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CHARGE

Enter a value or expression to apply a **Point charge** Q_P (SI unit: C) to points. This source represents an electric displacement field flowing out of the point. The default is 0 C.

🔍	Point Charge (on Axis) and Line Charge (Out-of-Plane)

Point Charge (on Axis)

The **Point Charge (on Axis)** node adds a point source to 2D axisymmetric components. The point charge represents an electric displacement field flowing out of the point.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

POINT SELECTION

	Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CHARGE (ON AXIS)

Enter a value or expression to apply a **Point charge** Q_P (SI unit: C) to points on an axis. This source represents an electric displacement field flowing out of the point. The default is 0 C.

	Point Charge and Line Charge (Out-of-Plane)

Change Cross Section

This node is available with 1D components. This setting overrides the global **Cross-Section Area** setting made in any physics interface that uses this feature. For 2D components, see Change Thickness (Out-of-Plane).

Use the **Change Cross Section** node to set the cross-section area for specific geometric entities.

CHANGE CROSS SECTION

Enter a value or expression for the **Cross-section area** A. The default value of one unit area is typically not representative for the actual domain. Instead, it describes a unit area that makes the 1D equation identical to the equation used for 3D components.

Change Thickness (Out-of-Plane)

This node is available for 2D components. This setting overrides the global **Thickness** setting made in any physics interface that uses this node. For 1D components, see Change Cross Section.

Use the **Change Thickness (Out-of-Plane)** node to set the out-of-plane thickness for specific geometric entities.

CHANGE THICKNESS (OUT-OF-PLANE)

Enter a value or expression for the **Out-of-plane thickness** d (SI unit: m). The default value is, in most cases, 1 unit length, which is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components.

Charge Conservation, Piezoelectric

	This feature is available with the Piezoelectricity interface, which requires either the Acoustics Module, or MEMS Module, or Structural Mechanics Module. See the individual documentation for information.

The **Charge Conservation, Piezoelectric** node is normally used together with a **Piezoelectric Effect** multiphysics coupling node and a corresponding **Piezoelectric Material** node in the **Solid Mechanics** interface. The node is added

by default to the **Electrostatics** interface when adding a Piezoelectricity interface. It is also available from the context menu (right-click the **Electrostatics** interface parent node) or from the **Physics** toolbar.

	When the **Charge Conservation, Piezoelectric** node is added to the electrostatics interface in the absence of an active **Piezoelectric Effect** multiphysics coupling node, the material behaves similarly to a Charge Conservation node, with electric properties corresponding to the relative permittivity entered (see below). The piezoelectric effect is *not* included in the corresponding equation system.

ELECTRIC DISPLACEMENT

If the node is used together with an active **Piezoelectric Effect** multiphysics coupling node, then these settings are locked. Note that if they are unlocked, then the material behaves like a dielectric and *not* a piezoelectric. In this case, the default is to take the **Relative permittivity** ε_{rS} (dimensionless) values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** and enter values or expressions in the field or matrix.

The Electric Currents Interface

The **Electric Currents (ec)** interface ( ), under the **AC/DC** > **Electric Fields and Currents** branch when adding a physics interface, is used to compute electric field, current, and potential distributions in conducting media under conditions where inductive effects are negligible; that is, when the skin depth is much larger than the studied device.

Depending on the licensed products, stationary, frequency-domain, small-signal analysis, and time-domain modeling are supported in all space dimensions. In the time and frequency domains, capacitive effects are also accounted for.

The physics interface solves a current conservation equation based on Ohm's law using the scalar electric potential as the dependent variable. The interface is typically used to model good conductors for which Ohm's law applies. It is not suitable for modeling poor conductors like air and insulators.

Current Conservation is the main node, which adds the equation for the electric potential and provides a Settings window for defining the electric conductivity as well as the constitutive relation for the electric displacement field and its associated material properties, such as the relative permittivity.

When this physics interface is added, these default nodes are also added to the **Model Builder** — **Current Conservation**, **Electric Insulation** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and current sources. You can also right-click **Electric Currents** to select physics features from the context menu.

Physics-Controlled Mesh

The physics-controlled mesh is controlled from the **Mesh** node's **Settings** window (if the **Sequence type** is **Physics-controlled mesh**). There, in the table in the **Physics-Controlled Mesh** section, find the physics interface in the **Contributor** column and select or clear the checkbox in the **Use** column on the same table row for enabling (the default) or disabling contributions from the physics interface to the physics-controlled mesh.

Information from the physics, such as the presence of an infinite elements domain or periodic condition, will be used to automatically set up an appropriate meshing sequence.

!	In the *COMSOL Multiphysics Reference Manual* see the Physics-Controlled Mesh section for more information about how to define the physics-controlled mesh.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `ec`.

CROSS-SECTION AREA (1D)

Enter a default value for the **Cross-section area** A (SI unit: m^2). The default value of 1 m^2 is typically not representative for a small domain. Instead it describes a unit area that makes the 1D equation identical to the equation used for 3D components. See also Change Cross Section (described for the Electrostatics interface).

THICKNESS (2D)

Enter a default value for the **Out-of-plane thickness** d (SI unit: m) (see Equation 10-3). The default value of 1 m is typically not representative for a thin dielectric medium, for example. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components. See also Change Thickness (Out-of-Plane) (described for the Electrostatics interface).

DEPENDENT VARIABLES

The dependent variable is the **Electric potential** V. You can change its name, which changes both the field name and the variable name. If the new name coincides with the name of another electric potential field in the model, the physics interfaces share degrees of freedom. The new name must not coincide with the name of a field of another type or with a component name belonging to some other field.

DISCRETIZATION

Select the shape order for the **Electric potential** dependent variable — **Linear**, **Quadratic** (the default), **Cubic**, **Quartic**, or **Quintic**. For more information about the **Discretization** section, see Settings for the Discretization Sections in the *COMSOL Multiphysics Reference Manual*.

- Domain, Boundary, Edge, Point, and Pair Nodes for the Electric Currents Interface
- Theory of Electric Currents

Pacemaker Electrode: Application Library path **COMSOL_Multiphysics/Electromagnetics/pacemaker_electrode**

Domain, Boundary, Edge, Point, and Pair Nodes for the Electric Currents Interface

The Electric Currents interface has these domain, boundary, edge, point, and pair nodes available from the **Physics** ribbon toolbar (Windows users) or **Physics** context menu (Mac or Linux users). You can also right-click to access the context menu (all users).

In general, to add a node, go to the **Physics** toolbar, no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the **Attributes** menu.

ABOUT THE BOUNDARY CONDITIONS

The exterior and interior boundary conditions listed in Table 10-2 are available. The relevant physics interface condition at interfaces between different media and interior boundaries is continuity; that is,

$$\mathbf{n}_2 \cdot (\mathbf{J}_1 - \mathbf{J}_2) = 0$$

which is the natural boundary condition.

AVAILABLE NODES

These nodes are available for this physics interface, listed in alphabetical order. Also see Table 10-2 for a list of interior and exterior boundary conditions, including edge, point, and pair availability.

- Boundary Current Source
- Contact Impedance
- Current Conservation
- Current Source
- Distributed Impedance
- Electric Insulation
- External Current Density
- Initial Values
- Line Current Source
- Line Current Source (on Axis)
- Normal Current DensityPoint Current Source
- Sector Symmetry
- Symmetry Plane (for Electric Field)

These nodes are described for the Electrostatics interface:

- Change Cross Section
- Change Thickness (Out-of-Plane)
- Electric Potential
- Ground
- Periodic Condition

In the *COMSOL Multiphysics Reference Manual*, see Table 2-4 for links to common sections and Table 2-5 for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node to the model that is valid on the axial symmetry boundaries only.

Table 10-2 lists the interior and exterior boundary conditions available with this physics interface. It also includes edge, point, and pair availability.

TABLE 10-3: INTERIOR AND EXTERIOR BOUNDARY CONDITIONS (INCLUDING EDGE, POINT, AND PAIR AVAILABILITY) FOR THE ELECTRIC CURRENTS INTERFACE.

NODE	INTERIOR	EXTERIOR	ALSO AVAILABLE FOR
Boundary Current Source	x		pairs

Normal Current Density		x	not applicable
Periodic Condition		x	not applicable
Symmetry Plane		x	not applicable

Current Conservation

The **Current Conservation** node adds the continuity equation for the electric potential and provides an interface for defining the electric conductivity as well as the constitutive relation and the relative permittivity for the displacement current.

MATERIAL TYPE

The **Material type** setting decides how materials behave and how material properties are interpreted when the mesh is deformed. Select **Solid** for materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame). Select **Nonsolid** for materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined. Select **From material** to pick up the corresponding setting from the domain material on each domain.

CONSTITUTIVE RELATION JC-E

By default, the **Electric conductivity** σ (SI unit: S/m) for the media is defined **From material**. Or select **User defined** or **Linearized resistivity**.

User Defined

For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** depending on the characteristics of the electric conductivity, and then enter values or expressions for the electric conductivity σ in the field or matrix. The default is 0 S/m. If type of temperature dependence is used other than a linear temperature relation, enter any expression for the conductivity as a function of temperature.

Linearized Resistivity

Select **Linearized resistivity** for a temperature-dependent conductivity (this occurs in, for example, Joule heating, and is also called resistive heating). The equation describing the conductivity:

$$\sigma = \frac{1}{\rho_0(1 + \alpha(T - T_{\mathrm{ref}}))}$$

where ρ_0 is the resistivity at the reference temperature T_{ref}, and α is the temperature coefficient of resistance, which describes how the resistivity varies with temperature.

The default **Reference resistivity** ρ_0 (SI unit: Ω·m), **Reference temperature** T_{ref} (SI unit: K), and **Resistivity temperature coefficient** α (SI unit: 1/K) are taken **From material**, which means that the values are taken from the domain (or boundary) material. T is the current temperature, which can be a value that is specified as a model input or the temperature from a heat transfer interface. The definition of the temperature field is in the **Model Inputs** section.

To specify other values for any of these properties, select **User defined** from the list and then enter a value or expression for each. The default values are:

- 1 Ω·m for the Reference resistivity
- 273.15 K for the Reference temperature, and
- 0 1/K for the Resistivity temperature coefficient

CONSTITUTIVE RELATION D-E

Select a **Dielectric model** to describe the macroscopic properties of the medium (relating the electric displacement $\mathbf{D}$ with the electric field $\mathbf{E}$) and the applicable material properties, such as the relative permittivity. For a description of the constitutive relations **Relative permittivity**, **Polarization**, and **Remanent electric displacement**, see **Constitutive**

Relation D-E as described for the Charge Conservation node for the Electrostatics interface. The constitutive relations specific to Electric Currents are:

- **Dielectric losses**: uses the constitutive relation $\mathbf{D} = \varepsilon_0(\varepsilon' - j\varepsilon'')\mathbf{E}$. Specify that the **Relative permittivity (real part)** ε' (dimensionless) and the **Relative permittivity (imaginary part)** ε'' (dimensionless) must be taken **From material** or be **User defined**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** and enter values or expressions in the field or matrix. The default is 1. Note that the material parameters **Relative permittivity (real part)** ε' and the **Relative permittivity (imaginary part)** ε'' form the complex relative permittivity $\varepsilon_r = \varepsilon' - j\varepsilon''$. The time-harmonic Sign Convention requires a lossy material to have a positive material parameter ε''.
- **Loss tangent, loss angle**: uses the constitutive relation $\mathbf{D} = \varepsilon_0\varepsilon'(1 - j\tan\delta)\mathbf{E}$. Specify the **Relative permittivity (real part)** ε' (dimensionless) and **Loss angle** δ (SI unit: rad).
- **Loss tangent, dissipation factor**: uses the constitutive relation $\mathbf{D} = \varepsilon_0\varepsilon'(1 - j\tan\delta)\mathbf{E}$. Specify the **Relative permittivity (real part)** ε' (dimensionless) and the **Dissipation factor** $\tan\delta$ (dimensionless).

Initial Values

The **Initial Values** node adds an initial value for the electric potential that can serve as an initial condition for a transient simulation or as an initial guess for a nonlinear solver. If more than one set of initial values is required, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and current sources. Add more **Initial Values** nodes from the **Physics** toolbar.

INITIAL VALUES

Enter a value or expression for the initial value of the **Electric potential** V (SI unit: V). The default value is 0 V.

External Current Density

The **External Current Density** node adds an externally generated current density $\mathbf{J}_e$, which appears in Ohm's law

$$\mathbf{J} = \sigma\mathbf{E} + \mathbf{J}_e$$

and in the equation that the physics interface defines.

The external current density does not contribute to the losses (due to Joule heating), since there is no electric field associated with it. To include the contribution to the losses from the external current density, select the **Add contribution of the external current density to the losses** checkbox. Then select an option from the **External losses** list — **From domain conductivity** (the default) or **User defined**. If **From domain conductivity** is selected, the heat source is computed using the conductivity specified in the material model feature (such as **Current Conservation**) that is applied in the domain. For **User defined**, enter a value for Q_e (SI unit: $\mathrm{W/m^3}$) to specify a user-defined heat source.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

EXTERNAL CURRENT DENSITY

Based on space dimension, enter the coordinates (**x**, **y**, and **z** for 3D components, for example) of the **External current density** $\mathbf{J}_e$ (SI unit: $\mathrm{A/m^2}$). The defaults are 0 $\mathrm{A/m^2}$.

Current Source

The **Current Source** node adds a distributed current source Q_j in the equation that the physics interface defines. Use this node with caution as it can violate the current conservation law that is inherent in Maxwell–Ampère's law.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

CURRENT SOURCE

Enter a value or expression for the **Current source** Q_j (SI unit: A/m^3). The default is 0 A/m^3.

Electric Insulation

The **Electric Insulation** node, which is the default boundary condition, adds electric insulation as the boundary condition:

$$\mathbf{n} \cdot \mathbf{J} = 0$$

This boundary condition means that no electric current flows into the boundary. At interior boundaries, it means that no current can flow through the boundary and that the electric potential is discontinuous across the boundary. It is also applicable at symmetric boundaries where the potential is known to be symmetric with respect to the boundary.

Electric insulation as the default boundary condition is not applicable to interior boundaries. To add electric insulation to an interior boundary, add an **Electric Insulation** node in addition to the one that represents the default boundary condition.

Boundary Current Source

The **Boundary Current Source** node adds a current source Q_j on the boundary.

$$\mathbf{n} \cdot (\mathbf{J}_1 - \mathbf{J}_2) = Q_j$$

It is applicable to interior boundaries that represent either a source or a sink of current. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or click **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

BOUNDARY CURRENT SOURCE

Enter a value or expression for the **Boundary current source** Q_j (SI unit: A/m^2). The default is 0 A/m^2.

Normal Current Density

The **Normal Current Density** node is applicable to exterior boundaries that represent either a source or a sink of current. It provides a condition for specifying the normal current density as an inward or outward current flow:

$$-\mathbf{n} \cdot \mathbf{J} = J_n$$

Or alternatively, as a current density $\mathbf{J}_0$:

$$\mathbf{n} \cdot \mathbf{J} = \mathbf{n} \cdot \mathbf{J}_0$$

The normal current density is positive when the current flows inward in the domain. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

NORMAL CURRENT DENSITY

Select a **Type** — **Inward current density** (the default) or **Current density**.

- For **Inward current density** enter a value or expression for the **Normal current density** J_n (SI unit: A/m^2). Use a positive value for an inward current flow or a negative value for an outward current flow. The default is 0 A/m^2.
- For **Current density** enter values or expressions for the components of the **Current density** $\mathbf{J}_0$ (SI unit: A/m^2). The defaults are 0 A/m^2.

Distributed Impedance

The **Distributed Impedance** node adds a distributed impedance boundary condition to a model.

The **Harmonic Perturbation** subnode (it is of the exclusive type) is available from the context menu (right-click the parent node) or in the **Physics** toolbar, click the **Attributes** menu and select **Harmonic Perturbation**. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

Use this boundary condition to model a thin sheet of a resistive material connected to a reference potential V_{ref}.

The layer impedance can be specified either with the bulk material conductivity σ_s, the relative permittivity ε_r and layer thickness d_s, or directly with the surface resistance ρ_s and capacitance C_s. Assuming DC currents, the equation is:

$$\mathbf{n} \cdot (\mathbf{J}_1 - \mathbf{J}_2) = \frac{\sigma_s}{d_s}(V - V_{\text{ref}})$$

$$\mathbf{n} \cdot (\mathbf{J}_1 - \mathbf{J}_2) = \frac{1}{\rho_s}(V - V_{\text{ref}})$$

DISTRIBUTED IMPEDANCE

Enter the reference potential V_{ref} (SI unit: V). The default is 0 V.

Select a potentially complex-valued **Layer specification** — **Thin layer** (the default) or **Surface impedance**.

- For **Thin layer**, enter values or expressions for the:
  - **Surface thickness** d_s (SI unit: m). The default is $5 \cdot 10^{-3}$ m (5 mm).
  - **Electric conductivity** σ (SI unit: S/m) and **Relative permittivity** ε_r (dimensionless). The defaults take values **From material**. For **User defined**, enter different values or expressions. The default electric conductivity is $1 \cdot 10^{-2}$ S/m and the default relative permittivity is 1.
- For **Surface impedance**, enter values or expressions for the **Surface resistance** ρ_s (SI unit: $\Omega \cdot \text{m}^2$) and the **Surface capacitance** C_s (SI unit: F/m^2). The default surface impedance is $1 \cdot 10^{-8}$ $\Omega \cdot \text{m}^2$ and the default surface capacitance is 0 F/m^2.

Contact Impedance

Use the **Contact Impedance** node on interior boundaries to model a thin layer of resistive material. It can also be added as a pair using a **Pair Contact Impedance** node. The feature allows specifying the contact impedance either by entering the properties of the material together with the layer thickness, or by entering the impedance properties of the thin layer directly.

The feature applies the following conditions that relate the normal electric current density with the jump in the electric potential:

$$\mathbf{n} \cdot \mathbf{J}_1 = \frac{\sigma}{d_s}(V_1 - V_2)$$

$$\mathbf{n} \cdot \mathbf{J}_2 = \frac{\sigma}{d_s}(V_2 - V_1)$$

$$\mathbf{n} \cdot \mathbf{J}_1 = \frac{1}{\rho_s}(V_1 - V_2)$$

$$\mathbf{n} \cdot \mathbf{J}_2 = \frac{1}{\rho_s}(V_2 - V_1)$$

The first two equations refer to a layer impedance specified using the bulk material conductivity σ_s and the layer thickness d_s, while the last two equations refer to the case in which the surface resistance ρ_s is specified. The indices 1 and 2 refer to the two sides of the boundary. These parameters work the same as with Distributed Impedance.

CONTACT IMPEDANCE

Select a potentially complex-valued **Layer specification** — **Thin layer** (the default) or **Surface impedance**.

- For **Thin layer**, enter values or expressions for the:
  - **Surface thickness** d_s (SI unit: m). The default is $5 \cdot 10^{-3}$ m (5 mm).
  - **Electric conductivity** σ (SI unit: S/m) and **Relative permittivity** ε_r (dimensionless). The defaults take values **From material**. For **User defined**, enter different values or expressions. The default electric conductivity is $1 \cdot 10^{-2}$ S/m and the default relative permittivity is 1.
- For **Surface impedance**, enter values or expressions for the **Surface resistance** ρ_s (SI unit: $\Omega \cdot m^2$) and the **Surface capacitance** C_s (SI unit: F/m^2). The default surface impedance is $1 \cdot 10^{-8}$ $\Omega \cdot m^2$ and the default surface capacitance is 0 F/m^2.

Thin-Film Resistance: Application Library path **COMSOL_Multiphysics/Electromagnetics/thin_film_resistance**

Sector Symmetry

Select **Sector Symmetry** at interfaces between rotating objects where sector symmetry is used. It is only available for pairs. A default subnode is added. Right-click to select additional features from the **Fallback Features** submenu. In 2D, this feature assumes rotation around the origin.

This feature is always used in conjunction with a Periodic Condition on adjacent radial sector boundaries. Note that the same periodic condition feature cannot be used on both sides of where the sector symmetry boundaries connect with the periodic boundaries. At least two periodic condition features are required for the model to compute correctly.

PAIR SELECTION

When using nonconforming meshes on the source and destination of a pair, for numerical stability, a finer mesh should be applied on the destination side for any pair with a condition that imposes a coupling or a constraint across the pair. The sector symmetry feature falls into this category.

SECTOR SETTINGS

Enter the **Number of sectors (<50)** n_{sect}. The default is 2.

Select a **Type of periodicity** — **Continuity** (the default) or **Antiperiodicity**.

Based on space dimension, enter values or expressions in the table for the **Axis of rotation** $\mathbf{a}_{rot}$.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. The constraint setting can be set to **Pointwise constraints** (default), or **Weak constraints**. Additionally, the **Nitsche constraints** option is available for the scalar potential in the **Electric Currents**, **Magnetic Field,**

No Currents, and **Rotating Machinery, Magnetic** interfaces. The displacement current term is excluded from the **Nitsche constraints** in the **Electric Currents interface** and is therefore valid in the quasistationary approximation.

⚠	The **Nitsche constraints** option assumes the quasistatic approximation and is applicable only for pairs adjacent to domains with small or no displacement currents or induced eddy currents normal to the pair boundary. In addition, nonlinear material models in the neighboring domains are not supported.

Line Current Source

The **Line Current Source** node adds a line source to edges in 3D components and to points in 2D and 2D axisymmetric components. The line source represents electric current per unit length.

EDGE OR POINT SELECTION

⚠	Beware that constraining the potential on edges or points usually yields a current outflow that is mesh dependent.

LINE CURRENT SOURCE

Enter a value or expression to apply a **Line current source** Q_j (SI unit: A/m). This source represents electric current per unit length. The default is 0 A/m.

🔍	Line Current Source (on Axis) for 2D axisymmetric components.

Line Current Source (on Axis)

The **Line Current Source (on Axis)** node adds a line source to boundaries in 2D axisymmetric components. The line source represents electric current per unit length.

LINE CURRENT SOURCE (ON AXIS)

Enter a value or expression to apply a **Line current source** Q_j (SI unit: A/m) to boundaries. This source represents electric current per unit length.

🔍	Line Current Source

Point Current Source

The **Point Current Source** node adds a point source and represents an electric current flowing out of the point. Add point sources to 3D components from the **Points** menu. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

POINT SELECTION

	Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CURRENT SOURCE

Enter a value or expression to apply a **Point current source** Q_j (SI unit: A) to points. This source represents an electric current flowing out of the point.

	• Line Current Source for 2D components • Point Current Source (on Axis) for 2D axisymmetric components

Point Current Source (on Axis)

The **Point Current Source (on Axis)** node adds a point source and represents an electric current flowing out of the point in 2D axisymmetric components.

POINT SELECTION

	Beware that constraining the potential on points usually yields a current outflow that is mesh dependent.

POINT CURRENT SOURCE

Enter a value or expression to apply a **Point current source** Q_j (SI unit: A) to points. This source represents an electric current flowing out of the point.

	• Point Current Source for 3D components • Line Current Source for 2D components

The Magnetic Fields Interface

The **Magnetic Fields (mf)** interface ( ), found under the **AC/DC** > **Electromagnetic Fields** branch when adding a physics interface, is used to compute magnetic field and induced current distributions in and around coils, conductors, and magnets. Depending on the licensed products, stationary, frequency-domain, small-signal analysis, and time-domain modeling are supported in 2D and 3D. Note that the frequency and time-domain formulations become ill-posed when approaching the static limit. You can extend the useful frequency range downward by adding a low conductivity.

The physics interface solves Maxwell's equations, which are formulated using the magnetic vector potential and, optionally for coils, the scalar electric potential as the dependent variables.

The main node is the **Free Space** feature, which solves Ampère's law in free space. This adds the equation for the magnetic vector potential and assumes that all domains have a uniform relative magnetic permeability and permittivity of one.

When this physics interface is added, these default nodes are also added to the **Model Builder** — **Magnetic Fields**, **Free Space**, **Magnetic Insulation** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement boundary conditions and external currents. You can also right-click **Magnetic Fields** to select physics features from the context menu.

Physics-Controlled Mesh

The physics-controlled mesh is controlled from the **Mesh** node's **Settings** window (if the **Sequence type** is **Physics-controlled mesh**). There, in the table in the **Physics-Controlled Mesh** section, find the physics interface in the **Contributor** column and select or clear the checkbox in the **Use** column on the same table row for enabling (the default) or disabling contributions from the physics interface to the physics-controlled mesh.

Information from the physics, such as the presence of an infinite elements domain or periodic condition, will be used to automatically set up an appropriate meshing sequence.

!	In the *COMSOL Multiphysics Reference Manual* see the Physics-Controlled Mesh section for more information about how to define the physics-controlled mesh.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `mf`.

BACKGROUND FIELD

This section allows the specification of a background magnetic vector potential (that generates a background magnetic flux density). The only option to **Solve for** is **Full field**.

COMPONENTS

The current vector has the same direction as the magnetic vector potential. This setting also controls the direction in which applied and induced currents can flow in the model. The default option is to solve for the out-of-plane component only. Therefore, the only **Components** option is **Out-of-plane vector potential**.

THICKNESS

For 2D components, enter a value or expression for the global **Out-of-plane thickness** d (SI unit: m). The default of 1 m is typically not representative for a thin domain. Instead it describes a unit thickness that makes the 2D equation identical to the equation used for 3D components.

Use the Change Thickness (Out-of-Plane) node (described for the Electrostatics interface) to define specific geometric entities (for example, domains) instead of a global setting for the thickness.

ERROR CHECK

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

When the **Check applicability of features in study** checkbox is selected, any features that are incompatible with the study will generate an error message when trying to solve or show the default solver. No solver will be generated. Clear the checkbox and you will be able to run the model, possibly with runtime errors instead. It is available to allow the advanced user to tweak any feature and use it outside of its intended study scope.

DEPENDENT VARIABLES

The dependent variable is the **Magnetic vector potential** A. You can change both its field name and the individual component variable names. If the new field name coincides with the name of another magnetic vector potential field in the model, the physics interfaces share degrees of freedom and component names. The new field name must not coincide with the name of a field of another type, or with a component name belonging to some other field. Component names must be unique within a model, except for fields of the same type sharing a common field name.

DISCRETIZATION

Select the shape order for the **Magnetic vector potential** dependent variable — **Linear**, **Quadratic** (the default), or **Cubic**. For more information about the **Discretization** section, see Settings for the Discretization Sections in the *COMSOL Multiphysics Reference Manual*.

- Domain, Boundary, Point, and Pair Nodes for the Magnetic Fields Interface
- Computing Lumped ParametersTheory of Magnetic Fields

Quadrupole Lens in 2D: Application Library path **COMSOL_Multiphysics/Electromagnetics/quadrupole**

Domain, Boundary, Point, and Pair Nodes for the Magnetic Fields Interface

The Magnetic Fields interface has these domain, boundary, point, and pair nodes available, which are listed in alphabetical order.

About the Boundary Conditions

With no surface currents present, the physics interface conditions

$$\mathbf{n}_2 \times (\mathbf{A}_1 - \mathbf{A}_2) = \mathbf{0}$$
$$\mathbf{n}_2 \times (\mathbf{H}_1 - \mathbf{H}_2) = \mathbf{0}$$

need to be fulfilled. Because **A** is being solved for, the tangential component of the magnetic potential is always continuous, and thus the first condition is automatically fulfilled. The second condition is equivalent to the natural boundary condition and is hence also fulfilled unless surface currents are explicitly introduced.

Table 10-2 lists the interior and exterior boundary conditions available with this physics interface.

TABLE 10-4: INTERIOR AND EXTERIOR BOUNDARY CONDITIONS FOR THE MAGNETIC FIELDS INTERFACE.

NODE	INTERIOR	EXTERIOR
Magnetic Field		x
Magnetic Insulation	x	x
Magnetic Potential	x	x
Perfect Magnetic Conductor	x	x
Periodic Condition		x
Surface Current Density	x	x
Symmetry Plane		x

Available Nodes

These nodes, listed in alphabetical order, are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (Mac or Linux users), or by right-clicking to access the context menu (all users).

In general, to add a node, go to the **Physics** toolbar no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the **Attributes** menu.

Also see Table 10-2 for a list of interior and exterior boundary conditions.

- Free Space
- Ampère's Law
- External Current Density
- Initial Values
- Line Current (Out-of-Plane)
- Magnetic Field
- Magnetic Insulation (the default boundary condition)
- Magnetic Potential
- Perfect Magnetic Conductor
- Surface Current Density
- Symmetry Plane (for Magnetic Flux Density)
- Velocity (Lorentz Term)

For 2D axisymmetric components, the COMSOL software takes the axial symmetry boundaries (at $r = 0$) into account and adds an **Axial Symmetry** node to the component that is valid on the axial symmetry boundaries only.

Infinite Elements, Perfectly Matched Layers, and Absorbing Layers

!	In the *COMSOL Multiphysics Reference Manual*, see Table 2-4 for links to common sections and Table 2-5 for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Free Space

For inductive and capacitive (sometimes resistive) analysis, it is quite common for the fields to extend into the environment of the device in question. It is therefore important not only to model the device itself, but also its (close) surroundings. Typically, this is done by adding a box or sphere around the device's geometry.

The default **Free Space** node is used to specify the physical conditions in close proximity to the device — *typically in air or vacuum*. It adds an Ampère's Law *governing equation* with a limited set of material models: the permeability μ_r and permittivity ε_r are assumed to be one, and the conductivity is taken from the **Stabilization conductivity**.

The Free Space feature provides a canvas on top of which the **Ampère's Law** feature and other features can be added to locally specify material properties and excitation forms.

STABILIZATION

For transient and frequency domain modeling of inductive devices, it is desirable to limit the contrast in conductivity. This improves the numerical stability. In reality, the conductivity may vary between 10^{-14} S/m (dry air) and $6 \cdot 10^{7}$ S/m (for copper), but from a numerical viewpoint any material that causes insignificant *eddy current* or *leakage current* loss is effectively an insulator. As a result, the "insulator conductivity" is often chosen to be much higher than the true material property (note that this reasoning does not hold for capacitive modeling).

A suitable rule of thumb for choosing the stabilization conductivity is given by the skin depth, as compared to the overall geometry size. The assumption is that if the skin depth in **Free Space** is around one hundred times the device size, the resulting loss and the impact on lumped device properties are insignificant. At the same time, the model will still be sufficiently stable. What is considered a good value will differ per model, though. It is therefore recommended to double-check the *free space loss* as compared to other loss terms in the model. If the stabilization conductivity has a negative impact on the overall model accuracy, consider lowering it. If the solver has trouble converging, consider raising it. Alternatively, consider using **Gauge Fixing**.

Stabilization Conductivity

The **Stabilization conductivity** allows for five options:

- **From material**; use the conductivity specified by the material.
- **Automatic** (default in 3D); set the skin depth δ_s to be 100 times the geometry size and use that to deduce the appropriate conductivity σ_{stab}. The **Typical frequency** used for this conversion is taken from the solver. If there is no such frequency available — as is the case for a *transient analysis* — a **Fallback frequency** is used. The appropriate fallback frequency may differ per model and is best determined manually. Note that in addition to the fallback frequency, a solver-independent (user defined) frequency is an option too. A good value is the typical operating frequency of the modeled device. For more information, see Stabilization.
- **From skin depth**; very similar to the option **Automatic**, but with the added advantage that a *user defined* skin depth can be set.

- **Off** (default in 2D); disable the stabilization conductivity altogether: $\sigma_{stab} = 0$. This models a perfect vacuum and is a good approximation for air. In 2D oftentimes only the out-of-plane magnetic vector potential is used, providing sufficient stability.
- **User defined**; specify a suitable stabilization conductivity directly.

Note that a **Fallback frequency** that is chosen too low may result in an overly damped model, just like a stabilization conductivity that is chosen too high, or a skin depth that is chosen too small. *The device's typical operating frequency, combined with a skin depth that is at least an order of magnitude larger than the device size, should provide a suitable stabilization conductivity.*

When in doubt, it is recommended to check the amount of resistive loss in the insulators and compare this against the overall device loss. Sweeping over the stabilization conductivity (investigating the effect of different amounts of stabilization) or comparing against a *Gauge Fixed* model with zero stabilization is an option too.

Ampère's Law

The **Ampère's Law** node adds Ampère's law for the magnetic field to a domain and provides an interface for defining the constitutive relation and its associated properties as well as electric properties. There are two types of Ampère's Law available; **Ampère's Law in Solids** and **Ampère's Law in Fluids**. This distinction decides how materials behave and how material properties are interpreted when the mesh is deformed.

Ampère's Law in Solids applies to materials whose properties change as functions of material strain, material orientation, and other variables evaluated in a material reference configuration (material frame).

Ampère's Law in Fluids applies to materials whose properties are defined only as functions of the current local state at each point in the spatial frame, and for which no unique material reference configuration can be defined.

In COMSOL versions **6.1** and earlier, this **Solids/Fluids** distinction was controlled within the **Ampère's Law** node by specifying **Solid/Nonsolid** in the **Material type** setting.

CONSTITUTIVE RELATION B-H

Specify the constitutive relation that describes the macroscopic properties of the medium (relating the magnetic flux density $\mathbf{B}$ and the magnetic field $\mathbf{H}$) and the applicable material properties, such as the relative permeability.

The equation for the selected constitutive relation displays under the list. For all options, the default uses values **From material**, or select **User defined** to enter a different value or expression.

Select a **Magnetization model** — **Relative permeability** (the default), **B-H curve**, **Magnetic losses**, **Remanent flux density**, **Magnetization**, or **Effective B-H curve**.

Ampère's Law in Fluids uses only **Relative Permeability** or **Magnetization**. The other constitutive relations are only accessible in **Ampère's Law in Solids**.

Relative Permeability

Select **Relative permeability** μ_r (dimensionless) to use the constitutive relation $\mathbf{B} = \mu_0\mu_r\mathbf{H}$. For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** and enter values or expressions in the field or matrix.

B-H Curve

Select **B-H curve** $\|\mathbf{H}\|$ (SI unit: A/m) to use a curve that relates magnetic flux density $\mathbf{B}$ and the magnetic field $\mathbf{H}$ as $\|\mathbf{H}\| = f(\|\mathbf{B}\|)$. Note that in literature $\mathbf{B}$ is typically given as a function of $\mathbf{H}$, as $\|\mathbf{B}\| = f(\|\mathbf{H}\|)$ or, when preserving direction: $\mathbf{B} = f(\|\mathbf{H}\|)\mathbf{H}/\|\mathbf{H}\|$. For the Ampère's Law feature, however, $\mathbf{B}$ is closely related to the degree of freedom $\mathbf{A}$ and then $\mathbf{H}$ is derived from that.

The **Magnetic field norm** and **Magnetic coenergy density** settings can take the values **From material** or **User defined**.

When **User defined** is selected, specify a user-defined expression for the magnetic field norm. The direction of the magnetic field is taken to be the same as the direction of the magnetic flux density at each point.

Magnetic Losses

Select **Magnetic losses** μ' and μ'' (dimensionless) to describe the relative permeability as a complex-valued quantity: $\mu_r = \mu' - i\mu''$, where μ' and μ'' are the real and imaginary parts, respectively. Note that the time-harmonic Sign Convention requires a lossy material to have a positive material parameter μ'' (see Modeling Losses in the Frequency Domain).

Remanent Flux Density

Select **Remanent flux density** $\mathbf{B}_r$ (SI unit: T) to use the constitutive relation $\mathbf{B} = \mu_0\mu_{rec}\mathbf{H} + \mathbf{B}_r$, where μ_{rec} and $\mathbf{B}_r$ are the recoil permeability and the remanent flux density respectively (the flux density when no magnetic field is present). The recoil permeability μ_{rec} is very similar to the relative permeability, and is valid as long as the magnet is subjected to normal operating conditions (it is only valid within the linear region close to the vertical axis $\mathbf{H} = 0$). $\mathbf{B}_r$ is given by taking the remanent flux density norm (typically, provided by the material) and multiplying it with a normalized direction field specified in the physics: $\mathbf{B}_r = \|\mathbf{B}_r\|\ \mathbf{e}/\|\mathbf{e}\|$.

- The default recoil permeability μ_{rec} (dimensionless) uses values **From material**. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** based on the characteristics of the recoil permeability and enter another value or expression in the field or matrix.
- The remanent flux density norm $\|\mathbf{B}_r\|$ is taken **From material** by default. The AC/DC branch in the material library contains a number of hard magnetic materials specifically for this purpose. Alternatively, choose **User defined**, and specify your own expression.
- Enter **x** and **y** components for the **Remanent flux direction** $\mathbf{e}$.

Magnetization

Select **Magnetization** $\mathbf{M}$ (SI unit: A/m) to use the constitutive relation $\mathbf{B} = \mu_0\mathbf{H} + \mu_0\mathbf{M}$. Enter **x** and **y** components.

Effective B-H Curve

Select **Effective B-H curve** $|\mathbf{H}|_{\mathbf{eff}}$ (SI unit: A/m) to use an effective curve that provides the local linearized relation between the magnetic flux density $\mathbf{B}$ and the magnetic field $\mathbf{H}$ in time-harmonic problems.

External Material

Select **External material** to use a curve that relates magnetic flux density $\mathbf{B}$ and the magnetic field $\mathbf{H}$ as $|\mathbf{H}| = f(|\mathbf{B}|)$ according to an externally coded function.

Specify the **External material** to use (from the **Materials** node under **Global Definitions**). This setting allows using material models or constitutive relations defined in an external library. See Working with External Materials for more information.

CONSTITUTIVE RELATION JC-E

This section is described for the Current Conservation feature.

CONSTITUTIVE RELATION D-E

The default **Relative permittivity** ε_r (dimensionless) for the media is used **From material** and defined on the shell domain. For **User defined**, select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** based on the characteristics of the permittivity and then enter values or expressions in the field or matrix.

Initial Values

The **Initial Values** node adds an initial value for the magnetic vector potential A that can serve as an initial value for a transient simulation or as an initial guess for a nonlinear solver.

INITIAL VALUES

Enter values or expressions for the **Magnetic vector potential** $\mathbf{A}$ (SI unit: Wb/m). The defaults are 0 Wb/m.

External Current Density

The **External Current Density** node adds an externally generated current density $\mathbf{J}_e$, which appears on the right-hand side of the equation that the Magnetic Fields interface defines.

Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

EXTERNAL CURRENT DENSITY

Enter a value or expression for each component of the **External current density** $\mathbf{J}_e$ (SI unit: A/m^2). The defaults are 0 A/m^2.

The external current density does not contribute to the losses (due to Joule heating), since there is no electric field associated with it. To include the contribution to the losses from the external current density, select the **Add contribution of the external current density to the losses** checkbox. Then select an option from the **External losses** list — **From domain conductivity** (the default) or **User defined**. If **From domain conductivity** is selected, the heat source is computed using the conductivity specified in the material model feature (such as **Ampère's Law**) that is applied in the domain. For **User defined**, enter a value for Q_e (SI unit: W/m^3) to specify a user-defined heat source.

Velocity (Lorentz Term)

The **Velocity (Lorentz term)** node adds velocity $\mathbf{v}$. The external current is equal to $\sigma\mathbf{v} \times \mathbf{B}$.

This node is available in 2D and 2D axisymmetry when only solving for the out-of-plane component of the magnetic vector potential.

- Correct use of the velocity feature requires deep physical insight. In situations when the moving domain is of bounded extent in the direction of the motion, material properties vary in this direction, or the domains contains magnetic sources that also move, the Lorentz term must not be used.

An operational definition of when it can be used is that the moving domain should only contain an induced magnetic source (magnetization plus eddy currents) that has to be stationary with respect to the motion. Thus, it cannot be used for modeling projectiles of finite length or projectiles containing magnets. It can be used to model conductive, homogeneous spinning disks (magnetic brakes); magnets over a moving infinite homogeneous plane

(maglev trains); and flow of homogeneous conducting fluid past a magnet (liquid metal pumps or Hall generators/thrusters, for example).

	If you are not sure how to proceed, contact the COMSOL Support Center: www.comsol.com/support.

VELOCITY (LORENTZ TERM)

User defined is selected by default. Enter the components for the **Velocity** vector $\mathbf{v}$ (SI unit: m/s) or, if present, select any velocity field defined in the model. For example, using the velocity field is useful when coupling to the velocity field of a fluid for a magnetohydrodynamic model.

Magnetic Insulation

The **Magnetic Insulation** node is the default boundary condition for the Magnetic Fields interface and adds a boundary condition that sets the tangential components of the magnetic potential to zero at the boundary $\mathbf{n} \times \mathbf{A} = 0$.

	• Strictly speaking, the tangential components of the magnetic potential is $(\mathbf{n} \times \mathbf{A}) \times \mathbf{n}$. • Magnetic insulation is a special case of the Magnetic Potential boundary condition that sets the tangential component of the magnetic potential to zero.

This node is used for the modeling of a lossless metallic surface, for example, a ground plane or as a symmetry type boundary condition. The node imposes symmetry for magnetic fields and "magnetic currents." In the transient and time harmonic formulations, it also imposes antisymmetry for electric fields and electric currents. The node supports induced electric surface currents and thus any prescribed or induced electric currents (volume, surface, or edge currents) flowing into a perfect electric conductor boundary are automatically balanced by induced surface currents.

The Magnetic Insulation node can also be applied on interior boundaries. The boundary will then support two surface current densities on the two sides, denoted bu `Jsu` (upside) and `Jsd` (downside).

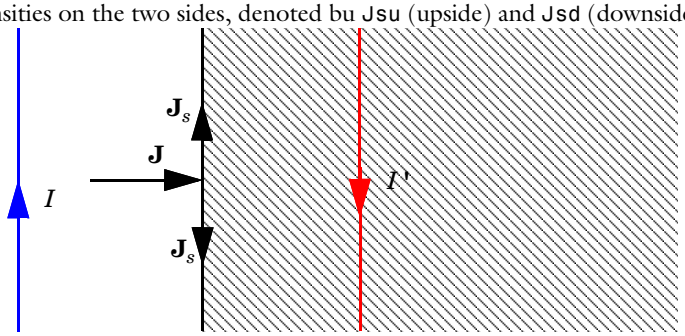

Figure 10-1: The magnetic insulation boundary condition is used on exterior and interior boundaries representing the surface of a lossless metallic conductor or (on exterior boundaries) a symmetry cut. The shaded (metallic) region is not part of the model but still carries effective mirror images of the sources. Note also that any current flowing into the boundary is perfectly balanced by induced surface currents. The tangential vector potential (and electric field) vanishes at the boundary.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

!	Weak constraints perform poorly when applied on vector elements. They should be used when the magnetic vector potential is discretized with Lagrange elements, for example, when solving for out-of-plane component in a two-dimensional component.

Magnetic Field

The **Magnetic Field** node adds a boundary condition for specifying the tangential component of the magnetic field at the boundary:

$$\mathbf{n} \times \mathbf{H} = \mathbf{n} \times \mathbf{H}_0$$

The **Harmonic Perturbation** subnode (it is of the exclusive type) is available from the context menu (right-click the parent node) or in the **Physics** toolbar by clicking the **Attributes** menu and selecting **Harmonic Perturbation**. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

MAGNETIC FIELD

Enter the value or expression for the **Magnetic Field** $\mathbf{H}_0$ (SI unit: A/m) vector coordinates. The defaults are 0 A/m.

Surface Current Density

The **Surface Current** node adds a boundary condition for a surface current density $\mathbf{J}_s$:

$$-\mathbf{n} \times \mathbf{H} = \mathbf{J}_s$$
$$\mathbf{n} \times (\mathbf{H}_1 - \mathbf{H}_2) = \mathbf{J}_s$$

These expressions apply to exterior and interior boundaries respectively. Add a contribution as a **Harmonic Perturbation** by right-clicking the parent node or clicking **Harmonic Perturbation** in the **Physics** toolbar. For more information see Harmonic Perturbation — Exclusive and Contributing Nodes.

SURFACE CURRENT

Enter values or expressions for the **Surface current density** $\mathbf{J}_{s0}$ (SI unit: A/m) coordinates. The defaults are 0 A/m.

Symmetry Plane (for Magnetic Flux Density)

The **Symmetry Plane** node adds a boundary condition that represents symmetry or antisymmetry in the magnetic flux density, depending on which option is chosen.

SYMMETRY TYPE

Choose between **Symmetry** and **Antisymmetry** for the magnetic flux density. If **Symmetry** is chosen, the boundary condition is

$$\mathbf{n} \cdot \mathbf{B} = 0$$

which states that the normal component of the magnetic flux density is zero. If **Antisymmetry** is chosen, the boundary condition becomes

$$\mathbf{n} \times \mathbf{B} = 0$$

Magnetic Potential

By default, the **Magnetic Potential** node adds a boundary condition for the magnetic vector potential:

$$\mathbf{n} \times \mathbf{A} = \mathbf{n} \times \mathbf{A}_0$$

where $\mathbf{A}_0$ is defined in the **Magnetic Potential** section. As the equation suggests, the boundary condition only guarantees that the tangential components of $\mathbf{A}$ and $\mathbf{A}_0$ are equal. Their normal components might deviate depending on specific situations.

MAGNETIC POTENTIAL

Enter a value or expression for the **Magnetic vector potential** $\mathbf{A}_0$ (SI unit: Wb/m) coordinates.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Perfect Magnetic Conductor

The **Perfect Magnetic Conductor** boundary condition $\mathbf{n} \times \mathbf{H} = 0$ is a special case of the surface current boundary condition that sets the tangential component of the magnetic field and thus also the surface current density to zero. On external boundaries, this can be interpreted as a "high surface impedance" boundary condition or used as a symmetry type boundary condition. It imposes symmetry for electric fields and electric currents. Electric currents (volume, surface, or edge currents) are not allowed to flow into a perfect magnetic conductor boundary as that would violate current conservation. On interior boundaries, the perfect magnetic conductor boundary condition literally sets the tangential magnetic field to zero, which, in addition to setting the surface current density to zero, also makes the tangential magnetic vector potential (and in dynamics the tangential electric field) discontinuous.

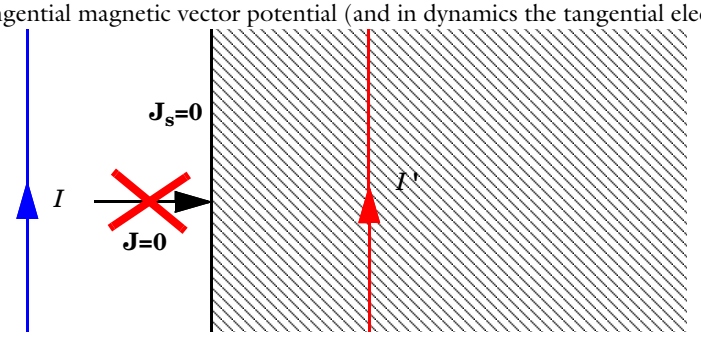

Figure 10-2: The perfect magnetic conductor boundary condition is used on exterior boundaries representing the surface of a high impedance region or a symmetry cut (equivalent to using antisymmetry in Symmetry Plane feature). The shaded (high impedance) region is not part of the model but carries effective mirror images of the sources. Note also that any electric current flowing into the boundary is forbidden as it cannot be balanced by induced electric surface currents. The tangential magnetic field vanishes at the boundary.

Line Current (Out-of-Plane)

Use the **Line Current (Out-of-Plane)** node, selected from the **Points** menu, to specify a line current out of the modeling plane. In axially symmetric geometries this is the rotational (azimuthal) direction; in 2D geometries this is the z direction.

LINE CURRENT (OUT-OF-PLANE)

Enter a value or expression for the **Out-of-plane current** I_0 (SI unit: A).

Line Current (on Axis)

The **Line Current (on Axis)** feature is available for 2D axisymmetric components. It applies to edges that coincide with the symmetry axis, and is active only when in-plane magnetic vector potential components are available (for more information, see Components). Use the **Line Current (on Axis)** feature to specify a line current along the symmetry axis.

LINE CURRENT (ON AXIS)

Enter a value or expression for the **Line current in z direction** I_z (SI unit: A).

11

The Pressure Acoustics Interface

This chapter describes how to use the Pressure Acoustics, Frequency Domain interface, found under the **Acoustics** > **Pressure Acoustics** branch ( ) when adding a physics interface.

In this chapter:

- Fundamentals of Acoustics
- The Pressure Acoustics, Frequency Domain Interface
- Theory for Pressure Acoustics, Frequency Domain

Fundamentals of Acoustics

This section includes a brief introduction to acoustics, gives some examples of standard acoustics problems, and provides a short introduction to the mathematical formulation of the governing equations.

In this section:

- Acoustics Explained
- Examples of Standard Acoustics Problems
- Different Acoustic Interfaces
- Mathematical Models for Acoustic Analysis

Acoustics Explained

Acoustics is the physics of sound. Sound is the sensation, as detected by the ear, of very small rapid changes in the air pressure above and below a static value. This static value is the atmospheric pressure (about 100,000 pascals), which varies slowly. A sound pressure wave is associated with a flow of energy — the intensity. Physically, sound in air is a longitudinal wave where the wave motion is in the direction of the movement of energy. The wave crests are the pressure maxima, while the troughs represent the pressure minima.

Sound results when the air is disturbed by some source. An example is a vibrating object, such as a speaker cone in a sound system. It is possible to see the movement of a bass speaker cone when it generates sound at a very low frequency. As the cone moves forward it compresses the air in front of it, causing an increase in air pressure. Then it moves back past its resting position and causes a reduction in air pressure. This process continues, radiating a wave of alternating high and low pressure propagating at the speed of sound.

The propagation of sound in solids happens through small-amplitude elastic oscillations of its shape. These elastic waves are transmitted to surrounding fluids as ordinary sound waves. The elastic sound waves in the solid are the counterpart to the pressure waves or compressible waves propagating in the fluid.

Examples of Standard Acoustics Problems

These standard problems or scenarios occur frequently when analyzing acoustics:

THE RADIATION PROBLEM

A vibrating structure (a speaker, for example) radiates sound into the surrounding space. A radiation boundary condition or perfectly matched layer (PML) is necessary to model the unbounded open domain.

THE SCATTERING PROBLEM

An incident wave impinges on a body and creates a scattered wave. A radiation boundary condition or PML is necessary. This could be a sonar application in underwater acoustics or an analysis of the scattered sound field around a human head.

THE SOUND FIELD IN AN INTERIOR SPACE

The acoustic waves stay in a finite volume so no radiation condition is necessary. For example, this case represents the sound inside a room or a car interior. A more advanced example is the sound inside a transducer like a microphone; in this case, the acoustic field should be solved with the Thermoviscous Acoustics interface. Analysis using thermoviscous acoustics requires the Acoustics Module.

COUPLED FLUID-ELASTIC STRUCTURE INTERACTION (STRUCTURAL ACOUSTICS)

If the radiating or scattering structure consists of an elastic material, the interaction must be considered between the body and the surrounding fluid. In the multiphysics coupling, the acoustic analysis provides a load (the sound pressure) to the structural analysis, and the structural analysis provides accelerations to the acoustic analysis.

THE TRANSMISSION PROBLEM

An incident sound wave propagates into a body, which can have different acoustic properties. Pressure and acceleration are continuous on the boundary. A typical transmission problem is that of modeling the behavior of mufflers.

AEROACOUSTICS PROBLEMS

The sound (noise) field is influenced by a background flow. This could be the propagating sound from a jet engine or the acoustic damping properties of a muffler with flow. Analysis of these types of problems requires the addition of the Acoustics Module.

POROELASTIC WAVES PROBLEM

If the acoustic waves are propagating inside the saturating fluid of porous material, the detailed coupling between the fluid pressure and the solid displacement needs to be taken into account. In cases when only the fluid pressure is of interest, the porous material can be modeled using an equivalent fluid model. Analysis of this type of problem requires the addition of the Acoustics Module.

TRANSDUCER PROBLEMS

Transducers are devices for transformation of one form of energy to another (electrical, mechanical, or acoustical). This type of problem is common in acoustics and is a true multiphysics problem involving electric, structural, and acoustic interfaces. Typical problems of this type involve modeling loudspeakers, microphones, and piezo transducers. Analysis of these types of problems requires the addition of the Acoustics Module.

Different Acoustic Interfaces

Depending on the basic dependent variable used to model the acoustic field, the acoustical interfaces can be divided into the following main categories.

- Pressure acoustics — The dependent variable is the acoustic pressure p.
- Acoustic-solid interaction — The dependent variables are the pressure p and the displacement field $\mathbf{u}$ in the solid. This type of problem requires the addition of the Acoustics Module.
- Poroelastic waves — The dependent variables are the pressure p inside the saturating fluid and the total displacement $\mathbf{u}$ of the porous matrix. This type of problem requires the addition of the Acoustics Module.
- Aeroacoustics — The dependent variables are the acoustic perturbations to the background mean flow fields. In the Linearized Potential Flow interface, it is the potential ϕ for the acoustic particle-velocity field $\mathbf{v} = \nabla\phi$. In the Linearized Euler interface, the dependent variables are the acoustic variations in pressure p, density ρ, and velocity field $\mathbf{u}$. In the linearized Navier–Stokes, they are the pressure p, velocity field $\mathbf{u}$, and temperature T. In the typical situation, the background fluid is in motion with, for example, a total velocity $\mathbf{u}_{\text{tot}} = \mathbf{u}_0 + \mathbf{u}$, split into a stationary background-flow velocity $\mathbf{u}_0$ and the particle velocity $\mathbf{u}$ associated with the acoustic waves. This type of problem requires the addition of the Acoustics Module.
- Thermoviscous acoustics — The dependent variables are the acoustic pressure p, the particle-velocity field $\mathbf{v}$, and the acoustic temperature variation T. This is a detailed acoustic model solving the full set of linearized equations for a compressible flow: Navier–Stokes (momentum conservation), continuity (mass conservation), and energy conservation equations. This type of problem requires the addition of the Acoustics Module.
- Geometrical acoustics — At high frequencies when the typical wavelength becomes comparable with the geometrical features, standard finite element methods are no longer appropriate. Instead the acoustic field can

be solved using ray tracing methods or energy methods. The Ray Acoustics and Acoustic Diffusion Equation interfaces apply here. This type of problem requires the addition of the Acoustics Module.

Mathematical Models for Acoustic Analysis

Standard acoustic problems involve solving for the small acoustic pressure variations p on top of the stationary background pressure p_0. Mathematically this represents a linearization (small parameter expansion) around the stationary quiescent values.

The governing equations for a compressible lossless (no thermal conduction and no viscosity) fluid flow problem are the momentum equation (Euler's equation) and the continuity equation. These are given by

$$\frac{\partial \mathbf{u}}{\partial t} + (\mathbf{u} \cdot \nabla)\mathbf{u} = -\frac{1}{\rho}\nabla p$$

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0$$

where ρ is the total density, p is the total pressure, and $\mathbf{u}$ is the velocity field. In classical pressure acoustics, all thermodynamic processes are assumed reversible and adiabatic, known as an isentropic process. The small parameter expansion is performed on a stationary fluid of density ρ_0 (SI unit: $\mathrm{kg/m^3}$) and at pressure p_0 (SI unit: Pa) such that

$$\begin{aligned} p &= p_0 + p' \\ \rho &= \rho_0 + \rho' \\ \mathbf{u} &= \mathbf{0} + \mathbf{u}' \end{aligned} \qquad \text{with} \qquad \begin{aligned} p' &\ll p_0 \\ \rho' &\ll \rho_0 \end{aligned}$$

where the primed variables represent the small acoustic variations. Inserting these into the governing equations and only retaining terms linear in the primed variables yields

$$\frac{\partial \mathbf{u}'}{\partial t} = -\frac{1}{\rho_0}\nabla p'$$

$$\frac{\partial \rho'}{\partial t} + \rho_0(\nabla \cdot \mathbf{u}') = 0$$

One of the dependent variables, the density, is removed by expressing it in terms of the pressure using a Taylor expansion (linearization):

$$\rho' = \left.\frac{\partial \rho_0}{\partial p}\right|_s p' = \frac{1}{c_s^2} p'$$

where c_s is recognized as the (isentropic) speed of sound (SI unit: m/s) at constant entropy s. The subscripts s and 0 are dropped in the following.

Finally, rearranging the equations (divergence of momentum equation inserted into the continuity equation) and dropping the primes yields the wave equation for sound waves in a lossless medium

$$\frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2} + \nabla \cdot \left(-\frac{1}{\rho}(\nabla p - \mathbf{q}_d)\right) = Q_m \tag{11-1}$$

The speed of sound is related to the compressibility of the fluid where the waves are propagating. The combination ρc^2 is called the *bulk modulus*, commonly denoted K (SI unit: N/m^2). The equation is further extended with two optional source terms:

- The *dipole source* $\mathbf{q}_\mathrm{d}$ (SI unit: N/m^3)
- The *monopole source* Q_m (SI unit: $1/\mathrm{s}^2$)

A special case is a time-harmonic wave, for which the pressure varies with time as

$$p(\mathbf{x}, t) = p(\mathbf{x}) e^{i\omega t}$$

where $\omega = 2\pi f$ (SI unit: rad/s) is the angular frequency and f (SI unit: Hz) is denoting the frequency. Assuming the same harmonic time-dependence for the source terms, the wave equation for acoustic waves reduces to an inhomogeneous Helmholtz equation

$$\nabla \cdot \left(-\frac{1}{\rho}(\nabla p - \mathbf{q}_d)\right) - \frac{\omega^2 p}{\rho c^2} = Q_m \,. \tag{11-2}$$

With the two source terms removed, this equation can also be treated as an eigenvalue PDE to solve for eigenmodes and eigenfrequencies.

Typical boundary conditions for the wave equation and the Helmholtz equation are:

- Sound-hard boundaries (walls)
- Sound-soft boundaries
- Impedance boundary conditions
- Radiation boundary conditions

In lossy media, an additional term of first order in the time derivative needs to be introduced to model attenuation of the sound waves

$$\frac{1}{\rho c^2}\frac{\partial^2 p}{\partial t^2} - d_\mathrm{a}\frac{\partial p}{\partial t} + \nabla \cdot \left(-\frac{1}{\rho}(\nabla p - \mathbf{q}_d)\right) = Q_m$$

where d_a is the damping coefficient. Note also that even when the sound waves propagate in a lossless medium, attenuation frequently occurs by interaction with the surroundings at the boundaries of the system.

The Pressure Acoustics, Frequency Domain Interface

The **Pressure Acoustics, Frequency Domain (acpr)** interface ( ), found under the **Pressure Acoustics** branch ( ) when adding a physics interface, is used to compute the pressure variation for propagation of acoustic waves in fluids at quiescent background conditions. It is suited for all frequency-domain simulations with harmonic variations of the pressure field.

The physics interface can be used for linear acoustics described by a scalar pressure variable. It includes domain conditions to model losses in a homogenized way, so-called fluid models for porous materials, as well as losses in narrow regions. Domain features also include background incident acoustic fields as well as domain monopole and dipole sources. The plane wave attenuation behavior of the acoustic waves may be entered as a user-defined quantity, or defined to be bulk viscous and thermal losses.

The physics interface solves the Helmholtz equation in the frequency domain for given frequencies, or as an eigenfrequency or modal analysis study.

An acoustics model can be part of a larger multiphysics model that describes, for example, the interactions between structures and acoustic waves. This physics interface is suitable for modeling acoustics phenomena that do not involve fluid flow.

The sound pressure p, which is solved for in pressure acoustics, represents the acoustic variations (or excess pressure) to the ambient pressure. In the absence of flow, the ambient pressure is simply the static absolute atmospheric pressure of 10^5 Pa.

When the geometrical dimensions of the acoustic problems are reduced from 3D to 2D (planar symmetry or axisymmetric) or to 1D axisymmetric, it is possible to specify an out-of-plane wave number k_z and a circumferential wave number m, when applicable. In this case the wave number used in the equations k_{eq} contains both the ordinary wave number k as well as the out-of-plane wave number and circumferential wave number, when applicable.

The following table lists the names and SI units for the most important physical quantities in the Pressure Acoustics, Frequency Domain interface:

TABLE 11-1: PRESSURE ACOUSTICS, FREQUENCY DOMAIN INTERFACE PHYSICAL QUANTITIES.

QUANTITY	SYMBOL	SI UNIT	ABBREVIATION
Pressure	p	Pascal	Pa
Density	ρ	kilogram/meter^3	kg/m^3
Frequency	f	Hertz	Hz
Wave number	k	1/meter	1/m
Dipole source	$\mathbf{q}_{\text{d}}$	newton/meter^3	N/m^3
Monopole source	Q_{m}	1/second^2	1/s^2
Speed of sound	c	meter/second	m/s
Specific acoustic impedance	Z	pascal-second/meter	Pa·s/m
Normal acceleration	a_n	meter/second^2	m/s^2
Source location	r_0	meter	m
Wave direction	$\mathbf{n}_{\text{k}}$	(dimensionless)	1

In the following descriptions of the functionality in this physics interface, the subscript c in ρ_c and c_c (the density and speed of sound, respectively) denotes that these can be complex-valued quantities in models with damping.

When this physics interface is added, these default nodes are also added to the **Model Builder** — **Pressure Acoustics Model**, **Sound Hard Boundary (Wall)**, and **Initial Values**.

Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and point conditions. You can also right-click **Pressure Acoustics** to select physics features from the context menu.

Physics Nodes — Equation Section

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `acpr`.

EQUATION

Expand the **Equation** section to see the equations solved for with the **Equation form** specified. The default selection is **Equation form** set to **Study controlled**. The available studies are selected under **Show equations assuming**.

- For **Study controlled**, the scaling and nonreflecting boundary settings are optimized for the numerical performance of the different solvers.
- For **Frequency domain**, enter the settings as described in Scaling Factor and Nonreflecting Boundary Condition Approximation.

PRESSURE ACOUSTICS EQUATION SETTINGS

- For 1D axisymmetric components, the default **Out-of-plane wave number** k_z (SI unit: rad/m) is 0 rad/m. The default **Circumferential wave number** m (dimensionless) is 0. The pressure has the form:

$$p(r, \varphi, z) = p(r)e^{-i(k_z z + m\varphi)}$$

- For 2D axisymmetric components, the default **Circumferential wave number** m (dimensionless) is 0. The pressure has the form:

$$p(r, \varphi, z) = p(r, z)e^{-im\varphi}$$

- For 2D components, the default **Out-of-plane wave number** k_z (SI unit: rad/m) is 0 rad/m. The pressure has the form:

$$p(x, y, z) = p(x, y)e^{-ik_z z}$$

Scaling Factor and Nonreflecting Boundary Condition Approximation

For all component dimensions, and if required, click to expand the **Equation** section, then select **Frequency domain** as the **Equation form** and enter the settings as described below.

The default **Scaling factor** Δ is $1/\omega^2$ and **Nonreflecting boundary condition approximation** is **Second order**. These values correspond to the equations for a Frequency Domain study when the equations are study controlled.

To get the equations corresponding to an Eigenfrequency study, change the **Scaling factor** Δ to 1 and the **Nonreflecting boundary conditions approximation** to **First order**.

SOUND PRESSURE LEVEL SETTINGS

The zero level on the dB scale varies with the type of fluid. That value is a reference pressure that corresponds to 0 dB. This variable occurs in calculations of the sound pressure level L_p based on the root mean square (rms) pressure p_{rms}, such that

$$L_p = 20\log\left(\frac{p_{rms}}{p_{ref}}\right) \qquad \text{with} \qquad p_{rms} = \sqrt{\frac{1}{2}pp^*}$$

where p_{ref} is the reference pressure and the star (*) represents the complex conjugate. This is an expression valid for the case of harmonically time-varying acoustic pressure p.

Select a **Reference pressure for the sound pressure level** based on the fluid type:

- **Use reference pressure for air** to use a reference pressure of 20 µPa ($20{\cdot}10^{-6}$ Pa).
- **Use reference pressure for water** to use a reference pressure of 1 µPa ($1{\cdot}10^{-6}$ Pa).
- **User-defined reference pressure** to enter a reference pressure $p_{ref,\,SPL}$ (SI unit: Pa). The default value is the same as for air, 20 µPa.

DEPENDENT VARIABLES

This physics interface defines one dependent variable (field), the **Pressure** p. If required, edit the name, which changes both the field name and the dependent variable name. If the new field name coincides with the name of another pressure field in the model, the interfaces share degrees of freedom and dependent variable name. The new field name must not coincide with the name of a field of another type, or with a component name belonging to some other field.

DISCRETIZATION

To display additional settings beyond the shape function orders in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

- Theory for Pressure Acoustics, Frequency Domain

Eigenmodes of a Room: Application Library path
COMSOL_Multiphysics/Acoustics/eigenmodes_of_room

Domain, Boundary, Edge, Point, and Pair Nodes for the Pressure Acoustics, Frequency Domain Interface

The Pressure Acoustics, Frequency Domain Interface has these domain, boundary, edge, point, and pair nodes, listed in alphabetical order, available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (macOS or Linux users), or by right-clicking to access the context menu (all users). Continuity in the total pressure is the default condition on interior boundaries.

In general, to add a node, go to the **Physics** toolbar no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the **Attributes** menu.

- Axial Symmetry
- Continuity
- Cylindrical Wave Radiation
- Dipole Source
- Impedance
- Incident Pressure Field
- Interior Sound Hard Boundary (Wall)
- Initial Values
- Monopole Source
- Normal Acceleration
- Periodic Condition
- Plane Wave Radiation
- Pressure Acoustics
- Pressure
- Sound Hard Boundary (Wall)
- Sound Soft Boundary
- Spherical Wave Radiation
- Symmetry

For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node to the component that is valid on the axial symmetry boundaries only.

See Table 2-4 for links to common sections and Table 2-5 for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Pressure Acoustics

The **Pressure Acoustics** node adds the equations for time-harmonic and eigenfrequency acoustics modeling in the frequency domain. In the **Settings** window, define the properties for the acoustics model and model inputs including temperature.

PRESSURE ACOUSTICS MODEL

The default **Fluid model** for pressure acoustics is a **Linear elastic** fluid. By default, the values for the **Density** ρ (SI unit: kg/m^3) and the **Speed of sound** c (SI unit: m/s) are taken **From material**. For **User defined**, enter other values for these properties.

Sound Hard Boundary (Wall)

The **Sound Hard Boundary (Wall)** adds a boundary condition for a sound hard boundary or wall. This is a boundary where the normal component of the acceleration is zero, such that

$$-\mathbf{n}\cdot\left(-\frac{1}{\rho_0}(\nabla p - \mathbf{q}_d)\right) = 0$$

For zero dipole source and constant fluid density, this means that the normal derivative of the pressure is zero at the boundary

$$\frac{\partial p}{\partial \mathbf{n}} = 0$$

Sound hard boundaries are available for all study types. Note that this condition is identical to the Symmetry condition.

Initial Values

The **Initial Values** node adds initial values for the sound pressure and the pressure time derivative that can serve as an initial guess for a nonlinear solver. If more than one initial value is needed, from the **Physics** toolbar click to add more **Initial Values** nodes.

INITIAL VALUES

Enter a value or expression for the initial values for the **Pressure** p (SI unit: Pa) and the **Pressure, first time derivative**, $\partial p/\partial t$ (SI unit: Pa/s). The defaults are 0 Pa and 0 Pa/s, respectively.

Monopole Source

Use the **Monopole Source** node to add the domain source term Q_m to the governing equation. A monopole source added to a domain has a uniform strength in all directions. In advanced models, this source term can, for example, be used to represent a domain heat source causing pressure variations. Add this node from the **More** submenu.

MONOPOLE SOURCE

Enter a **Monopole source** Q_m (SI unit: $1/\mathrm{s}^2$). The default is 0 $1/\mathrm{s}^2$.

Dipole Source

Use the **Dipole Source** node to add the domain source term $\mathbf{q}_\mathrm{d}$ to the governing equation. This source is typically stronger in two opposite directions. In advanced models, this term can, for example, be used to represent a uniform constant background flow convecting the sound field. Add this node from the **More** submenu.

DIPOLE SOURCE

Enter coordinates for the **Dipole source** $\mathbf{q}_\mathrm{d}$ (SI unit: $\mathrm{N/m}^3$). These are the individual components of the dipole source vector. The defaults are 0 $\mathrm{N/m}^3$.

Normal Acceleration

The **Normal Acceleration** adds an inward normal acceleration a_n:

$$-\mathbf{n}\cdot\left(-\frac{1}{\rho_0}(\nabla p-\mathbf{q}_d)\right)=a_\mathrm{n}$$

Alternatively, specify the acceleration $\mathbf{a}_0$ of the boundary. The part in the normal direction is used to define the boundary condition:

$$\mathbf{n}\cdot\left(-\frac{1}{\rho_0}(\nabla p-\mathbf{q}_d)\right)=\mathbf{n}\cdot\mathbf{a}_0$$

This feature represents an external source term. It can also be used to manually couple acoustics with a structural analysis for modeling acoustic-structure interaction.

NORMAL ACCELERATION

Select a **Type** — **Inward Acceleration** (the default) or **Acceleration**.

- For **Inward Acceleration**, enter the value of the **Inward acceleration** a_n (SI unit: $\mathrm{m/s}^2$). The default is 0 $\mathrm{m/s}^2$. Use a positive value for inward acceleration or a negative value for outward acceleration.
- For **Acceleration**, enter values for the components of the **Acceleration** $\mathbf{a}_0$ (SI unit: $\mathrm{m/s}^2$). The defaults are 0 $\mathrm{m/s}^2$.

Sound Soft Boundary

The **Sound Soft Boundary** adds a boundary condition for a sound soft boundary, where the acoustic pressure vanishes: $p = 0$. It is an appropriate approximation for a liquid-gas interface and in some cases for external waveguide ports.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Pressure

The **Pressure** node creates a boundary condition that acts as a pressure source at the boundary, which means a constant acoustic pressure p_0 is specified and maintained at the boundary: $p = p_0$. In the frequency domain, p_0 is the amplitude of a harmonic pressure source. The node is also available from the **Pairs** submenu as an option at interfaces between parts in an assembly.

PRESSURE

Enter the value of the **Pressure** p_0 (SI unit: Pa). The default is 0 Pa.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Impedance

The **Impedance** node adds an impedance boundary condition, which is a generalization of the sound-hard and sound-soft boundary conditions:

$$-\mathbf{n}\cdot\left(-\frac{1}{\rho_c}(\nabla p_\mathrm{t}-\mathbf{q}_\mathrm{d})\right) = -\frac{i\omega p_\mathrm{t}}{Z_\mathrm{i}}$$

Here Z_i is the acoustic input impedance of the external domain and it has the unit of a specific acoustic impedance. From a physical point of view, the acoustic input impedance is the ratio between the local pressure and local normal particle velocity.

The Impedance boundary condition is a good approximation for a locally reacting surface — a surface for which the normal velocity at any point depends only on the pressure at that exact point.

In the two opposite limits $Z_i \to \infty$ and $Z_i \to 0$, this boundary condition is identical to the Sound Hard Boundary (Wall) condition and the Sound Soft Boundary condition, respectively.

IMPEDANCE

The **Impedance model** available is **User defined**.

Enter the value of the **Impedance** Z_i (SI unit: Pa·s/m). The default value is set to the specific impedance of air 1.2 kg/m^3·343 m/s.

Symmetry

The **Symmetry** node adds a boundary condition where there is symmetry in the pressure. Use this condition to reduce the size of a model by cutting it in half where there are symmetries. In pressure acoustics, this boundary condition is mathematically identical to the Sound Hard Boundary (Wall) condition.

Plane Wave Radiation

The **Plane Wave Radiation** node adds a radiation boundary condition for a plane wave. If required, from the **Physics** toolbar, add an Incident Pressure Field to model an incoming wave. This radiation condition allows an outgoing plane wave to leave the modeling domain with minimal reflections when the angle of incidence is near to normal.

The *plane wave* type is suitable for both far-field boundaries and ports. Because many waveguide structures are only interesting in the plane-wave region, it is particularly relevant for ports. When using the radiation condition on an open far-field boundary, it is recommended to construct the boundary such that the incidence angle is near to normal. This of course requires a priori knowledge of the problem and the solution.

- An estimate of the reflection coefficient R_s, for the spurious waves reflecting off the plane wave radiation boundary, is, for incident plane waves at angle θ, given by the expression:

$$R_s = \left|\frac{\cos\theta - 1}{\cos\theta + 1}\right|^N$$

  where N is the order of the boundary condition (here 1 or 2). So at normal incidence ($\theta = 0$) there are no spurious reflections, while at an incidence angle of 30^0 for $N = 2$ (plane wave radiation in the frequency domain), for example, the amplitude of the spurious reflected wave is 0.5% of the incident.

	Automotive Muffler: Application Library path **COMSOL_Multiphysics/Acoustics/automotive_muffler**

Spherical Wave Radiation

The **Spherical Wave Radiation** node adds a radiation boundary condition for a spherical wave, for which you define the source location. If required, from the **Physics** toolbar add an Incident Pressure Field to model an incoming wave. This radiation condition allows an outgoing spherical wave to leave the modeling domain with minimal reflections. The geometry of the modeling domain should be adapted to have the outgoing spherical waves coincide with the boundary. This is in order to minimize spurious reflections.

SPHERICAL WAVE RADIATION

Enter coordinates for the **Source location** r_0 (SI unit: m). The defaults are 0 m.

Cylindrical Wave Radiation

The **Cylindrical Wave Radiation** node adds a radiation boundary condition for a cylindrical wave, for which you define the source location and the source axis direction. If required, from the **Physics** toolbar, add an Incident Pressure Field to model an incoming wave. This radiation condition allows an outgoing cylindrical wave to leave the modeling domain with minimal reflections. The geometry of the modeling domain should be adapted to have the outgoing cylindrical waves coincide with the boundary. This is in order to minimize spurious reflections.

CYLINDRICAL WAVE RADIATION

Enter coordinates for the **Source location** r_0 (SI unit: m) (the defaults are 0 m) and the **Source axis** direction r_{axis} (dimensionless) (the defaults are 0).

Incident Pressure Field

The **Incident Pressure Field** node is a subnode to all nonreflecting boundary conditions (plane, cylindrical, or spherical wave radiation). From the **Physics** toolbar, add to Plane Wave Radiation, Spherical Wave Radiation, or Cylindrical Wave Radiation nodes. If the incident pressure field p_i is a predefined plane wave, it is of the type:

$$p_i = p_0 e^{-i(\mathbf{k}\cdot\mathbf{r})} = p_0 e^{-ik_{eq}\left(\frac{\mathbf{r}\cdot\mathbf{e}_k}{\|\mathbf{e}_k\|}\right)}$$

where p_0 is the wave amplitude, $\mathbf{k}$ is the wave vector (with amplitude $k_{eq} = |\mathbf{k}|$ and wave direction vector $\mathbf{e}_k$), and $\mathbf{r}$ is the location on the boundary. The incident pressure field can also be a user-defined value or expression.

INCIDENT PRESSURE FIELD

From the **Incident pressure field type** list, select **Plane wave** to define an incident pressure field of plane wave type. Then enter a **Pressure amplitude** p_0 (SI unit: Pa) (the default is 0 Pa) and **Wave direction** $\mathbf{e}_k$ (SI unit: m).

Select **User defined** to enter the expression for the **Incident pressure field** p_i (SI unit: Pa) as a function of space. The default is 0 Pa.

Interior Sound Hard Boundary (Wall)

The **Interior Sound Hard Boundary (Wall)** node adds a boundary condition for a sound hard boundary or wall on interior boundaries. A sound-hard boundary is a boundary at which the normal component of the acceleration is zero:

$$-\mathbf{n}\cdot-\left(\frac{1}{\rho_c}(\nabla p_t - \mathbf{q}_d)\right)_1 = 0 \qquad -\mathbf{n}\cdot\left(\left(-\frac{1}{\rho_c}\right)(\nabla p_t - \mathbf{q}_d)\right)_2 = 0$$

where the subscripts 1 and 2 represent the two sides of the boundary. For zero dipole charge and constant fluid density, this means that the normal derivative of the pressure is zero at the boundary. On an interior sound hard boundary, the pressure is not continuous but is treated as a so-called slit feature.

Periodic Condition

The **Periodic Condition** node adds a periodic boundary condition that can be used to reduce the model size by using symmetries and periodicities in the geometry and physics interfaces being modeled.

BOUNDARY SELECTION

	The software usually automatically identifies the boundaries as either source boundaries or destination boundaries, as indicated in the selection list. This works fine for cases like opposing parallel boundaries. In other cases, right-click **Periodic Condition** and select **Manual Destination Selection** to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

DESTINATION SELECTION

This section is available for specifying the destination boundaries, if needed, when the **Manual Destination Selection** option is selected in the context menu for the **Periodic Condition** node. You can only select destination boundaries from the union of all source and destination boundaries.

PERIODICITY SETTINGS

Select a **Type of periodicity**: **Continuity** (the default) or **Antiperiodicity**.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

EXCLUDED EDGES, EXCLUDED POINTS

To display these sections (**Excluded Edges** in 3D geometries only), click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For more information about these sections, see Excluded Surfaces, Excluded Edges, and Excluded Points.

ORIENTATION OF SOURCE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Orientation of Source** section, see Orientation of Source and Destination.

MAPPING BETWEEN SOURCE AND DESTINATION

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Mapping Between Source and Destination** section, see Mapping Between Source and Destination.

Axial Symmetry

The **Axial Symmetry** node is a default node added for all 2D and 1D axisymmetric components. The boundary condition is active on all boundaries on the symmetry axis.

Continuity

Continuity is available as an option at interfaces between parts in a pair.

This condition gives continuity in total pressure and in the normal acceleration over the pair (subscripts 1 and 2 in the equation refer to the two sides in the pair):

$$-\mathbf{n}\cdot\left[-\left(\frac{1}{\rho_c}(\nabla p_t-\mathbf{q}_d)\right)_1-\left(-\frac{1}{\rho_c}(\nabla p_t-\mathbf{q}_d)\right)_2\right]=0$$

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Theory for Pressure Acoustics, Frequency Domain

The Pressure Acoustics, Frequency Domain Interface is designed for the analysis of various types of pressure acoustics problems in the frequency domain, all concerning pressure waves in a fluid. An acoustics model can be part of a larger multiphysics model that describes, for example, the interactions between structures and acoustic waves. This physics interface is suitable for modeling acoustics phenomena that do not involve fluid flow.

This physics interface solves for the acoustic pressure, p. It is available in all space dimensions — for 3D, 2D, and 1D Cartesian geometries as well as for 2D and 1D axisymmetric geometries.

These studies are discussed briefly in this section:

- Frequency Domain Study
- Eigenfrequency Study
- References for the Pressure Acoustics, Frequency Domain Interface

Frequency Domain Study

The frequency domain — or time-harmonic — formulation uses the inhomogeneous Helmholtz equation

$$\nabla \cdot \left(-\frac{1}{\rho_c}(\nabla p - \mathbf{q}_d)\right) - \frac{\omega^2 p}{\rho_c c_c^2} = Q_m \tag{11-3}$$

In this equation, $p = p(\mathbf{x}, \omega)$ (the dependence on ω is henceforth not explicitly indicated). With this formulation you can compute the frequency response of a system for a number of frequencies. The default frequency domain study sets up a parametric sweep over a frequency range using a harmonic load.

When there is damping, ρ_c and c_c are complex-valued quantities.

Equation 11-3 is the equation that the software solves for 3D geometries. In lower-dimensional and axisymmetric cases, restrictions on the coordinate dependence mean that the equations differ from case to case. Here is a brief summary of the situation.

2D

In 2D, the pressure is of the form

$$p(\mathbf{r}) = p(x, y)e^{-ik_z z}$$

which, inserted in Equation 11-3, gives

$$\nabla \cdot \left(-\frac{1}{\rho_c}(\nabla p - \mathbf{q}_d)\right) - \frac{1}{\rho_c}\left(\frac{\omega^2}{c_c^2} - k_z^2\right)p = Q_m \tag{11-4}$$

The *out-of-plane wave number*, k_z, can be set on the Pressure Acoustics page. By default its value is 0. In the mode analysis type, $-ik_z$ is used as the eigenvalue.

2D AXISYMMETRY

For 2D axisymmetric geometries, the independent variables are the radial coordinate, r, and the axial coordinate, z. The only dependence allowed on the azimuthal coordinate, φ, is through a phase factor,

$$p(r, \phi, z) = p(r, z)e^{-im\varphi} \tag{11-5}$$

where m denotes the *circumferential wave number*. Because the azimuthal coordinate is periodic, m must be an integer. Just like k_z in the 2D case, m can be set in the **Settings** window for Pressure Acoustics.

As a result of Equation 11-5, the equation to solve for the acoustic pressure in 2D axisymmetric geometries becomes

$$\frac{\partial}{\partial r}\left[-\frac{r}{\rho_c}\left(\frac{\partial p}{\partial r}-q_r\right)\right]+r\frac{\partial}{\partial z}\left[-\frac{1}{\rho_c}\left(\frac{\partial p}{\partial z}-q_z\right)\right]-\left[\left(\frac{\omega}{c_c}\right)^2-\left(\frac{m}{r}\right)^2\right]\frac{rp}{\rho_c}=rQ_m$$

1D AXISYMMETRY

In 1D axisymmetric geometries,

$$p(r,\phi,z)=p(r)e^{-i(k_z z+m\varphi)}$$

leading to the radial equation

$$\frac{\partial}{\partial r}\left[-\frac{r}{\rho_c}\left(\frac{\partial p}{\partial r}-q_r\right)\right]-\left[\left(\frac{\omega}{c_c}\right)^2-\left(\frac{m}{r}\right)^2-k_z^2\right]\frac{rp}{\rho_c}=rQ_m$$

where both the circumferential wave number m, and the *axial wave number* k_z, appear as parameters.

1D

The equation for the 1D case is obtained by taking the pressure to depend on a single Cartesian coordinate, x:

$$\frac{d}{dx}\left(-\frac{1}{\rho_c}\left(\frac{dp}{dx}-q_d\right)\right)-\frac{\omega^2}{\rho_c c_c^2}p=Q_m$$

Eigenfrequency Study

In the eigenfrequency formulation, the source terms are absent, and the eigenmodes and eigenfrequencies are solved for:

$$\nabla\cdot\left(-\frac{1}{\rho_c}\nabla p\right)+\frac{\lambda^2 p}{\rho_c c^2}=0 \tag{11-6}$$

The eigenvalue λ introduced in this equation is related to the eigenfrequency f and the angular frequency ω, through $\lambda=-i2\pi f=-i\omega$. Because they are independent of the pressure, the solver ignores any dipole and monopole sources unless a coupled eigenvalue problem is being solved.

Equation 11-6 applies to the 3D case. The equations solved in eigenfrequency studies in lower dimensions and for axisymmetric geometries are obtained from their time-harmonic counterparts, given in the previous subsection, by the substitution $\omega^2\rightarrow-\lambda^2$.

The Chemical Species Transport Interfaces

This chapter explains how to use the Transport of Diluted Species interface, found under the **Chemical Species Transport** branch ( ) when adding a physics interface. The Transport of Diluted Species interface is used to model and simulate mass transfer by diffusion and convection based on Fick's law of diffusion. The interface is also used in the Reacting Flow, Diluted Species multiphysics interface, which solves for coupled mass transport and fluid flow.

In this chapter:

- Theory for Transport of Diluted Species
- The Transport of Diluted Species Interface
- The Reacting Flow, Diluted Species Multiphysics Interface
- Mass Transfer Variables in the Transport of Diluted Species Interface

Theory for Transport of Diluted Species

The Transport of Diluted Species Interface provides a predefined modeling environment for studying the evolution of chemical species transported by diffusion and convection. The physics interface assumes that all species present are dilute; that is, that their concentration is low compared to a solvent fluid or solid. As a rule of thumb, a mixture containing several species can be considered dilute when the concentration of the solvent is more than 90 mol%. Due to the dilution, mixture properties such as density and viscosity can be assumed to correspond to those of the solvent.

When studying mixtures that are not dilute, the mixture and transport properties depend on the composition, and a different physics interface is recommended. See The Transport of Concentrated Species Interface in the *Chemical Reaction Engineering Module User's Guide* for more information.

Fick's law governs the diffusion of the solutes, dilute mixtures, or solutions, while the phenomenon of ionic migration is sometimes referred to as *electrokinetic flow*. The Transport of Diluted Species interface supports the simulations of chemical species transport by convection, migration, and diffusion in 1D, 2D, and 3D as well as for axisymmetric components in 1D and 2D.

In this section:

- Adding Transport Through Migration
- Material Balance Formulation
- Crosswind Diffusion
- Danckwerts Inflow Boundary Condition
- Equilibrium Reaction Theory
- Mass Balance Equation
- Mass Sources for Species Transport
- Solving a Diffusion Equation Only
- Supporting Electrolytes
- References

Note: Some features explained in this section require certain add-on modules. For details see https://www.comsol.com/products/specifications/

The section also includes the theory for The Transport of Diluted Species in Porous Media Interface:

- Adsorption
- Convection in Porous Media
- Diffusion in Porous Media
- Dispersion
- Mass Balance Equation for Transport of Diluted Species in Porous Media
- Mass Transport in Fractures
- Reactions

Mass Balance Equation

The default node attributed to the Transport of Diluted Species interface models chemical species transport through diffusion and convection and solves the mass conservation equation for one or more chemical species i:

$$\frac{\partial c_i}{\partial t} + \nabla \cdot \mathbf{J}_i + \mathbf{u} \cdot \nabla c_i = R_i \tag{12-1}$$

Equation 12-1 in its form above includes the transport mechanisms diffusion and convection. If *Migration in Electric Field* is activated (only available in some add-on products), the migration mechanism will be added to the equation as well. See more details in the section Adding Transport Through Migration.

- c_i is the concentration of the species (SI unit: mol/m^3)
- D_i denotes the diffusion coefficient (SI unit: m^2/s)
- R_i is a reaction rate expression for the species (SI unit: mol/(m^3·s))
- $\mathbf{u}$ is the mass averaged velocity vector (SI unit: m/s)
- $\mathbf{J}_i$ is the mass flux diffusive flux vector (SI unit: mol/(m^2·s))

The mass flux relative to the mass averaged velocity, $\mathbf{J}_i$ (SI unit: mol/(m^2·s)), is associated with the mass balance equation above and used in boundary conditions and flux computations. The Transport of Diluted Species interface always includes mass transport due to molecular diffusion. In this case the mass flux $\mathbf{J}_i$ defines the diffusive flux vector

$$\mathbf{J}_i = -D\nabla c_i \tag{12-2}$$

An input field for the diffusion coefficient is available.

When *Migration in Electric Fields* is activated, the migration term is also added to the diffusive flux vector as shown in the section Adding Transport Through Migration.

The third term on the left side of Equation 12-1 describes the convective transport due to a velocity field $\mathbf{u}$. This field can be expressed analytically or obtained from coupling the physics interface to one that solves for fluid flow, such as *Laminar Flow*. Note that all fluid flow interfaces solve for the mass averaged velocity.

On the right-hand side of the mass balance equation (Equation 12-1), R_i represents a source or sink term, typically due to a chemical reaction or desorption on a porous matrix. To specify R_i, another node must be added to the Transport of Diluted Species interface — the **Reaction** node for example, which includes an input field for specifying a reaction expression using the variable names of all participating species.

Equilibrium Reaction Theory

The feature Equilibrium Reaction is described in this section. A chemical equilibrium reaction system is defined by the stoichiometry of the reaction and the relation between the chemical activities of the chemical species participating in the reaction (the equilibrium condition).

The kinetics of the reaction is so fast that the equilibrium condition is fulfilled at all times in all space coordinates.

The equilibrium condition is commonly based on the stoichiometric coefficients, ν_i (dimensionless), of the reaction; the species activities of the reacting species a_i (dimensionless); and an equilibrium constant, K_{eq} (1) according to

$$K_{\text{eq}} = \frac{\prod_{i \in \text{ products}} a_i^{\nu_i}}{\prod_{i \in \text{ reactants}} a_i^{-\nu_i}}$$

where the species activities are defined as

$$a_i = \gamma_{c,i}\frac{c_i}{c_{\text{a0}}}$$

where c_{a0} (SI unit: mol/m^3) is the standard molarity, and $\gamma_{c,i}$ (dimensionless) an activity coefficient.

Defining the stoichiometric coefficients positive for products and negative for reactants, the above equilibrium condition can also be written

$$K_{\text{eq}} = \prod_i a_i^{\nu_i}$$

The Equilibrium Reaction node solves for a reaction rate so that the equilibrium condition is always fulfilled in the domain. It is available for the Chemical Reaction Engineering Module; Battery Design Module; Corrosion Module; Electrochemistry Module; Electrodeposition Module; and Fuel Cell & Electrolyzer Module.

$\gamma_{c,i}$ is set to unity when the Equilibrium constant is selected in the Settings window. For nonunity activity coefficients, a user-defined equilibrium condition can be used.

EQUILIBRIUM REACTIONS AND INFLOW BOUNDARY CONDITIONS

Contradictory constraints arise if the boundary conditions for concentrations or activities are set so that the domain equilibrium condition is not fulfilled. Special treatment is therefore needed at Inflow boundaries, where the concentrations are set for all species in the mass transport interfaces.

One way of avoiding competing constraints on an inflow boundary is to add an additional reaction coordinate degree of freedom, solved for to create a set of modified inflow concentrations that fulfill the domain equilibrium condition. The reaction coordinate gives rise to a concentration shift, which is the offset to the inflow concentrations provided by the user. The shift for each species obeys the stoichiometry of the reaction and the equilibrium expression. The modified inflow concentrations are then used in the boundary conditions for the domain mass transport equations. The resulting modified inflow concentrations can be seen as the stationary solution for a batch reactor with the user inflow concentrations as initial concentrations. In addition, the domain reaction rate degree of freedom of the equilibrium reaction is constrained to zero on all Inflow boundaries.

EQUILIBRIUM REACTIONS AND CONCENTRATION BOUNDARY CONDITIONS

No special treatment is made with regards to input concentration values of the Concentration boundary node. Using this feature, you can explicitly set one or a set of concentrations, and the equilibrium condition acts on the rest of the concentrations. However, there is no solution to the problem if more concentrations than the number of species minus the number of equilibrium reactions are set using this feature.

EQUILIBRIUM REACTIONS AND TIME-DEPENDENT SIMULATIONS

Spurious oscillations may occur in a time-dependent problem if the initial conditions do not fulfill the equilibrium condition. Since equilibrium reactions are assumed to be infinitely fast, the solution is to initialize the problem using an additional study step, solving for a stationary problem with all nonequilibrium reaction rates set to zero. Manual scaling of the reaction rate dependent variables is needed in this study step.

Material Balance Formulation

The default node attributed to The Transport of Diluted Species Interface assumes chemical species transport through diffusion and convection (depending on the modules licensed, a checkbox to activate migration is available) and implements the mass balance equation in Equation 12-1.

Two formulations of the mass balance are available, these are referred to as the nonconservative and conservative form:

$$\text{nonconservative: } \frac{\partial c}{\partial t} + \nabla \cdot \mathbf{J}_i + \mathbf{u} \cdot \nabla c = R \qquad (12\text{-}3)$$

$$\text{conservative: } \frac{\partial c}{\partial t} + \nabla \cdot \mathbf{J}_i + \nabla \cdot (c\mathbf{u}) = R \tag{12-4}$$

In these equations $\mathbf{J}_i$ is the diffusive flux vector, $\mathbf{u}$ is the solvent velocity field, and R is a production or consumption rate expression. The nonconservative is often more numerically robust, and therefore chosen by default for the interface. This formulation however disregards density changes in the fluid. This can be seen by expanding the conservative convection term using the chain rule. One of the resulting terms, $c\nabla\cdot\mathbf{u}$, equals zero for an incompressible fluid which results in the nonconservative form. To switch between the two formulations, click the **Show** button ( ) and select **Advanced Physics Options**.

Solving a Diffusion Equation Only

Remove the convection term from Equation 12-3 and Equation 12-4 by clearing the Convection checkbox in the Transport Mechanisms section for The Transport of Diluted Species Interface. The equation then becomes

$$\frac{\partial c}{\partial t} = \nabla \cdot \mathbf{J}_i + R$$

Mass Sources for Species Transport

Note: The features below are only available in a limited set of add-on products. For a detailed overview of which features are available in each product, visit https://www.comsol.com/products/specifications/

There are two types of mass sources in the Transport of Diluted Species interface: point sources and line sources.

POINT SOURCE

A point source is theoretically formed by assuming a mass injection/ejection, Q_c (SI unit: mol/(m^3·s)), in a small volume δV and then letting the size of the volume tend to zero while keeping the total mass flux constant. Given a point source strength, $\dot{q}_{p,c}$ (SI unit: mol/s), this can be expressed as

$$\lim_{\delta V \to 0} \int_{\delta V} Q_c = \dot{q}_{p,c} \tag{12-5}$$

An alternative way to form a point source is to assume that mass is injected/extracted through the surface of a small object. Letting the object surface area tend to zero while keeping the mass flux constant results in the same point source. For this alternative approach, effects resulting from the physical object's volume need to be neglected.

The weak contribution

$$\dot{q}_{p,c}\text{test}(c)$$

is added at a point in the geometry. As can be seen from Equation 12-5, Q_c must tend to plus or minus infinity as δV tends to zero. This means that in theory the concentration also tends to plus or minus infinity.

Observe that "point" refers to the physical representation of the source. A point source can therefore only be added to points in 3D components and to points on the symmetry axis in 2D axisymmetry components. Other geometrical points in 2D components represent physical lines.

The finite element representation of Equation 12-5 corresponds to a finite concentration at a point with the effect of the point source spread out over a region around the point. The size of the region depends on the mesh and on

the strength of the source. A finer mesh gives a smaller affected region but also a more extreme concentration value. It is important not to mesh too finely around a point source since this can result in unphysical concentration values. It can also have a negative effect on the condition number for the equation system.

LINE SOURCE

A line source can theoretically be formed by assuming a source of strength $Q_{l,c}$ (SI unit: mol/(m^3·s)), located within a tube with cross section δS and then letting δS tend to zero while keeping the total mass flux per unit length constant. Given a line source strength, $\dot{q}_{l,c}$ (SI unit: mol/(m·s)), this can be expressed as

$$\lim_{\delta S \to 0} \int_{\delta S} Q_{l,c} = \dot{q}_{l,c} \tag{12-6}$$

As in the point source case, an alternative approach is to assume that mass is injected/extracted through the surface of a small object. This results in the same mass source, but requires that effects resulting from the physical object's volume are neglected.

The weak contribution

$$q_{l,c}\text{test}(c)$$

is added on lines in 3D or at points in 2D (which represent cut-through views of lines). Line sources can also be added on the axisymmetry line in 2D axisymmetry components. It cannot, however, be added on geometrical lines in 2D since those represent physical planes.

As with a point source, it is important not to mesh too finely around the line source.

For feature node information, see Line Mass Source and Point Mass Source.

Adding Transport Through Migration

Note: Migration is only available in a limited set of add-on products. For a detailed overview of which features are available in each product, visit https://www.comsol.com/products/specifications/

In addition to transport due to convection and diffusion, the Transport of Diluted Species interface supports ionic species transport by *migration*. This is done by selecting the Migration in Electric Field checkbox under the Transport Mechanisms section for the physics interface. The mass balance then becomes:

$$\frac{\partial c_i}{\partial t} + \nabla \cdot (-D_i \nabla c_i - z_i u_{m,i} F c_i \nabla V + c_i \mathbf{u}) = R_i \tag{12-7}$$

where

- c_i (SI unit: mol/ m^3) denotes the concentration of species i
- D_i (SI unit: m^2/s) is the diffusion coefficient of species i
- $\mathbf{u}$ (SI unit: m/s) is the fluid velocity
- F (SI unit: A·s/mol) refers to Faraday's constant
- V (SI unit: V) denotes the electric potential

- z_i (dimensionless) is the charge number of the ionic species, and
- $u_{\mathrm{m},i}$ (SI unit: mol·s/kg) is its ionic mobility

In this case the diffusive flux vector is

$$\mathbf{J}_i = -D_i \nabla c_i - z_i u_{\mathrm{m},i} F c_i \nabla V$$

The velocity, $\mathbf{u}$, can be a computed fluid velocity field from a Fluid Flow interface or a specified function of the spatial variables x, y, and z. The potential can be provided by an expression or by coupling the system of equations to a current balance, such as the Electrostatics interface. Sometimes it is assumed to be a supporting electrolyte present, which simplifies the transport equations. In that case, the modeled charged species concentration is very low compared to other ions dissolved in the solution. Thus, the species concentration does not influence the solution's conductivity and the net charge within the fluid.

The Nernst–Einstein relation can in many cases be used for relating the species mobility to the species diffusivity according to

$$u_{m,i} = \frac{D_i}{RT}$$

where R (SI unit: J/(mol·K)) is the molar gas constant and T (SI unit: K) is the temperature.

Note: In the *Nernst–Planck Equations* interface, the ionic species contribute to the charge transfer in the solution. It includes an *electroneutrality condition* and also computes the electric potential field in the electrolyte. For more information, see Theory for the Nernst–Planck Equations Interface. This interface is included in the Chemical Reaction Engineering Module.

Supporting Electrolytes

In *electrolyte* solutions, a salt can be added to provide a high electrolyte conductivity and decrease the ohmic losses in a cell. These solutions are often called *supporting electrolytes*, buffer solutions, or carrier electrolytes. The added species, a negative and a positive ion pair, predominates over all other species. Therefore, the supporting electrolyte species can be assumed to dominate the current transport in the solution. In addition, the predominant supporting ions are usually selected so that they do not react at the electrode surfaces since the high conductivity should be kept through the process, that is, they should not be electroactive species. This also means that the concentration gradients of the predominant species in a supporting electrolyte are usually negligible.

Modeling and solving for a supporting electrolyte in the *Electrostatics* or *Secondary Current Distribution* interfaces will give a potential distribution that drives the migration in the Transport of Diluted Species Interface.

The current density vector is proportional to the sum of all species fluxes as expressed by Faraday's law:

$$\mathbf{i} = F \sum_i z_i \mathbf{N}_i$$

The electroneutrality condition ensures that there is always a zero net charge at any position in a dilute solution. Intuitively, this means that it is impossible to create a current by manually pumping positive ions in one direction and negative ions in the other. Therefore, the convective term is canceled out to yield the following expression for the electrolyte current density, where j denotes the supporting species:

$$\mathbf{i} = F\sum_j -z_j^2 u_{\mathrm{m},j} F c_j \nabla\phi \tag{12-8}$$

Equation 12-8 is simply Ohm's law for ionic current transport and can be simplified to

$$\mathbf{i} = -\kappa\nabla\phi \tag{12-9}$$

where κ is the conductivity of the supporting electrolyte. A current balance gives the current and potential density in the cell

$$\nabla \cdot \mathbf{i} = 0$$

which, in combination with Equation 12-9, yields:

$$\nabla \cdot (-\kappa\nabla\phi) = 0 \tag{12-10}$$

Equation 12-10 can be easily solved using the Electrostatics or Secondary Current Distribution interface and, when coupled to the Transport in Diluted Species interface, the potential distribution shows up in the migration term.

Crosswind Diffusion

Transport of diluted species applications can often result in models with a very high cell Péclet number — that is, systems where convection or migration dominates over diffusion. Streamline diffusion and crosswind diffusion are of paramount importance to obtain physically reasonable results. The Transport of Diluted Species interface provides two crosswind diffusion options using different formulations. Observe that crosswind diffusion makes the equation system nonlinear even if the transport equation is linear.

DO CARMO AND GALEÃO

This is the formulation described in Numerical Stabilization in the *COMSOL Multiphysics Reference Manual*. The method reduces over- and undershoots to a minimum, even for anisotropic meshes.

In some cases, the resulting nonlinear equation system can be difficult to converge. This can happen when the cell Péclet number is very high and the model contains many thin layers, such as contact discontinuities. You then have three options:

- Refine the mesh, especially in regions with thin layers.
- Use a nonlinear solver with a constant damping factor less than one.
- Switch to the Codina crosswind formulation.

CODINA

The Codina formulation is described in Ref. 1. It adds diffusion strictly in the direction orthogonal to the streamline direction. Compared to the do Carmo and Galeão formulation, the Codina formulation adds less diffusion but is not as efficient at reducing over- and undershoots. It also does not work as well for anisotropic meshes. The advantage is that the resulting nonlinear system is easier to converge and that underresolved gradients are less smeared out.

Danckwerts Inflow Boundary Condition

Constraining the composition to fixed values at an inlet to a reactor may sometimes result in issues with unreasonably high reaction rates or singularities at the inlet boundary. These problems may many times be mitigated by using a flux boundary condition instead, based on the upstream concentrations and the fluid velocity at the boundary. In chemical engineering, this type of flux boundary condition is also known as a Danckwerts condition.

Use the Danckwerts condition to specify inlet conditions for domains where high reaction rates are anticipated in the vicinity to the inlet (Ref. 2).

Given an upstream concentration $c_{i,0}$, the Danckwerts inflow boundary condition prescribed the total flux as

$$\mathbf{n} \cdot (\mathbf{J}_i + \mathbf{u}c_i) = \mathbf{n} \cdot (\mathbf{u}c_{i,0}) \tag{12-11}$$

Mass Balance Equation for Transport of Diluted Species in Porous Media

VARIABLY SATURATED POROUS MEDIA

The following equations for the molar concentrations, c_i, describe the transport of solutes in a variably saturated porous medium for the most general case, when the pore space is primarily filled with liquid but also contain pockets or immobile gas:

$$\frac{\partial}{\partial t}(\theta_l c_i) + \frac{\partial}{\partial t}(\rho c_{P,i}) + \frac{\partial}{\partial t}(\theta_g c_{G,i}) + \mathbf{u} \cdot \nabla c_i = \nabla \cdot [(D_{D,i} + D_{e,i})\nabla c_i] + R_i + S_i \tag{12-12}$$

On the left-hand side of Equation 12-12, the first three terms correspond to the accumulation of species within the liquid, solid, and gas phases, while the last term describes the convection due to the velocity field $\mathbf{u}$ (SI unit: m/s).

In Equation 12-12 c_i denotes the concentration of species i in the liquid (SI unit: mol/m^3), $c_{P,i}$ the amount adsorbed to solid particles (moles per unit dry weight of the solid), and $c_{G,i}$ the concentration of species i in the gas phase.

The equation balances the mass transport throughout the porous medium using the porosity ε_p, the liquid volume fraction θ_l; the dry bulk density, $\rho = (1 - \varepsilon_p)\rho_s$, and the solid phase density ρ_s.

For saturated porous media, the liquid volume fraction θ_l is equal to the porosity ε_p, but for unsaturated porous media, they are related by the saturation s as $\theta_l = \varepsilon_p s$. The resulting gas volume fraction in the case of an unsaturated porous medium is

$$\theta_g = \varepsilon_p - \theta_l = (1 - s)\varepsilon_p$$

On the right-hand side of Equation 12-12, the first term introduces the spreading of species due to mechanical mixing resulting from the porous media (dispersion), as well as from diffusion and volatilization to the gas phase. The dispersion tensor is denoted D_D (SI unit: m^2/s) and the effective diffusion by D_e (SI unit: m^2/s).

The last two terms on the right-hand side of Equation 12-12 describe production or consumption of the species; R_i is a reaction rate expression which can account for reactions in the liquid, solid, or gas phase, and S_i is an arbitrary source term, for example due to a fluid flow source or sink.

Adsorption

The time evolution of the adsorption, the solute transport to or from the solid phase, is defined by assuming that the amount of solute adsorbed to the solid, $c_{P,i}$, is a function of the concentration in the fluid c_i. This implies that the solute concentration in the liquid and solid phase are in instant equilibrium. The adsorption term can be expanded to give

$$\frac{\partial}{\partial t}(\rho c_{P,i}) = \rho \frac{\partial c_{P,i}}{\partial c_i}\frac{\partial c_i}{\partial t} - c_{P,i}\rho_s \frac{\partial \varepsilon_p}{\partial t} = \rho K_{P,i}\frac{\partial c_i}{\partial t} - c_{P,i}\rho_s \frac{\partial \varepsilon_p}{\partial t} \tag{12-13}$$

where $K_{P,i} = \partial c_{P,i}/\partial c_i$ is the adsorption isotherm.

Volatilization

Volatilization is the process where a solute species in the liquid is transported to the gas phase due to vaporization. Assuming that the amount of solute in the gas phase, $c_{G,i}$, is a linear function of the liquid phase concentration, the volatilization term is defined as

$$\frac{\partial}{\partial t}\theta_g c_{G,i} = \theta_g \frac{\partial c_{G,i}}{\partial c_i}\frac{\partial c_i}{\partial t} + k_{G,i} c_i \frac{\partial \theta_g}{\partial t} = \theta_g k_{G,i}\frac{\partial c_i}{\partial t} + k_{G,i} c_i \frac{\partial \theta_g}{\partial t} \quad (12\text{-}14)$$

where $k_{G,i} = \partial c_{G,i}/\partial c_i$ is the linear volatilization.

SATURATED POROUS MEDIA

In the case of transport in a saturated porous medium, $\theta_l = \varepsilon_p$, and the governing equations are

$$\frac{\partial}{\partial t}(\varepsilon_p c_i) + \frac{\partial}{\partial t}(\rho c_{P,i}) + \mathbf{u}\cdot\nabla c_i = \nabla\cdot[(D_{D,i} + D_{e,i})\nabla c_i] + R_i + S_i \quad (12\text{-}15)$$

Convection in Porous Media

Convection (also called advection) describes the movement of a species, such as a pollutant, with the bulk fluid velocity. The velocity field **u** corresponds to a superficial volume average over a unit volume of the porous medium, including both pores and matrix. This velocity is sometimes called *Darcy velocity*, and defined as volume flow rates per unit cross section of the medium. This definition makes the velocity field continuous across the boundaries between porous regions and regions with free flow.

The velocity field to be used in the Model Inputs section on the physics interface can, for example, be prescribed using the velocity field from a Darcy's Law or a Brinkman Equations interface.

The average linear fluid velocities $\mathbf{u}_a$, provides an estimate of the fluid velocity within the pores:

$$\mathbf{u}_a = \frac{\mathbf{u}}{\varepsilon_p} \quad \text{Saturated}$$

$$\mathbf{u}_a = \frac{\mathbf{u}}{\theta_l} \quad \text{Unsaturated}$$

where ε_p is the porosity and $\theta_l = s\varepsilon_p$ the liquid volume fraction, and s the saturation, a dimensionless number between 0 and 1.

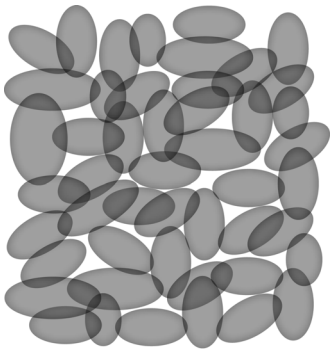

Figure 12-1: A block of a porous medium consisting of solids and the pore space between the solid grains. The average linear velocity describes how fast the fluid moves within the pores. The Darcy velocity attributes this flow over the entire fluid-solid face.

MATERIAL BALANCE FORMULATION

The Transport of Diluted Species interface in porous media includes two formulations of the material balance. The conservative formulation of the species equations in Equation 12-12 is written as:

$$\frac{\partial}{\partial t}(\theta_l c_i) + \frac{\partial}{\partial t}(\rho c_{P,i}) + \frac{\partial}{\partial t}(\theta_g c_{G,i}) + \nabla \cdot \mathbf{u} c_i = \nabla \cdot [(D_{D,i} + D_{e,i})\nabla c_i] + R_i + S_i \quad (12\text{-}16)$$

If the conservative formulation is expanded using the chain rule, then one of the terms from the convection part, $c_i \nabla \cdot \mathbf{u}$, would equal zero for an incompressible fluid and would result in the nonconservative formulation described in Equation 12-12.

When using the nonconservative formulation, which is the default, the fluid is assumed incompressible and divergence free: $\nabla \cdot \mathbf{u} = 0$. The nonconservative formulation improves the stability of systems coupled to a momentum equation (fluid flow equation).

To switch between the two formulations, click the **Show** button ( ) and select **Advanced Physics Options**. In the section **Advanced Settings** select either **Nonconservative** (the default) or **Conservative**. The conservative formulation should be used for compressible flow.

Diffusion in Porous Media

The effective diffusion in porous media, D_e, depends on the structure of the porous material and the phases involved. Dependent on whether the transport of diluted species occurs in free flow or in saturated or unsaturated porous media, the effective diffusivity is defined as:

$$D_e = D_F \quad \text{Free Flow}$$

$$D_e = \frac{\varepsilon_p}{\tau_L} D_L \quad \text{Saturated Porous Media}$$

$$D_e = \frac{\theta_l}{\tau_L} D_L \quad \text{Unsaturated Porous Media}$$

$$D_e = \frac{\theta_l}{\tau_L} D_L + \frac{\theta_g}{\tau_G} k_G D_G \quad \text{Unsaturated with Volatilization}$$

Here D_F, D_L, and D_G are the single-phase diffusion coefficients for the species diluted in a fluid, a pure liquid, and a gas phase, respectively (SI unit: m^2/s), and τ_F, τ_L, and τ_G are the corresponding tortuosity factors (dimensionless).

The tortuosity factor accounts for the reduced diffusivity due to the fact that the solid grains impede Brownian motion. The interface provides predefined expressions to compute the tortuosity factors in partially saturated porous media according to the Millington and Quirk model (Ref. 3):

$$\tau_L = \theta_l^{-7/3}\varepsilon_p^{\ 2},\ \tau_G = \theta_g^{-7/3}\varepsilon_p^{\ 2}$$

and Bruggeman model

$$\tau_L = \theta_l^{-5/2}\varepsilon_p^{\ 2},\ \tau_G = \theta_g^{-5/2}\varepsilon_p^{\ 2}$$

For saturated porous media $\theta_l = \varepsilon_p$. The fluid tortuosity for the Millington and Quirk model is

$$\tau_L = \varepsilon_p^{-1/3}$$

and for the Bruggeman model the tortuosity is defined as

$$\tau_L = \varepsilon_p^{-1/2}$$

User defined expressions for the tortuosity factor can also be applied.

Dispersion

The contribution of dispersion to the mixing of species typically overshadows the contribution from molecular diffusion, except when the fluid velocity is very low.

The spreading of mass, as a fluid travel through a porous medium is caused by several contributing effects. Local variations in fluid velocity lead to mechanical mixing referred to as dispersion occurs because the fluid in the pore space flows around solid particles, so the velocity field varies within pore channels. The spreading in the direction parallel to the flow, or *longitudinal dispersivity*, typically exceeds the *transverse dispersivity* from up to an order of magnitude. Being driven by the concentration gradient alone, molecular diffusion rate is low relative to the mechanical dispersion, except at very low fluid velocities.

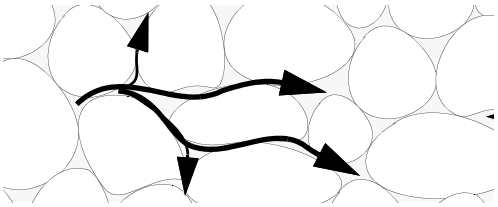

Figure 12-2: Spreading of fluid around solid particles in a porous medium.

The dispersion is controlled through the dispersion tensor D_D. The tensor components can either be given by user-defined values or expressions or derived from the directional dispersivities.

Using the longitudinal and transverse dispersivities in 2D, the dispersivity tensor components are (Ref. 5):

$$D_{Dii} = \alpha_L\frac{u_i^2}{|\mathbf{u}|} + \alpha_T\frac{u_j^2}{|\mathbf{u}|}$$

$$D_{\mathrm{D}ij} = D_{\mathrm{D}ji} = (\alpha_\mathrm{L} - \alpha_\mathrm{T})\frac{u_i u_j}{|\mathbf{u}|}$$

In these equations, $D_{\mathrm{D}ii}$ (SI unit: m^2/s) are the principal components of the dispersivity tensor, and $D_{\mathrm{D}ji}$ and $D_{\mathrm{D}ji}$ are the cross terms. The parameters α_L and α_T (SI unit: m) specify the longitudinal and transverse dispersivities; and u_i (SI unit: m/s) stands for the velocity field components.

In order to facilitate modeling of stratified porous media in 3D, the tensor formulation by Burnett and Frind (Ref. 4) can be used. Consider a transverse isotropic media, where the strata are piled up in the z direction, the dispersivity tensor components are:

$$\begin{aligned}
D_{\mathrm{L}xx} &= \alpha_1\frac{u^2}{|\mathbf{u}|} + \alpha_2\frac{v^2}{|\mathbf{u}|} + \alpha_3\frac{w^2}{|\mathbf{u}|}\\
D_{\mathrm{L}yy} &= \alpha_1\frac{v^2}{|\mathbf{u}|} + \alpha_2\frac{u^2}{|\mathbf{u}|} + \alpha_3\frac{w^2}{|\mathbf{u}|}\\
D_{\mathrm{L}zz} &= \alpha_1\frac{w^2}{|\mathbf{u}|} + \alpha_3\frac{u^2}{|\mathbf{u}|} + \alpha_3\frac{v^2}{|\mathbf{u}|}\\
D_{\mathrm{L}xy} &= D_{\mathrm{L}yx} = (\alpha_1 - \alpha_2)\frac{uv}{|\mathbf{u}|}\\
D_{\mathrm{L}xz} &= D_{\mathrm{L}zx} = (\alpha_1 - \alpha_3)\frac{uw}{|\mathbf{u}|}\\
D_{\mathrm{L}yz} &= D_{\mathrm{L}zy} = (\alpha_1 - \alpha_3)\frac{vw}{|\mathbf{u}|}
\end{aligned} \tag{12-17}$$

In Equation 12-17 the fluid velocities u, v, and w correspond to the components of the velocity field $\mathbf{u}$ in the x, y, and z directions, respectively, and α_1 (SI unit: m) is the longitudinal dispersivity. If z is the vertical axis, α_2 and α_3 are the dispersivities in the transverse horizontal and transverse vertical directions, respectively (SI unit: m). Setting $\alpha_2 = \alpha_3$ gives the expressions for isotropic media shown in Bear (Ref. 5 and Ref. 6).

Adsorption

As species travel through a porous medium they typically attach to (adsorb), and detach (desorb) from the solid phase, which slows chemical transport through the porous medium. Adsorption and desorption respectively reduces or increases species concentrations in the fluid. The adsorption properties vary between chemicals, so a plume containing multiple species can separate into components (Ref. 7). The Adsorption feature includes four predefined and one user-defined relationships to predict the solid concentrations, $c_{\mathrm{P}i}$ from the concentration in the liquid phase, c_i:

$$\begin{aligned}
c_\mathrm{P} &= c_{\mathrm{P}\max}\frac{K_\mathrm{L}c}{1 + K_\mathrm{L}c} && \text{Langmuir}\\
c_\mathrm{P} &= K_\mathrm{F}\left(\frac{c}{c_\mathrm{ref}}\right)^N && \text{Freundlich}\\
c_\mathrm{P} &= c_{\mathrm{P}\max}\frac{b_\mathrm{T}c}{\left(1 + (b_\mathrm{T}c)^{N_\mathrm{T}}\right)^{1/N_\mathrm{T}}} && \text{Toth}\\
c_\mathrm{P} &= \frac{K_\mathrm{B}c_0 c}{(c_\mathrm{S} - c)\left(1 + (K_\mathrm{B} - 1)\frac{c}{c_\mathrm{S}}\right)} && \text{BET}
\end{aligned} \tag{12-18}$$

The above equations contains the following parameters:

- Freundlich (Ref. 8)
  - Freundlich constant K_F (SI unit:·mol/kg), Freundlich exponent N_F (dimensionless), and reference concentration c_{ref} (SI unit: mol/m^3).
- Langmuir (Ref. 9)
  - Langmuir constant K_L (SI unit: m^3/mol), and adsorption maximum c_{Pmax} (SI unit: mol/kg).
- Toth (Ref. 10)
  - Toth constant b_T (SI unit: m^3/mol), Toth exponent N_T (dimensionless), and adsorption maximum c_{Pmax} (SI unit: mol/kg).
- BET (Brunauer–Emmett–Teller, Ref. 11)
  - BET constant K_B (dimensionless), the monolayer adsorption capacity c_0 (SI unit: mol/kg) and the saturation concentration, c_S (SI unit: mol/m^3).

These predefined expressions are adsorption isotherms that describe the amount of species sorbed to the solid. Applying the isotherms, as defined in the Adsorption section above, assumes that adsorption is at equilibrium locally. This implies that the species phase transfer, between the fluid and the solid phase (within the porous medium), is much faster than the transport within the fluid phase.

Using a Species Source feature, arbitrary expressions can be entered to define, for example, nonequilibrium and temperature-dependent adsorption laws, in the manner of Fetter (Ref. 12), or Bear and Verruijt (Ref. 13).

The retardation factor, RF, describes how adsorption slows the solute velocity, $\mathbf{u}_c$, relative to the average linear velocity of the fluid, $\mathbf{u}_a$, as in

$$RF = 1 + \frac{\rho_b}{\theta}\frac{\partial c_P}{\partial c} = \frac{\mathbf{u}_a}{\mathbf{u}_c}$$

If the contaminant moves at the average linear velocity of the fluid for $RF = 1$. For $RF > 1$, the contaminant velocity is lower than the fluid velocity owing to residence time on solids.

Reactions

Chemical reactions of all types influence species transport in porous media. Examples include biodegradation, radioactive decay, transformation to tracked products, temperature- and pressure-dependent functions, exothermic reactions, and endothermic reactions. The reactions represent change in species concentration per unit volume porous medium per time. Reaction terms are used on the right-hand side of the governing equation to represent these processes. For reactions in a fluid phase, multiply the expression by the fluid volume fraction θ. Similarly, solid phase reaction expressions include the bulk density, ρ_b, and gas phase reactions include the gas volume fraction, a_v.

The following expressions define some common types of reactions:

$$R_{Li} = -\theta\frac{\ln 2}{\lambda_{Li}}c_i \quad \text{Radioactive decay — liquid}$$

$$R_{Pi} = -\rho_b\frac{\ln 2}{\lambda_{Pi}}\left(\frac{\partial c_{Pi}}{\partial c_i}\right)c_i \quad \text{Radioactive decay — solid}$$

$$R_{Gi} = -\frac{\ln 2}{\lambda_{Gi}}a_v\left(\frac{\partial c_{Gi}}{\partial c}\right)c_i \quad \text{Radioactive decay — gas}$$

$$R_{Lk} = \theta\zeta_{Li}c_i \quad \text{Creation from parent } c_{Li} \text{ — liquid}$$

$$R_{Pk} = \rho_b\zeta_{Pi}\left(\frac{\partial c_{Pi}}{\partial c_i}\right)c_i \quad \text{Creation from sorbed parent } c_{Pi} \text{ — solid}$$

$$R_{Gk} = -\zeta a_v\left(\frac{\partial c_{Gi}}{\partial c}\right)c_i \quad \text{Reaction — gas}$$

where λ is the chemical half life, ζ is a reaction rate, and the subscripts L, P, and G denote liquid, solid, and gas phases, respectively. In the equations, the reactions either depend on liquid concentration c_i or solid phase concentrations c_{Pi} obtained using the sorption derivative with c_i or gas phase concentration c_{Gi} depending on the gas volume fraction, the volatilization, and the liquid concentration.

Reaction rates can vary with results from other equations in your model, such as temperature. For example, enter the Arrhenius rate law given in Ref. 14:

$$\zeta_T = \zeta_R \exp\left[\frac{E_a(T - T_R)}{R_u T T_R}\right] \tag{12-19}$$

In Equation 12-19, T denotes the current absolute temperature, T_R denotes the reference absolute temperature, E_a is the activation energy, and R_u is the universal gas constant.

Mass Transport in Fractures

When thin fractures occur in porous media, fluid flow tends to move faster along the fracture than in the surrounding media. The transport of chemical species therefore also occur also faster in the direction of the fractures.

The fluid flow in a fracture can be modeled using Darcy's law formulated in a thin sheet of porous medium (a fracture):

$$\mathbf{u} = \frac{\kappa}{\mu}\nabla_t p$$

Here $\mathbf{u}$ is the tangential Darcy velocity, κ is the fracture permeability, μ the fluid's dynamic viscosity, and $\nabla_t p$ is the tangential gradient of the fluid pressure.

The equation to solve for mass transport of species c_i in a thin fracture, embedded in a porous media, is derived from Equation 12-12. The resulting equation is:

$$d_{fr}\left(\frac{\partial \rho_b c_{P,i}}{\partial t} + \frac{\partial \varepsilon_p c_i}{\partial t} + \nabla_t \cdot (D_{e,i}\nabla_t c_i) + \mathbf{u}\cdot\nabla_t c_i\right) = d_{fr}R_i + d_{fr}S_i + n_0 \tag{12-20}$$

Here d_{fr} is the fracture thickness, $c_{P,i}$ the amount of species adsorbed to (or desorbed from) the porous matrix (moles per unit dry weight of the solid), ε_p is the fracture porosity, and D_e is the effective diffusivity. The first two terms on the right hand side represent source terms from reactions, and n_0 corresponds to out-of plane flux from the adjacent porous domain.

In order to arrive at the tangential differential equation, the gradient is split into the contributions normal and tangential to the fracture:

$$\nabla c_i = \nabla_n c_i + \nabla_t c_i$$

The normal gradient is defined in the direction normal to the boundary representing the fracture and the tangential gradient is defined along the boundary. Assuming that the variations in the normal (thin) direction of the fracture are negligible compared to those in the tangential direction, the gradient is simplified as:

$$\nabla c_i = \nabla_t c_i$$

Using The Transport of Diluted Species in Fractures Interface, the transport along fracture boundaries alone is solved for. In this case the transport in the surrounding porous media neglected and the out-of plane flux n_0 vanishes.

See Fracture for more information about the boundary feature solving Equation 12-20. See for more information about the physics interface solving the equation on boundaries only.

The Transport of Diluted Species Interface

Mass transfer is an important part of chemical engineering because this field considers the conversion of one type of substance into another. A lot of this occurs through chemical reactions, although separation and other unit operations are an important part. You can use the Transport of Diluted Species interface to model transport of a diluted species in chemical systems by convection and diffusion.

In the Transport of Diluted Species interface, Fick's law describes the diffusive transport in the flux vector. Fick's law is adequate when the diffusing species is dilute with respect to a solvent. Assuming a binary mixture of solute A in solvent B, concentrations of up to 10 mol% of A can be considered dilute.

The optional Chemical Reaction Engineering Module has an extension of this physics interface for modeling multicomponent convection, diffusion, and migration (electrokinetic flow).

The **Transport of Diluted Species (tds)** interface ( ), found under the **Chemical Species Transport** branch ( ), is used to calculate the concentration field of a dilute solute in a solvent. Transport and reactions of the species dissolved in a gas, liquid, or solid can be handled with this interface. The driving forces for transport can be diffusion by Fick's law, convection when coupled to a flow field, and migration, when coupled to an electric field.

The interface supports simulation of transport by convection and diffusion in 1D, 2D, and 3D as well as for axisymmetric components in 1D and 2D. The dependent variable is the molar concentration, c. Modeling multiple species transport is possible, whereby the physics interface solves for the molar concentration, c_i, of each species i.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `tds`.

DOMAIN SELECTION

If any part of the model geometry should not partake in the mass transfer model, remove that part from the selection list.

OUT-OF-PLANE THICKNESS

For 2D components, the **Thickness** field (default value: 1 m) defines a parameter for the thickness of the geometry perpendicular to the two-dimensional cross-section. Both constant and varying thicknesses are supported. The value of this parameter is used, among other things, to automatically calculate molar flow rates from the total molar flux.

CROSS-SECTIONAL AREA

For 1D components, enter a **Cross-sectional area** A_c (SI unit: m^2) to define a parameter for the area of the geometry perpendicular to the 1D component. Both constant and varying areas are supported. The value of this parameter is used, among other things, to automatically calculate molar flow rates from the total molar flux. The default is 1 m^2.

TRANSPORT MECHANISMS

Mass transport due to diffusion is always included. Use the checkboxes available under **Additional transport mechanisms** to control other transport mechanisms.

Note: Some of the additional transport mechanisms listed below are only available in certain products. For details see https://www.comsol.com/products/specifications/.

- By default, the **Convection** checkbox is selected. Clear the checkbox to disable convective transport.
- Select the **Migration in electric field** checkbox to activate transport of ionic species in an electric field. See further the theory section Adding Transport Through Migration.

!	Transport of ionic species in an electric field is available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

Mass Transport in Porous Media

The **Mass transport in porous media** checkbox activates functionality specific to species transport in porous media:

- Porous Medium
- Unsaturated Porous Medium
- Porous Electrode Coupling
- Volatilization
- Species Source

!	Note: Mass transport in porous media is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

CONSISTENT STABILIZATION

To display this sections, click the **Show** button ( ) and select **Stabilization**.

- When the **Crosswind diffusion** checkbox is selected, a weak term that reduces spurious oscillations is added to the transport equation. The resulting equation system is always nonlinear. There are two options for the **Crosswind diffusion type**:
  - **Do Carmo and Galeão** — the default option. This type of crosswind diffusion reduces undershoots and overshoots to a minimum but can in rare cases give equation systems that are difficult to fully converge.
  - **Codina** — this option is less diffusive compared to the Do Carmo and Galeão option but can result in more undershoots and overshoots. It is also less effective for anisotropic meshes. The Codina option activates a text field for the **Lower gradient limit** g_{lim}. Its defaults to `0.1[mol/m^3]/tds.helem`, where `tds.helem` is the local element size.
- For both consistent stabilization methods, select an **Equation residual**. **Approximate residual** is the default and means that derivatives of the diffusion tensor components are neglected. This setting is usually accurate enough and is computationally faster. If required, select **Full residual** instead.

INCONSISTENT STABILIZATION

To display this section, click the **Show** button ( ) and select **Stabilization**. By default, the **Isotropic diffusion** checkbox is not selected, because this type of stabilization adds artificial diffusion and affects the accuracy of the original problem. However, this option can be used to get a good initial guess for under resolved problems.

ADVANCED SETTINGS

To display this section, click the **Show** button ( ) and select **Advanced Physics Options**. Normally these settings do not need to be changed. Select a **Material Balance Form** — **Nonconservative** (the default) or **Conservative**. The conservative formulation should be used for compressible flow. See Material Balance Formulation for more information.

DISCRETIZATION

To display all settings available in this section, click the **Show** button ( ) and select **Advanced Physics Options**.

The **Compute boundary fluxes** checkbox is activated by default so that COMSOL Multiphysics computes predefined accurate boundary flux variables. When this option is selected, the solver computes variables storing accurate boundary fluxes from each boundary into the adjacent domain.

If the checkbox is cleared, the COMSOL Multiphysics software instead computes the flux variables from the dependent variables using extrapolation, which is less accurate in postprocessing results but does not create extra dependent variables on the boundaries for the fluxes.

The flux variables affected in the interface are:

- `ndflux_`*c* (where *c* is the dependent variable for the concentration). This is the normal diffusive flux and corresponds to the boundary flux when diffusion is the only contribution to the flux term.
- `ntflux_`*c* (where *c* is the dependent variable for the concentration). This is the normal total flux and corresponds to the boundary flux plus additional transport terms, for example, the convective flux when you use the nonconservative form.

Also the **Apply smoothing to boundary fluxes** checkbox is available if the previous checkbox is selected. The smoothing can provide a more well-behaved flux value close to singularities.

For details about the boundary fluxes settings, see Computing Accurate Fluxes in the *COMSOL Multiphysics Reference Manual*.

The **Value type when using splitting of complex variables** setting should in most pure mass transfer problems be set to **Real**, which is the default. It makes sure that the dependent variable does not get affected by small imaginary contributions, which can occur, for example, when combining a Time Dependent or Stationary study with a frequency-domain study. For more information, see Splitting Complex-Valued Variables in the *COMSOL Multiphysics Reference Manual*.

DEPENDENT VARIABLES

The dependent variable name is the **Concentration** *c* by default. The names must be unique with respect to all other dependent variables in the component.

Add or remove species variables in the model and also change the names of the dependent variables that represent the species concentrations.

Enter the **Number of species**. Use the **Add concentration** (+) and **Remove concentration** ( ) buttons as needed.

The Transport of Diluted Species in Porous Media Interface

This interface ( ), found under the **Chemical Species Transport** branch ( ), is used to calculate the species concentration and transport in free and porous media. The interface is the same as the *Transport of Diluted Species* interface but it uses other defaults: The Mass Transport in Porous Media property is selected, and a Porous Medium node is added by default. The interface includes reaction rate expressions and solute sources for modeling of species transport and reaction in porous media.

This interface is dedicated to modeling transport in porous media, including immobile and mobile phases, where the chemical species may be subjected to diffusion, convection, migration, dispersion, adsorption, and volatilization in porous media. It supports cases where either the solid phase substrate is exclusively immobile, or when a gas-filling medium is also assumed to be immobile.

It applies to one or more diluted species or solutes that move primarily within a fluid that fills (saturated) or partially fills (unsaturated) the voids in a solid porous medium. The pore space not filled with fluid contains an immobile gas phase. Models including a combination of porous media types can be studied.

The main feature nodes are the **Porous Medium** and **Unsaturated Porous Medium** nodes, which add the equations for the species concentrations and provide an interface for defining the properties of the porous media, as well as additional properties governing adsorption, volatilization, dispersion and diffusion, migration, and the velocity field to model convection.

The physics interface can be used for stationary and time-dependent analysis.

When this physics interface is added, these default nodes are also added to the **Model Builder** — **Porous Medium**, **No Flux** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions, reaction rate expressions, and species sources. You can also right-click **Transport of Diluted Species in Porous Media** to select physics features from the context menu.

SETTINGS

The rest of the settings are the same as The Transport of Diluted Species Interface.

Some features require certain add-on modules. For details see https://www.comsol.com/products/specifications/

For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node that is valid on boundaries representing the symmetry axis.

In the *COMSOL Multiphysics Reference Manual*, see Table 2-4 for links to common sections and Table 2-5 for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Prescribing Conditions on Fluid-Solid Interfaces

Defining conditions on interfaces between different phases, typically a wall in contact with a fluid, it is worthwhile to be careful with how variables in the conditions are evaluated. COMSOL Multiphysics supports that variables are defined differently on adjacent domains (or any other geometry dimension). Evaluating a variable with differing definitions, the mean value is returned on a boundary separating the different domains. The density, pressure, or

temperature are examples of variables that may differ in a fluid and a solid. In order to specify on which side a variable is evaluated, the up and down operators (described in the *COMSOL Multiphysics Reference Manual*) can be used.

Species Properties

Use this node to define parameters specific to each of the species. It is available when the **Migration in electric field** checkbox is selected in the Transport Mechanisms section of the interface.

The node will change its label depending on what inputs are available in the node. If only **Charge** is available, it will be labeled "Species charges".

CHARGE

Enter the charge number z_c (dimensionless, but requires a plus or minus sign) for each species.

ACTIVITY

This section is available when the **Species Activity** combo box is set to **Debye–Hückel** or **User defined**.

If **Debye–Hückel** is selected, enter the ion size number, a_0, for each species. If **User defined** is selected, enter the activity coefficient, f, for each species.

Fluid

The settings in this node are dependent on the checkboxes selected under Transport Mechanisms in the **Settings** window for the Transport of Diluted Species interface. It includes only the sections required by the activated transport mechanisms. It has all the equations defining transport of diluted species as well as inputs for the material properties.

MODEL INPUTS

The temperature model input is always available. Select the source of the **Temperature**. For **User defined**, enter a value or expression for the temperature in the input field. This input option is always available.

You can also select the temperature solved for by a Heat Transfer interface added to the model component. These physics interfaces are available for selection in the **Temperature** list.

CONVECTION

If transport by convection is active, the velocity field of the solvent needs to be specified. Select the source of the **Velocity field**. For **User defined**, enter values or expressions for the velocity components in the input fields. This input option is always available.

You can also select the velocity field solved for by a Fluid Flow interface added to the model component. These physics interfaces are available for selection in the **Velocity field** list.

DIFFUSION

Use this section to specify diffusion coefficients describing the diffusion of each species in the solvent fluid.

Use the **Source** list to select diffusion coefficients defined in a material or a Chemistry interface.

Select **Material** to use a diffusion coefficient in a material available in the model. User-defined property groups including a diffusion coefficient output property are available for selection in the **Fluid diffusion coefficient** list.

Select **Chemistry** to use a diffusion coefficient from a Chemistry interface added to model component. Diffusion coefficients are automatically defined when **Calculate transport properties** is selected on the interface level of a Chemistry interface. All defined diffusion coefficients are available for selection in the **Fluid diffusion coefficient** list.

For **User defined**, enter a value or expression for the **Fluid diffusion coefficient** D_c of each species in the corresponding input field. This can be a scalar value for isotropic diffusion or a tensor describing anisotropic diffusion. Select the appropriate tensor type — **Isotropic**, **Diagonal**, **Symmetric**, or **Full** that describes the diffusion transport, and then enter the values in the corresponding element (one value for each species).

Note that multiple species, as well as Migration in Electric fields (described below) is only available for certain COMSOL Multiphysics add-on products. See details: https://www.comsol.com/products/specifications/.

MIGRATION IN ELECTRIC FIELD

This section is available when the **Migration in electric field** checkbox is selected. From the **Electric potential** list, select the source of the electric field.

- Enter a value or expression for the **Electric potential** V, which is **User defined**; this input option is always available.
- Select the electric potential solved by an AC/DC-based interface that has also been added to the model.
- Select the electric potential defined or solved by Electrochemistry interface that has been added to the component.

By default the **Mobility** is set to be calculated based on the species diffusivity and the temperature using the **Nernst-Einstein relation**. For **User defined**, and under **Mobility**, select the appropriate scalar or tensor type — **Isotropic**, **Diagonal**, **Symmetric**, or **Full** — and type in the value of expression of the mobility $u_{m,c}$.

Enter the **Charge number** z_c (dimensionless, but requires a plus or minus sign) for each species.

The temperature (if you are using mobilities based on the Nernst–Einstein relation) is taken from **Model Inputs** section.

Note that the migration in electric fields feature is only available in some COMSOL products. See details: https://www.comsol.com/products/specifications/.

EXAMPLE MODELS

	• *Separation Through Dialysis*: Application Library path **Chemical_Reaction_Engineering_Module/Mixing_and_Separation/dialysis** Web link: https://www.comsol.com/model/separation-through-dialysis-258
	• *Transport in an Electrokinetic Valve*: Application Library path **Microfluidics_Module/Fluid_Flow/electrokinetic_valve** Web link: https://www.comsol.com/model/transport-in-an-electrokinetic-valve-603

Solid

Use this node to describe diffusion in a solid phase domain. In this feature, the activities of the species are assumed to be ideal.

DIFFUSION

Specify the diffusion coefficients describing the diffusion of each species in the solid.

Enter a value or expression for the **Diffusion coefficient** D_c of each species in the corresponding input field. This can be a scalar value for isotropic diffusion or a tensor describing anisotropic diffusion. Select the appropriate tensor

type — **Isotropic**, **Diagonal**, or **Symmetric** that describes the diffusion transport, and then enter the values in the corresponding element (one value for each species).

ADVANCED

This section is only available with the **Advanced Physics Options** selected and when the model contains a split between the material frame and the spatial frame. A split of these frames occurs when using a **Moving Mesh** node or a Structural Mechanics interface like **Solid Mechanics**. In such a model, the reference geometry (the material frame) differs from the deformed geometry (the spatial frame). The diffusive transport of species is solved for on the material frame, but the equation is adjusted for geometry deformations so that species conservation is achieved on the spatial frame. Use the **Diffusion model** to define the frame of reference for the diffusion tensor.

Select **Reference geometry based (Lagrangian)** to specify the diffusion tensor in the undeformed geometry, implying that the diffusion is defined in the material frame (indicated by coordinates X, Y, Z). This is the preferred setting for an anisotropic diffusion in combination with solid body translation or rotation. Also in general when the diffusion tensor components have been measured in an undeformed geometry.

Select **Deformed geometry based (Eulerian)** to specify the diffusion tensor in the deformed geometry. This means that the diffusion is defined in the spatial frame (indicated by coordinates x, y, z). Use this setting when the diffusion tensor components have been measured in a deformed geometry.

The **Advanced Physics Options** is found in the **Show More Options** dialog, accessed by clicking the **Show More Options** button ( ).

Note that multiple species are only available for certain COMSOL Multiphysics add-on products. See details: https://www.comsol.com/products/specifications/.

Initial Values

The **Initial Values** node specifies the initial values for the concentration of each species. These serve as an initial guess for a stationary solver or as initial conditions for a transient simulation.

DOMAIN SELECTION

If there are several types of domains with different initial values defined, it might be necessary to remove some domains from the selection. These are then defined in an additional **Initial Values** node.

INITIAL VALUES

Enter a value or expression for the initial value of the **Concentration** or concentrations, c_i. This also serves as a starting guess for stationary problems.

Mass-Based Concentrations

Use the **Mass-Based Concentrations** node to add postprocessing variables for mass-based concentrations (SI unit: kg/m^3) and mass fractions (dimensionless) for all species.

MIXTURE PROPERTIES

The default **Solvent density** ρ_{solvent} is taken **From material**. For **User defined**, enter a value or expression manually. Define the **Molar mass** of each species, which is needed to calculate the mass-based concentration.

Reactions

Use the **Reactions** node to account for the consumption or production of species through chemical reactions. Define the rate expressions as required.

DOMAIN SELECTION

From the **Selection** list, choose the domains on which to define rate expression or expressions that govern the source term in the transport equations.

Several reaction nodes can be used to account for different reactions in different parts for the modeling geometry.

REACTION RATES

Add a rate expression R_i (SI unit: mol/(m^3·s)) for species i. Enter a value or expression in the field. Note that if you have the *Chemistry* interface available, provided with the *Chemical Reaction Engineering Module*, the reaction rate expressions can be automatically generated and picked up using the drop-down lists. For an example, see the application *Fine Chemical Production in a Plate Reactor* as linked below.

REACTING VOLUME

This section is only available when the Mass Transport in Porous Media property is available and selected. See https://www.comsol.com/products/specifications/ for more details on availability.

When specifying reaction rates for a species in porous media, the specified reaction rate may have the basis of the total volume, the pore volume, or in the case of using the volume of a particular phase (applicable when modeling an unsaturated porous medium).

- For **Total volume**, the reaction expressions, in mol/(m^3·s), are specified per unit volume of the model domain (multiplied by unity).
- For **Pore volume**, the reaction expressions, in mol/(m^3·s), are specified per unit volume of total pore space. The reaction expressions will be multiplied by the domain porosity, ε_p. (ε_p equals unity for nonporous domains).
- For **Liquid phase**, the reaction expressions, in mol/(m^3·s), are specified per unit volume of liquid in the pore space. The expressions will be multiplied by the liquid volume fraction θ_l. (θ_l equals the porosity (ε_p) on Porous Medium domains).
- For **Gas phase**, the reaction expressions, in mol/(m^3·s), are multiplied by the gas volume fraction $\theta_g = \varepsilon_p - \theta_l$. θ_g equals 0 for Porous Medium domains.

FURTHER READING

See the theory chapter on chemical species transport, starting with the section *Mass Balance Equation*.

- *Fine Chemical Production in a Plate Reactor*: Application Library path **Chemical_Reaction_Engineering_Module/ Reactors_with_Mass_and_Heat_Transfer/plate_reactor**

  Web link: https://www.comsol.com/model/fine-chemical-production-in-a-plate-reactor-8589

No Flux

This node is the default boundary condition on exterior boundaries. It should be used on boundaries across which there is no mass flux, typically solid walls where no surface reactions occur. The condition applied for each species corresponds to

$$-\mathbf{n} \cdot (-D\nabla c) = 0$$

where $\mathbf{n}$ denotes the outward pointing normal of the boundary. When the mass transport includes migration of ionic species, the no flux condition is:

$$-\mathbf{n} \cdot (-D\nabla c - zu_m Fc\nabla\phi) = 0$$

CONVECTION

By default, the feature prescribes a vanishing flux due to diffusion and migration in an electric field. This is the appropriate no flux condition when the relative convective velocity at the boundary is zero. When the fluid velocity at the boundary is not equal to that of the boundary, it is often convenient to prescribe the total flux including the convection. To do this select **Include** in the **Convection** section.

When including the convection, the no flux condition prescribed is

$$-\mathbf{n} \cdot (-D\nabla c + \mathbf{u}c) = 0$$

or

$$-\mathbf{n} \cdot (-D\nabla c - zu_{\mathrm{m}}Fc\nabla\phi + \mathbf{u}c) = 0$$

when migration of ionic species is included.

Inflow

Use this node to specify all species concentrations at an inlet boundary.

If you want to specify the concentration of a subset of the partaking species, this can be done by using the Concentration node instead.

For the **Electroanalysis** interface, this node is available when you select the **Convection** checkbox on the physics interface **Settings** window.

CONCENTRATION

For the concentration of each species $c_{0,c}$ (SI unit: $\mathrm{mol/m^3}$), enter a value or expression.

BOUNDARY CONDITION TYPE

The option **Concentration constraint** constrains the concentration values on the boundary by the use of pointwise constraints.

The other option, **Flux (Danckwerts)** can be used when the concentration at the boundary is not known, or when it varies in a nontrivial manner. This may, for example, be useful when reactions with high reaction rates occur in the vicinity of the inlet. In this case the concentration far upstream of the boundary is instead prescribed. The **Flux (Danckwerts)** condition prescribes the total flux defined by the upstream concentration and the fluid velocity at the boundary.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options**. You can find details about the different constraint settings in the section Constraint Reaction Terms in the *COMSOL Multiphysics Reference Manual*.

FURTHER READING

See the theory chapter in the section Danckwerts Inflow Boundary Condition.

Outflow

Apply this condition at outlets boundaries where species should be transported out of the model domain by fluid motion or by an electric field (in the case of ions). It is assumed that convection and migration (in an electric field) are the dominating transport mechanisms across the boundary, and therefore that the diffusive transport can be ignored, that is:

$$\mathbf{n} \cdot (-D\nabla c) = 0$$

Note that the **Convection** or the **Migration in electric field** transport mechanisms needs to be included for this node to be available.

Concentration

This condition node adds a boundary condition for the species concentration. For example, a $c = c_0$ condition specifies the concentration of species c.

CONCENTRATION

Individually specify the concentration for each species. Select the checkbox for the **Species** to specify the concentration, and then enter a value or expression in the corresponding field. To use another boundary condition for a specific species, click to clear the checkbox for the concentration of that species.

When defining conditions on boundaries between different phases, see the section Prescribing Conditions on Fluid-Solid Interfaces.

CONSTRAINT SETTINGS

To display this section, click the **Show** button ( ) and select **Advanced Physics Options**. You can find details about the different constraint settings in the section Constraint Reaction Terms in the *COMSOL Multiphysics Reference Manual*.

Flux

This node can be used to specify the species molar flux across a boundary. The flux can for example occur due to chemical reactions or a phase change at the boundary. The flux can also represent the transport to or from a surrounding environment currently not included model.

The prescribed flux of a species c is by default defined as

$$-\mathbf{n} \cdot (-D\nabla c) = J_0$$

where $\mathbf{n}$ denotes the outward pointing normal of the boundary. When the mass transport includes migration of ionic species, the flux is defined as:

$$-\mathbf{n} \cdot (-D\nabla c - zu_{\mathrm{m}}Fc\nabla\phi) = J_0$$

The flux prescribed, J_0, can include any arbitrary user-specified expression. It can be constant or a function of a dependent variable or independent variable. Common examples are a flux dependent of the concentration, temperature, pressure, or the electric potential ϕ.

When defining conditions on boundaries between different phases, see the section Prescribing Conditions on Fluid-Solid Interfaces.

CONVECTION

By default, the flux due to diffusion and migration in an electric field is prescribed. This is the appropriate flux condition when the relative velocity at the boundary is zero. When the fluid velocity is not equal to that of the boundary, it is often convenient to prescribe the total flux, including the convection. To do this select **Include** in the **Convection** section.

When including the convection, the prescribed flux is defined as:

$$-\mathbf{n} \cdot (-D\nabla c + \mathbf{u}c) = J_0$$

or

$$-\mathbf{n}\cdot(-D\nabla c - zu_{\mathrm{m}}Fc\nabla\phi + \mathbf{u}c) = J_0$$

when migration of ionic species is included.

INWARD FLUX

Select the Species checkbox for the species for which to specify the flux, and enter a value or expression for the inward flux in the corresponding field. Use a minus sign when specifying a flux directed out of the system. To use another boundary condition for a specific species, click to clear the checkbox for that species.

External convection

Set **Flux type** to **External convection** to prescribe a flux to or from an exterior domain (not modeled) assumed to include convection. The exterior can for example include a forced convection to control the temperature or to increase the mass transport. In this case the prescribed mass flux corresponds to

$$J_0 = k_{\mathrm{c}}(c_{\mathrm{b}} - c)$$

where k_{c} is a mass transfer coefficient and c_{b} is the bulk concentration, the typical concentration far into the surrounding exterior domain.

Symmetry

The **Symmetry** node can be used to represent boundaries where the species concentration is symmetric, that is, where there is no mass flux across the boundary.

This boundary condition is identical to that of the No Flux node.

Flux Discontinuity

This node represents a discontinuity in the mass flux across an interior boundary:

$$-\mathbf{n}\cdot[(\mathbf{J}+\mathbf{u}c)_{\mathrm{u}} - (\mathbf{J}+\mathbf{u}c)_{\mathrm{d}}] = N_0 \qquad \mathbf{J} = -D\nabla c$$

where the value N_0 (SI unit: mol/(m^2·s)) specifies the jump in total flux at the boundary. This can be used to model a boundary source, for example a surface reaction, adsorption, or desorption.

FLUX DISCONTINUITY

In this section the jump in species flux (or surface source) is specified.

Select the Species checkbox for the species to specify and enter a value or expression for the material flux jump in the corresponding field. To use a different boundary condition for a specific species, click to clear the checkbox for the flux discontinuity of that species.

Partition Condition

The **Partition Condition** node can be used to prescribe the relation between the concentration of a solute species in two adjoining immiscible phases. It can for example be used on interior boundaries separating two liquid phases, a gas-liquid interface, or on a boundary separating a liquid phase and a solid or porous media.

Select **Partition coefficient** from the **Relation** list to prescribe a linear relationship between the concentration on either side of a boundary. For a species concentration c_i, the ratio between the concentration on the upside and on the downside of the boundary ($c_{i,\mathrm{u}}$ and $c_{i,\mathrm{d}}$ respectively) is then defined in terms of a partition coefficient K_i in the manner of

$$K_i = \frac{c_{i,\mathrm{u}}}{c_{i,\mathrm{d}}}$$

Use the associated input field to prescribe the partition coefficient for each species.

Select **User defined** from the **Relation** list to set up a nonlinear relation between the up and downside concentrations. For such relations $f(c_i)_\mathrm{u} = f(c_i)_\mathrm{d}$, where $f(c_i)_\mathrm{u}$ is the expression enforced on the upside. Use the associated input fields to enter the upside and downside expressions for each species.

The up and downside of the selected boundary is indicated with a red arrow in the Graphics window. The arrow points from the downside into the upside. Select the **Reverse direction** checkbox to reverse the direction of the arrow on the selected boundary, and update the definition of the up and downside concentrations accordingly.

	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

FURTHER READING

For an example of using a partition condition, see this application example:

	Separation Through Dialysis: Application Library path **Chemical_Reaction_Engineering_Module/Mixing_and_Separation/dialysis**

Periodic Condition

The **Periodic Condition** node can be used to define periodicity for the mass transport between two sets of boundaries. The node prescribes continuity in the concentration and the mass flux between the “source” and the “destination” side, respectively. Note that these names are arbitrary and does not influence the direction in which mass is transported. It is dictated by mass transfer equations in the adjacent domains.

BOUNDARY SELECTION

The node can be activated on more than two boundaries, in which case the feature tries to identify two separate surfaces that each consist of one or several connected boundaries.

DESTINATION SELECTION

For more complex geometries, it might be necessary to specify the destination selection manually. To do so, right-click the **Periodic Condition** node and choose **Manual Destination Selection**. You can then specify the boundaries that constitute the destination surfaces in the **Destination Selection** section.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

ORIENTATION OF SOURCE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Orientation of Source** section, see Orientation of Source and Destination.

ORIENTATION OF DESTINATION

This section appears if the setting for **Transform to intermediate map** in the **Orientation of Source** section is changed from the default value, **Automatic**, and **Advanced Physics Options** is selected in the **Show More Options** dialog. For information about the **Orientation of Destination** section, see Orientation of Source and Destination.

MAPPING BETWEEN SOURCE AND DESTINATION

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Mapping Between Source and Destination** section, see Mapping Between Source and Destination.

FURTHER READING

For an example of using a periodic condition, see this application example:

	The KdV Equation and Solitons: Application Library path **COMSOL_Multiphysics/Equation_Based/kdv_equation**

Line Mass Source

The **Line Mass Source** feature models mass flow originating from a tube or line region with an infinitely small radius.

	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

SELECTION

The **Line Mass Source** feature is available for all dimensions, but the applicable selection differs between the dimensions.

MODEL DIMENSION	APPLICABLE GEOMETRICAL ENTITY
2D	Points
2D Axisymmetry	Points not on the symmetry axis and the symmetry axis
3D	Edges

SPECIES SOURCE

Enter the source strength, $\dot{q}_{l,c}$, for each species (SI unit: mol/(m·s)). A positive value results in species injection from the line into the computational domain, and a negative value means that the species is removed from the computational domain.

Line sources located on a boundary affect the adjacent computational domains. This effect makes the physical strength of a line source located in a symmetry plane twice the given strength.

Point Mass Source

The **Point Mass Source** feature models mass flow originating from an infinitely small domain around a point.

	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

SPECIES SOURCE

Enter the source strength, $\dot{q}_{p,c}$, for each species (SI unit: mol/s). A positive value results in species injection from the point into the computational domain, and a negative value means that the species is removed from the computational domain.

Point sources located on a boundary or on an edge affect the adjacent computational domains. This has the effect, for example, that the physical strength of a point source located in a symmetry plane is twice the given strength.

Open Boundary

Use this node to set up mass transport across boundaries where both convective inflow and outflow can occur. On the parts of the boundary where fluid flows into the domain, an exterior species concentration is prescribed. On the remaining parts, where fluid flows out of the domain, a condition equivalent to the **Outflow** node is instead prescribed.

The direction of the flow across the boundary is typically calculated by a fluid flow interface and is provided as a model input to the Transport of Diluted Species interface.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

EXTERIOR CONCENTRATION

Enter a value or expression for the **Exterior concentration**.

Thin Diffusion Barrier

Use this boundary condition to model a thin layer through which mass is transported by diffusion only. The node is applicable on interior boundaries and can be used to avoid meshing thin structures.

THIN DIFFUSION BARRIER

Specify the **Layer thickness**, d_s, and input a **Diffusion coefficient**, $D_{s,c}$, for each of the species included.

Thin Impermeable Barrier

This feature models a thin mass transfer barrier. It is available on interior boundaries and introduces a discontinuity in the concentration across the boundary. On each side, a no-flux condition is prescribed for the mass transport implying that it acts as a barrier. The feature can be used to avoid meshing thin structures.

Solving a model involving coupled fluid flow and mass transfer, the Thin Impermeable Barrier feature can be combined with an Interior Wall feature in order to model a thin solid wall.

Equilibrium Reaction

Use this node to model a reaction where the kinetics is so fast that the equilibrium condition is fulfilled at all times. The node solves for an additional degree of freedom (the reaction rate R_{eq}) to fulfill the equilibrium condition at all times in all space coordinates.

If the **Apply equilibrium condition on inflow boundaries** checkbox is selected, the specified inflow concentration values in all active **Inflow** boundary nodes for the physics interface are modified to comply with the equilibrium condition.

- A necessary requirement for this is feature to be available is that two or more species are solved for by the interface.
- This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

EQUILIBRIUM CONDITION

The list defaults to **Equilibrium constant** or select **User defined**. For either option, the **Apply equilibrium condition on inflow boundaries** checkbox is selected by default.

For **Equilibrium constant**, enter an **Equilibrium constant** K_{eq} (dimensionless). Also enter a value or expression for the **Unit activity concentration** C_{a0} (SI unit: mol/m^3). Selecting **Equilibrium constant** defines an equilibrium condition based on the stoichiometric coefficients, the species activities, and the law of mass action.

For **User defined**, enter an **Equilibrium expression** E_{eq} (dimensionless).

STOICHIOMETRIC COEFFICIENTS

Enter a value for the stoichiometric coefficient ν_c (dimensionless). The default is 0. Use negative values for reactants and positive values for products in the modeled reaction.

Species with a stoichiometric coefficient value of 0 are not affected by the **Equilibrium Reaction** node.

Surface Reactions

The **Surface Reactions** node can be used to account for the species boundary flux due to chemical reactions occurring on a surface (heterogeneous reactions). For a domain species participating in a surface reaction, the boundary flux corresponds to the reaction rate at the surface.

SURFACE REACTION RATE

Specify the surface reaction rate J_0 of each species resulting from the reactions. Note that if you have the Chemistry interface available, provided with the Chemical Reaction Engineering Module, the reaction rate expressions can be automatically generated and picked up using the drop-down list.

When defining conditions on boundaries between different phases, see the section Prescribing Conditions on Fluid-Solid Interfaces.

FURTHER READING

For an example of using the Surface Reactions node, see this application example:

Chemical Vapor Deposition of GaAs: Application Library path **Chemical_Reaction_Engineering_Module/Reactors_with_Mass_and_Heat_Transfer/gaas_cvd**

Surface Equilibrium Reaction

Use this node to model an equilibrium reaction on a boundary (surface). The settings for this node are similar to Equilibrium Reaction. Note that a necessary requirement for this is feature to be available is that two or more species are solved for by the interface.

When defining conditions on boundaries between different phases, see the section Prescribing Conditions on Fluid-Solid Interfaces.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

Fast Irreversible Surface Reaction

This boundary node defines an irreversible reaction where the kinetics is so fast that the only factor limiting the reaction rate is the transport of a species to the reacting surface.

The node will set the **Rate limiting species concentration to zero** at the boundary, and balance the fluxes of the species participating in the reaction and the current densities according to the Stoichiometric Coefficients settings.

When defining conditions on boundaries between different phases, see the section Prescribing Conditions on Fluid-Solid Interfaces.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

Porous Electrode Coupling

Use this node to add a molar source in a domain that is coupled to one or multiple Porous Electrode Reaction nodes of an Electrochemistry Interface.

The molar source is calculated from the number of electrons, stoichiometric coefficients, and volumetric current densities of the coupled porous electrode reactions specified in the **Reaction Coefficients** subnodes.

In the Transport of Concentrated Species interface, the molar sources (or sinks) are multiplied by the species molar masses to obtain the corresponding mass sources.

Additional Reaction Coefficients subnodes are available from the context menu (right-click the parent node) as well as from the **Physics** toolbar, **Attributes** menu.

Note that if you are also modeling the momentum transport and expect a nonnegligible total mass source or sink, which is often the case in gas diffusion electrodes, you need to also add a corresponding mass source/sink in the Fluid Flow interface. (A **Reacting Flow** multiphysics node adds the associated source/sink term in a Fluid Flow interface automatically.)

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

Reaction Coefficients

Add this node to the Electrode Surface Coupling and Porous Electrode Coupling features to define molar fluxes and sources based on electrode current densities in an **Electrochemistry** interface.

The molar flux or source is proportional to the stoichiometric coefficients and the current density according to Faraday's law.

Current densities from **Electrode Reaction** (i_{loc}, SI unit: A/m^2) or **Porous Electrode Reaction** nodes (i_{v}, SI unit: A/m^3) of any **Electrochemistry** interface in the model are available for selection as the **Coupled reaction**, and user-defined expressions are also supported.

Enter the **Number of participating electrons** n_m (dimensionless) and the **Stoichiometric coefficient** v_c (dimensionless) as explained in the theory section linked below.

Use multiple subnodes to couple to multiple reactions.

Electrode Surface Coupling

Use this node to define a flux boundary condition based on current densities of one or multiple Electrode Reaction nodes in an Electrochemistry interface.

The flux is proportional to the current densities and the stoichiometric coefficients according to Faraday's law as defined by summation over the Reaction Coefficients subnodes.

Note that if you are also modeling the momentum transport and expect a nonnegligible total mass flux over the boundary, which is often the case for gas diffusion electrodes, you need to also add a corresponding Electrode Surface Coupling node in the Fluid Flow interface.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

Porous Medium

Use this node to model the concentration of diluted species transported by a solvent (mobile fluid phase) through interstices in a solid porous medium. In addition to transport due to convection and diffusion, the node contains functionality to include species evolution through adsorption and dispersion.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

Species transport through a porous medium is affected both by properties of the fluid phase, and as well as properties of the solid matrix. These properties are defined in the Fluid (Porous Medium) and Porous Matrix subnodes respectively. The Porous Medium node supports material properties using a Porous Material node, where properties are defined per phase in a similar manner.

Add an Adsorption or a Dispersion subfeature to the **Porous Medium** to account for the corresponding transport mechanism.

Fluid (Porous Medium)

Use this node to specify the mass transfer in the mobile fluid solvent filling the pores of a porous medium. It is used as a subnode to Porous Medium.

MODEL INPUTS

The temperature model input is always available. By default, the **Temperature** model input is set to **Common model input**, and the temperature is controlled from Default Model Inputs under **Global Definitions** or by a locally defined

Model Input. If a Heat Transfer interface is included in the component, it controls the temperature **Common model input**. Alternatively, the temperature field can be selected from another physics interface. All physics interfaces have their own tags (**Name**). For example, if a Heat Transfer in Fluids interface is included in the component, the **Temperature (ht)** option is available for T.

You can also select **User defined** from the **Temperature** model input in order to manually prescribe T.

CONVECTION

If transport by convection is active, the velocity field of the solvent needs to be specified. For **User defined**, enter values or expressions for the velocity components in the input fields. This input option is always available. You can also select the velocity field solved for by a Fluid Flow interface added to the model component. These physics interfaces are available for selection in the **Velocity field** list.

DIFFUSION

Use this section to specify diffusion coefficients describing the diffusion of each species in the solvent fluid.

Use the **Source** list to select to pick up diffusion coefficients defined in a material or a Chemistry interface.

Select **Material**, and a **Fluid material** to use a diffusion coefficient in a material available in the model. User-defined property groups including a diffusion coefficient output property are available for selection in the **Fluid diffusion coefficient** list.

Select **Chemistry** to use a diffusion coefficient from a Chemistry interface added to model component. Diffusion coefficients are automatically defined when **Calculate transport properties** is selected on the interface level of a Chemistry interface. All defined diffusion coefficients are available for selection in the **Fluid diffusion coefficient** list.

For **User defined**, enter a value or expression for the **Fluid diffusion coefficient** $D_{\mathrm{F,i}}$ of each species in the corresponding input field.

In a porous medium the diffusivity is reduced due to the fact that the solid grains impede Brownian motion. Select an **Effective diffusivity model** to account for the reduced diffusivity. The available models are **Millington and Quirk model** (the default), **Bruggeman model**, **Tortuosity model**, or **No correction**. For **Tortuosity model**, enter a value for the tortuosity $\tau_{\mathrm{F,i}}$ (dimensionless).

Note that multiple species, as well as Migration in Electric fields (described below) is only available for certain COMSOL Multiphysics add-on products.For details, see https://www.comsol.com/products/specifications/.

MIGRATION IN ELECTRIC FIELD

This section is available when the **Migration in electric field** checkbox is selected. From the **Electric potential** list, select the source of the electric field.

- For **User defined**, enter a value or expression for the **Electric potential** V. This input option is always available.
- Select the electric potential solved by an AC/DC-based interface that has added to the component.
- Select the electric potential defined or solved for by an Electrochemistry interface added to the component.

By default the **Mobility** is set to be calculated based on the species effective diffusivity and the temperature using the **Nernst-Einstein relation**. For **User defined**, select the appropriate scalar or tensor type — **Isotropic**, **Diagonal**, **Symmetric**, or **Full** — and type in the value or expression of the effective mobility $u_{\mathrm{me,i}}$.

Enter the **Charge number** z_{c} for each species.

Porous Matrix

This node sets the porosity when modeling transport of diluted species in a Porous Medium or an Unsaturated Porous Medium. The porosity corresponds to the volume fraction occupied by the species containing fluid.

- By default the porosity of the solid matrix, ε_p, is taken **From material**. The **Porous Matrix** node supports the use of a **Porous Material** added to the Materials branch. In this case the porosity is defined in the manner of

$$\varepsilon_p = 1 - \sum_i \theta_{s,i} - \sum_i \theta_{imf,i}$$

  where $\theta_{s,i}$ and $\theta_{imf,i}$ are the volume fractions given in **Solid** and **Immobile Fluids** subnodes under the **Porous Material** node.

- Select **From pellet bed densities** to compute the porosity using the (dry bulk) **Bed density** ρ_b and the (single phase) **Pellet density** ρ_{pe}. The porosity is then defined from

$$\varepsilon_p = 1 - \frac{\rho_b}{\rho_{pe}}$$

- For **User defined**, enter a value or expression for the porosity.

Dispersion

Local variations in the velocity as the fluid flows around solid particles lead to mechanical mixing, referred to as dispersion. Use this feature to account for dispersion in a Porous Medium or a Unsaturated Porous Medium

This subfeature is available when both the **Mass transfer in porous media mass transfer** checkbox and the **Convection** checkbox are selected in the **Settings** window for the physics interface.

Select the **Specify dispersion for each species individually** checkbox to specify the dispersion tensor D_D (SI unit: m^2/s) for each species separately. When not selected the same dispersion tensor D_D is used for all species.

Select an option from the **Dispersion tensor** list — **Dispersivity** or **User defined**.

Select **Dispersivity** to specify the dispersion in terms of dispersivities (SI unit: m). Select an option from the **Dispersivity model** list: **Isotropic** (the default) or **Transverse isotropic** based on the properties of the porous media. For isotropic porous media, specify the longitudinal and transverse dispersivities. For transverse isotropic porous media, specify the longitudinal, horizontal transverse, and vertical transverse dispersivities.

For **User defined**, specify the dispersion components in terms of constants or expressions. Select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** to enable the appropriate tensor components.

Unsaturated Porous Medium

Use this node to model the concentration of diluted species transported by a solvent (mobile fluid phase) through interstices in a solid porous medium. In addition to transport due to convection and diffusion, the node contains functionality to include species evolution through adsorption and dispersion.

Use this node to model the concentration of diluted species transported by a liquid (mobile fluid phase) in a partially filled solid porous medium. The interstices of the porous medium contains the liquid carrier phase and gas

pockets. Apart from convection and diffusion, the node contains functionality to include species evolution through adsorption, dispersion, and volatilization.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

The properties of each phase present are defined using the Liquid, the Gas, and the Porous Matrix subnodes respectively. The Unsaturated Porous Medium node supports material properties using a Porous Material node, where properties are defined per phase in a similar manner.

Add an Adsorption or a Dispersion subfeature to the **Unsaturated Porous Medium** to account for the corresponding transport mechanism.

Liquid

Use this node to specify the mass transfer in the mobile liquid solvent present in the pores of the Unsaturated Porous Medium.

MODEL INPUTS

The temperature model input is always available. By default, the **Temperature** model input is set to **Common model input**, and the temperature is controlled from Default Model Inputs under **Global Definitions** or by a locally defined Model Input. If a Heat Transfer interface is included in the component, it controls the temperature **Common model input**. Alternatively, the temperature field can be selected from another physics interface. All physics interfaces have their own tags (**Name**). For example, if a Heat Transfer in Fluids interface is included in the component, the **Temperature (ht)** option is available for T.

You can also select **User defined** from the **Temperature** model input in order to manually prescribe T.

SATURATION

Select **Saturation** or **Liquid volume fraction** from the list.

For **Saturation**, enter a value for s (dimensionless) between 0 and 1. The liquid volume fraction is then computed from the saturation and porosity as $\theta_l = \varepsilon_p s$.

For **Liquid volume fraction**, enter a value for θ_l (dimensionless) between 0 and the value of the porosity.

Select a **Liquid fraction time change**: **Liquid fraction constant in time** (the default), **Time change in liquid fraction**, or **Time change in pressure head**.

- For **Time change in fluid fraction**, enter $\mathrm{d}\theta/\mathrm{d}t$ (SI unit: 1/s).
- For **Time change in pressure head**, enter $\mathrm{d}H_p/\mathrm{d}t$ (SI unit: m/s) and a **Specific moisture capacity** C_m (SI unit: 1/m). If a Darcy's Law interface is included in the component, the time change in pressure head solved for can be selected.

CONVECTION

If transport by convection is active, the velocity field of the solvent needs to be specified. For **User defined**, enter values or expressions for the velocity components in the input fields. This input option is always available. You can also select the velocity field solved for by a Fluid Flow interface added to the model component. These physics interfaces are available for selection in the **Velocity field** list.

DIFFUSION

Use this section to specify diffusion coefficients describing the diffusion of each species in the solvent liquid.

Use the **Source** list to select to pick up diffusion coefficients defined in a material or a Chemistry interface.

Select **Material**, and a **Liquid material** to use a diffusion coefficient in a material available in the model. User-defined property groups including a diffusion coefficient output property are available for selection in the **Liquid diffusion coefficient** list.

Select **Chemistry** to use a diffusion coefficient from a Chemistry interface added to model component. Diffusion coefficients are automatically defined when **Calculate transport properties** is selected on the interface level of a Chemistry interface. All defined diffusion coefficients are available for selection in the **Liquid diffusion coefficient** list.

For **User defined**, enter a value or expression for the **Liquid diffusion coefficient** $D_{\mathrm{L,i}}$ of each species in the corresponding input field.

In a porous medium the diffusivity is reduced due to the fact that the solid grains impede Brownian motion. Select an **Effective diffusivity model, liquid** to account for the reduced diffusivity in the liquid. The available models are **Millington and Quirk model** (the default), **Bruggeman model**, **Tortuosity model**, or **No correction**. For **Tortuosity model**, enter a value for the tortuosity $\tau_{\mathrm{L,i}}$ (dimensionless).

Note that multiple species, as well as Migration in Electric fields (described below) is only available for certain COMSOL Multiphysics add-on products. For details see: https://www.comsol.com/products/specifications/.

MIGRATION IN ELECTRIC FIELD

This section is available when the **Migration in electric field** checkbox is selected. From the **Electric potential** list, select the source of the electric field.

- For **User defined**, enter a value or expression for the **Electric potential** V. This input option is always available.
- Select the electric potential solved by an AC/DC-based interface that has added to the component.
- Select the electric potential defined or solved for by an Electrochemistry interface added to the component.

By default the **Mobility** is set to be calculated based on the species effective diffusivity and the temperature using the **Nernst-Einstein relation**. For **User defined**, select the appropriate scalar or tensor type — **Isotropic**, **Diagonal**, **Symmetric**, or **Full** — and type in the value or expression of the effective mobility $u_{\mathrm{me,i}}$.

Enter the **Charge number** z_{c} for each species.

Gas

Use this node to specify the mass transfer in the gas phase present in the pores of the Unsaturated Porous Medium.

DIFFUSION

The settings for the diffusion of each species in the gas phase are identical to those in the Liquid subnode.

VOLATILIZATION

Enter a value for the volatilization isotherm $k_{\mathrm{G,c}}$ (dimensionless) for each species.

Adsorption

Use this node to model adsorption of the (fluid phase) solute species onto the surface of the porous matrix. It is available as a subnode to the Porous Medium and the Unsaturated Porous Medium nodes.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

MATRIX PROPERTIES

The density of the porous media is needed when modeling adsorption to the surface of the porous matrix. Choose to input either the **Dry bulk density** ρ, or the **Solid phase density** ρ_s. The former is the density of the porous matrix including empty pores, while the latter corresponds to the density of the pure solid phase. The density can be defined from the domain material by selecting **From material**, or from a user defined expression. When a **Porous Material** is used on the selection, the density will be requested from a **Solid** subfeature. Several **Solid** features can be used to model a homogeneous mixture of several solid components.

ADSORPTION

Select an **Adsorption isotherm** — **Langmuir**, **Freundlich**, **Toth**, **BET**, or **User defined** to specify how to compute c_P, the amount of species sorbed to the solid phase (moles per unit dry weight of the solid):

- For **Langmuir**:

$$c_P = c_{P\max}\frac{K_L c}{1+K_L c} \quad , \quad K_P = \frac{\partial c_P}{\partial c} = \frac{K_L c_{P\max}}{(1+K_L c)^2}$$

  Enter a **Langmuir constant** $k_{L,c}$ (SI unit: m^3/mol) and an **Adsorption maximum** $c_{p,max,c}$ (SI unit: mol/kg).

- For **Freundlich**:

$$c_P = K_F\left(\frac{c}{c_{ref}}\right)^N \quad , \quad K_P = \frac{\partial c_P}{\partial c} = N\frac{c_P}{c}$$

  Enter a **Freundlich constant** $k_{F,c}$ (SI unit: mol/kg), a **Freundlich exponent** $N_{F,c}$ (dimensionless), and a **Reference concentration** $c_{ref,c}$ (SI unit: mol/m^3).

- For **Toth**:

$$c_P = c_{P\max}\frac{b_T c}{(1+(b_T c)^{N_T})^{1/N_T}}$$

and

$$K_P = \frac{\partial c_P}{\partial c} = c_{P\max} b_T (1+(b_T c)^{N_T})^{-\left(1+\frac{1}{N_T}\right)}$$

  Enter a **Toth constant** $b_{T,c}$ (SI unit: m^3/mol), a **Toth exponent** $N_{T,c}$ (dimensionless), and an **Adsorption maximum** $c_{p,max,c}$ (SI unit: mol/kg).

- For **BET (Brunauer-Emmett-Teller)**:

$$c_P = \frac{K_B c_0 c}{(c_S - c)\left(1+(K_B-1)\frac{c}{c_S}\right)}$$

and

$$K_P = \frac{\partial c_P}{\partial c} = \frac{K_B c_0 c_S((K_B-1)c^2 + c_S^2)}{(c-c_S)^2(c_S+(K_B-1)c)^2}$$

  Enter a **BET constant** $K_{B,c}$ (dimensionless), a **Monolayer adsorption capacity** $c_{0,c}$ (SI unit: mol/kg), and an **Saturation concentration** $c_{S,c}$ (SI unit: mol/m^3).

- For **User defined** enter an **Adsorption isotherm** $c_{P,c}$ (SI unit: mol/kg):

$$c_p = f(c)$$

For more information, see Adsorption in the theory section of the *Chemical Reaction Engineering Module User's Guide*.

FURTHER READING

See the theory chapter in the section The Transport of Diluted Species in Porous Media Interface.

Volatilization

This feature is available when the **Mass transfer in porous media** checkbox is selected in the **Settings** window for the physics interface.

Use this feature to model mass transfer at the boundary due to volatilization. The species dissolved in the liquid are assumed to be vaporized at the boundary, and transported into the surrounding bulk region due to convection and diffusion. The mass transfer at the boundary is defined as

$$-\mathbf{n} \cdot \mathbf{J}_c = -h_c(k_{G,c}c - c_{Gatm,c})$$

where h_c is the mass transfer coefficient, $k_{G,c}$ the volatilization coefficient, and $c_{Gatm,c}$ the concentration in the surrounding atmosphere.

!	This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

VOLATILIZATION

Enter a **Mass transfer coefficient** h_c defining the transfer into the surrounding media. This can be given by boundary layer theory. When assuming that no convective flow is present in the surrounding, the mass transfer coefficient can be defined from the gas diffusion coefficient D_{Gc} and the thickness of the diffusion layer d_s in the manner of

$$h_c = \frac{D_{Gc}}{d_s}$$

Also give the atmospheric concentration for each species, $c_{Gatm,c}$. The **Volatilization** coefficient $k_{G,c}$ for each species are taken from the adjacent Unsaturated Porous Medium domain.

Species Source

In order to account for consumption or production of species in porous domains, the **Species Source** node adds source terms expressions S_i to the right-hand side of the species transport equations.

DOMAIN SELECTION

From the **Selection** list, choose the domains on which to define rate expression or expressions that govern the source term in the transport equations.

If there are several types of domains, with subsequent and different reactions occurring within them, it might be necessary to remove some domains from the selection. These are then defined in an additional **Species Source** node.

SPECIES SOURCE

Add a source term S_i (SI unit: mol/(m^3·s)) for each of the species solved for. Enter a value or expression in the field of the corresponding species.

Hygroscopic Swelling

The **Hygroscopic Swelling** multiphysics coupling node ( ) is used for moisture concentration coupling between the Solid Mechanics interface and either the Transport of Diluted Species or Transport of Diluted Species in Porous Media interfaces.

Hygroscopic swelling is an effect of internal strain caused by changes in moisture content. This volumetric strain can be written as

$$\varepsilon_{\mathrm{hs}} = \beta_{\mathrm{h}} M_{\mathrm{m}} (c_{\mathrm{mo}} - c_{\mathrm{mo,ref}})$$

where β_{h} is the coefficient of hygroscopic swelling, M_{m} is the molar mass, c_{mo} is the moisture concentration, and $c_{\mathrm{mo,ref}}$ is the strain-free reference concentration.

This feature requires a license of either the MEMS Module or the Structural Mechanics Module. The multiphysics feature will appear automatically if both the Transport of Diluted Species and the Solid Mechanics interfaces are added to the same component. For the most current information about licensing, please see https://www.comsol.com/products/specifications/.

FURTHER READING

More information about how to use hygroscopic swelling can be found in the Hygroscopic Swelling section in the *Structural Mechanics Module User's Guide*.

More information about multiphysics coupling nodes can be found in the section The Multiphysics Branch.

Out-of-Plane Flux

The out-of-plane flux node is used to prescribe a flux in an out-of-plane domain, and it can be used to reduce a model geometry to 2D, or even 1D, when the concentration variation is small in one or more directions. This could be the case for example when the object to model is thin or slender. Figure 12-3 shows examples of possible situations in which this type of geometry reduction can be applied.

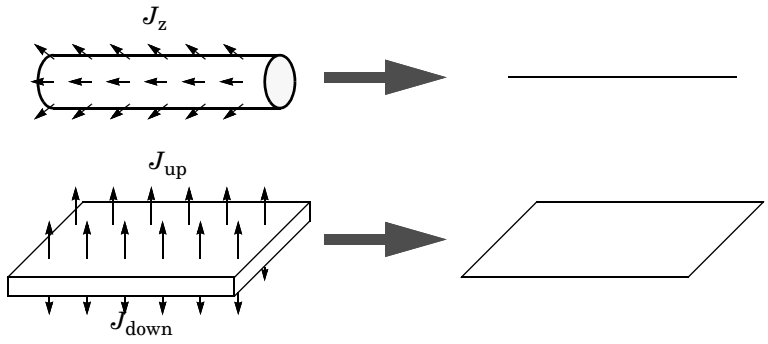

Figure 12-3: Geometry reduction from 3D to 1D (top) and from 3D to 2D (bottom).

For a 1D component this node adds a single out-of-plane molar flux $J_{0,z,i}$ for species i. For a 2D component two fluxes can be prescribed for each species; $J_{0,u,i}$ for the upside of the domain, and $J_{0,d,i}$ for the downside of the domain.

The fluxes are added as a source contribution to the right-hand side of the transport equation. For example, in 2D components with diffusion, convection, and out-of-plane flux present, the mass transfer of species i is defined by the mass conservation equation

$$\frac{\partial c_i}{\partial t} + \nabla \cdot \mathbf{J}_i + \mathbf{u} \cdot \nabla c_i = R_i + S_{\mathrm{opf},i}, \tag{12-21}$$

where $S_{\mathrm{opf},i}$ is the out-of-plane source for species i

$$S_{\mathrm{opf},i} = \frac{J_{0,i}}{d_z} = \frac{J_{0,\mathrm{u},i} + J_{0,\mathrm{d},i}}{d_z}.$$

For external convection on the upside and the downside of the domain, the out-of-plane flux is

$$J_{0,i} = k_{\mathrm{c,u},i}(c_{\mathrm{b,u},i} - c_i) + k_{\mathrm{c,d},i}(c_{\mathrm{b,d},i} - c_i)$$

where k_c is a mass transfer coefficient and c_b is the bulk concentration, the typical concentration far into the surrounding exterior domain. The prescribed flux, J_0, can include any arbitrary user-specified expressions. It can be a constant or a function of a dependent variable or independent variables.

UPSIDE INWARD FLUX

For 1D components, enter the **cross-sectional perimeter** P_c to get the out-of-plane flux

$$J_{0,i} = P_c J_{0,z,i}.$$

The default value of P_c is the circumference. Either keep the default value, for a circular cross-section shape, or edit the value to get a user-defined shape of the out-of-plane cross-section.

The available flux type options are **General inward flux** and **External convection**. Select the **Species** checkbox for the species for which to specify the flux, and enter a value or expression for the inward flux in the corresponding field. Use a minus sign when specifying a flux directed out of the system. To use another boundary condition for a specific species, click to clear the checkbox for that species.

Set **Flux type** to **External convection** to prescribe a flux to or from an exterior domain (not modeled) assumed to include convection. The exterior can for example include a forced convection to control the temperature or to increase the mass transport. In this case the prescribed mass flux corresponds to

$$J_0 = k_c(c_b - c)$$

where k_c is a mass transfer coefficient and c_b is the bulk concentration, the typical concentration far into the surrounding exterior domain.

DOWNSIDE INWARD FLUX

The available options are **General inward flux** and **External convection**. The settings are the same as for the Upside Inward Flux section.

FURTHER READING

For an example of using the Out-of-Plane Flux node, see this application example:

Cross-Flow Mass Transfer in a Thin Domain: Application Library path **Chemical_Reaction_Engineering_Module/Tutorials/thin_domain**

Fracture

Use this node to model mass transport along thin fractures in porous media. The node assumes that the transport in the tangential direction along the fracture is dominant as a result of lower flow resistance.

The Fracture feature has two default subfeatures — the Fluid (Fracture) subfeature where convection and diffusion are specified and the Fracture Material subfeature where the porosity ε_p is defined.

This feature is only available in a limited set of add-on products. See https://www.comsol.com/products/specifications/ for more details on availability.

FRACTURE PROPERTIES

Specify a value for the **Fracture thickness** d_{fr}.

For the **Fracture** boundary condition, there are a number of **Attributes** available which can be accessed either via the **Physics** Ribbon toolbar (for Windows) or by right-clicking on the **Fracture** node. These attributes are identical to the Boundary, Edge, Point, and Pair Nodes for the Transport of Diluted Species in Fractures Interface described, for example, in the *Chemical Reaction Engineering Module User's Guide*.

Fluid (Fracture)

Use this node to specify the mass transfer in the mobile fluid solvent filling the pores of a fracture.

It uses the same input options as the Fluid (Porous Medium) subfeature under the Porous Medium feature. There are further details about the settings.

MODEL INPUTS

The temperature model input is always available. By default, the **Temperature** model input is set to **Common model input**, and the temperature is controlled from **Default Model Inputs** under **Global Definitions** or by a locally defined **Model Input**. If a Heat Transfer interface is included in the component, it controls the temperature **Common model input**. Alternatively, the temperature field can be selected from another physics interface. All physics interfaces have their own tags (**Name**). For example, if a Heat Transfer in Fluids interface is included in the component, the **Temperature (ht)** option is available for T.

CONVECTION

If transport by convection is active, the velocity field of the solvent needs to be specified. Select an option from the **Velocity field** list to specify the convective velocity along the fracture. For a consistent model, use a Fracture feature in a Darcy's Law interface to compute the fluid flow velocity in the fracture.

For **User defined**, enter values or expressions for the velocity components in the table shown

DIFFUSION

Use this section to specify diffusion coefficients describing the diffusion of each species in the solvent fluid.

The **Diffusion** settings are similar to those for the diffusion coefficients in the Fluid (Porous Medium) node under Porous Medium.

Fracture Material

Specify the **Porosity** ε_p (dimensionless) of the porous matrix. This is by default taken **From material**. Select **From pellet bed densities** to compute the porosity from the (dry bulk) **Bed density** ρ_b and the (single phase) **Pellet density** ρ_{pe} through the relation

$$\varepsilon_p = 1 - \frac{\rho_b}{\rho_{pe}}$$

For **User defined**, enter a value or expression for the porosity.

The Reacting Flow, Diluted Species Multiphysics Interface

Reacting Flow, Diluted Species is a predefined multiphysics interface that couples fluid flow with mass transport and reactions.

Selecting **Laminar Flow, Diluted Species** under the **Chemical Species Transport** > **Reacting Flow** branch of the **Model Wizard** or **Add Physics** windows, a **Laminar Flow** interface and a **Transport of Diluted Species** interface are added to the Model Builder.

In addition, the Multiphysics node is added, which includes the multiphysics coupling feature **Reacting Flow, Diluted Species**. The **Reacting Flow, Diluted** feature controls the coupling between the separate interfaces in order to facilitate easy set up of models.

In this section:

- The Reacting Laminar Flow, Diluted Species Interface
- The Reacting Flow, Diluted Species Coupling Feature
- Physics Interface Features

The Reacting Laminar Flow, Diluted Species Interface

The **Reacting Laminar Flow, Diluted Species** multiphysics interface ( ) is used to simulate laminar flow coupled to transport of dilute solutes in a gas or liquid.

It combines the **Laminar Flow**, and **Transport of Diluted Species** interfaces. The **Reacting Flow, Diluted Species** multiphysics coupling, which is added automatically, couples fluid flow and mass transport. The fluid flow can either be free flow or flow in a porous medium. The mass transfer solves for the development of one or several solutes dissolved in a gas or liquid solvent.

The interface can be used for stationary and time-dependent analysis in 2D, 2D axial symmetry, and 3D.

On the constituent physics interfaces:

The equations solved by the **Laminar Flow** interface are the Navier–Stokes equations for conservation of momentum and the continuity equation for conservation of mass. A **Fluid Properties** feature is active by default on the entire interface selection. A **Porous Medium** feature can be added in order to model flow in porous media by solving the Brinkman equations.

The **Transport of Diluted Species** interface solves for an arbitrary number of concentrations. The species equations include transport by convection, diffusion and, optionally, migration in an electric field.

!	Note that multiple species is only available for certain COMSOL Multiphysics add-on products. See details: https://www.comsol.com/products/specifications/.

The Reacting Flow, Diluted Species Coupling Feature

The **Reacting Flow, Diluted Species** ( ) multiphysics coupling is used to simulate mass transport and reactions in a gas or liquid.

DOMAIN LEVEL SYNCHRONIZATION

The **Reacting Flow, Diluted Species** coupling synchronizes the features from a Single-Phase Flow, or Brinkman Equations, interface and a Transport of Diluted Species interface. When added, the velocity field used by the Transport of Diluted Species interface is synchronized to the one computed in the fluid flow interface.

TURBULENT MASS TRANSFER

When a turbulence model is used, the **Reacting Flow, Diluted Species** coupling applies turbulence modeling for the mass transport in the following manners:

- Turbulent mass transport is added, defined from the turbulent viscosity and a turbulent Schmidt number (for more information, see Turbulent Mass Transport Models).
- Mass transport wall functions. When a turbulence model using wall functions is used for the fluid flow, the Reacting Flow coupling automatically adds wall functions for the mass transport on the same boundaries (for more information, see Mass Transport Wall Functions).

SETTINGS

The **Label** is the default multiphysics coupling feature name.

The **Name** is used primarily as a scope prefix for variables defined by the coupling node. Refer to such variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different coupling nodes or physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first multiphysics coupling feature in the model) is `rfd1`.

DOMAIN SELECTION

The **Reacting Flow, Diluted Species** coupling is automatically defined on the intersection of the selections for the coupled interfaces.

The **Selection** list displays the domains where the coupling feature is active.

COUPLED INTERFACES

This section defines the physics involved in the multiphysics coupling. The **Fluid flow** and **Species transport** lists include all applicable physics interfaces.

The default values depend on how this coupling node is created.

- If it is added from the **Physics** ribbon (Windows users), **Physics** contextual toolbar (macOS and Linux users), or context menu (all users), then the first physics interface of each type in the component is selected as the default.
- If it is added automatically when a multiphysics interface is chosen in the **Model Wizard** or **Add Physics** window, then the two participating physics interfaces are selected.

You can also select **None** from either list to uncouple the node from a physics interface. If the physics interface is removed from the **Model Builder**, for example **Laminar Flow** is deleted, then the **Fluid Flow** list defaults to **None** as there is nothing to couple to.

Click the **Go to Source** buttons ( ) to move to the main physics interface node for the selected physics interface.

	If a physics interface is deleted and then added to the model again, then in order to reestablish the coupling, you need to choose the physics interface again from the **Fluid flow** or **Species transport** lists. This is applicable to all multiphysics coupling nodes that would normally default to the once present interface. See Multiphysics Modeling Workflow in the *COMSOL Multiphysics Reference Manual*.

TURBULENCE

When the fluid flow interface uses a turbulence model, select an option from the **Mass transport turbulence model** list — **Kays–Crawford**, **High Schmidt Number**, or **User-defined turbulent Schmidt number**.

For **User-defined turbulent Schmidt number**, enter a **Turbulent Schmidt number** Sc_T (dimensionless).

The turbulent mass transfer added to the concentration equations is defined as

$$\mathbf{J}_{T,i} = -\frac{\mu_T}{Sc_T}\nabla c_i$$

where μ_T is the turbulent viscosity defined by the flow interface, and the turbulent Schmidt number, Sc_T, depends on the **Mass transport turbulence model** used.

Physics Interface Features

Physics nodes are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (macOS or Linux users), or right-click to access the context menu (all users).

	In general, to add a node, go to the **Physics** toolbar, no matter what operating system you are using.

LAMINAR FLOW

The available physics features for The Laminar Flow interface are listed in the section Domain, Boundary, Pair, and Point Nodes for Single-Phase Flow.

TRANSPORT OF DILUTED SPECIES

The available physics features for The Transport of Diluted Species interface are listed in the section Domain, Boundary, and Pair Nodes for the Transport of Diluted Species Interface.

Mass Transfer Variables in the Transport of Diluted Species Interface

In this section:

- Predefined Variables
- Global Variables
- Domain Fluxes
- Boundary Fluxes

Predefined Variables

This section lists the most common predefined variables available to evaluate fluxes, sources, and integral quantities used in mass balances. All the variable names begin with the physics interface name (the prefix). By default, the Transport of Diluted Species interface prefix is `tds`. As an example, you can access the variable named `dflux` using `tds.dflux` (as long as the physics interface is named `tds`).

TABLE 12-1: MASS TRANSFER VARIABLES.

VARIABLE	NAME	GEOMETRIC ENTITY LEVEL
`nmflow`	Normal molar flow rate	Global
`cflux`	Convective flux	Domain
`cfluxMag`	Convective flux magnitude	Domain
`dflux`	Diffusive flux	Domain
`dfluxMag`	Diffusive flux magnitude	Domain
`domflux`	Domain flux	Domain
`dpflux`	Dispersive flux	Domain
`mflux`	Electrophoretic flux	Domain
`mfluxMag`	Electrophoretic flux magnitude	Domain
`R`	Total rate expression	Domain
`tflux`	Total flux	Domain
`tfluxMag`	Total flux magnitude	Domain
`bndFlux`	Boundary flux	Boundary
`cbf`	Convective boundary flux	Boundary
`ncflux`	Normal convective flux	Boundary
`ndflux`	Normal diffusive flux	Boundary
`nmflux`	Normal electrophoretic flux	Boundary
`ntflux`	Normal total flux	Boundary

Global Variables

This section describes variables defined by integrals.

NORMAL MOLAR FLOW RATE

The Normal molar flow rate variable is a global variable defined by the features Inflow, Outflow, Flux, and Concentration. It corresponds to the integral of the Normal total flux, `ntflux`, over the feature's boundary selection (here denoted $\partial\Omega$):

$$\texttt{nmflow} = \int_{\partial\Omega} \texttt{ntflux} dA$$

Domain Fluxes

On domains, the mass fluxes are vector quantities. In addition to the flux variables, there are also predefined flux magnitudes (scalar quantities) for the domains.

CONVECTIVE FLUX

The convective flux variable, `cflux`, is defined as the concentration times the velocity field:

$$\texttt{cflux} = c\mathbf{u}$$

CONVECTIVE FLUX MAGNITUDE

The convective flux magnitude, `cfluxMag`, is the magnitude of the convective flux, defined as the square root of the sum of the convective flux components squared:

$$\texttt{cfluxMag} = \sqrt{\texttt{cflux}_x^2 + \texttt{cflux}_y^2 + \texttt{cflux}_z^2}$$

DIFFUSIVE FLUX

The diffusive flux variable, `dflux`, is defined as the negative of the diffusion coefficient times the concentration gradient:

$$\texttt{dflux} = -D\nabla c$$

DIFFUSIVE FLUX MAGNITUDE

The diffusive flux magnitude, `dfluxMag`, is the magnitude of the diffusive flux, defined as the square root of the sum of the diffusive flux components squared:

$$\texttt{dfluxMag} = \sqrt{\texttt{dflux}_x^2 + \texttt{dflux}_y^2 + \texttt{dflux}_z^2}$$

DOMAIN FLUX

The variable `domflux` is used to calculate fluxes if the **Compute boundary fluxes** checkbox is cleared, see Computing Accurate Fluxes. The flux variables `ndflux` and `ntflux` are then computed from the dependent variables using extrapolation. In a system with only diffusive flux, `domflux` is defined as the diffusive flux times the out-of-plane geometry extension, d (out-of-plane thickness for 2D systems, or cross-sectional area for a 1D or 1D axisymmetric system):

$$\texttt{domflux} = \texttt{dflux} \cdot d$$

In a system with convection using the conservative form (see Material Balance Formulation) the `domflux` variable is defined as:

$$\texttt{domflux} = (\texttt{dflux} + \texttt{cflux})d$$

DISPERSIVE FLUX

The predefined variable `dpflux` is available when both the **Mass transfer in porous media** checkbox, and the **Convection** checkbox are selected in the **Settings** window for the physics interface.

Dispersion, or dispersive flux, is defined as the negative of the dispersion tensor, D_D times the gradient of concentration:

$$\mathtt{dpflux} = -D_D \nabla c$$

ELECTROPHORETIC FLUX

Transport of ionic species through migration, as described in section Adding Transport Through Migration, is described by the electrophoretic flux variable `mflux`:

$$\mathtt{mflux} = -z u_\mathrm{m} \mathrm{F} c \nabla V$$

ELECTROPHORETIC FLUX MAGNITUDE

The diffusive flux magnitude, `dfluxMag`, is the magnitude of the electrophoretic flux, defined as the square root of the sum of the electrophoretic flux components squared:

$$\mathtt{mfluxMag} = \sqrt{\mathtt{mflux}_x^2 + \mathtt{mflux}_y^2 + \mathtt{mflux}_z^2}$$

TOTAL RATE EXPRESSION

The variable for a species total rate expression, R, is defined as the sum of all the reaction rates for that species. As an example, for a species i reacting in a first order, irreversible reaction j the total rate expression is:

$$R_i = \sum_j \nu_{ij} r_j = r_j = -k_j c_i$$

TOTAL FLUX

Total flux is the sum of all mass transport fluxes present. The definition of total flux, `tflux`, will depend on the transport mechanisms available in the system. As an example, the total flux in a system with diffusion and migration of ionic species is:

$$\mathtt{tflux} = \mathtt{dflux} + \mathtt{mflux}$$

TOTAL FLUX MAGNITUDE

The total flux magnitude is the magnitude of the total flux:

$$\mathtt{tfluxMag} = \sqrt{\mathtt{tflux}_x^2 + \mathtt{tflux}_y^2 + \mathtt{tflux}_z^2}$$

Boundary Fluxes

All domain fluxes (vector quantities) are also available as boundary fluxes. The boundary fluxes are equal to the value of the flux on adjacent domains. Additionally, normal boundary fluxes (scalar quantities) are available on boundaries.

BOUNDARY FLUX

The variable `bndFlux` is defined using the Boundary Flux Operators: uflux and dflux. These operators are used when the **Compute boundary fluxes** checkbox is selected, see Computing Accurate Fluxes.

On exterior boundaries, `bndFlux` is defined as:

- `bndFlux` = – `dflux_spatial`(c)/d, if the adjacent domain is on the downside
- `bndFlux` = – `uflux_spatial`(c)/d, if the adjacent domain is on the upside

The up and downside is defined by the surface normal, which points from downside to the upside. On interior boundaries, `bndFlux` is the mean of the fluxes on both sides:

$$\texttt{bndFlux} = 0.5(\texttt{uflux_spatial}(c) - \texttt{dflux_spatial}(c))/d$$

Also, d is the out-of-plane geometry extension (out-of-plane thickness for 2D systems, or cross-sectional area for a 1D or 1D axisymmetric system).

CONVECTIVE BOUNDARY FLUX

The variable `cbf` is used to account for convection when defining boundary conditions and is defined as:

$$\texttt{cbf} = c(\mathbf{u} \cdot \mathbf{n})$$

NORMAL CONVECTIVE FLUX

The variable `ncflux` is defined as:

$$\texttt{ncflux} = \texttt{cflux} \cdot \mathbf{n}$$

NORMAL DIFFUSIVE FLUX

The variable `ndflux` is defined as:

$$\texttt{ndflux} = \texttt{dflux} \cdot \mathbf{n}$$

NORMAL ELECTROPHORETIC FLUX

The variable `nmflux` is defined as:

$$\texttt{nmflux} = \texttt{mflux} \cdot \mathbf{n}$$

NORMAL TOTAL FLUX

The variable `ntflux` is defined as:

$$\texttt{ntflux} = \texttt{bndFlux}$$

for a system without convection, or a system with convection and a conservative form for the convective term.

In a system with convection, and a nonconservative convective form, the normal total flux is:

$$\texttt{ntflux} = \texttt{bndFlux+ncflux}$$

13

The Fluid Flow Interface

This chapter explains how to use the Laminar Flow interface, found under the **Fluid Flow** > **Single-Phase Flow** branch ( ) when adding a physics interface. This physics interface is used to model and simulate fluid mechanics for laminar, incompressible fluids. The engineering community often uses the term *CFD*, *computational fluid dynamics*, to refer to the numerical simulation of fluids.

See The Nonisothermal Flow and Conjugate Heat Transfer Interfaces for details about the modeling of laminar nonisothermal flows.

The optional *CFD Module* includes support for turbulent flow, turbulent nonisothermal flow, multiphase flow, and many other fluid flow related features.

In this chapter:

- Theory of Laminar Flow
- The Single-Phase Flow, Laminar Flow Interface

Theory of Laminar Flow

The theory for the Single-Phase Flow, Laminar Flow interface is described in this section:

- General Single-Phase Flow Theory
- Compressible Flow
- Weakly Compressible Flow
- The Mach Number Limit
- Incompressible Flow
- The Reynolds Number
- Gravity
- Theory for the Wall Boundary Condition
- Prescribing Inlet and Outlet Conditions
- Fully Developed Flow (Inlet)
- Fully Developed Flow (Outlet)
- Normal Stress Boundary Condition
- Porous Interface
- Mass Sources for Fluid Flow
- Numerical Stability — Stabilization Techniques for Fluid Flow
- Solvers for Laminar Flow
- Pseudo Time Stepping for Laminar Flow Models
- Nitsche Constraints
- Particle Tracing in Fluid Flow
- References for the Single-Phase Flow, Laminar Flow Interfaces

The theory about most boundary conditions is found in Ref. 2.

General Single-Phase Flow Theory

The Single-Phase Fluid Flow interfaces are based on the Navier–Stokes equations, which in their most general form read

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0 \tag{13-1}$$

$$\rho \frac{\partial \mathbf{u}}{\partial t} + \rho(\mathbf{u} \cdot \nabla)\mathbf{u} = \nabla \cdot [-p\mathbf{I} + \mathbf{K}] + \mathbf{F} \tag{13-2}$$

$$\rho C_p \left(\frac{\partial T}{\partial t} + (\mathbf{u} \cdot \nabla)T \right) = -(\nabla \cdot \mathbf{q}) + \mathbf{K}:\mathbf{S} - \frac{T}{\rho} \frac{\partial \rho}{\partial T}\bigg|_p \left(\frac{\partial p}{\partial t} + (\mathbf{u} \cdot \nabla)p \right) + Q \tag{13-3}$$

where

- ρ is the density (SI unit: kg/m^3)

- $\mathbf{u}$ is the velocity vector (SI unit: m/s)
- p is pressure (SI unit: Pa)
- $\mathbf{I}$ is the identity matrix (unitless)
- $\mathbf{K}$ is the viscous stress tensor (SI unit: Pa)
- $\mathbf{F}$ is the volume force vector (SI unit: N/m^3)
- C_p is the specific heat capacity at constant pressure (SI unit: J/(kg·K))
- T is the absolute temperature (SI unit: K)
- $\mathbf{q}$ is the heat flux vector (SI unit: W/m^2)
- Q contains the heat sources (SI unit: W/m^3)
- $\mathbf{S}$ is the strain-rate tensor:

$$\mathbf{S} = \frac{1}{2}(\nabla\mathbf{u} + (\nabla\mathbf{u})^T)$$

The operation ":" denotes a contraction between tensors defined by

$$\mathbf{a}:\mathbf{b} = \sum_n \sum_m a_{nm} b_{nm} \tag{13-4}$$

This is sometimes referred to as the double dot product.

Equation 13-1 is the continuity equation and represents conservation of mass. Equation 13-2 is a vector equation which represents conservation of momentum. Equation 13-3 describes the conservation of energy, formulated in terms of temperature. This is an intuitive formulation that facilitates boundary condition specifications.

To close the equation system, Equation 13-1 through Equation 13-3, constitutive relations are needed.

For a Newtonian fluid, which has a linear relationship between stress and strain, Stokes (Ref. 1) deduced the following expression:

$$\mathbf{K} = 2\mu\mathbf{S} - \frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I} \tag{13-5}$$

The dynamic viscosity, μ (SI unit: Pa·s), for a Newtonian fluid is allowed to depend on the thermodynamic state but not on the velocity field. All gases and many liquids can be considered Newtonian.

For an inelastic non-Newtonian fluid, the relationship between stress and strain rate is nonlinear, and an apparent viscosity is introduced instead of the dynamic viscosity. Examples of non-Newtonian fluids are honey, mud, blood, liquid metals, and most polymer solutions.

In theory, the same equations describe both laminar and turbulent flows. In practice, however, the mesh resolution required to simulate turbulence with the Laminar Flow interface makes such an approach impractical.

There are several books where derivations of the Navier–Stokes equations and detailed explanations of concepts such as Newtonian fluids can be found. See, for example, the classical text by Batchelor (Ref. 3) and the more recent work by Panton (Ref. 4).

Many applications describe isothermal flows for which Equation 13-3 is decoupled from Equation 13-1 and Equation 13-2.

2D AXISYMMETRIC FORMULATIONS

A 2D axisymmetric formulation of Equation 13-1 and Equation 13-2 requires $\partial/\partial\phi$ to be zero. That is, there must be no gradients in the azimuthal direction. A common additional assumption is, however, that $u_\phi = 0$. In such cases, the ϕ-equation can be removed from Equation 13-2. The resulting system of equations is both easier to converge and computationally less expensive compared to retaining the ϕ-equation. The default 2D axisymmetric formulation of Equation 13-1 and Equation 13-2 therefore assumes that

$$\partial/\partial\phi = 0$$
$$u_\phi = 0$$

Compressible Flow

The equations of motion for a single-phase fluid are the continuity equation:

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{u}) = 0 \tag{13-6}$$

and the momentum equation:

$$\rho \frac{\partial \mathbf{u}}{\partial t} + \rho \mathbf{u} \cdot \nabla \mathbf{u} = -\nabla p + \nabla \cdot \left(\mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T) - \frac{2}{3}\mu(\nabla \cdot \mathbf{u})\mathbf{I} \right) + \mathbf{F} \tag{13-7}$$

These equations are applicable for incompressible as well as for compressible flow with density and viscosity variations.

Weakly Compressible Flow

The same equations as for Compressible Flow are applied for weakly compressible flow. The only difference is that the density is evaluated at the reference pressure. The density may be a function of other quantities, in particular it may be temperature dependent.

The weakly compressible flow equations are valid for incompressible as well as compressible flow with density variations independent of the pressure.

Provided that the densities dependency pressure is specified through model inputs, the density is automatically evaluated at the reference pressure level.

The Mach Number Limit

An important dimensionless number in fluid dynamics is the Mach number, Ma, defined by

$$\mathrm{Ma} = \frac{|\mathbf{u}|}{a}$$

where a is the speed of sound. A flow is formally incompressible when $\mathrm{Ma} = 0$. This is theoretically achieved by letting the speed of sound tend to infinity. The Navier–Stokes equations then have the mathematical property that pressure disturbances are instantaneously propagated throughout the entire domain. This results in a parabolic equation system.

The momentum equation, Equation 13-7, is parabolic for unsteady flow and elliptic for steady flow, whereas the continuity equation, Equation 13-6, is hyperbolic for both steady and unsteady flow. The combined system of equations is thus hybrid parabolic-hyperbolic for unsteady flow and hybrid elliptic-hyperbolic for steady flow. An exception occurs when the viscous term in Equation 13-7 becomes vanishingly small, such as at an outflow boundary, in which case the momentum equation becomes locally hyperbolic. The number of boundary conditions

to apply on the boundary then depends on the number of characteristics propagating into the computational domain. For the purely hyperbolic system, the number of characteristics propagating from the boundary into the domain changes as the Mach number passes through unity. Hence, the number of boundary conditions required to obtain a numerically well-posed system must also change. The compressible formulation of the laminar and turbulent interfaces uses the same boundary conditions as the incompressible formulation, which implies that the compressible interfaces are not suitable for flows with a Mach number larger than or equal to one. Yet, the practical Mach number limit is lower than one. The main reason is that the numerical scheme (stabilization and boundary conditions) of the Laminar Flow interface does not recognize the direction and speed of pressure waves. The fully compressible Navier–Stokes equations do, for example, start to display very sharp gradients already at moderate Mach numbers. But the stabilization for the single-phase flow interface does not necessarily capture these gradients. It is impossible to give an exact limit where the low Mach number regime ends and the moderate Mach number regime begins, but a rule of thumb is that the Mach number effects start to appear at $\mathrm{Ma} = 0.3$. For this reason, the compressible formulation is referred to as *Compressible flow (Ma<0.3)* in COMSOL Multiphysics.

Incompressible Flow

When the temperature variations in the flow are small, a single-phase fluid can often be assumed incompressible; that is, ρ is constant or nearly constant. This is the case for all liquids under normal conditions and also for gases at low velocities. For constant ρ, Equation 13-6 reduces to

$$\rho \nabla \cdot \mathbf{u} = 0 \tag{13-8}$$

and Equation 13-7 becomes

$$\rho \frac{\partial \mathbf{u}}{\partial t} + \rho(\mathbf{u} \cdot \nabla)\mathbf{u} = \nabla \cdot [-p\mathbf{I} + \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T)] + \mathbf{F} \tag{13-9}$$

Provided that the densities dependency on temperature and pressure is specified through model inputs, the density is evaluated at the reference pressure level and at the reference temperature. However, if the density is a function of other quantities such as a concentration field, or if the density is specified by a user defined expression, the user has to make sure that the density is defined as constant when the incompressible flow formulation is used.

The Reynolds Number

A fundamental characteristic in analyses of fluid flow is the Reynolds number:

$$\mathrm{Re} = \frac{\rho U L}{\mu}$$

where U denotes a velocity scale, and L denotes a representative length. The Reynolds number represents the ratio between inertial and viscous forces. At low Reynolds numbers, viscous forces dominate and tend to damp out all disturbances, which leads to laminar flow. At high Reynolds numbers, the damping in the system is very low, giving small disturbances the possibility to grow by nonlinear interactions. If the Reynolds number is high enough, the flow field eventually ends up in a chaotic state called turbulence.

Note that the Reynolds number can have different meanings depending on the length scale and velocity scale. To be able to compare two Reynolds numbers, they must be based on equivalent length and velocity scales.

The Fluid Flow interfaces automatically calculate the local cell Reynolds number $\mathrm{Re}^c = \rho|\mathbf{u}|h/(2\mu)$ using the element length h for L and the magnitude of the velocity vector u for the velocity scale U. This Reynolds number is not related to the character of the flow field, but to the stability of the numerical discretization. The risk for numerical oscillations in the solution increases as Re^c grows. The cell Reynolds number is a predefined quantity available for visualization and evaluation (typically it is available as: `spf.cellRe`).

DEFINITION

The gravity force is defined from the acceleration of gravity vector, $\mathbf{g}$, and the density, ρ. Under usual conditions and in Cartesian coordinates with the z-axis in the vertical direction,

$$\mathbf{g} = \begin{pmatrix} 0 \\ 0 \\ -g_{\text{const}} \end{pmatrix}.$$

When gravity is considered, a volume force equal to $\rho\mathbf{g}$ is included in the momentum equation. For example, for laminar weakly compressible flow, it reads:

$$\rho\frac{\partial \mathbf{u}}{\partial t} + \rho\mathbf{u}\cdot\nabla\mathbf{u} = \nabla\cdot\left(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I}\right) + \mathbf{F} + \rho\mathbf{g} \tag{13-10}$$

Introducing a constant reference density ρ_{ref}, and assuming that $\mathbf{g}$ is homogeneous, this equation is equivalently written:

$$\begin{aligned}&\rho\frac{\partial \mathbf{u}}{\partial t} + \rho\mathbf{u}\cdot\nabla\mathbf{u} = \\ &\nabla\cdot\left(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I} + \rho_{\text{ref}}\mathbf{g}\cdot(\mathbf{r}-\mathbf{r}_{\text{ref}})\right) + \mathbf{F} + (\rho-\rho_{\text{ref}})\mathbf{g}\end{aligned} \tag{13-11}$$

where $\mathbf{r}$ is the position vector and $\mathbf{r}_{\text{ref}}$ is an arbitrary reference position vector.

From this equation, it is convenient to define the reduced pressure which accounts for the hydrostatic pressure, $\tilde{p} = p - \rho_{\text{ref}}\mathbf{g}\cdot(\mathbf{r}-\mathbf{r}_{\text{ref}})$

$$\begin{aligned}&\rho\frac{\partial \mathbf{u}}{\partial t} + \rho\mathbf{u}\cdot\nabla\mathbf{u} = \nabla\cdot\left(-\tilde{p}\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I}\right) + \\ &\mathbf{F} + (\rho-\rho_{\text{ref}})\mathbf{g}\end{aligned} \tag{13-12}$$

In Equation 13-12, the gravity force is written $(\rho - \rho_{\text{ref}})\mathbf{g}$.

PRESSURE FORMULATION

When the relative pressure is used (default option) the interface dependent variable represents the relative pressure and the absolute pressure is defined as $p_A = p_{\text{ref}} + p$. When the pressure is used to define a boundary condition (for example, when p_0 defines the pressure condition at an outlet), it represents the relative pressure. Hence defining the outlet pressure as $p_{\text{hydro,approx}} = -\rho_{\text{ref}}\mathbf{g}\cdot(\mathbf{r}-\mathbf{r}_{\text{ref}})$ compensates for the gravity force for an ambient reference pressure of 0 Pa when the density is constant, there is no external force, and provided p_{ref}, $\mathbf{g}$, and $\mathbf{r}_0$ are defined consistently.

When the reduced pressure is used, the interface dependent variable (named p by default) represents the reduced pressure. The absolute pressure is then defined as $p_A = p_{\text{ref}} - \rho_{\text{ref}}\mathbf{g}\cdot(\mathbf{r}-\mathbf{r}_{\text{ref}}) + p$. In this case when the pressure is used to define a boundary condition (for example, to define a pressure condition at an outlet), its value corresponds to the reduced pressure. Hence, the prescribed pressure compensates for an approximate hydrostatic pressure, $p_{\text{hydro,approx}} = -\rho_{\text{ref}}\mathbf{g}\cdot(\mathbf{r}-\mathbf{r}_{\text{ref}})$, which is exact only when the density is constant and there is no external force.

PRESSURE BOUNDARY CONDITION

For an immobile fluid the momentum equation simplifies to $\nabla\cdot(p\mathbf{I}) = \mathbf{F} + \rho\mathbf{g}$ or

$\nabla \cdot (-\tilde{p}\mathbf{I}) = \mathbf{F} + (\rho - \rho_{ref})\mathbf{g}$ depending on the pressure formulation.

For incompressible flow, assuming there are no external forces, this leads respectively to $p = -\rho_{ref}\mathbf{g} \cdot (\mathbf{r} - \mathbf{r}_{ref}) + p_0$ or $\tilde{p} = p_0$.

Theory for the Wall Boundary Condition

See Wall for the node settings. Note that some modules have additional theory sections describing options available with that module.

SLIP

The Slip condition assumes that there are no viscous effects at the slip wall and hence, no boundary layer develops. From a modeling point of view, this is a reasonable approximation if the important effect of the wall is to prevent fluid from leaving the domain. Mathematically, the constraint can be formulated as:

$$\mathbf{u} \cdot \mathbf{n} = 0, \qquad (-p\mathbf{I} + \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^{\mathrm{T}}))\mathbf{n} = \mathbf{0}$$

The no-penetration term takes precedence over the Neumann part of the condition and the above expression is therefore equivalent to

$$\mathbf{u} \cdot \mathbf{n} = 0, \qquad \mathbf{K}_n - (\mathbf{K}_n \cdot \mathbf{n})\mathbf{n} = \mathbf{0}$$
$$\mathbf{K}_n = \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^{\mathrm{T}})\mathbf{n}$$

expressing that there is no flow across the boundary and no viscous stress in the tangential direction.

For a moving wall with translational velocity $\mathbf{u}_{tr}$, $\mathbf{u}$ in the above equations is replaced by the relative velocity $\mathbf{u}_{rel} = \mathbf{u} - \mathbf{u}_{tr}$.

SLIDING WALL

The sliding wall option is appropriate if the wall behaves like a conveyor belt; that is, the surface is sliding in its tangential direction. The wall does not have to actually move in the coordinate system.

- In 2D, the tangential direction is unambiguously defined by the direction of the boundary, but the situation becomes more complicated in 3D. For this reason, this boundary condition has slightly different definitions in the different space dimensions.
- For 2D and 2D axisymmetric components, the velocity is given as a scalar U_w and the condition prescribes

  $$\mathbf{u} \cdot \mathbf{n} = 0, \qquad \mathbf{u} \cdot \mathbf{t} = U_w$$

  where $\mathbf{t} = (n_y, -n_x)$ for 2D and $\mathbf{t} = (n_z, -n_r)$ for axial symmetry.
- For 3D components, the velocity is set equal to a given vector $\mathbf{u}_w$ projected onto the boundary plane:

  $$\mathbf{u} = \frac{\mathbf{u}_w - (\mathbf{n} \cdot \mathbf{u}_w)\mathbf{n}}{\left\|\mathbf{u}_w - (\mathbf{n} \cdot \mathbf{u}_w)\mathbf{n}\right\|}\left\|\mathbf{u}_w\right\|$$

  The normalization makes $\mathbf{u}$ have the same magnitude as $\mathbf{u}_w$ even if $\mathbf{u}_w$ is not exactly parallel to the wall.

CONSTRAINT SETTINGS

The wall feature uses three different techniques to constrain the velocity field:

- **Pointwise constraints** is the standard technique to enforce strong constraints in the finite element method. The desired value of the velocity is prescribed at each node point in the mesh. Since the constraint is enforced locally at each node, only local values are affected by the constraint and the constraints are independent of each other.

The solvers can therefore eliminate both the constrained degrees of freedom and the constraint force terms, effectively reducing the number of degrees of freedom being solved for.

The main advantage of pointwise constraints is that they enforce the constraint exactly pointwise. This means that they do not introduce any leakage of the velocity across the wall, unless specified. The main disadvantage of pointwise constraints is that they introduce locking effects when trying to impose a no-penetration condition for the velocity, $\mathbf{u} \cdot \mathbf{n} = 0$, on curved walls or walls with sharp corners.

- **Weak constraints** is an alternative method to prescribe the velocity. It consists on enforcing the boundary condition for the velocity via *Lagrange multipliers*. Their main advantage is that the Lagrange multiplier can provide an accurate representation of the reaction flux at the wall. Their main disadvantage is that they introduce extra unknowns, and are usually difficult to combine with other constraint methods on adjacent boundaries. Moreover, they may require extra constraints for the Lagrange multipliers. For more information, see Weak Constraints in the *COMSOL Multiphysics Reference Manual*.
- **Nitsche constraints** use a numerical flux to prescribe the velocity at the wall. They impose the constraint in an integral sense rather than pointwise, and do not suffer from the locking effects introduced by pointwise constraints when trying to prescribe a no penetration condition for the velocity. They are also better behaved when prescribing nonlinear constraints. Their main disadvantage is that the constraint is only imposed approximately, and may produce small leaks. For more information, see Nitsche Constraints.

The following combination of Constraint techniques can be selected in the **Constraint Setting** sections of Wall boundary conditions:

- **Automatic** (default) use different constraint methods depending on whether only the normal component of the velocity is prescribed, such as in the no penetration condition, $\mathbf{u} \cdot \mathbf{n} = 0$, imposed, for example, in Slip walls or No Slip walls using Wall Functions or Automatic Wall Treatment, or both tangential and normal components are prescribed, as is the case of No Slip walls in laminar flow.

  Nitsche constraints are used to impose the no penetration condition for Slip walls. When a No Slip condition is prescribed, pointwise constraints are used except for moving walls where Nitsche constraints are used.
- **Pointwise constraints**
- **Nitsche constraints**
- **Weak constraints** — these are not available on Interior Walls.
- **Mixed constraints** — this option is only available when both the tangential and normal components of the velocity need to be prescribed. The velocity on the wall normal direction is imposed via pointwise constraints. The constraint for the tangential directions is relaxed, and Nitsche constraints are used instead. This provides improved accuracy and performance when working with coarse boundary layer meshes. For more information, see Ref. 18.

Prescribing Inlet and Outlet Conditions

The Navier–Stokes equations can show large variations in mathematical behavior, ranging from almost completely elliptic to almost completely hyperbolic. This has implications when it comes to prescribing admissible boundary conditions. There is also a discrepancy between mathematically valid boundary conditions and practically useful boundary conditions. See Inlet and Outlet for the node settings.

INLET CONDITIONS

An inlet requires specification of the velocity components. The most robust way to do this is to prescribe a velocity field using a Velocity condition.

A common alternative to prescribing the complete velocity field is to prescribe a pressure and all but one velocity component. The pressure cannot be specified pointwise because this is mathematically over-constraining. Instead the pressure can be specified via a stress condition:

$$-p + 2\mu\frac{\partial u_n}{\partial n} = F_n \tag{13-13}$$

where $\partial u_n/\partial n$ is the normal derivative of the normal velocity component. Equation 13-13 is prescribed by the Pressure condition in the Inlet and Outlet features and the Normal stress condition in the Open Boundary and Boundary Stress features. Equation 13-13 is mathematically more stringent compared to specifying the pressure pointwise and at the same time cannot guarantee that p obtains the desired value. In practice, p is close to F_n, except for low Reynolds number flows where viscous effects are the only effects that balance the pressure. In addition to Equation 13-13, all but one velocity component must be specified. For low Reynolds numbers, this can be specified by a vanishing tangential stress condition:

$$\mu\frac{\partial u_t}{\partial n} = 0$$

which is what the Normal stress condition does. Vanishing tangential stress becomes a less well-posed inlet condition as the Reynolds number increases. The Pressure condition in the Inlet feature therefore requires a flow direction to be prescribed, which provides a well-posed condition independent of Reynolds number.

OUTLET CONDITIONS

The most common approach is to prescribe a pressure via a normal stress condition on the outlet. This is often accompanied by a vanishing tangential stress condition:

$$\mu\frac{\partial u_t}{\partial n} = 0$$

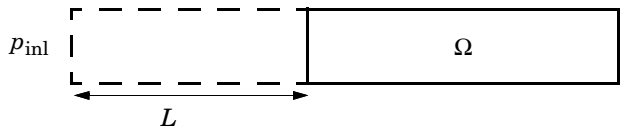
where $\partial u_t/\partial n$ is the normal derivative of the tangential velocity field. It is also possible to prescribe u_t to be zero. The latter option should be used with care since it can have a significant effect on the upstream solution.

The elliptic character of the Navier–Stokes equations mathematically permits specifying a complete velocity field at an outlet. This can, however, be difficult to apply in practice. The reason being that it is hard to prescribe the outlet velocity so that it is consistent with the interior solution at each point. The adjustment to the specified velocity then occurs across an outlet boundary layer. The thickness of this boundary layer depends on the Reynolds number; the higher the Reynolds number, the thinner the boundary layer.

Normal Stress Boundary Condition

Fully Developed Flow (Inlet)

The **Fully developed flow** boundary condition can be understood from the following figure:



The flow to the domain Ω is assumed to enter through a straight channel of length L. The channel is a virtual extrusion of the inlet cross section and a pressure constant pressure P_{inl} is applied on the inlet of the virtual channel.

The Fully Developed Flow boundary condition prescribes that the tangential flow component on the boundary is zero:

$$\mathbf{u} - (\mathbf{u}\cdot\mathbf{n})\mathbf{n} = \mathbf{0}$$

The momentum equation for a fully developed flow in the virtual extrusion of the inlet cross section can then be projected onto the inlet boundary with the following weak equation as the result:

$$\int_{\partial\Omega} \left(\left(L\left(-\mu(\nabla_{\mathbf{t}}\mathbf{u} + (\nabla_{\mathbf{t}}\mathbf{u})^T) + \frac{(p + P_{\text{inl}})}{2}\mathbf{I} \right) : (\nabla_{\mathbf{t}}\hat{\mathbf{u}}) \right) - P_{\text{inl}}(\mathbf{n} \cdot \hat{\mathbf{u}}) \right)$$

The exact value of L is somewhat arbitrary as long as it is not too high or too low. L is therefore set to ten times the inlet edge length in 2D and to ten times the square root of the inlet area in 2D axisymmetry and in 3D.

The fact that the velocity profile is not prescribed, but rather the solution of a projected weak contribution, means that the actual velocity profile that is obtained on the inlet can deviate from the analytical fully developed flow profile (in cases such an analytical solution exists) if required by the solution inside the computational domain, Ω. This is most notably if the flow is strongly curved just downstream of the inlet. This can, for example, be the case if an object is positioned just downstream of the inlet or if the adjacent boundaries are not orthogonal to the inlet. The analytical solution can in these cases be recovered by including a little bit of the inlet channel in the computational domain.

The inlet pressure, P_{inl}, must be solved for and the its equation is a discrete algebraic equation (DAE) for P_{inl}. When, for example, the average velocity is specified, the DAE reads

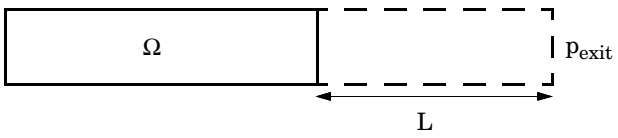
$$(\langle \mathbf{u} \cdot \mathbf{n} \rangle + U_{\text{av}})\hat{P}_{\text{inl}}$$

where <·> denotes the average over the inlet. Since the equation for P_{inl} is a DAE (the equation for P_{inl} does not contain P_{inl}), it must be solved coupled to Navier–Stokes and it must be treated by a Vanka presmoother and postsmoother if iterative solvers are used.

The boundary conditions for the virtual inlet channel are inherited from the boundaries adjacent to the inlet channel. Virtual boundaries adjacent to walls (except slip walls) are treated as no-slip walls. Virtual boundaries adjacent to any other type of boundary are treated as slip-walls (or equivalently as symmetry boundaries). So in the figure above, if the lower boundary of Ω is a no-slip wall and the top boundary is a symmetry boundary, the lower boundary of the virtually extruded channel becomes a no-slip wall and the upper boundary becomes a symmetry boundary.

Fully Developed Flow (Outlet)

The **Fully developed flow** boundary condition can be understood from the following figure:



The flow to the domain Ω is assumed to enter through a straight channel of length L. The channel is a virtual extrusion of the inlet cross section and a pressure constant pressure P_{exit} is applied on the inlet of the virtual channel.

The Fully Developed Flow boundary condition prescribes that the tangential flow component on the boundary is zero:

$$\mathbf{u} - (\mathbf{u} \cdot \mathbf{n})\mathbf{n} = \mathbf{0}$$

The momentum equation for a fully developed flow in the virtual extrusion of the inlet cross section can then be projected onto the inlet boundary with the following weak equation as the result:

$$\int_{\partial\Omega}\left(\left(L\left(-\mu(\nabla_{\mathbf{t}}\mathbf{u}+(\nabla_{\mathbf{t}}\mathbf{u})^T)+\frac{(p+P_{\text{exit}})}{2}\mathbf{I}\right):(\nabla_{\mathbf{t}}\hat{\mathbf{u}})\right)-P_{\text{exit}}(\mathbf{n}\cdot\hat{\mathbf{u}})\right)$$

The exact value of L is somewhat arbitrary as long as it is not too high or too low. L is therefore set to ten times the inlet edge length in 2D and to ten times the square root of the inlet area in 2D axisymmetry and in 3D.

The fact that the velocity profile is not prescribed, but rather the solution of a projected weak contribution, means that the actual velocity profile that is obtained on the outlet can deviate from the analytical fully developed flow profile (in cases such an analytical solution exists) if required by the solution inside the computational domain, Ω. The inlet pressure, P_{exit}, must be solved for and the its equation is a discrete algebraic equation (DAE) for P_{exit}. When, for example, the average velocity is specified, the DAE reads

$$(\langle\mathbf{u}\cdot\mathbf{n}\rangle+U_{\text{av}})\hat{P}_{\text{exit}}$$

where <·> denotes the average over the inlet. Since the equation for P_{ext} is a DAE, it must be solved coupled to Navier–Stokes and it must be treated by a Vanka presmoother and postsmoother if iterative solvers are used.

The boundary conditions for the virtual outlet channel are inherited from the boundaries adjacent to the outlet channel. Virtual boundaries adjacent to walls (except slip walls) are treated as no-slip walls. Virtual boundaries adjacent to any other type of boundary are treated as slip-walls (or equivalently as symmetry boundaries).

Normal Stress Boundary Condition

The total stress on the boundary is set equal to a stress vector of magnitude f_0, oriented in the negative normal direction:

$$\left(-p\mathbf{I}+\left(\mu(\nabla\mathbf{u}+(\nabla\mathbf{u})^T)-\frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I}\right)\right)\mathbf{n}=-f_0\mathbf{n}$$

$$(-p\mathbf{I}+\mu(\nabla\mathbf{u}+(\nabla\mathbf{u})^T))\mathbf{n}=-f_0\mathbf{n}$$

using the compressible/weakly compressible and the incompressible formulation, respectively.

This implies that the total stress in the tangential direction is zero. This boundary condition implicitly sets a constraint on the pressure which for 2D flows is

$$p=2\mu\frac{\partial u_n}{\partial n}+f_0 \tag{13-14}$$

If $\partial u_n/\partial n$ is small, Equation 13-14 states that $p\approx f_0$.

The Normal Stress condition is the mathematically correct version of the Pressure Conditions condition (Ref. 4), but it is numerically less stable.

Pressure Boundary Condition

For single-phase flow, a mathematically correct natural boundary condition for outlets is

$$\left(-p\mathbf{I}+\mu(\nabla\mathbf{u}+(\nabla\mathbf{u})^T)-\frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I}\right)\mathbf{n}=-p_0\mathbf{n} \tag{13-15}$$

$$(-p\mathbf{I}+\mu(\nabla\mathbf{u}+(\nabla\mathbf{u})^T))\mathbf{n}=-p_0\mathbf{n} \tag{13-16}$$

using the compressible/weakly compressible and the incompressible formulation, respectively.

This is a normal stress condition together with a no-tangential-stress condition. When $\mu > 0$, Equation 13-15 or Equation 13-16 can be supplemented with a tangential velocity condition

$$\mathbf{u} \cdot \mathbf{t} = 0 \tag{13-17}$$

If so, the no-tangential-stress condition is overridden. An issue with Equation 13-15 or Equation 13-16 is that it does not strongly enforce unidirectional flow on the boundary. If the prescribed pressure on an outlet is too high, parts of the outlet can actually have inflow. This is not as much of an issue for the Navier–Stokes equations as it is an issue for scalar transport equations solved along with the Navier–Stokes equations. Hence, when applying the **Pressure** boundary condition at an outlet or inlet you can further constrain the flow. With the **Suppress backflow** option

$$\begin{gathered}\left(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla \cdot \mathbf{u})\mathbf{I}\right)\mathbf{n} = -\hat{p}_0\mathbf{n} \\ (-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T))\mathbf{n} = -\hat{p}_0\mathbf{n} \\ \hat{p}_0 \le p_0\end{gathered}, \tag{13-18}$$

the normal stress is adjusted to keep

$$\mathbf{u} \cdot \mathbf{n} \ge 0 \tag{13-19}$$

Equation 13-18 effectively means that the prescribed pressure is p_0 if $\mathbf{u} \cdot \mathbf{n} \ge 0$, but smaller at locations where $\mathbf{u} \cdot \mathbf{n} < 0$. This means that Equation 13-18 does not completely prevent backflow, but the backflow is substantially reduced. Backflow is suppressed also when external forces are acting on the fluid, provided the magnitude of these forces are of the same order as the dynamic pressure at the outlet.

A pressure condition can also be applied at an inlet. In this case, either the normal stress is prescribed

$$\begin{gathered}\mathbf{n}^T\left(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla \cdot \mathbf{u})\mathbf{I}\right)\mathbf{n} = -\hat{p}_0 \\ \mathbf{n}^T(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T))\mathbf{n} = -\hat{p}_0 \\ \hat{p}_0 \ge p_0\end{gathered} \tag{13-20}$$

together with the tangential condition in Equation 13-17, or, a general flow direction is prescribed.

$$\begin{gathered}\mathbf{r}_\mathbf{u}^T\left(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla \cdot \mathbf{u})\mathbf{I}\right)\mathbf{n} = -\hat{p}_0(\mathbf{r}_\mathbf{u} \cdot \mathbf{n}) \\ \mathbf{r}_\mathbf{u}^T(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T))\mathbf{n} = -\hat{p}_0(\mathbf{r}_\mathbf{u} \cdot \mathbf{n}) \\ \hat{p}_0 \ge p_0 \\ \mathbf{u} - (\mathbf{u} \cdot \mathbf{r}_\mathbf{u})\mathbf{r}_\mathbf{u} = \mathbf{0},\ \mathbf{r}_\mathbf{u} = \frac{\mathbf{d}_\mathbf{u}}{\|\mathbf{d}_\mathbf{u}\|}\end{gathered} \tag{13-21}$$

The “>” option is used with suppress backflow to have $\mathbf{u} \cdot \mathbf{n} \le 0$ or $\mathbf{u} \cdot \mathbf{r}_\mathbf{u} \ge 0$.

For incompressible single-phase flow, it is also allowed to specify the total pressure, p_{tot}, instead of the static pressure, p_{stat}, on inlet and outlet boundaries. It is more useful, for example, in pump applications. The pressure is then prescribed at the boundaries using Bernoulli’s principle,

$$p = p_{\text{stat}} = p_{\text{tot}} - \frac{1}{2}\rho|\mathbf{u}|^2 \tag{13-22}$$

The equation is imposed with two options: **Average** and **Pointwise**.

In the first option, p_{stat} is prescribed by:

$$\mathbf{n}^T(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T))\mathbf{n} = \mathbf{n}^T(-p_{\text{stat}}\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T))\mathbf{n} \tag{13-23}$$

where p_{tot} and $|\mathbf{u}|^2$ are averaged over the boundaries using the `aveop` operator:

$$p_{\text{stat}} = \text{aveop}(p_{\text{tot}}) - \frac{1}{2}\rho \cdot \text{aveop}(|\mathbf{u}|^2)$$

For the second option, Equation 13-22 is prescribed pointwise.

See Inlet, Outlet, Open Boundary, and No Viscous Stress for the individual node settings. Note that some modules have additional theory sections describing options available with that module.

Porous Interface

This condition properly accounts for a sudden jump in porosity ε_p across boundary between different domains, giving the corresponding jump in stress across the interface. The emergence of a boundary layer on the upstream side of the interface is also revealed, which provides modifications to the behavior of the tangential velocity near the interface. The feature helps to avoid the need to add a very thin transition region, in which $\varepsilon_{p,\text{upstream}}$ changes to $\varepsilon_{p,\text{downstream}}$ continuously, while solving the Brinkman equation in such situations. Below, '–' and '+' (used as subscripts and superscripts) refer to the upstream and downstream side of the interface, respectively.

Whatever the option for **Continuity conditions** is chosen, the velocity conditions are

$$[\rho(\mathbf{u}\cdot\mathbf{n})]\Big|_-^+ = 0, \qquad \mathbf{u}_t\Big|_-^+ \equiv [\mathbf{u} - (\mathbf{u}\cdot\mathbf{n})\mathbf{n}]\Big|_-^+ = 0$$

That is, the mass flux and tangential velocity across the interface are constant, and $\mathbf{n}$ is assumed to be a normal pointing from '–' to '+'. **Velocity and stress** option just imposes usual stress continuity adding a correction for a possible jump in density:

$$\left[p\mathbf{n} - \mathbf{K}\mathbf{n} + \rho(\mathbf{u}\cdot\mathbf{n})\left(\left[\frac{1}{\varepsilon_p}\right]_{\text{av}}\right)^2\mathbf{u}\right]\Bigg|_-^+ = 0$$

The option **Velocity and porosity-corrected stress** (default) adds a contribution due to the inertial term, which is nontrivial (gives nonzero effect) when ε_p jumps across the interface:

$$\left[p\mathbf{n} - \mathbf{K}\mathbf{n} + \rho(\mathbf{u}\cdot\mathbf{n})\left(\left[\frac{1}{\varepsilon_p}\right]_{\text{av}}\right)^2\mathbf{u} + \rho(\mathbf{u}\cdot\mathbf{n})\left(\frac{1}{2\varepsilon_p^2}\right)\mathbf{u}_{\text{av}}\right]\Bigg|_-^+ = 0$$

Notice that $\left[\frac{1}{\varepsilon_p}\right]_{\text{av}} = \left(\left[\frac{1}{\varepsilon_p}\right]_- + \left[\frac{1}{\varepsilon_p}\right]_+\right)/2$, $\mathbf{u}_{\text{av}} = (\mathbf{u}_- + \mathbf{u}_+)/2$ and so on.

Then, the **Velocity and porosity-corrected stress with loss** option has a 'pressure loss' term:

$$\left[p\mathbf{n} - \mathbf{K}\mathbf{n} + \rho(\mathbf{u}\cdot\mathbf{n})\left(\left[\frac{1}{\varepsilon_p}\right]_{\text{av}}\right)^2\mathbf{u} + \rho(\mathbf{u}\cdot\mathbf{n})\left(\frac{1}{2\varepsilon_p^2}\right)\mathbf{u}_{\text{av}}\right]\Bigg|_-^+ + p^{(\text{loss})}\mathbf{n} = 0$$

This loss occurs in the downstream direction. Its mechanism is similar to the mechanism of common engineering 'total pressure loss'. Indeed, 'expansion' and 'contraction' across the interface experienced by the flow on the microscopic level (due to increasing or decreasing porosity, ε_p, respectively), are roughly equivalent to expansion and contraction of flow in a pipe with geometrical variations. Accordingly, it is assumed that only the normal velocity component is responsible for the loss. In the case of normal flow and negligible viscous term the pipe-analogy is quite exact.

Subsequently, **Pressure loss model** should be specified. Choosing **User-defined loss coefficients** requires values of **Expansion loss coefficient** and **Contraction loss coefficient** ($K_{exp} = 1$ and $K_{contr} = 0.5$ are default values). The resulting losses on the 'expansion' and 'contraction' boundaries are:

$$p^{(\text{loss,expansion})} = K_{\text{exp}}\left(\left(\frac{\rho(\mathbf{u}\cdot\mathbf{n})^2}{2\varepsilon_p^2}\right)_-\right),$$

$$p^{(\text{loss,contraction})} = K_{\text{contr}}\left(\frac{\rho(\mathbf{u}\cdot\mathbf{n})^2}{2\varepsilon_p^2}\right)_+$$

Borda–Carnot option results in the following losses:

$$p^{(\text{loss,expansion})} = \frac{\rho_{\text{av}}}{2}\left(\left[\frac{(\mathbf{u}\cdot\mathbf{n})}{\varepsilon_p}\right]_+ - \left[\frac{(\mathbf{u}\cdot\mathbf{n})}{\varepsilon_p}\right]_-\right)^2,$$

$$p^{(\text{loss,contraction})} = \frac{1}{2}\left(\frac{\rho(\mathbf{u}\cdot\mathbf{n})^2}{\varepsilon_p^2}\right)_+ \left(\frac{1}{c_{\text{vc}}} - 1\right)^2$$

and requires to choose **Vena contracta model**. The **User defined** option asks for value of **Vena contracta coefficient** ($c_{vc} = 0.5$ by default). **Weisbach** option computes the coefficient based on the ratio of porosities across the interface:

$$c_{\text{vc}} = c_{\text{vc,ll}} + (1 - c_{\text{vc,ll}})\left(\frac{\varepsilon_{p,+}}{\varepsilon_{p,-}}\right)^{n_{\text{vc}}}$$

and requires inputs for **Lower limit** and **Exponent** ($c_{\text{vc,ll}} = 0.63$ and $n_{\text{vc}} = 3$ are default values).

Although the velocity conditions formally look the same for all **Continuity conditions** options, the latter two (containing the inertial correction due to the porosity jump) lead to an extra nontrivial effect. Namely, the tangential velocity exponentially evolves over a boundary layer formed on the upstream side of the interface boundary. This boundary layer has a characteristic length equal to

$$l_- = \frac{\mu\varepsilon_{p,-}}{\rho(\mathbf{u}\cdot\mathbf{n})}$$

The ratio of the tangential velocities right after the interface ('downstream') and outside the boundary layer ('upstream infinity') is

$$\frac{|\mathbf{u}_{\text{t,+}}|}{|\mathbf{u}_{\text{t,upstream infinity}}|} = \frac{2\varepsilon_{p,+}/\varepsilon_{p,-}}{\varepsilon_{p,+}/\varepsilon_{p,-} + \varepsilon_{p,-}/\varepsilon_{p,+}}$$

In terms of the interstitial velocity, $\mathbf{u}^{(i)} = \mathbf{u}/\varepsilon_p$, this results in:

$$\frac{|\mathbf{u}^{(\text{i})}_{\text{t,+}}|}{|\mathbf{u}^{(\text{i})}_{\text{t,upstream infinity}}|} = \frac{2}{\varepsilon_{p,+}/\varepsilon_{p,-} + \varepsilon_{p,-}/\varepsilon_{p,+}} \le 1$$

Obviously, tangential component of the interstitial kinetic energy is lost across the interface. For low viscosity and high normal-flow component, when l_u is much lower than l_{geom} (the characteristic geometry length) there are apparent variations in $\mathbf{u}_t$ and $\mathbf{u}^{(i)}{}_t$ in a thin boundary layer on the upstream side of the interface. However, for the cases with high viscosity or nearly interface-parallel flow, l_u is much larger than l_{geom}, and any variations in $\mathbf{u}_t$ and $\mathbf{u}^{(i)}{}_t$ are virtually invisible.

Notice that the feature does not take into account possible underresolved porous scale, as is described in Theory for the Free and Porous Media Flow, Darcy Interface.

Mass Sources for Fluid Flow

There are two types of mass sources in a Single-Phase Flow interface: point sources and line sources.

These features require at least one of the following licenses: Battery Design Module, CFD Module, Chemical Reaction Engineering Module, Corrosion Module, Electrochemistry Module, Electrodeposition Module, Fuel Cell & Electrolyzer Module, Microfluidics Module, Pipe Flow Module, Polymer Flow Module, or Subsurface Flow Module.

POINT SOURCE

A point source is theoretically formed by taking a mass injection/ejection, $\dot{Q}$ (SI unit: kg/(m^3·s)), in a small volume δV and then letting the size of the volume tend to zero while keeping the total mass flux constant. Given a point source strength, $\dot{q}_{\text{p}}$ (SI unit: kg/s), this can be expressed as

$$\lim_{\delta V \to 0} \int_{\delta V} \dot{Q} = \dot{q}_{\text{p}} \tag{13-24}$$

An alternative way to form a point source/sink is to assume that mass is injected/extracted through the surface of a small object. Letting the object surface area tend to zero while keeping the mass flux constant, results in the same point source. For this alternative approach, effects resulting from the physical object volume, such as drag and fluid displacement, need to be neglected.

The weak contribution

$$\dot{q}_{\text{p}}\text{test}(p)$$

is added to a point in the geometry. As can be seen from Equation 13-24, $\dot{Q}$ must tend to plus or minus infinity as δV tends to zero. This means that in theory the pressure also tends to plus or minus infinity.

Observe that "point" refers to the physical representation of the source. A point source can therefore only be added to points in 3D components and to points on the symmetry axis in 2D axisymmetry components. Other geometrical points in 2D components represent physical lines.

The finite element representation of Equation 13-24 corresponds to a finite pressure in a point with the effect of the point source spread out over a region around the point. The size of the region depends on the mesh and on the strength of the source. A finer mesh gives a smaller affected region, but also a more extreme pressure value. It is important not to mesh too finely around a point source since the resulting pressure can result in unphysical values for the density, for example. It can also have a negative effect on the condition number for the equation system.

LINE SOURCE

A line source can theoretically be formed by assuming a source of strength $\dot{Q}$ (SI unit: kg/(m^3·s)), located within a tube with cross-sectional area δS and then letting δS tend to zero, while keeping the total mass flux per unit length constant. Given a line source strength, $\dot{q}_l$ (SI unit: kg/(m·s)), this can be expressed as

$$\lim_{\delta S \to 0} \int_{\delta S} \dot{Q} = \dot{q}_l \tag{13-25}$$

As in the point source case, an alternative approach is to assume that mass is injected/extracted through the surface of a small object. This results in the same mass source, but requires that effects on the fluid resulting from the physical object volume are neglected.

The weak contribution

$$\dot{q}_l \text{test}(p)$$

is added to lines in 3D or to points in 2D (which represent cut-through views of lines). Line sources can also be added to the axisymmetry line in 2D axisymmetry components. It cannot, however, be added to geometrical lines in 2D because they represent physical planes.

As with a point source, it is important not to mesh too finely around the line source.

	For feature node information, see Line Mass Source and Point Mass Source.

	For the Reacting Flow in Porous Media, Diluted Species interface, which is available with the CFD Module, Chemical Reaction Engineering Module, or Battery Design Module, these shared physics nodes are renamed as follows: • The **Line Mass Source** node is available as two nodes, one for the fluid flow (**Fluid Line Source**) and one for the species (**Species Line Source**). • The **Point Mass Source** node is available as two nodes, one for the fluid flow (**Fluid Point Source**) and one for the species (**Species Point Source**).

Numerical Stability — Stabilization Techniques for Fluid Flow

The momentum equation (Equation 13-7 or Equation 13-9) is a (nonlinear) convection-diffusion equation. Such equations can easily become unstable if discretized using the Galerkin finite element method. Stabilized finite element methods are usually necessary in order to obtain physical solutions. The stabilization settings are found in the main Fluid Flow interface features. To display this section, click the **Show More Options** button ( ) and select **Stabilization** in the **Show More Options** dialog.

There are three types of stabilization methods available for Navier–Stokes — *streamline diffusion*, *crosswind diffusion*, and *isotropic diffusion*. Streamline diffusion and crosswind diffusion are consistent stabilization methods, whereas isotropic diffusion is an inconsistent stabilization method.

For optimal functionality, the exact weak formulations of and constants in the streamline diffusion and crosswind diffusion methods depend on the order of the shape functions (basis functions) for the elements. The values of constants in the streamline diffusion and crosswind diffusion methods follow Ref. 5 and Ref. 6.

STREAMLINE DIFFUSION

For strongly coupled systems of equations, the streamline diffusion method must be applied to the system as a whole rather than to each equation separately. These ideas were first explored by Hughes and Mallet (Ref. 8) and were later extended to Galerkin least-squares (GLS) applied to the Navier–Stokes equations (Ref. 9). This is the streamline diffusion formulation that COMSOL Multiphysics supports.

Streamline diffusion is active by default because it is necessary when convection is dominating the flow.

The governing equations for incompressible flow are subject to the Babuška–Brezzi condition, which states that the shape functions (basis functions) for pressure must be of lower order than the shape functions for velocity. If the incompressible Navier–Stokes equations are stabilized by streamline diffusion, it is possible to use equal-order interpolation. Hence, streamline diffusion is necessary when using first-order elements for both velocity and pressure. This applies also if the model is solved using geometric multigrid (either as a solver or as a preconditioner) and at least one multigrid hierarchy level uses linear Lagrange elements.

CROSSWIND DIFFUSION

Crosswind diffusion can also be formulated for systems of equations, and when applied to the Navier–Stokes equations it becomes a shock-capturing operator. COMSOL Multiphysics supports the formulation in Ref. 9 with a shock-capturing viscosity of the Hughes–Mallet type Ref. 8.

Incompressible flows do not contain shock waves, but crosswind diffusion is still useful for introducing extra diffusion in sharp boundary layers and shear layers that otherwise would require a very fine mesh to resolve.

Crosswind diffusion is active by default as it makes it easier to obtain a solution even if the problem is fully resolved by the mesh. Crosswind diffusion also enables the iterative solvers to use inexpensive presmoothers. If crosswind diffusion is deactivated, more expensive preconditioners must be used instead.

STABILIZATION TIME SCALES

The time-scale tensor for time-dependent problems should in theory depend on a time-scale that many references just set to the time-step taken by the time-solver, Δt (see, for example, Ref. 9 and Ref. 10). This simple approach does not, however, necessarily reflect on the actual time-scales in the physics. A typical example is reacting flows where the time step is often guided by fast reactions, while the flow develops relatively slowly. The COMSOL Multiphysics software can therefore replace Δt^2 in the time-scale tensor with measures of type $(1/(\Delta \tilde{t})^2)^{-1}$, which are calculated from projections of weak expressions in a fashion similar to those in Ref. 11. These measures of the time scale are used when **Use dynamic subgrid time scale** is activated.

The **Limit small time steps effect on stabilization time scale** option can be used to ramp down the time-step contribution in the stabilization when the time step becomes much smaller than the convective and diffusive time scales. This option prevents loss of pressure stabilization at such small time steps.

ISOTROPIC DIFFUSION

Isotropic diffusion adds diffusion to the Navier–Stokes equations. Isotropic diffusion significantly reduces the accuracy of the solution but does a very good job at reducing oscillations. The stability of the continuity equation is not improved.

Numerical Stabilization and Iterative

Solvers for Laminar Flow

The Navier–Stokes equations constitute a nonlinear equation system. A nonlinear solver must hence be applied to solve the problem. The nonlinear solver iterates to reach the final solution. In each iteration, a linearized version of

the nonlinear system is solved using a linear solver. In the time-dependent case, a time marching method must also be applied. The default suggestions for each of these solver elements are discussed below.

NONLINEAR SOLVER

The nonlinear solver method depends on if the model solves a stationary or a time-dependent problem.

Stationary Solver

In the stationary case, a fully coupled, damped Newton method is applied. The initial damping factor is low since a full Newton step can be harmful unless the initial values are close to the final solution. The nonlinear solver algorithm automatically regulates the damping factor in order to reach a converged solution.

For advanced models, the automatically damped Newton method might not be robust enough. A pseudo time-stepping algorithm can then be invoked. See Pseudo Time Stepping for Laminar Flow Models.

Time-Dependent Solver

In the time-dependent case, the initial guess for each time step is (loosely speaking) the previous time step, which is a very good initial value for the nonlinear solver. The automatic damping algorithm is then not necessary. The damping factor in the Newton method is instead set to a constant value slightly smaller than one. Also, for the same reason, it suffices to update the Jacobian once per time step.

It is seldom worth the extra computational cost to update the Jacobian more than once per time step. For most models it is more efficient to restrict the maximum time step or possibly lower the damping factor in the Newton method.

LINEAR SOLVER

The linearized Navier–Stokes equation system has saddle point character, unless the density depends on the pressure. This means that the Jacobian matrix has zeros on the diagonal. Even when the density depends on the pressure, the equation system effectively shares many numerical properties with a saddle point system.

For small 2D and 3D models, the default solver suggestion is a direct solver. Direct solvers can handle most nonsingular systems and are very robust and also very fast for small models. Unfortunately, they become slow for large models and their memory requirement scales as somewhere between $N^{1.5}$ and N^2, where N is the number of degrees of freedom in the model. The default suggestion for large 2D and 3D models is therefore the iterative GMRES solver. The memory requirement for an iterative solver optimally scales as N.

GMRES is accelerated by a multigrid method, per default the smoothed aggregation algebraic multigrid (SAAMG) method. The cost of SAAMG is typically very low compared to the number of GMRES iterations necessary if no multigrid method is used. As the name implies, SAAMG builds its coarser meshes algebraically, so the application requires no additional meshes in order to employ SAAMG. In contrast, the geometric multigrid (GMG) method requires actual meshes. If a sufficient number of multigrid levels can be constructed, GMG is often faster than SAAMG. GMG is also superior for cluster computations and for shared-memory computations with many cores. When the default linear solver is GMRES, an optional, but deactivated, linear solver node is available where GMRES is accelerated by GMG.

Multigrid methods need smoothers, but the saddle point character of the linear system restricts the number of applicable smoothers. The choices are further restricted by the anisotropic meshes frequently encountered in fluid-flow problems. The efficiency of the smoothers is highly dependent on the numerical stabilization. Iterative solvers perform at their best when both Streamline Diffusion and Crosswind Diffusion are active.

The default smoother for P1+P1 elements is SCGS. This is an efficient and robust smoother specially designed to solve saddle point systems on meshes that contain anisotropic elements. The SCGS smoother works well even without crosswind diffusion. SCGS can sometimes work for higher-order elements, especially if **Method** in the SCGS settings is set to **Mesh element lines**. But there is no guarantee for this, so the default smoother for higher order elements is an SOR Line smoother. SOR Line handles mesh anisotropy but does not formally address the saddle

point character. It does, however, function in practice provided that streamline diffusion and crosswind diffusion are both active.

A different kind of saddle point character can arise if the equation system contains ODE variables. Some advanced boundary conditions can add equations with such variables. These variables must be treated with the Vanka algorithm. SCGS includes an option to invoke Vanka. Models with higher-order elements must apply SCGS or use the Vanka smoother. The latter is the default suggestion for higher-order elements, but it does not work optimally for anisotropic meshes.

TIME-DEPENDENT SOLVERS

The default time-dependent solver for Navier–Stokes is the BDF method with maximum order set to two. Higher BDF orders are not stable for transport problems in general nor for Navier–Stokes in particular.

BDF methods have been used for a long time and are known for their stability. However, they can have severe damping effects, especially the lower-order methods. Hence, if robustness is not an issue, a model can benefit from using the generalized-α method instead. Generalized-α is a solver that has properties similar to those of the second-order BDF solver but it is much less diffusive.

Both BDF and generalized-α are per default set to automatically adjust the time step. While this works well for many models, extra efficiency and accuracy can often be gained by specifying a maximum time step. It is also often beneficial to specify an initial time step to make the solver progress smoothly in the beginning of the time series.

- Stationary Solver

Pseudo Time Stepping for Laminar Flow Models

A stationary formulation has per definition no time derivatives and Equation 13-9 reduces to:

$$\rho(\mathbf{u}\cdot\nabla)\mathbf{u} = \nabla\cdot[-p\mathbf{I}+\mu(\nabla\mathbf{u}+(\nabla\mathbf{u})^T)]+\mathbf{F} \tag{13-26}$$

Solving Equation 13-26 requires a starting guess that is close enough to the final solution. If no such guess is at hand, the fully transient problem can be solved instead. This is, however, a rather costly approach in terms of computational time. An intermediate approach is to add a fictitious time derivative to Equation 13-26:

$$\rho\frac{\mathbf{u}-\text{nojac}(\mathbf{u})}{\Delta\tilde{t}}+\rho(\mathbf{u}\cdot\nabla)\mathbf{u} = \nabla\cdot[-p\mathbf{I}+\mu(\nabla\mathbf{u}+(\nabla\mathbf{u})^T)]+\mathbf{F}$$

where $\Delta\tilde{t}$ is a *pseudo time step*. Since $\mathbf{u}$–nojac($\mathbf{u}$) is always zero, this term does not affect the final solution. It does, however, affect the discrete equation system and effectively transforms a nonlinear iteration into a step of size $\Delta\tilde{t}$ of a time-dependent solver.

Pseudo time stepping is not active per default. The pseudo time step $\Delta\tilde{t}$ can be chosen individually for each element based on the local CFL number:

$$\Delta\tilde{t} = \text{CFL}_{\text{loc}}\frac{h}{|\mathbf{u}|}$$

where h is the mesh cell size. A small CFL number means a small time step. It is practical to start with a small CFL number and gradually increase it as the solution approaches steady state.

If the automatic expression for $\mathrm{CFL}_{\mathrm{loc}}$ is set to the built-in variable `CFLCMP`, then the automatic setting suggests a PID regulator for the pseudo time step in the default solver. The PID regulator starts with a small CFL number and increases $\mathrm{CFL}_{\mathrm{loc}}$ as the solution comes closer to convergence.

The default manual expression is

$$\begin{aligned} &1.3^{\min(\mathrm{niterCMP},\,9)} + \\ &\mathrm{if}(\mathrm{niterCMP} > 20,\, 9 \cdot 1.3^{\min(\mathrm{niterCMP}-20,\,9)},\, 0) + \\ &\mathrm{if}(\mathrm{niterCMP} > 40,\, 90 \cdot 1.3^{\min(\mathrm{niterCMP}-40,\,9)},\, 0) \end{aligned} \tag{13-27}$$

The variable `niterCMP` is the nonlinear iteration number. It is equal to one for the first nonlinear iteration. $\mathrm{CFL}_{\mathrm{loc}}$ starts at 1.3 and increases by 30% each iteration until it reaches $1.3^9 \approx 10.6$. It remains there until iteration number 20 at which it starts to increase until it reaches approximately 106. A final increase after iteration number 40 then takes it to 1060. Equation 13-27 can, for some advanced flows, increase $\mathrm{CFL}_{\mathrm{loc}}$ too slowly or too quickly. $\mathrm{CFL}_{\mathrm{loc}}$ can then be tuned for the specific application.

For details about the CFL regulator, see Pseudo Time Stepping.

Nitsche Constraints

Some boundary conditions are implemented using Nitsche constraints. These boundary conditions include

- Wall — Slip, sliding walls, and moving walls (that is, walls with nonzero translational velocity).
- Periodic Flow Condition
- Flow Continuity

The formulation used in the Fluid Flow interfaces in single-phase flow interfaces corresponds to the Symmetric Interior Penalty Galerkin method (SIPG). The SIPG method can be regarded to satisfy the boundary conditions in an integral sense rather than pointwise. More information on SIPG can be found in Ref. 15.

In particular, the SIPG formulation includes a penalty parameter that must be large enough for the formulation to be coercive. The higher the value, the better the boundary condition is fulfilled, but a too high value results in an ill-conditioned equation system. The penalty parameter is implemented according to Ref. 16.

Particle Tracing in Fluid Flow

The Particle Tracing Module is available to assist with these types of modeling problems.

It is possible to model particle tracing with COMSOL Multiphysics provided that the impact of the particles on the flow field is negligible. First compute the flow field, and then, as an analysis step, calculate the motion of the particles. The motion of a particle is defined by Newton's second law

$$m\frac{d^2\mathbf{x}}{dt^2} = \mathbf{F}\left(t, \mathbf{x}, \frac{d\mathbf{x}}{dt}\right)$$

where $\mathbf{x}$ is the position of the particle, m the particle mass, and $\mathbf{F}$ is the sum of all forces acting on the particle. Examples of forces acting on a particle in a fluid are the drag force, the buoyancy force, and the gravity force. The drag force represents the force that a fluid exerts on a particle due to a difference in velocity between the fluid and the particle. It includes the viscous drag, the added mass, and the Basset history term. Several empirical expressions have been suggested for the drag force. One of those is the one proposed by Khan and Richardson (Ref. 13). That

expression is valid for spherical particles for a wide range of particle Reynolds numbers. The particle Reynolds number is defined as

$$\mathrm{Re}_p = \frac{|\mathbf{u} - \mathbf{u}_p| 2r\rho}{\mu}$$

where $\mathbf{u}$ is the velocity of the fluid, $\mathbf{u}_p$ the particle velocity, r the particle radius, ρ the fluid density, and μ the dynamic viscosity of the fluid. The empirical expression for the drag force according to Khan and Richardson is

$$\mathbf{F} = \pi r^2 \rho |\mathbf{u} - \mathbf{u}_p| (\mathbf{u} - \mathbf{u}_p)[1.84\mathrm{Re}_p^{-0.31} + 0.293\mathrm{Re}_p^{0.06}]^{3.45}$$

The model *Flow Past a Cylinder* (Application Library path **COMSOL_Multiphysics/Fluid_Dynamics/cylinder_flow**) demonstrates how to add and set up particle tracing in a plot group using the **Particle Tracing with Mass** node. It uses the predefined Khan–Richardson model for the drag force and neglects gravity and buoyancy forces.

The Single-Phase Flow, Laminar Flow Interface

In this section:

- The Laminar Flow Interface
- Domain, Boundary, Pair, and Point Nodes for Single-Phase Flow

- Theory of Laminar Flow

In the *COMSOL Multiphysics Reference Manual*, see Table 2-4 for links to common sections such as **Discretization**, **Consistent Stabilization**, **Inconsistent Stabilization**, and **Advanced Settings** sections, some of them accessed by clicking the **Show** button ( ) and choosing the applicable option. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

The Laminar Flow Interface

The **Laminar Flow (spf)** interface ( ) is used to compute the velocity and pressure fields for the flow of a single-phase fluid in the laminar flow regime. A flow remains laminar as long as the Reynolds number is below a certain critical value. At higher Reynolds numbers, disturbances have a tendency to grow and cause transition to turbulence. This critical Reynolds number depends on the model, but a classical example is pipe flow, where the critical Reynolds number is known to be approximately 2000.

The physics interface supports incompressible flow, weakly compressible flow (the density depends on temperature but not on pressure), and compressible flow at low Mach numbers (typically less than 0.3). It also supports flow of non-Newtonian fluids.

The equations solved by the Laminar Flow interface are the Navier–Stokes equations for conservation of momentum and the continuity equation for conservation of mass.

The Laminar Flow interface can be used for stationary and time-dependent analyses. Time-dependent studies should be used in the high-Reynolds number regime as these flows tend to become inherently unsteady.

When the Laminar Flow interface is added, the following default nodes are also added in the **Model Builder**: **Fluid Properties**, **Wall** (the default boundary condition is **No slip**), and **Initial Values**. Other nodes that implement, for example, boundary conditions and volume forces, can be added from the **Physics** toolbar or from the context menu displayed when right-clicking **Laminar Flow**.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Physics interface variables can be referred to using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `spf`.

PHYSICAL MODEL

Compressibility

Depending of the fluid properties and the flow regime, three options are available for the **Compressibility** option. In general the computational complexity increases from **Incompressible flow** to **Weakly compressible flow** to **Compressible flow (Ma<0.3)** but the underlying hypotheses are increasingly more restrictive in the opposite direction.

When the **Incompressible flow** option (default) is selected, the incompressible form of the Navier–Stokes and continuity equations is applied. In addition, the fluid density is evaluated at the **Reference pressure level** defined in this section. The **Reference temperature** is set to 293.15 K.

The **Weakly compressible flow** option models compressible flow when the pressure dependency of the density can be neglected. When selected, the compressible form of the Navier–Stokes and continuity equations is applied. In addition, the fluid density is evaluated at the **Reference pressure level** defined in this section.

When the **Compressible flow (Ma<0.3)** option is selected, the compressible form of the Navier–Stokes and continuity equations is applied. $\mathrm{Ma} < 0.3$ indicates that the inlet and outlet conditions, as well as the stabilization, may not be suitable for transonic and supersonic flow. For more information, see The Mach Number Limit.

Porous Media Domains

With the addition of various modules, the **Enable porous media domains** checkbox is available. Selecting this option, a **Fluid and Matrix Properties** node, a **Mass Source** node, and a **Forchheimer Drag** subnode are added to the physics interface. These are described for the **Brinkman Equations** interface in the respective module's documentation. The **Fluid and Matrix Properties** can be applied on all domains or on a subset of the domains.

Include Gravity

When the **Include gravity** checkbox is selected, a global **Gravity** feature is shown in the interface model tree, and the buoyancy force is included in the Navier–Stokes equations.

Also, when the **Include gravity** checkbox is selected, the **Use reduced pressure** option changes the pressure formulation from using the total pressure (default) to using the reduced pressure. This option is suitable for configurations where the density changes are very small; otherwise, the default formulation can be used. For more information, see Gravity

Reference Values

Reference values are global quantities used to evaluate the density of the fluid when the **Incompressible flow** or the **Weakly compressible flow** option is selected.

Reference pressure level There are generally two ways to include the pressure in fluid flow computations: either to use the absolute pressure $p_A = p + p_{\mathrm{ref}}$, or the gauge pressure p. When p_{ref} is nonzero, the physics interface solves for the gauge pressure whereas material properties are evaluated using the absolute pressure. The reference pressure level is also used to define the reference density.

Reference temperature The reference temperature is used to define the reference density.

Reference position When **Include gravity** is selected, the reference position can be defined. It corresponds to the location where the total pressure (that includes the hydrostatic pressure) is equal to the **Reference pressure level**.

DEPENDENT VARIABLES

The following dependent variables (fields) are defined for this physics interface — the **Velocity field** $\mathbf{u}$ and its components, and the **Pressure** p.

If required, the names of the field, component, and dependent variable can be edited. Editing the name of a scalar dependent variable changes both its field name and the dependent variable name. If a new field name coincides with the name of another field of the same type, the fields share degrees of freedom and dependent variable names. A

new field name must not coincide with the name of a field of another type or with a component name belonging to some other field. Component names must be unique within a model except when two fields share a common field name.

CONSISTENT STABILIZATION

To enable this section, click the **Show More Options** button ( ) and select **Stabilization** in the **Show More Options** dialog.

There are two *consistent stabilization methods*: **Streamline diffusion** and **Crosswind diffusion**. Usually, both checkboxes for these methods are selected by default and should remain selected for optimal performance. Consistent stabilization methods do not perturb the original transport equation. Streamline diffusion must be selected when using equal-order interpolation for pressure and velocity.

Select the **Use dynamic subgrid time scale** checkbox to estimate the influence of temporal variations in the velocity field, instead of using the inverse time step, in the consistent stabilization terms. This checkbox is selected by default

Select the **Limit small time steps effect on stabilization time scale** checkbox to prevent loss of stabilization at small time steps.

INCONSISTENT STABILIZATION

To enable this section, click the **Show More Options** button ( ) and select **Stabilization** in the **Show More Options** dialog.

There is usually just one *inconsistent stabilization method* — **Isotropic diffusion**. This method is equivalent to adding a term to the diffusion coefficient in order to dampen the effect of oscillations by making the system somewhat less dominated by convection. If possible, minimize the use of the inconsistent stabilization method because by using it you no longer solve the original problem. By default, the **Isotropic diffusion** checkbox is not selected because this type of stabilization adds artificial diffusion and affects the accuracy of the original problem. However, this option can be used to get a good initial guess for underresolved problems.

If required, select the **Isotropic diffusion** checkbox and enter a **Tuning parameter** δ_{id} as a scalar positive value. The default value is 0.25 (a reasonable value to start with is roughly 0.5 divided by the element order). A higher value adds more isotropic diffusion.

- Numerical Stability — Stabilization Techniques for Fluid Flow

ADVANCED SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. Normally these settings do not need to be changed.

The **Use pseudo time stepping for stationary equation form** is per default set to **Automatic from physics**. This option can add pseudo time derivatives to the equation when the **Stationary equation** form is used in order to speed up convergence. Pseudo time stepping is triggered when the Laminar Flow interface is selected in some multiphysics coupling features. Set **Automatic from physics** to **On** to apply pseudo time stepping also for laminar flows. Set it to **Off** to disable pseudo time stepping completely.

When **Use pseudo time stepping for stationary equation form** is set to **Automatic from physics** or **On**, a **CFL number expression** should also be defined. For the default **Automatic** option, the local CFL number (from the Courant–Friedrichs–Lewy condition) is determined by a PID regulator.

The **Use Block Navier-Stokes preconditioner** checkbox under **Linear solver** is available when the **Compressibility** option is set to **Incompressible flow**. When this checkbox is selected, the default solver for time-dependent study steps will

use the Block Navier–Stokes preconditioner in iterative solvers for the velocity and pressure. Using this preconditioner may result in shorter solution times for large time dependent problems with high Reynolds numbers.

- Pseudo Time Stepping for Laminar Flow Models
- Domain, Boundary, Pair, and Point Nodes for Single-Phase Flow
- Theory of Laminar Flow
- Block Navier–Stokes in the *COMSOL Multiphysics Reference Manual*.

DISCRETIZATION

The default discretization for Laminar Flow is **P1+P1** elements — that is, piecewise linear interpolation for velocity and pressure. This is suitable for most flow problems.

Some higher-order interpolations are also available, and they can be cost-effective options to obtain high accuracy for flows with low Reynolds numbers.

The **P2+P2** and **P3+P3** options, the equal-order interpolation options, are the preferred higher-order options because they have higher numerical accuracy than the mixed-order options **P2+P1** and **P3+P2**. The equal-order interpolation options do, however, require streamline diffusion to be active.

Flow Past a Cylinder: Application Library path

Domain, Boundary, Pair, and Point Nodes for Single-Phase Flow

The following nodes, listed in alphabetical order, are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (Mac or Linux users), or by right-clicking to access the context menu (all users).

- Boundary Stress
- Flow Continuity
- Fluid Properties
- Gravity
- Initial Values
- Inlet
- Line Mass Source[1]
- Open Boundary
- Outlet
- Periodic Flow Condition
- Point Mass Source[1]
- Porous Interface
- Pressure Point Constraint
- Symmetry
- Volume Force
- Wall

[1] A feature that may require an additional license

For 2D axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and adds an **Axial Symmetry** node that is valid on the axial symmetry boundaries only.

In the *COMSOL Multiphysics Reference Manual*, see Table 2-4 for links to common sections and Table 2-5 to common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

	For a detailed overview of the functionality available in each product, visit https://www.comsol.com/products/specifications/

Fluid Properties

The **Fluid Properties** node adds the momentum and continuity equations solved by the physics interface, except for volume forces, which are added by the Volume Force feature. The node also provides an interface for defining the material properties of the fluid.

MODEL INPUTS

Fluid properties, such as density and viscosity, can be defined through user inputs, variables, or by selecting a material. For the latter option, additional inputs, for example temperature or pressure, may be required to define these properties.

Temperature

By default, the **Temperature** model input is set to **Common model input**, and the temperature is controlled from Default Model Inputs under **Global Definitions** or by a locally defined Model Input. If a Heat Transfer interface is included in the component, it controls the temperature **Common model input**. Alternatively, the temperature field can be selected from another physics interface. All physics interfaces have their own tags (**Name**). For example, if a Heat Transfer in Fluids interface is included in the component, the **Temperature (ht)** option is available for T.

You can also select **User defined** from the **Temperature** model input in order to manually prescribe T.

Absolute Pressure

This input appears when a material requires the absolute pressure as a model input. The absolute pressure is used to evaluate material properties, but it also relates to the value of the calculated pressure field. There are generally two ways to calculate the pressure when describing fluid flow: either to solve for the absolute pressure or for a pressure (often denoted gauge pressure) that relates to the absolute pressure through a reference pressure.

The choice of pressure variable depends on the system of equations being solved. For example, in a unidirectional incompressible flow problem, the pressure drop over the modeled domain is probably many orders of magnitude smaller than the atmospheric pressure, which, when included, may reduce the stability and convergence properties of the solver. In other cases, such as when the pressure is part of an expression for the gas volume or the diffusion coefficients, it may be more convenient to solve for the absolute pressure.

The default **Absolute pressure** p_A is $p + p_{\text{ref}}$, where p is the dependent pressure variable from the Navier–Stokes or RANS equations, and p_{ref} is from the user input defined at the physics interface level. When p_{ref} is nonzero, the physics interface solves for a gauge pressure. If the pressure field instead is an absolute pressure field, p_{ref} should be set to 0.

The **Absolute pressure** field can be edited by clicking **Make All Model Inputs Editable** ( ) and entering the desired value in the input field.

	Model Inputs and Multiphysics Couplings in the *COMSOL Multiphysics Reference Manual*

FLUID PROPERTIES

Density

The density can either be specified by a material, or by a **User defined** expression. The density in a material can depend on temperature and pressure, and these dependencies are automatically replaced by p_{ref} for weakly compressible flows and p_{ref} and T_{ref} for incompressible flows (as specified by the **Compressibility** setting at the physics interface level). If density variations with respect to pressure are to be included in the computations, **Compressibility** must be set to compressible. Any dependencies in the density on quantities other than temperature and pressure must be consistent with the **Compressibility** setting at the interface level.

Dynamic Viscosity

The **Dynamic viscosity** μ describes the relationship between the shear rate and the shear stresses in a fluid. Intuitively, water and air have low viscosities, and substances often described as thick (such as oil) have higher viscosities.

Volume Force

The **Volume Force** node specifies the volume force $\mathbf{F}$ on the right-hand side of the momentum equation.

$$\rho\frac{\partial \mathbf{u}}{\partial t} + \rho(\mathbf{u}\cdot\nabla)\mathbf{u} = \nabla\cdot\left[-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I}\right] + \mathbf{F}$$

If several volume-force nodes are added to the same domain, then the sum of all contributions are added to the momentum equation.

Initial Values

The initial values serve as initial conditions for a transient simulation or as an initial guess for a nonlinear solver in a stationary simulation. Note that for a transient compressible-flow simulation employing a material for which the density depends on the pressure (such as air), discontinuities in the initial values trigger pressure waves even when the Mach number is small. The pressure waves must be resolved and this puts a restriction on the time step.

INITIAL VALUES

Initial values or expressions should be specified for the **Velocity field** $\mathbf{u}$ and the **Pressure** p.

When **Include gravity** is selected and **Use reduced pressure** not selected in the interface **Physical model** section, the **Compensate for hydrostatic pressure approximation** (named **Compensate for hydrostatic pressure** for compressible flows) checkbox is available and selected by default. When it is selected, the hydrostatic pressure is automatically added to the pressure entered in p user input.

Wall

The **Wall** node includes a set of boundary conditions describing fluid-flow conditions at stationary, moving, and leaking walls. For turbulent flow, the description may involve wall functions and asymptotic expressions for certain turbulence variables.

BOUNDARY CONDITION

Select a **Boundary condition** for the wall.

- No Slip
- Slip
- Leaking Wall

No Slip

No slip is the default boundary condition to model solid walls. A no-slip wall is a wall where the fluid velocity relative to the wall velocity is zero. For a stationary wall that means that $\mathbf{u} = 0$.

Slip

The **Slip** option prescribes a no-penetration condition, $\mathbf{u}\cdot\mathbf{n} = 0$. It is implicitly assumed that there are no viscous effects at the slip wall and hence, no boundary layer develops. From a modeling point of view, this can be a reasonable approximation if the main effect of the wall is to prevent fluid from leaving the domain.

Leaking Wall

This boundary condition may be used to simulate a wall where fluid is leaking into or leaving the domain with the velocity $\mathbf{u} = \mathbf{u}_l$ through a perforated wall. The components of the **Fluid velocity** $\mathbf{u}_l$ on the leaking wall should be specified.

WALL MOVEMENT

This section contains controls to describe the wall movement relative to the lab (or spatial) frame.

The **Translational velocity** setting controls the translational wall velocity, $\mathbf{u}_{tr}$. The list is per default set to **Automatic from frame**. The physics automatically detects if the spatial frame moves. This can for example happen if an ALE interface is present in the model component. If there is no movement $\mathbf{u}_{tr} = \mathbf{0}$. If the frame moves, $\mathbf{u}_{tr}$ becomes equal to the frame movement. $\mathbf{u}_{tr}$ is accounted for in the actual boundary condition prescribed in the **Boundary condition** section.

Select **Zero (Fixed wall)** from **Translational velocity** selection list to prescribe $\mathbf{u}_{tr} = \mathbf{0}$.

Select **Manual** from **Translational velocity** selection list in order to manually prescribe **Velocity of moving wall**, $\mathbf{u}_{tr}$. This can for example be used to model an oscillating wall where the magnitude of the oscillations are very small compared to the rest of the model. Specifying translational velocity manually does not automatically cause the associated wall to move. An additional Moving Mesh node needs to be added from Definitions to physically track the wall movement in the spatial reference frame.

The **Sliding wall** option is appropriate if the wall behaves like a conveyor belt with the surface sliding in a tangential direction. A velocity is prescribed at the wall and the boundary itself does not have to actually move relative to the reference frame.

- For 3D components, values or expressions for the **Velocity of sliding wall** $\mathbf{u}_w$ should be specified. If the velocity vector entered is not in the plane of the wall, COMSOL Multiphysics projects it onto the tangential direction. Its magnitude is adjusted to be the same as the magnitude of the vector entered.
- For 2D components, the tangential direction is unambiguously defined by the direction of the boundary. For this reason, the sliding wall boundary condition has different definitions in different space dimensions. A single entry for the **Velocity of the tangentially moving wall** U_w should be specified in 2D.

CONSTRAINT SETTINGS

This section is displayed by clicking the **Show More Options** button ( ) and selecting **Advanced Physics Options** in the **Show More Options** dialog. The **Constraints** settings can be set to **Automatic**, **Pointwise constraints**, **Nitsche constraints**, or **Weak constraints**. **Mixed constraints** can be selected when imposing a no slip condition exactly.

Depending on the constraint method selected, the following settings are available:

- **Apply reaction terms on** can be set to **Individual dependent variables** (default) or **All physics (symmetric)**. This setting is not available when **Nitsche constraints** is selected.

- Select **Elemental** (default) or **Nodal** under **Constraint method**. This setting is not available for **Nitsche constraints** or **Weak constraints**.

- Theory for the Wall Boundary Condition
- The Moving Mesh Interface

Inlet

This condition should be used on boundaries for which there is a net flow into the domain. To obtain a numerically well-posed problem, it is advisable to also consider the Outlet conditions when specifying an Inlet condition. For example, if the pressure is specified at the outlet, the velocity may be specified at the inlet, and vice versa. Specifying the velocity vector at both the inlet and the outlet may cause convergence difficulties.

BOUNDARY CONDITION

The available **Boundary condition** options for an inlet are **Velocity, Fully developed flow**, and **Pressure**. After selecting a **Boundary Condition** from the list, a section with the same or a similar name displays underneath. For example, if **Velocity** is selected, a **Velocity** section, where further settings are defined, is displayed.

VELOCITY

The **Normal inflow velocity** is specified as $\mathbf{u} = -\mathbf{n}U_0$, where $\mathbf{n}$ is the boundary normal pointing out of the domain and U_0 is the normal inflow speed.

The **Velocity field** option sets the velocity vector to $\mathbf{u} = \mathbf{u}_0$. The components of the inlet velocity vector $\mathbf{u}_0$ should be defined for this choice.

PRESSURE CONDITIONS

This option specifies the normal stress, which in most cases is approximately equal to the pressure.

- For incompressible flow, the **Pressure** list has two options, **Static** and **Total**. For weakly compressible and compressible flow, the static pressure should be specified in the text field.
  - If **Pressure** is **Static**, and the reference pressure p_{ref}, defined at the physics interface level, is equal to 0, the value of the pressure p_0, at the boundary, is the absolute pressure. Otherwise, p_0 is the relative pressure at the boundary.
  - If **Pressure** is **Total**, the **Average** checkbox is available and cleared by default to prescribe the total pressure pointwise. If it is selected, the averaged total pressure is imposed in the weak forms instead.

  When **Include gravity** is selected and **Use reduced pressure** not selected in the interface **Physical model** section, the **Compensate for hydrostatic pressure approximation** (named **Compensate for hydrostatic pressure** for incompressible flows) checkbox is available and selected by default. When it is selected, the hydrostatic pressure is automatically added to the pressure entered in p_0 user input.
- The **Suppress backflow** option adjusts the inlet pressure locally in order to reduce the amount of fluid exiting the domain through the boundary. If you clear the suppress backflow option, the inlet boundary can become an outlet depending on the pressure field in the rest of the domain.
- **Flow direction** controls in which direction the fluid enters the domain.
  - For **Normal flow**, it prescribes zero tangential velocity component.
  - For **User defined**, an **Inflow velocity direction** $\mathbf{d}_\mathbf{u}$ (dimensionless) should be specified. The magnitude of $\mathbf{d}_\mathbf{u}$ does not matter, only the direction. $\mathbf{d}_\mathbf{u}$ must point into the domain.

FULLY DEVELOPED FLOW

The **Fully developed flow** option adds contributions to the inflow boundary, which force the flow toward the solution for a fully developed channel flow. The channel can be thought of as a virtual extrusion of the inlet cross section. The inlet boundary must hence be flat in order for the fully developed flow condition to work properly. In 2D axisymmetric models, the inlet normal must be parallel to the symmetry axis.

Select an option to control the flow rate at the inlet:

- **Average velocity**, U_{av}.
- **Flow rate**, V_0. Two-dimensional models also require an **Entrance thickness**, D_z, which is the out-of-plane thickness of the extruded entrance channel.
- **Average pressure**, P_{av}. Note that P_{av} is the average pressure on the inflow boundary.

The **Apply condition on each disjoint selection separately** checkbox is selected per default. When this setting is selected, the fully developed flow condition is applied separately on each disjoint selection. If this option is not selected, the condition is applied over the whole feature selection. The **Apply condition on each disjoint selection separately** should be disabled only if the flow conditions are known to be identical on each disjoint boundary.

The fully developed flow condition requires any volume force to be approximately aligned with the normal of the inlet boundary. The exception is gravity when the **Include gravity** setting is selected in the physics interface settings. Unless **Use reduced pressure** is also selected, an option to **Compensate for hydrostatic pressure** or **Compensate for hydrostatic pressure approximation** becomes available. It is selected per default and should only be deselected if the inlet normal is aligned with the gravity force and you want to specify an average pressure that includes the hydrostatic pressure.

CONSTRAINT SETTINGS

This section is displayed by clicking the **Show** button ( ) and selecting **Advanced Physics Options**.

- Prescribing Inlet and Outlet Conditions
- Normal Stress Boundary Condition

Outlet

This condition should be used on boundaries for which there is a net outflow from the domain. To obtain a numerically well-posed problem, it is advisable to also consider the Inlet conditions when specifying an Outlet condition. For example, if the velocity is specified at the inlet, the pressure may be specified at the outlet, and vice versa. Specifying the velocity vector at both the inlet and the outlet may cause convergence difficulties. Selecting appropriate outlet conditions for the Navier–Stokes equations is a nontrivial task. Generally, if there is something interesting happening at an outflow boundary, the computational domain should be extended to include this phenomenon.

BOUNDARY CONDITION

The available **Boundary condition** options for an outlet are **Pressure, Velocity, Fully developed flow**, and **Mass flow**.

PRESSURE CONDITIONS

This option specifies the normal stress, which in most cases is approximately equal to the pressure. The tangential stress component is set to zero.

- For incompressible flow, the **Pressure** list has two options, **Static** and **Total**. For weakly compressible and compressible flow, the static pressure should be specified in the text field.
  - If **Pressure** is **Static**, and the reference pressure p_{ref}, defined at the physics interface level, is equal to 0, the value of the pressure p_0, at the boundary, is the absolute pressure. Otherwise, p_0 is the relative pressure at the boundary.
  - If **Pressure** is **Total**, the **Average** checkbox is available and selected by default to prescribed the averaged total pressure in the weak forms. If it is cleared, the total pressure is imposed pointwise.

When **Include gravity** is selected and **Use reduced pressure** not selected in the interface **Physical model** section, the **Compensate for hydrostatic pressure approximation** (named **Compensate for hydrostatic pressure** for incompressible flows) checkbox is available and selected by default. When it is selected, the hydrostatic pressure is automatically added to the pressure entered in p_0 user input.

- The **Normal flow** option changes the no tangential stress condition to a no tangential velocity condition. This forces the flow to exit (or enter) the domain perpendicularly to the outlet boundary.
- The **Suppress backflow** checkbox is selected by default. This option adjusts the outlet pressure in order to reduce the amount of fluid entering the domain through the boundary.

VELOCITY

See the **Inlet** node Velocity section for the settings.

FULLY DEVELOPED FLOW

This boundary condition is applicable when the flow exits the domain into a long pipe or channel, at the end of which a flow profile is fully developed.

The channel can be thought of as a virtual extrusion of the outlet cross section. The outlet boundary must hence be flat in order for the fully developed flow condition to work properly. In 2D axisymmetric models, the outlet normal must be parallel to the symmetry axis.

Select an option to control the flow rate at the outlet:

- **Average velocity**, U_{av}.
- **Flow rate**, V_0. Two-dimensional models also require an **Entrance thickness**, D_z, which is the out-of-plane thickness of the extruded entrance channel.
- **Average pressure**, P_{av}. Observe that P_{av} is the average pressure on the outflow.

The **Apply condition on each disjoint selection separately** checkbox is selected per default. When this setting is selected, the fully developed flow condition is applied separately on each disjoint selection. If this option is not selected, the condition is applied over the whole feature selection. The **Apply condition on each disjoint selection separately** should be disabled only if the flow conditions are known to be identical on each disjoint boundary.

The fully developed flow condition requires any volume force to be approximately aligned with the normal of the outlet boundary. The exception is gravity when the **Include gravity** setting is selected in the physics interface settings. Unless **Use reduced pressure** is also selected, an option to **Compensate for hydrostatic pressure** or **Compensate for hydrostatic pressure approximation** becomes available. It is selected per default and should only be deselected if the outlet normal is aligned with the gravity force and you want to specify an average pressure that includes the hydrostatic pressure.

CONSTRAINT SETTINGS

Prescribing Inlet and Outlet Conditions

Symmetry

This node provides a boundary condition for symmetry boundaries. It should only be used when the geometry and expected solution have mirror symmetry. By using symmetries in a model its size can be reduced by one-half or more, making this an efficient tool for solving large problems.

The **Symmetry** boundary condition prescribes no penetration and vanishing shear stresses. The boundary condition is a combination of a Dirichlet condition and a Neumann condition:

$$\mathbf{u}\cdot\mathbf{n} = 0, \qquad \left(-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^T) - \frac{2}{3}\mu(\nabla\cdot\mathbf{u})\mathbf{I}\right)\mathbf{n} = 0$$

$$\mathbf{u}\cdot\mathbf{n} = 0, \qquad (-p\mathbf{I} + \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^{\mathrm{T}}))\mathbf{n} = 0$$

for the compressible and incompressible formulations. The Dirichlet condition takes precedence over the Neumann condition, and the above equations are equivalent to the following equation for both the compressible and incompressible formulations:

$$\mathbf{u}\cdot\mathbf{n} = 0, \qquad \mathbf{K} - (\mathbf{K}\cdot\mathbf{n})\mathbf{n} = 0$$
$$\mathbf{K} = \mu(\nabla\mathbf{u} + (\nabla\mathbf{u})^{\mathrm{T}})\mathbf{n}$$

BOUNDARY SELECTION

For 2D axial symmetry, a boundary condition does not need to be defined for the symmetry axis at $r = 0$. The software automatically provides a condition that prescribes $u_r = 0$ and vanishing stresses in the z direction and adds an **Axial Symmetry** node that implements these conditions on the axial symmetry boundaries only.

CONSTRAINT SETTINGS

This section is displayed by clicking the **Show** button ( ) and selecting **Advanced Physics Options**.

Open Boundary

The **Open Boundary** condition describes boundaries in contact with a large volume of fluid. Fluid can both enter and leave the domain on boundaries with this type of condition.

BOUNDARY CONDITIONS

The **Boundary condition** options for open boundaries are **Normal stress** and **No viscous stress**.

Normal Stress

The **Normal stress** f_0 condition implicitly imposes $p \approx \mathrm{f}_0$.

When **Include gravity** is selected and **Use reduced pressure** not selected in the interface **Physical model** section, the **Compensate for hydrostatic pressure approximation** (named **Compensate for hydrostatic pressure** for incompressible flows) checkbox is available and selected by default. When it is selected, the hydrostatic pressure is automatically added to the pressure entered in f_0 user input.

No Viscous Stress

The **No Viscous Stress** condition specifies vanishing viscous stress on the boundary. This condition does not provide sufficient information to fully specify the flow at the open boundary and must at least be combined with pressure constraints at adjacent points.

The **No viscous stress** condition prescribes:

$$\left(\mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T) - \frac{2}{3}\mu(\nabla \cdot \mathbf{u})\mathbf{I}\right)\mathbf{n} = \mathbf{0}$$

$$\mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T)\mathbf{n} = \mathbf{0}$$

for the compressible and the incompressible formulations. This condition can be useful in some situations because it does not impose any constraint on the pressure. A typical example is a model with volume forces that give rise to pressure gradients that are hard to prescribe in advance. To make the model numerically stable, this boundary condition should be combined with a point constraint on the pressure.

Boundary Stress

The **Boundary Stress** node adds a boundary condition that represents a general class of conditions also known as traction boundary conditions.

BOUNDARY CONDITION

The **Boundary condition** options for the boundary stress are **General stress**, **Normal stress**, and **Normal stress, normal flow**.

General Stress

When **General stress** is selected, the components for the **Stress F** should be specified. The total stress on the boundary is set equal to the given stress **F**:

$$\left(-p\mathbf{I} + \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T) - \frac{2}{3}\mu(\nabla \cdot \mathbf{u})\mathbf{I}\right)\mathbf{n} = \mathbf{F}$$

$$(-p\mathbf{I} + \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T))\mathbf{n} = \mathbf{F}$$

for the compressible and the incompressible formulations.

This boundary condition implicitly sets a constraint on the pressure that for 2D flows is

$$p = 2\mu\frac{\partial u_n}{\partial n} - \mathbf{n} \cdot \mathbf{F} \tag{13-28}$$

If $\partial u_n/\partial n$ is small, Equation 13-28 states that $p \approx -\mathbf{n}\cdot\mathbf{F}$.

Normal Stress

Normal Stress is described for the Open Boundary node.

Normal Stress, Normal Flow

For **Normal stress, normal flow**, the magnitude of the **Normal stress** f_0 should be specified. The tangential velocity is set to zero on the boundary:

$$\mathbf{n}^T\left(-p\mathbf{I} + \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T) - \frac{2}{3}\mu(\nabla \cdot \mathbf{u})\mathbf{I}\right)\mathbf{n} = -\mathrm{f}_0, \qquad \mathbf{t} \cdot \mathbf{u} = 0$$

$$\mathbf{n}^T(-p\mathbf{I} + \mu(\nabla \mathbf{u} + (\nabla \mathbf{u})^T))\mathbf{n} = -\mathrm{f}_0, \qquad \mathbf{t} \cdot \mathbf{u} = 0$$

for the compressible and the incompressible formulations.

This boundary condition implicitly sets a constraint on the pressure that for 2D flows is

$$p = 2\mu\frac{\partial u_n}{\partial n} + f_0 \tag{13-29}$$

If $\partial u_n/\partial n$ is small, Equation 13-29 states that $p \approx f_0$.

When **Include gravity** is selected and **Use reduced pressure** not selected in the interface **Physical model** section, the **Compensate for hydrostatic pressure approximation** (named **Compensate for hydrostatic pressure** for incompressible flows) checkbox is available and selected by default. When it is selected, the hydrostatic pressure is automatically added to the pressure entered in f_0 or $p_{\text{hydro}}\mathbf{n}$ is added to $\mathbf{F}$ depending on the selected option.

CONSTRAINT SETTINGS

This section is displayed by clicking the **Show** button ( ) and selecting **Advanced Physics Options**.

If Normal Stress, Normal Flow is selected as the **Boundary condition**, then to **Apply reaction terms on** all dependent variables, the **All physics (symmetric)** option should be selected. Alternatively, the **Individual dependent variables** could be selected to restrict the reaction terms as needed.

Periodic Flow Condition

The **Periodic Flow Condition** splits its selection into a source group and a destination group (the **Destination Selection** section is optional). Fluid that leaves the domain through one of the destination boundaries enters the domain through the corresponding source boundary. This corresponds to a situation where the geometry is a periodic part of a larger geometry. If the boundaries are not parallel to each other, the velocity vector is automatically transformed.

If the boundaries are curved, the orientation of the source must be specified manually (see Orientation of Source).

No input is required when **Compressible flow (Ma<0.3)** is selected for **Compressibility** under the **Physical Model** section for the physics interface. Typically when a periodic boundary condition is used with a compressible flow, the pressure is the same at both boundaries and the flow is driven by a volume force.

BOUNDARY SELECTION

The software usually automatically identifies the boundaries as either source boundaries or destination boundaries, as indicated in the selection list. This works fine for cases like opposing parallel boundaries. In other cases, right-click **Periodic Flow Condition** and select **Manual Destination Selection** to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

DESTINATION SELECTION

This section is available for specifying the destination boundaries, if needed, when the **Manual Destination Selection** option is selected in the context menu for the **Periodic Flow Condition** node. You can only select destination boundaries from the union of all source and destination boundaries.

FLOW CONDITION

This section is available when **Incompressible flow** is selected for **Compressibility** under the **Physical Model** section for the physics interface.

The **Flow Condition** at the boundary is specified through a value or expression for either the **Pressure difference**, $p_{\text{src}} - p_{\text{dst}}$, or the **Mass flow**, $\dot{m}$. The mass flow option ensures a pressure difference is achieved across the source and destination boundaries. This pressure difference can, for example, drive the fully developed flow in a channel.

To set up a periodic boundary condition, both boundaries must be selected in the **Periodic Flow Condition** node. COMSOL Multiphysics automatically assigns one boundary as the source and the other as the destination. To manually set the destination selection, a **Destination Selection** subnode is available from the context menu (by right-clicking the parent node) or from the **Physics** toolbar, **Attributes** menu. All destination sides must be connected.

ORIENTATION OF SOURCE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Orientation of Source** section, see Orientation of Source and Destination in the *COMSOL Multiphysics Reference Manual*.

ORIENTATION OF DESTINATION

This section appears if the setting for **Transform to intermediate map** in the **Orientation of Source** section is changed from the default value, **Automatic**, and **Advanced Physics Options** is selected in the **Show More Options** dialog. For information about the **Orientation of Destination** section, see Orientation of Source and Destination in the *COMSOL Multiphysics Reference Manual*.

MAPPING BETWEEN SOURCE AND DESTINATION

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Mapping Between Source and Destination** section, see Mapping Between Source and Destination in the *COMSOL Multiphysics Reference Manual*.

Porous Interface

The **Porous Interface** condition is designed to properly account for a sudden jump in porosity, ε_p, across a boundary between different domains. It describes possible discontinuity of stress across the interface, and also reveals modified behavior of tangential velocity due to boundary layer on the upstream side of the interface. Choose among the following options under the **Continuity conditions**:

- **Velocity and stress** — stress continuity is invoked;
- **Velocity and porosity-corrected stress** (default)— the sum of stress and a contribution due to the inertial term being constant across the interface;
- **Velocity and porosity-corrected stress with loss** — the sum of the stress and a contribution due to the inertial term is lost in the downstream direction.

All three options give continuity of the velocity across the interface in constant-density flows, while in case of a jump in density:

1. give continuity of the mass flux (product of density and normal velocity) and tangential velocity;
2. account for the density-jump correction in the stress condition.

When **Velocity and porosity-corrected stress with loss** is chosen, a **Pressure loss model** needs to be specified. The options are:

- **User-defined loss coefficients** (default). Enter values for **Expansion loss coefficient** and **Contraction loss coefficient**;
- **Borda–Carnot**. Specify **Vena contracta model**.

Vena contracta model allows two options:

- **User defined** (default) — enter value of **Vena contracta coefficient**;
- **Weisbach** — enter values of **Lower limit** and **Exponent**.

Notice that the notions ‘expansion’ and ‘contraction’ used in this section correspond not to geometrical changes, but to the variations of the microscopic structure across the interface in the flow direction — increasing or decreasing porosity, ε_p, respectively.

Flow Continuity

The **Flow Continuity** condition is suitable for pairs where the boundaries match; it prescribes that the flow field is continuous across the pair.

The parts of the boundary where a source boundary lacks a corresponding destination boundary and vice versa will get conditions from other boundary conditions under the physics interface acting as fallback boundary conditions on the nonoverlapping parts. By default, the Wall node is used as fallback unless another feature has been selected for the boundary.When the condition is set for pairs adjacent to domains with different porosity ε_p, it imposes conditions identical to the **Porous Interface** feature, which is designed to properly account for a sudden jump in porosity. See the section Porous Interface above for further details (note that the **Flow Continuity** does not account for the density-jump corrections),

About Pairs

Pressure Point Constraint

The **Pressure Point Constraint** condition can be used to specify the pressure level. If it is not possible to specify the pressure level using a boundary condition, the pressure level must be set in some other way, for example, by specifying a fixed pressure at a point.

PRESSURE CONSTRAINT

The relative pressure value is set by specifying the **Pressure** p_0. If the reference pressure p_{ref} defined at the physics interface level is equal to zero, p_0 represents the absolute pressure.

When **Include gravity** is selected and **Use reduced pressure** not selected in the interface **Physical model** section, the **Compensate for hydrostatic pressure approximation** (named **Compensate for hydrostatic pressure** for incompressible flows) checkbox is available and selected by default. When it is selected, the hydrostatic pressure is automatically added to the pressure entered in p_0 user input.

CONSTRAINT SETTINGS

This section is displayed by clicking the **Show** button ( ) and selecting **Advanced Physics Options**.

The **Apply reaction terms on** setting is set per default to **Individual dependent variables**. **All physics (symmetric)** cannot be used together with a segregated solver when fluid flow is coupled with Moving Mesh, Level Set, or Phase Field in Fluids.

Point Mass Source

This feature requires at least one of the following licenses: Battery Design Module, CFD Module, Chemical Reaction Engineering Module, Corrosion Module, Electrochemistry Module, Electrodeposition Module, Fuel Cell & Electrolyzer Module, Microfluidics Module, Pipe Flow Module, or Subsurface Flow Module.

The **Point Mass Source** feature models mass flow originating from an infinitely small domain centered around a point.

For the Reacting Flow in Porous Media, Diluted Species interface, which is available with the CFD Module, Chemical Reaction Engineering Module, or Battery Design Module, there are two nodes: one for the fluid flow (**Fluid Point Source**) and one for the species (**Species Point Source**).

SOURCE STRENGTH

The source **Mass flux**, $\dot{q}_p$ should be specified. A positive value results in mass being ejected from the point into the computational domain. A negative value results in mass being removed from the computational domain.

Point sources located on a boundary or on an edge affect the adjacent computational domains. This has the effect, for example, that a point source located on a symmetry plane has twice the given strength.

Mass Sources for Fluid Flow

Line Mass Source

This feature requires at least one of the following licenses: Battery Design Module, CFD Module, Chemical Reaction Engineering Module, Corrosion Module, Electrochemistry Module, Electrodeposition Module, Fuel Cell & Electrolyzer Module, Microfluidics Module, Pipe Flow Module, or Subsurface Flow Module.

The **Line Mass Source** feature models mass flow originating from a tube region with infinitely small radius.

For the Reacting Flow in Porous Media, Diluted Species interface, which is available with the CFD Module, Chemical Reaction Engineering Module, or Battery Design Module, there are two nodes, one for the fluid flow (**Fluid Line Source**) and one for the species (**Species Line Source**).

SELECTION

The **Line Mass Source** feature is available for all dimensions, but the applicable selection differs between the dimensions.

MODEL DIMENSION	APPLICABLE GEOMETRICAL ENTITY
2D	Points
2D Axisymmetry	Points not on the axis of symmetry
3D	Edges

SOURCE STRENGTH

The source **Mass flux**, $\dot{q}_l$, should be specified. A positive value results in mass being ejected from the line into the computational domain and a negative value means that mass is removed from the computational domain.

Line sources located on a boundary affect the adjacent computational domains. This, for example, has the effect that a line source located on a symmetry plane has twice the given strength.

Mass Sources for Fluid Flow

Gravity

The **Gravity** global feature is automatically added when **Include gravity** is selected at the interface level in the **Physical Model** settings. It defines the gravity forces from the **Acceleration of gravity** value.

ACCELERATION OF GRAVITY

The **Acceleration of gravity** (SI unit m/s, default value $-g_{const}\mathbf{e_z}$ in 2D axial symmetry and 3D and $-g_{const}\mathbf{e_y}$ in 2D) is used to define the gravity forces. It should be a global quantity.

14

The Heat Transfer Interfaces

This chapter describes the different types of heat transfer interfaces (Heat Transfer in Solids, Heat Transfer in Fluids, and Heat Transfer in Solids and Fluids), the Conjugate Heat Transfer, Laminar Flow interface, and the Joule Heating interface, all found under the **Heat Transfer** branch ( ) when adding a physics interface. It also contains information about heat transfer variables, suitable solver settings, and a brief theory background.

In this chapter:

- Theory for Heat Transfer
- About the Heat Transfer Interfaces
- The Heat Transfer in Solids Interface
- The Heat Transfer in Fluids Interface
- The Heat Transfer in Solids and Fluids Interface
- The Joule Heating Interface
- The Nonisothermal Flow and Conjugate Heat Transfer Interfaces
- Domain Features
- Boundary Features
- Edge and Point Features
- Heat Transfer Variables
- Using the Boundary Conditions for the Heat Transfer Interfaces
- Heat Transfer Consistent and Inconsistent Stabilization Methods
- Handling Frames in Heat Transfer
- Solver Settings

Theory for Heat Transfer

Theory for Heat Transfer in Solids

The Heat Transfer in Solids Interface solves for the following equation:

$$\rho C_p\left(\frac{\partial T}{\partial t} + \mathbf{u}_{\text{trans}} \cdot \nabla T\right) + \nabla \cdot (\mathbf{q} + \mathbf{q}_{\text{r}}) = -\alpha T : \frac{dS}{dt} + Q \tag{14-1}$$

The different quantities involved here are recalled below:

- ρ is the density (SI unit: kg/m^3)
- C_p is the specific heat capacity at constant stress (SI unit: J/(kg·K))
- T is the absolute temperature (SI unit: K)
- $\mathbf{u}_{\text{trans}}$ is the velocity vector of translational motion (SI unit: m/s)
- $\mathbf{q}$ is the heat flux by conduction (SI unit: W/m^2)
- $\mathbf{q}_{\text{r}}$ is the heat flux by radiation (SI unit: W/m^2)
- α is the coefficient of thermal expansion (SI unit: 1/K)
- S is the second Piola-Kirchhoff stress tensor (SI unit: Pa)
- Q contains additional heat sources (SI unit: W/m^3)

For a steady-state problem the temperature does not change with time and the terms with time derivatives disappear.

The first term on the right-hand side of Equation 14-1 is the *thermoelastic damping* and accounts for thermoelastic effects in solids:

$$Q_{\text{ted}} = -\alpha T : \frac{dS}{dt} \tag{14-2}$$

It should be noted that the d/dt operator is the material derivative.

Theory for Heat Transfer in Fluids

The Heat Transfer in Fluids Interface solves for the following equation (11.2-5 in Ref. 5):

$$\rho C_p\left(\frac{\partial T}{\partial t} + \mathbf{u} \cdot \nabla T\right) + \nabla \cdot (\mathbf{q} + \mathbf{q}_{\text{r}}) = \alpha_p T\left(\frac{\partial p}{\partial t} + \mathbf{u} \cdot \nabla p\right) + \tau : \nabla \mathbf{u} + Q \tag{14-3}$$

considering that:

- the Cauchy stress tensor, σ, is split into static and deviatoric parts as in:

$$\sigma = -p\mathbf{I} + \tau$$

- the dependent variables are the temperature, T, and pressure, p.

The different quantities involved here are recalled below:

- ρ is the density (SI unit: kg/m^3)
- C_p is the specific heat capacity at constant pressure (SI unit: J/(kg·K))
- T is the absolute temperature (SI unit: K)
- $\mathbf{u}$ is the velocity vector (SI unit: m/s)

- $\mathbf{q}$ is the heat flux by conduction (SI unit: W/m^2)
- $\mathbf{q}_r$ is the heat flux by radiation (SI unit: W/m^2)
- α_p is the coefficient of thermal expansion (SI unit: $1/K$):

$$\alpha_p = -\frac{1}{\rho}\frac{\partial \rho}{\partial T}$$

  for ideal gases, the thermal expansion coefficient takes the simpler form $\alpha_p = 1/T$
- p is the pressure (SI unit: Pa)
- τ is the viscous stress tensor (SI unit: Pa)
- Q contains heat sources other than viscous dissipation (SI unit: W/m^3)

For a steady-state problem the temperature does not change with time and the terms with time derivatives disappear.

The first term of the right-hand side of Equation 14-3 is the *work done by pressure changes* and is the result of heating under adiabatic compression as well as some thermoacoustic effects. It is generally small for low Mach number flows.

$$Q_p = \alpha_p T\left(\frac{\partial p}{\partial t} + \mathbf{u} \cdot \nabla p\right) \tag{14-4}$$

The second term represents viscous dissipation in the fluid:

$$Q_{vd} = \tau : \nabla \mathbf{u} \tag{14-5}$$

About the Heat Transfer Interfaces

COMSOL Multiphysics includes the following interfaces for heat transfer:

- Heat Transfer in Solids
- Heat Transfer in Fluids
- Heat Transfer in Solids and Fluids
- Conjugate Heat Transfer, Laminar Flow (multiphysics interface)
- Joule Heating (multiphysics interface)

They are used to compute the temperature field.

The Conjugate Heat Transfer, Laminar Flow interface also computes the pressure and velocity fields.

In addition, the Joule Heating interface computes an electric potential field.

The main dependent variable is the temperature, T.

The heat transfer interfaces and the multiphysics couplings can be used for modeling heat transfer by conduction and convection as well as conjugate heat transfer and electromagnetic heating.

Space Dimensions

The physics interfaces are available in 1D, 2D, and 3D and for axisymmetric components with cylindrical coordinates in 1D and 2D.

All the interfaces apply in domains, with features available at each geometric level (volumes, surfaces, edges, and points).

Study Types

Stationary and time-dependent studies are available with the Heat Transfer interfaces.

You can consider a heat transfer problem as stationary if the temperature field is independent of time at each point. The system is said to be at thermal equilibrium. It happens when the conditions are independent of time or vary on a time scale large enough so that they can be approximated as constant. This type of study can be used as an initial step for a time-dependent analysis.

For other cases, use a time-dependent study instead.

Study and Study Step Types

Versions of the Heat Transfer Interface

The versions of the main physics interface (ht) for heat transfer are:

- The Heat Transfer in Solids Interface
- The Heat Transfer in Fluids Interface
- The Heat Transfer in Solids and Fluids Interface

After selecting a version, default nodes are added under the main node, which then defines which version of the Heat Transfer interface is added. Depending on the version of the physics interface selected, the default nodes vary. For example:

- If **Heat Transfer in Solids** ( ) is selected, a **Heat Transfer in Solids (ht)** interface is added with a default **Solid** model.
- If **Heat Transfer in Fluids** ( ) is selected, a **Heat Transfer in Fluids (ht)** interface is added with a default **Fluid** model.
- If **Heat Transfer in Solids and Fluids** ( ) is selected, a **Heat Transfer in Solids and Fluids (ht)** interface is added with the default **Solid** and **Fluid** models.

Settings for the Heat Transfer Interface

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `ht`.

PHYSICAL MODEL

In 2D and 1D axisymmetric components, set the **Thickness** d_z, which is the thickness of the domain in the out-of-plane direction. The default value is 1 m.

In 1D components, set the **Cross-sectional area** A_c and the **Cross sectional perimeter** P_c of the domain. Default values are 1 m^2 and 1 m, respectively.

CONSISTENT STABILIZATION

The **Streamline diffusion** checkbox is selected by default and should remain selected for optimal performance for heat transfer in fluids or other applications that include a convective or translational term. **Crosswind diffusion** provides extra diffusion in regions with sharp gradients. The added diffusion is orthogonal to the streamlines, so streamline diffusion and crosswind diffusion can be used simultaneously. The **Crosswind diffusion** checkbox is also selected by default and is only available when the **Streamline diffusion** checkbox is selected.

INCONSISTENT STABILIZATION

The **Isotropic diffusion** checkbox is not selected by default.

	Heat Transfer Consistent and Inconsistent Stabilization Methods

DISCRETIZATION

The shape functions used for the temperature are **Quadratic Lagrange** for the modeling of heat transfer in solids, **Linear** for the modeling of heat transfer in fluids. To display more than the shape functions in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. See the description of each version of the physics interface for more details.

DEPENDENT VARIABLES

The Heat Transfer interfaces have the dependent variable **Temperature** T. The dependent variable names can be changed. Editing the name of a scalar dependent variable changes both its field name and the dependent variable name. If a new field name coincides with the name of another field of the same type, the fields share degrees of

freedom and dependent variable names. A new field name must not coincide with the name of a field of another type or with a component name belonging to some other field.

The Heat Transfer in Solids Interface

The **Heat Transfer in Solids** ( ) interface is used to model heat transfer in solids by conduction, convection, and radiation. A Solid model is active by default on all domains. All functionality for including other domain types, such as a fluid domain, is also available.

The temperature equation defined in solid domains corresponds to the differential form of the Fourier's law that may contain additional contributions like heat sources.

When this version of the physics interface is added, these default nodes are added to the **Model Builder** — **Solid**, **Thermal Insulation** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and sources. You can also right-click **Heat Transfer is Solids** to select physics features from the context menu.

DISCRETIZATION

By default, the shape functions used for the temperature are **Quadratic Lagrange**.

To display more than the shape functions in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. See Settings for the Heat Transfer Interface for a description of the other settings.

	See Table 2-4 for links to common sections and Table 2-5 to common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Feature Nodes for the Heat Transfer in Solids Interface

This section details the nodes available with The Heat Transfer in Solids Interface with default settings:

- Domain Nodes for the Heat Transfer in Solids Interface
- Boundary Nodes for the Heat Transfer in Solids Interface
- Edge Nodes for the Heat Transfer in Solids Interface
- Point Nodes for the Heat Transfer in Solids Interface

DOMAIN NODES FOR THE HEAT TRANSFER IN SOLIDS INTERFACE

The Heat Transfer in Solids Interface has the following domain nodes:

- Cross Section
- Thickness
- Heat Source
- Fluid
- Solid
- Initial Values
- Translational Motion

BOUNDARY NODES FOR THE HEAT TRANSFER IN SOLIDS INTERFACE

The Heat Transfer in Solids Interface has the following boundary nodes:

- Boundary Heat Source
- Continuity
- Heat Flux
- Line Heat Source on Axis
- Outflow
- Periodic Condition
- Surface-to-Ambient Radiation
- Symmetry
- Temperature
- Thermal Insulation
- Thin Layer

EDGE NODES FOR THE HEAT TRANSFER IN SOLIDS INTERFACE

The Heat Transfer in Solids Interface has the following edge node (3D components only): Line Heat Source

POINT NODES FOR THE HEAT TRANSFER IN SOLIDS INTERFACE

The Heat Transfer in Solids Interface has the following point nodes: Point Heat Source and Point Heat Source on Axis

The Heat Transfer in Fluids Interface

The **Heat Transfer in Fluids** ( ) interface is used to model heat transfer in fluids by conduction, convection, and radiation. A Fluid model is active by default on all domains. All functionality for including other domain types, such as a solid domain, is also available.

The temperature equation defined in fluid domains corresponds to the convection-diffusion equation that may contain additional contributions like heat sources.

When this version of the physics interface is added, these default nodes are added to the **Model Builder** — **Fluid**, **Thermal Insulation** (the default boundary condition), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions and sources. You can also right-click **Heat Transfer in Fluids** to select physics features from the context menu.

DISCRETIZATION

By default, the shape functions used for the temperature are **Linear**.

To display more than the shape functions in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. The rest of the settings are the same as for The Heat Transfer in Solids Interface. See Settings for the Heat Transfer Interface for a description of the other settings.

See Table 2-4 for links to common sections and Table 2-5 to common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

The Heat Transfer in Solids and Fluids Interface

The **Heat Transfer in Solids and Fluids** ( ) interface is automatically added when the predefined multiphysics interface **Laminar Flow** under the **Conjugate Heat Transfer** branch is added.

It is used to model heat transfer in solids and fluids by conduction and convection. A Solid model is active by default on all domains, and a Fluid model is also added but not active.

The settings are the same as for The Heat Transfer in Fluids Interface. This means that a first order discretization of the temperature is set by default.

The settings and the feature nodes are the same as for The Heat Transfer in Fluids Interface.

The Joule Heating Interface

The **Joule Heating** interface ( ) is used to model resistive heating and, depending on additional licensed products, dielectric heating in devices where inductive effects are negligible; that is, when the skin depth is much larger than the studied device. This multiphysics interface adds an Electric Currents interface and a Heat Transfer in Solids interface. The multiphysics couplings add the electromagnetic power dissipation as a heat source, and the electromagnetic material properties can depend on the temperature.

Depending on the licensed products, stationary modeling, time-domain modeling are supported in all space dimensions. In addition, combinations of frequency-domain modeling for the Electric Currents interface and stationary modeling for the Heat Transfer in Solids interface, called frequency-stationary and frequency-transient modeling, are supported.

When a predefined **Joule Heating** interface is added from the **AC/DC** > **Electromagnetic Heating** or **Heat Transfer** > **Electromagnetic Heating** branch ( ) of the **Model Wizard** or **Add Physics** windows, **Electric Currents** and **Heat Transfer in Solids** interfaces are added to the Model Builder. In addition, The Multiphysics Branch is added, which automatically includes the multiphysics coupling feature **Electromagnetic Heating**.

On the Constituent Physics Interfaces

The Electric Currents interface computes electric field, current, and potential distributions in conducting media under conditions where inductive effects are negligible; that is, when the skin depth is much larger than the studied device. Depending on the licensed products, time and frequency domain formulations that account for capacitive effects are also provided. The Electric Currents interface solves a current conservation equation based on Ohm's law using the scalar electric potential as the dependent variable.

The Heat Transfer in Solids interface provides features for modeling heat transfer by conduction, convection, and radiation. A Heat Transfer in Solids model is active by default on all domains. All functionality for including other domain types, such as a fluid domain, is also available. The temperature equation defined in solid domains corresponds to the differential form of the Fourier's law that may contain additional contributions like heat sources.

In previous versions of COMSOL Multiphysics, a specific physics interface called Joule Heating was added to the Model Builder. Now, a predefined multiphysics coupling approach is used, improving the flexibility and design options for your modeling. For specific details, see Multiphysics Modeling Workflow.

SETTINGS FOR PHYSICS INTERFACES AND COUPLING FEATURE

When physics interfaces are added using the predefined couplings, for example **Joule Heating**, specific settings are included with the physics interfaces and the coupling features.

However, if physics interfaces are added one at a time, followed by the coupling features, these modified settings are not automatically included.

For example, if single **Electric Currents** and **Heat Transfer in Solids** interfaces are added, the COMSOL Multiphysics software adds an empty **Multiphysics** node. When you right-click this node, you can choose **Electromagnetic Heating** from the available coupling features, but the modified settings are not included.

TABLE 14-1: MODIFIED SETTINGS FOR A JOULE HEATING INTERFACE.

PHYSICS INTERFACE OR COUPLING FEATURE	MODIFIED SETTINGS (IF ANY)
Electric Currents	No changes.
Heat Transfer in Solids	No changes.
Electromagnetic Heating	The **Domain Selection** is the same as that of the participating physics interfaces. The **Boundary Selection** is the same as the exterior and interior boundaries of the **Domain Selection** of the participating physics interfaces. The corresponding **Electric Currents** and **Heat Transfer in Solids** interfaces are preselected in the Coupled Interfaces section.

PHYSICS INTERFACE AND COUPLING FEATURE

Coupling Feature

The Electromagnetic Heating multiphysics coupling node is described in this section.

Physics Interface Features

Physics nodes are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (macOS or Linux users), or right-click to access the context menu (all users).

In general, to add a node, go to the **Physics** toolbar, no matter what operating system you are using.

- The available physics features for the heat transfer interfaces are listed in the sections Domain Features, Boundary Features, and Edge and Point Features.
- For information about the available physics features for the Electric Currents interface, see The Electric Currents Interface.

If you have an add-on module, such as the Heat Transfer Module or AC/DC Module, there are additional specialized physics nodes available and described in the individual module documentation.

Thermal Microactuator Simplified: Application Library path **COMSOL_Multiphysics/Multiphysics/thermal_actuator_simplified**

Electromagnetic Heating

The **Electromagnetic Heating** multiphysics coupling ( ) adds the source term Q_e (SI unit: W/m^3) to account for resistive heating in the heat equation:

$$\rho C_p \frac{\partial T}{\partial t} - \nabla \cdot (k \nabla T) = Q_e \tag{14-6}$$

The resistive heating (ohmic heating) due to the electric current is

$$Q_e = \mathbf{J} \cdot \mathbf{E}$$

where $\mathbf{J}$ is the current density (SI unit: A/m^2), and $\mathbf{E}$ is the electric field strength (SI unit: V/m).

In addition, it maps the electromagnetic surface losses as a heat source on the boundary (SI unit: W/m^2) in the heat transfer part of the model.

SETTINGS

The **Label** is the default multiphysics coupling name.

The **Name** is used primarily as a scope prefix for variables defined by the coupling node. Refer to such variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different coupling nodes or physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first multiphysics coupling in the model) is `emh1`.

DOMAIN SELECTION

When nodes are added from the context menu, you can select **Manual** (the default) from the **Selection** list to choose specific domains to define the electromagnetic heat source or select **All domains** as needed.

When **Electromagnetic Heating** is added as an effect of adding a **Joule Heating** or **Joule Heating and Thermal Expansion** interface, the selection is the same as for the participating interfaces.

Only domains that are active in the physics interfaces selected in the **Coupled Interfaces** section can be selected.

BOUNDARY SELECTION

When nodes are added from the context menu, you can select **Manual** (the default) from the **Selection** list to choose specific boundaries to define the electromagnetic boundary heat source or select **All boundaries** as needed.

When **Electromagnetic Heating** is added as an effect of adding a **Joule Heating** or **Joule Heating and Thermal Expansion** interface, the selection is the same as the exterior and interior boundaries of the **Domain Selection** of the participating physics interfaces.

Only boundaries that are active in the physics interfaces selected in the **Coupled Interfaces** section can be selected.

COUPLED INTERFACES

This section defines the physics involved in the multiphysics coupling. By default, the applicable physics interface is selected in the **Electromagnetic** list to apply the **Heat transfer** to its physics interface to establish the coupling.

The default values depend on how the coupling node is created.

- If it is added from the **Physics** ribbon (Windows users), **Physics** contextual toolbar (macOS and Linux users), or context menu (all users), then the first physics interface of each type in the component is selected as the default.
- If it is added automatically when a multiphysics interface is selected in the **Model Wizard** or **Add Physics** window, then the two participating physics interfaces are selected.

You can also select **None** from either list to uncouple the **Electromagnetic Heating** node from a physics interface. If the physics interface is removed from the **Model Builder** (for example, **Heat Transfer in Solids** is deleted), then the **Heat transfer** list defaults to **None** as there is nothing to couple to.

Click the **Go to Source** button ( ) to move to the main physics interface node for the selected physics interface.

	If a physics interface is deleted and then added to the model again, then in order to reestablish the coupling, you need to choose the physics interface again from the **Heat transfer** or **Electromagnetic** lists. This is applicable to all multiphysics coupling nodes that would normally default to the once present physics interface. See Multiphysics Modeling Workflow.

The Nonisothermal Flow and Conjugate Heat Transfer Interfaces

The Nonisothermal Flow and Conjugate Heat Transfer interfaces combine the heat equation with laminar flow in a **Fluid** domain. The coupling with turbulent flow in **Fluid**, **Porous Medium**, and **Moist Air** domain models is available with add-on modules. The advantage of using the multiphysics interfaces is that predefined couplings are available in both directions. In particular, physics interfaces use the same definition of the density, which can therefore be a function of both pressure and temperature. Solving this coupled system of equations usually requires numerical stabilization accounting for the couplings, which the predefined multiphysics interfaces also set up.

When a multiphysics interface is added from the **Heat Transfer** > **Conjugate Heat Transfer** branch or the **Fluid Flow** > **Nonisothermal Flow** branch of the **Model Wizard** or **Add Physics** windows, the **Single-Phase Flow** interface (laminar flow) and a **Heat Transfer** interface are added to the Model Builder. In addition, the **Multiphysics** node is added, which includes the multiphysics coupling feature **Nonisothermal Flow**.

Settings for Physics Interfaces and Coupling Feature

When physics interfaces are added using the predefined couplings, specific settings are included with the physics interfaces and the coupling features.

TABLE 14-2: MODIFIED SETTINGS FOR THE NONISOTHERMAL FLOW AND CONJUGATE HEAT TRANSFER INTERFACES.

PHYSICS OR COUPLING INTERFACE	MODIFIED SETTINGS (IF ANY)
Heat Transfer in Solids	Discretization order from temperature Lagrange shape function is 1. A **Fluid** feature is added with an empty default editable selection. The **Absolute pressure**, p_A (**Model Input** section) and the **Velocity field**, $\mathbf{u}$ (**Heat Convection** section) are automatically set to the variables from the **Nonisothermal Flow** multiphysics coupling feature.
Heat Transfer in Fluids	In the **Fluid** default feature, the **Absolute pressure**, p_A (**Model Input** section) and the **Velocity field**, $\mathbf{u}$ (**Heat Convection** section) are automatically set to the variables from the **Nonisothermal Flow** multiphysics coupling feature.
Laminar Flow	In the **Fluid Properties** default feature, the **Density**, ρ is automatically set to the variable from the **Nonisothermal Flow** multiphysics coupling feature. The **Compressibility** option is set to **Weakly Compressible**. The **Use pseudo time stepping for stationary equation form** checkbox is automatically selected under the **Advanced Settings** section.
Nonisothermal Flow	The Laminar Flow and heat-transfer interfaces are preselected.

Note that these settings may be overridden if another predefined coupling is added.

Nonisothermal Flow

Use the **Nonisothermal Flow** multiphysics coupling ( ) to simulate fluid flows where the fluid properties depend on temperature. Models can also include heat transfer in solids. The physics interface supports low Mach numbers (typically less than 0.3).

The Nonisothermal Flow, Laminar Flow and Conjugate Heat Transfer, Laminar Flow interfaces solve for conservation of energy, mass, and momentum in fluids and for conservation of energy in solids.

This multiphysics coupling defines p and $\mathbf{u}$ variables in order to set the **Absolute pressure** in the **Model Input** section and the **Velocity field** in the **Heat Convection** section of the **Fluid** feature in the Heat Transfer interface. In addition, it provides all the fluids quantities that may be needed by the Heat Transfer interface (for example, viscosity).

In the Fluid Flow interface, it sets the **Temperature** in the **Model Input** section and defines the **Density** in the **Fluid Properties** section of the **Fluid Properties** feature.

It also synchronizes the definition of the reference temperature to be used for incompressible flows. In addition, it also accounts for the multiphysics stabilization terms.

The **Nonisothermal Flow** coupling node triggers pseudo time stepping when **Use pseudo time stepping for stationary equation form** in the **Fluid Flow** interface is set to **Automatic from physics**.

The multiphysics stabilizations (streamline diffusion and crosswind diffusion) are controlled by the Fluid Flow interface. For example, the multiphysics streamline diffusion can be disabled in a **Laminar Flow** physics node, in the **Stabilization** section. The stabilization selected in the Heat Transfer interface has no effect if the multiphysics coupling stabilization is active but remains active if not. However, the isotropic diffusion is not a multiphysics stabilization and is controlled by each physics interface.

Finally, when one of the physics interfaces or the multiphysics coupling is not solved in a study step, then the stabilization of each solved physics is used instead of the coupled stabilization, and the solver suggestions are uncoupled.

SETTINGS

The **Label** is the default multiphysics coupling feature name.

The **Name** is used primarily as a scope prefix for variables defined by the coupling node. Refer to such variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different coupling nodes or physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first multiphysics coupling feature in the model) is `nitf1`.

DOMAIN SELECTION

When nodes are added from the context menu, you can select **Manual** (the default) from the **Selection** list to choose specific domains to define the nonisothermal flow, or select **All domains** as needed.

COUPLED INTERFACES

This section defines the physics involved in the multiphysics coupling. The **Fluid flow** and **Heat transfer** lists include all applicable physics interfaces.

The default values depend on how this coupling node is created.

- If it is added from the **Physics** ribbon (Windows users), **Physics** contextual toolbar (Mac and Linux users), or context menu (all users), then the first physics interface of each type in the component is selected as the default.
- If it is added automatically when a multiphysics interface is chosen in the **Model Wizard** or **Add Physics** window, then the two participating physics interfaces are selected.

You can also select **None** from either list to uncouple the node from a physics interface. If the physics interface is removed from the **Model Builder** — for example, **Heat Transfer in Fluids** is deleted — then the **Heat transfer** list defaults to **None** as there is nothing to couple to.

MATERIAL PROPERTIES

Select an option from the **Specify density** list: **From heat transfer interface** (the default), **From fluid flow interface**, **Custom, linearized density**, or **Custom**.

For **Custom, linearized density**, enter the **Reference density** ρ_{ref} (SI unit: kg/m^3) and the **Coefficient of thermal expansion** α_p (SI unit: $1/\text{K}$), or select **From material**, or select a variable in the list if available. When **Custom, linearized density** is selected, regardless how the properties are defined they should be constant. If material properties are not constant you should consider using any of the other options to define the density.

For **Custom**, enter a **Density** ρ (SI unit: kg/m^3), or select a density in the list if available.

The density definition in the **Nonisothermal Flow** node ensures that the same definition of the density is used on the fluid flow and heat transfer interfaces. When the fluid flow compressibility setting is set to **Incompressible** then the thermal conductivity and the heat capacity are evaluated at the **Reference temperature** defined in the fluid flow interface.

LOCATION IN USER INTERFACE

Context Menus

Multiphysics > **Nonisothermal Flow**

when any version of the **Single-Phase Flow** interface is added together with **Heat Transfer in Fluids** (or another version of the Heat Transfer Interface, with a **Fluid** feature active).

Physics Interface Features

Physics nodes are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (Mac or Linux users), or right-click to access the context menu (all users).

In general, to add a node, go to the **Physics** toolbar, no matter what operating system you are using.

HEAT TRANSFER IN FLUIDS

The available physics features for The Heat Transfer in Fluids Interface are listed in Feature Nodes for the Heat Transfer in Fluids Interface. Also see Fluid for details about that feature.

LAMINAR FLOW

The available physics features for The Laminar Flow Interface are listed in the section Domain, Boundary, Pair, and Point Nodes for Single-Phase Flow.

Domain Features

Cross Section

Use this node with 1D components to model domains with another cross-sectional area or another cross-sectional perimeter than the global one that is used in the Heat Transfer interface **Physical Model** section. In 1D geometries, the temperature is assumed to be constant in the radial direction, and the heat equation is modified to account for that.

CROSS SECTION

Enter values for the **Cross-sectional area** A_c and the **Cross-sectional perimeter** P_c to set the cross section of the domain in the plane perpendicular to the 1D geometry.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Solids > **Cross Section**

Heat Transfer in Fluids > **Cross Section**

Heat Transfer in Solids and Fluids > **Cross Section**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Domains > *interface* > **Cross Section**

Thickness

Use this node with 2D components to model domains with another thickness than the overall thickness that is specified in the Heat Transfer interface **Physical Model** section. In 2D geometries, the temperature is assumed to be constant in the out-of-plane direction (z direction with default spatial coordinate names).

THICKNESS

Specify a value for the **Thickness** d_z of the domain in the out-of-plane direction. This value replaces the overall thickness in the domains that are selected in the **Domain Selection** section, and is used to multiply some terms into the heat equation.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Solids > **Thickness**

Heat Transfer in Fluids > **Thickness**

Heat Transfer in Solids and Fluids > **Thickness**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Domains > *interface* > **Thickness**

Heat Source

This node describes heat generation within the domain. You express heating and cooling with positive and negative values, respectively. Add one or more nodes as needed — all heat sources within a domain contribute to the total heat source.

The **Heat Source** node adds a source term Q to the right-hand side of the heat equation:

$$Q = Q_0$$

Specify Q_0 as the heat per unit volume, as a linear heat source, or as a heat rate.

HEAT SOURCE

Click the **General source** (the default), **Linear source**, or **Overall heat transfer rate** buttons.

- For **General source** enter a value for the distributed heat source Q_0 when the default option (**User defined**) is selected. See also Additional General Source Options to use predefined heat sources available from other interfaces.
- For **Linear source** enter a value for the **Production/absorption coefficient** q_s used in the predefined linear expression. The advantage of writing the source on this form is that it can be accounted for in the streamline diffusion stabilization. The stabilization applies when q_s is independent of the temperature, but some stability can be gained as long as q_s is only weakly dependent on the temperature.
- For **Overall heat transfer rate** enter a value for the heat rate P_0. In this case $Q_0 = P_0/V$, where V is the total volume of the selected domains.

Additional General Source Options

For the general heat source Q_0 there are predefined heat sources available (in addition to a **User defined** heat source) when simulating heat transfer together with electrical or electromagnetic interfaces. Such sources represent, for example, ohmic heating and induction heating. Depending on additional physics interfaces, the following are available:

- With the addition of an Electric Currents interface, the **Total power dissipation density (ec)** heat source is available from the **General source** list.
- With the addition of any version of the Electromagnetic Waves interface (which requires the RF Module), the **Total power dissipation density (emw)** and **Electromagnetic power loss density (emw)** heat sources are available from the **General source** list.
- With the addition of a Magnetic Fields interface (a 3D component requires the AC/DC Module), the **Electromagnetic heating (mf)** heat source is available from the **General source** list.
- With the addition of a Magnetic and Electric Fields interface (which requires the AC/DC Module), the **Electromagnetic heating (mef)** heat source is available from the **General source** list.

Stabilization Techniques

For the definition of a localized heat source, see Line Heat Source, Point Heat Source and Point Heat Source on Axis.

For the definition of a heat on a boundary, see Boundary Heat Source.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Solids > **Heat Source**
Heat Transfer in Fluids > **Heat Source**
Heat Transfer in Solids and Fluids > **Heat Source**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Domains > *interface* > **Heat Source**

Fluid

This node uses the following version of the heat equation to model heat transfer in fluids:

$$\rho C_p \frac{\partial T}{\partial t} + \rho C_p \mathbf{u} \cdot \nabla T + \nabla \cdot \mathbf{q} = Q$$
$$\mathbf{q} = -k\nabla T \tag{14-7}$$

with the following material properties, fields, and sources:

- ρ (SI unit: kg/m^3) is the fluid density.
- C_p (SI unit: J/(kg·K)) is the fluid heat capacity at constant pressure.
- k (SI unit: W/(m·K)) is the fluid thermal conductivity (a scalar or a tensor if the thermal conductivity is anisotropic).
- $\mathbf{u}$ (SI unit: m/s) is the fluid velocity field, either an analytic expression or a velocity field from a Fluid Flow interface.
- Q (SI unit: W/m^3) is the heat source (or sink). Add one or several heat sources as separate physics features. See the Heat Source node for an example.

For a steady-state problem the temperature does not change with time and the first term disappears.

MODEL INPUTS

This section has fields and values that are inputs to expressions that define material properties. If such user-defined property groups are added, the model inputs appear here. For all model inputs, you can select **Common model input** to use a model input defined under **Global Definitions**.

Temperature

This section is available when temperature-dependent material properties are used. By default the temperature of the parent interface is used and the section is not editable. To edit the **Temperature** field, click **Make All Model Inputs Editable** ( ). The available options are **User defined** (default), **Common model input**, and all temperature variables from the physics interfaces included in the model. These physics interfaces have their own tags (the **Name**). For example, if a **Heat Transfer in Fluids** interface is included in the model, the **Temperature (ht)** option is available.

Absolute Pressure

The absolute pressure is used in some predefined quantities that include the enthalpy (the energy flux, for example).

The default **Absolute pressure** p_A is taken from **Common model input**. It corresponds to the `minput.pA` variable, set to 1 atm by default. To edit it, click the **Go to Source** button ( ), and in the **Default Model Inputs** node under **Global Definitions**, set a value for the **Pressure** in the **Expression for remaining selection** section. When additional physics interfaces are added to the model, the absolute pressure variables defined by these physics interfaces can also be

selected from the list. For example, if a **Laminar Flow** interface is added you can select **Absolute pressure (spf)** from the list. The last option is **User defined**.

Concentration

From the **Concentration** c (SI unit: mol/m^3 or kg/m^3) list, select an existing concentration variable from another physics interface, if any concentration variables exist, or select **User defined** to enter a value or expression for the concentration. This section can be edited anytime a material property is concentration dependent; for example, when the **Fluid type** is set to **Moist air** with **Input quantity** set to **Concentration**.

HEAT CONVECTION

The default **Velocity field u** is **User defined**. For **User defined** enter values or expressions for the components based on space dimensions. You can also select an existing velocity field in the component (for example, **Velocity field (spf)** from a **Laminar Flow** interface).

HEAT CONDUCTION, FLUID

The thermal conductivity k describes the relationship between the heat flux vector $\mathbf{q}$ and the temperature gradient ∇T in $\mathbf{q} = -k\nabla T$, which is Fourier's law of heat conduction. Enter this quantity as power per length and temperature.

The default **Thermal conductivity** k is taken **From material**. For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** based on the characteristics of the thermal conductivity, and enter another value or expression. For **Isotropic** enter a scalar which will be used to define a diagonal tensor. For the other options, enter values or expressions into the editable fields of the tensor.

THERMODYNAMICS, FLUID

This section defines the thermodynamics properties of the fluid.

The heat capacity at constant pressure C_p describes the amount of heat energy required to produce a unit temperature change in a unit mass.

The ratio of specific heats γ is the ratio between the heat capacity at constant pressure, C_p, and the heat capacity at constant volume, C_v. When using the ideal gas law to describe a fluid, specifying γ is sufficient to evaluate C_p. For common diatomic gases such as air, $\gamma = 1.4$ is the standard value. Most liquids have $\gamma = 1.1$ while water has $\gamma = 1.0$. γ is used in the streamline stabilization and in the variables for heat fluxes and total energy fluxes. It is also used if the ideal gas law is applied.

When the density is not taken from a **Nonisothermal Flow** or a **Nonisothermal Mixture Model** coupling node, you should select a **Fluid type** option for the specification of the material properties. The available **Fluid type** options are **From material**, **Ideal gas**, and **Gas/Liquid** (default). After selecting a **Fluid type** from the list, further settings display underneath. See Nonisothermal Mixture Model in the *CFD Module User's Guide* for details.

From Material

This option automatically detects whether the material applied on each domain selection is an ideal gas or not, and uses the relevant properties from the **Material** node for either case.

By using the following definition of the density for an ideal gas:

$$\rho = \frac{p_A}{R_s T}$$

with R_s the specific gas constant, p_A the absolute pressure, and T the temperature, the evaluation of the isobaric compressibility coefficient, α_p, and of the isothermal Joule-Thomson coefficient, μ_{JT}, is simplified. This may

improve efficiency, when computing pressure work in compressible nonisothermal flows for example, or when modeling inflow conditions.

The Air material, from the Built-in materials database, has an **Ideal gas** property group, and is thus detected as an ideal gas by the **Fluid** node. The Liquids and Gases Material Library, available with some COMSOL products, also provides such materials.

The **Density**, the **Heat capacity at constant pressure**, and the **Ratio of specific heats** are automatically taken **From material** and no further setting is required. For the specification of user defined material properties, the Ideal Gas or Gas/Liquid options should be used instead.

Ideal Gas

This option uses the ideal gas law to describe the fluid. Only two properties are needed to define the thermodynamics of the fluid:

- The gas constant, with two options for the **Gas constant type**: **Specific gas constant** R_s or **Mean molar mass** M_n. If **Mean molar mass** is selected the software uses the universal gas constant $R = 8.314$ J/(mol·K), which is a built-in physical constant, to calculate the specific gas constant.
- Either the **Heat capacity at constant pressure** C_p or **Ratio of specific heats** γ by selecting the option from the **Specify Cp or** γ list. For an ideal gas, it is sufficient to specify either C_p or the ratio of specific heats, γ, as these properties are interdependent.

Gas/Liquid

This option specifies the **Density**, the **Heat capacity at constant pressure**, and the **Ratio of specific heats** for a general gas or liquid.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Solids > **Fluid**
Heat Transfer in Fluids > **Fluid**
Heat Transfer in Solids and Fluids > **Fluid**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Domains > *interface* > **Fluid**

Solid

This node uses this version of the heat equation to model heat transfer in solids:

$$\rho C_p \frac{\partial T}{\partial t} + \rho C_p \mathbf{u} \cdot \nabla T + \nabla \cdot \mathbf{q} = Q$$
$$\mathbf{q} = -k\nabla T \tag{14-8}$$

with the following material properties, fields, and sources:

- ρ (SI unit: kg/m^3) is the solid density.
- C_p (SI unit: J/(kg·K)) is the solid heat capacity at constant pressure.

- k (SI unit: W/(m·K)) is the solid thermal conductivity (a scalar or a tensor if the thermal conductivity is anisotropic).
- $\mathbf{u}$ (SI unit: m/s) is the velocity field defined by the Translational Motion subnode when parts of the model are moving in the material frame.
- Q (SI unit: W/m^3) is the heat source (or sink). Add one or several heat sources as separate physics features. See the Heat Source node.

For a steady-state problem the temperature does not change with time and the first term disappears.

HEAT CONDUCTION, SOLID

The thermal conductivity k describes the relationship between the heat flux vector $\mathbf{q}$ and the temperature gradient ∇T in $\mathbf{q} = -k\nabla T$, which is Fourier's law of heat conduction. Enter this quantity as power per length and temperature.

The default **Thermal conductivity** k is taken **From material**. For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** based on the characteristics of the thermal conductivity, and enter another value or expression. For **Isotropic** enter a scalar which will be used to define a diagonal tensor. For the other options, enter values or expressions into the editable fields of the tensor.

The components of the thermal conductivity k when given on tensor form (k_{xx}, k_{yy}, and so on, representing an anisotropic thermal conductivity) are available as `ht.kxx`, `ht.kyy`, and so on (using the default name `ht`). The single scalar mean effective thermal conductivity `ht.kmean` is the mean value of the diagonal elements k_{xx}, k_{yy}, and k_{zz}. For an isotropic thermal conductivity, `ht.k_iso` contains its value.

Fourier's law assumes that the thermal conductivity tensor is symmetric. A nonsymmetric tensor can lead to unphysical results.

THERMODYNAMICS, SOLID

This section sets the thermodynamics properties of the solid.

The heat capacity at constant pressure describes the amount of heat energy required to produce a unit temperature change in a unit mass.

The **Density** ρ and **Heat capacity at constant pressure** C_p should be specified.

In addition, the thermal diffusivity α, defined as $k/(\rho C_p)$ (SI unit: m^2/s), is also a predefined quantity. The thermal diffusivity can be interpreted as a measure of thermal inertia (heat propagates slowly where the thermal diffusivity is low, for example). The components of the thermal diffusivity α, when given on tensor form (α_{xx}, α_{yy}, and so on, representing an anisotropic thermal diffusivity) are available as `ht.alphaTdxx`, `ht.alphaTdyy`, and so on (using the default physics name `ht`). The single scalar mean thermal diffusivity `ht.alphaTdMean` is the mean value of the diagonal elements α_{xx}, α_{yy}, and α_{zz}. The denominator ρC_p is the effective volumetric heat capacity which is also available as a predefined quantity, `ht.C_eff`.

Theory for Heat Transfer in Solids

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Domains > *interface* > **Initial Values**

Translational Motion

This subnode provides movement by translation to the model for heat transfer in solids. It adds the following contribution to the right-hand side of Equation 14-8, defined in the parent node:

$$-\rho C_p \mathbf{u}_{\text{trans}} \cdot \nabla T$$

The contribution describes the effect of a moving coordinate system, which is required to model, for example, a moving heat source.

Special care must be taken on boundaries where $\mathbf{n} \cdot \mathbf{u}_{\text{trans}} \neq 0$. The Heat Flux boundary condition does not, for example, work on boundaries where $\mathbf{n} \cdot \mathbf{u}_{\text{trans}} < 0$.

DOMAIN SELECTION

By default, the selection is the same as for the **Solid** node that it is attached to, but it is possible to use more than one **Translational Motion** subnode, each covering a subset of the **Solid** node's selection.

TRANSLATIONAL MOTION

The x, y, and z (in 3D) components of the **Velocity field** $\mathbf{u}_{\text{trans}}$ should be specified in this section.

Boundary Features

Boundary Heat Source

This node models a heat source (or heat sink) that is embedded in the boundary. When selected as a **Pair Boundary Heat Source**, it also prescribes that the temperature field is continuous across the pair.

PAIR SELECTION

If this node is selected from the **Pairs** menu, then from the **Pairs** list, choose **From list** (the default), **All**, **All contact pairs**, or **All identity pairs**. If you choose **From list**, select the pairs where you want to impose continuity across the pair boundaries by clicking the **Add** button (+) and choose the pairs to add from the list in the **Add** dialog that opens; then click **OK**. A pair has to be created first. See Identity, Contact, and Sector Symmetry Pairs in the *COMSOL Multiphysics Reference Manual* for more details.

BOUNDARY HEAT SOURCE

Click the **General source** (the default) or **Heat rate** button.

- For **General source** enter a value for the boundary heat source Q_b when the default option, **User defined**, is selected.

  A positive Q_b corresponds to heating and a negative Q_b corresponds to cooling. For the general boundary heat source Q_b, there are predefined heat sources available when simulating heat transfer together with electrical or electromagnetic interfaces. Such sources represent, for example, ohmic heating and induction heating.
- For **Heat rate** enter the heat rate P_b. In this case $Q_b = P_b/A$, where A is the total area of the selected boundaries.

FRAME SELECTION

The settings are the same as for the Heat Source node and are described under **Frame Selection**.

SOURCE POSITION

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Select a **Source position** to define a side where the heat source is defined — **Layer** (the default), **Upside**, or **Downside**. This setting has no effect unless the temperature differs from one side of the boundary to the other. Typically when **Boundary Heat Source** contributes with a **Thin Layer** feature.

	To define the boundary heat source Q_b as a function of the temperature, use the local temperature variable on the selected boundary, `ht.bhs1.Tvar`, that corresponds to the appropriate variable (upside, downside, or average temperature of a layer, wall temperature with turbulence modeling), depending on the model configurations.

	Upside and downside settings can be visualized by plotting the global normal vector (`nx`, `ny`, `nz`), that always points from downside to upside. Note that the normal vector (`ht.nx`, `ht.ny`, `ht.nz`) may be oriented differently. See Tangent and Normal Variables.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Solids > **Boundary Heat Source**
Heat Transfer in Fluids > **Boundary Heat Source**
Heat Transfer in Solids and Fluids > **Boundary Heat Source**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Boundaries > *interface* > **Boundary Heat Source**
Pairs > *interface* > **Pair Boundary Heat Source**

Continuity

This node can be added to pairs. It prescribes that the temperature field is continuous across the pair. **Continuity** is only suitable for pairs where the boundaries match.

PAIR SELECTION

If this node is selected from the **Pairs** menu, then from the **Pairs** list, choose **From list** (the default), **All**, **All contact pairs**, or **All identity pairs**. If you choose **From list**, select the pairs where you want to impose continuity across the pair boundaries by clicking the **Add** button (+) and choose the pairs to add from the list in the **Add** dialog that opens; then click **OK**. A pair has to be created first. See Identity, Contact, and Sector Symmetry Pairs for more details.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Fluids > **Pairs** > **Continuity**
Heat Transfer in Solids and Fluids > **Pairs** > **Continuity**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Pairs > *interface* > **Continuity**

Heat Flux

Use this node to add heat flux across boundaries. A positive heat flux adds heat to the domain; change the sign of the flux to model an outward heat flux.

HEAT FLUX

Click to select the **General inward heat flux** (the default), **Convective heat flux**, or **Heat rate** button.

General Inward Heat Flux

It adds q_0 to the total flux across the selected boundaries. Enter a value for q_0 to represent a heat flux that enters the domain. For example, any electric heater is well represented by this condition, and its geometry can be omitted.

Convective Heat Flux

Enter a value for the **Heat transfer coefficient** h and an **External temperature**, T_{ext}. The value depends on the geometry and the ambient flow conditions. Convective heat flux is defined by $q_0 = h(T_{ext} - T)$.

Heat Rate

For **Heat rate** enter the heat rate P_0 across the boundaries where the **Heat Flux** node is active. In this case $q_0 = P_0/A$, where A is the total area of the selected boundaries.

FRAME SELECTION

The settings are the same as for the Heat Source node and are described under **Frame Selection**.

Heat Transfer in Solids and Fluids > **Line Heat Source on Axis**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Boundaries > *interface* > **Line Heat Source on Axis**

Outflow

This node provides a suitable boundary condition for convection-dominated heat transfer at outlet boundaries. In a model with convective heat transfer, this condition states that the only heat transfer occurring across the boundary is by convection. The temperature gradient in the normal direction is zero, and there is no radiation. This is usually a good approximation of the conditions at an outlet boundary in a heat transfer model with fluid flow.

BOUNDARY SELECTION

In most cases, the Outflow node does not require any user input. If required, select the boundaries that are convection-dominated outlet boundaries.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Solids > **Outflow**

Heat Transfer in Fluids > **Outflow**
Heat Transfer in Solids and Fluids > **Outflow**

Ribbon
Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Boundaries > *interface* > **Outflow**

Periodic Condition

Use this node to add periodic temperature conditions to boundary pairs.

BOUNDARY SELECTION

The software usually automatically identifies the boundaries as either source boundaries or destination boundaries, as indicated in the selection list. This works fine for cases like opposing parallel boundaries. In other cases, right-click **Periodic Condition** and select **Manual Destination Selection** to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

DESTINATION SELECTION

This section is available for specifying the destination boundaries, if needed, when the **Manual Destination Selection** option is selected in the context menu for the **Periodic Condition** node. You can only select destination boundaries from the union of all source and destination boundaries.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

The **Constraint** settings can be set to **Nitsche constraints** (default), **Pointwise constraints**, or **Weak constraints**.

- Constraint Reaction Terms
- Weak Constraints
- Constraint Settings

PERIODIC CONDITION

Enter a **Temperature offset** ΔT to the temperature periodicity. The default value is 0 K, so that the source and destination temperatures are equal.

ORIENTATION OF SOURCE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Orientation of Source** section, see Orientation of Source and Destination.

MAPPING BETWEEN SOURCE AND DESTINATION

For information about the **Mapping Between Source and Destination** section, see Mapping Between Source and Destination.

Heat Transfer in Solids and Fluids > **Periodic Condition**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Boundaries > *interface* > **Periodic Condition**

Surface-to-Ambient Radiation

Use this node to account for radiation from boundaries to the ambient. The net inward heat flux from surface-to-ambient radiation is

$$-\mathbf{n}\cdot\mathbf{q} = \varepsilon\sigma(T_{\mathrm{amb}}^4 - T^4)$$

where ε is the surface emissivity, σ is the Stefan-Boltzmann constant (a predefined physical constant), and T_{amb} is the ambient temperature.

MODEL INPUT

This section has fields and values that are inputs to expressions that define material properties. If such user-defined property groups are added, the model inputs appear here.

Temperature

This section is available when temperature-dependent material properties are used. By default, the temperature of the parent interface is used and the section is not editable. To edit the **Temperature** field, click **Make All Model Inputs Editable** ( ). The available options are **User defined** (default), **Common model input** (the `minput.T` variable, set to 293.15 K by default), and all temperature variables from the physics interfaces included in the model. To edit the `minput.T` variable, click the **Go to Source** button ( ), and in the **Default Model Inputs** node under **Global Definitions**, set a value for the **Temperature** in the **Expression for remaining selection** section.

RADIATION SETTINGS

Define on which side of the boundary is the ambient domain that receives the radiation, by selecting a **Radiation direction**: **Upside** or **Downside**. This setting has no effect unless the temperature differs from one side of the boundary to the other.

	Upside and downside settings can be visualized by plotting the global normal vector (`nx`, `ny`, `nz`), that always points from downside to upside. Note that the normal vector (`ht.nx`, `ht.ny`, `ht.nz`) may be oriented differently. See Tangent and Normal Variables in the *COMSOL Multiphysics Reference Manual*.

SURFACE-TO-AMBIENT RADIATION

Surface emissivity

The default **Surface emissivity** ε (a dimensionless number between 0 and 1) is taken **From material**. For **User defined**, it should be specified. An emissivity of 0 means that the surface emits no radiation at all while an emissivity of 1 means that it is a perfect blackbody.

Ambient temperature

For **User defined**, enter an **Ambient temperature** T_{amb}. The default value is approximately room temperature, 293.15 K (20°C). Else, select an **Ambient temperature** defined in an **Ambient Properties** node under **Definitions** > **Shared Properties**.

LOCATION IN USER INTERFACE

Context Menus

Heat Transfer in Solids > **Surface-to-Ambient Radiation**
Heat Transfer in Fluids > **Surface-to-Ambient Radiation**
Heat Transfer in Solids and Fluids > **Surface-to-Ambient Radiation**

Ribbon

Physics Tab with **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Boundaries > **Heat Sources** > **Surface-to-Ambient Radiation**

Symmetry

This node provides a boundary condition for symmetry boundaries. This boundary condition is similar to a Thermal Insulation condition, and it means that there is no heat flux across the boundary.

LOCATION IN USER INTERFACE

Context menus

Heat Transfer in Solids > **Symmetry**
Heat Transfer in Fluids > **Symmetry**
Heat Transfer in Solids and Fluids > **Symmetry**

Ribbon

Physics Tab with *interface* as **Heat Transfer in Solids**, **Heat Transfer in Fluids**, or **Heat Transfer in Solids and Fluids** selected:

Boundaries > *interface* > **Symmetry**

Temperature

Use this node to specify the temperature somewhere in the geometry, for example, on boundaries.

PAIR SELECTION

If this node is selected from the **Pairs** menu, then from the **Pairs** list, choose **From list** (the default), **All**, **All contact pairs**, or **All identity pairs**. If you choose **From list**, select the pairs where you want to impose continuity across the pair boundaries by clicking the **Add** button (+) and choose the pairs to add from the list in the **Add** dialog that opens; then click **OK**. A pair has to be created first. See Identity, Contact, and Sector Symmetry Pairs for more details.

TEMPERATURE

The equation for this condition is $T = T_0$, where T_0 is the prescribed temperature on the boundary. Enter the value or expression for the **Temperature** T_0.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. The **Constraint** settings can be set to **Pointwise constraints** (default), **Weak constraints**, or **Nitsche constraints**. Select **Weak constraints** to replace the standard constraints with a weak implementation. Select **Nitsche constraints** when **Pointwise constraints** and **Weak constraints** do not work satisfactorily.

The **Nitsche constraints** option is especially useful to prevent oscillations on inlet boundaries where convection dominates. Unlike the **Pointwise constraints** and **Weak constraints**, these constraints do not enforce the temperature on the boundary extremities. This is relevant on fluid inlets where the temperature condition should not be enforced on the walls at the inlet extremities. Note that **Nitsche constraints** are not supported for resistive thin layers or with turbulent wall functions.

Thermal Insulation

This node is the default boundary condition for all Heat Transfer interfaces. This boundary condition means that there is no heat flux across the boundary:

$$-\mathbf{n} \cdot \mathbf{q} = 0$$

and hence specifies where the domain is well insulated. Intuitively, this equation says that the temperature gradient across the boundary is zero. For this to be true, the temperature on one side of the boundary must equal the temperature on the other side. Because there is no temperature difference across the boundary, heat cannot transfer across it.

Thin Layer

This node defines the thermal conductivity and thermodynamics properties of a resistive material located on internal or external boundaries. This material can be formed of one or more layers.

When the layer is a bad thermal conductor compared to the adjacent geometry, the tangential heat flux can be neglected and only the heat flux across the layer's thickness is considered. The layer can be constituted of multiple sublayers with specific thickness and thermal properties. This condition may also be used to enforce consistent initial conditions.

LAYER SELECTION

Select the applicable layers (the default setting is **All layered materials**) defining the required material properties for the node.

If no layered materials have been included yet, there is a shorthand available for creating a **Single Layer Material**, a **Layered Material Link**, or a **Layered Material Stack** (the plus, next to the **Layered Material** list).

When a layered material stack or link is selected from the **Layered Material** list, clear the checkboxes corresponding to layers where the node should not be applied in the **Selection** table.

You can visualize the selected layered materials and layers in each layered material by clicking the **Layer Cross Section Preview** and **Layer 3D Preview** buttons.

The desired selection for the node may correspond to boundaries with different layered materials. The **All layered materials** option allows to gather these materials to make the desired selection applicable for the node on the union of the boundaries where the layered materials are defined.

See Layered Material, Layered Material Link, Layered Material Stack, Layered Material Link (Subnode), and Single Layer Materials in the *COMSOL Multiphysics Reference Manual*.

MODEL INPUT

This section has fields and values that are inputs to expressions that define material properties. If such user-defined property groups are added, the model inputs appear here.

Volume reference temperature

This section is available when a temperature-dependent density defined in a material is used. On the material frame, the density is evaluated onto a reference temperature to ensure mass conservation in the presence of temperature variations. By default the **Common model input** is used. This corresponds to the variable `minput.Tempref`, which is set by default to 293.15 K. To edit it, click the **Go to Source** button ( ), and in the **Default Model Inputs** node

under **Global Definitions**, set a value for the **Volume reference temperature** in the **Expression for remaining selection** section.

The other options are **User defined** and all temperature variables from the physics interfaces included in the model.

This model input does not override the **Reference temperature** T_{ref} set in the **Physical Model** section of the physics interface, and that is used to evaluate the reference enthalpy, and a reference density for incompressible nonisothermal flows.

Temperature

This section is available when temperature-dependent material properties are used. By default the temperature of the parent interface is used and the section is not editable. To edit the **Temperature** field, click **Make All Model Inputs Editable** ( ). The available options are **User defined** (default), **Common model input** (the `minput.T` variable, set to 293.15 K by default), and all temperature variables from the physics interfaces included in the model. To edit the `minput.T` variable, click the **Go to Source** button ( ), and in the **Default Model Inputs** node under **Global Definitions**, set a value for the **Temperature** in the **Expression for remaining selection** section.

LAYER MODEL

The only option for **Layer type** is **Thermally thick approximation**.

From the **Specify** list select **Layer properties** (the default) or **Thermal resistance**, to set either the **Thermal conductivity** k or the **Thermal resistance** R_{s}.

HEAT CONDUCTION

The default **Thermal conductivity** k is taken **From layered material**. For **User defined** select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** to enter another value or expression.

Alternatively, set a value for the **Thermal resistance** R_{s} if **Specify** is set to **Thermal resistance** in the **Layer Model** section.

THERMODYNAMICS

By default the **Density** ρ and **Heat capacity at constant pressure** C_p of the layer are taken **From layered material**. For **User defined** enter other values or expressions. These properties are only used in time-dependent studies, but must be set in all cases.

Edge and Point Features

Line Heat Source

This node models a heat source (or sink) that is so thin that it has no thickness in the model geometry. It is available in 3D on edges. In 2D and 2D axisymmetric, it is available on points.

In theory, the temperature in a line source in 3D is plus or minus infinity (to compensate for the fact that the heat source does not have any volume). The finite element discretization used in COMSOL Multiphysics returns a finite temperature distribution along the line, but that distribution must be interpreted in a weak sense.

LINE HEAT SOURCE

Click the **General source** (the default) or **Heat rate** button.

- If **General source** is selected, enter a value for the distributed heat source, Q_l in unit power per unit length. A positive Q_l corresponds to heating while a negative Q_l corresponds to cooling.
- If **Heat rate** is selected, enter the heat rate P_l.

FRAME SELECTION

The settings are the same as for the Heat Source node and are described under **Frame Selection**.

support > **Line Heat Source**

with *support* as **Edges** in 3D and **Points** in 2D.

Point Heat Source

This node, available for 3D components, models a heat source (or sink) that is so small that it can be considered to have no spatial extension.

In theory, the temperature in a point source in 3D is plus infinity (to compensate for the fact that the heat source does not have a spatial extension). The finite element discretization used in COMSOL Multiphysics returns a finite value, but that value must be interpreted in a weak sense.

POINT HEAT SOURCE

Enter the **Point heat source** Q_p in unit power. A positive Q_p corresponds to heating while a negative Q_p corresponds to cooling.

FRAME SELECTION

This section is not available if the **Specify heat source radius option** is disabled. The settings are the same as for the Heat Source node and are described under **Frame Selection**.

Heat Transfer Variables

In this section:

- Predefined Variables
- Global Variables
- Domain Heat Fluxes
- Domain Heat Fluxes
- Boundary Heat Fluxes
- Internal Boundary Heat Fluxes
- Domain Heat Sources
- Boundary Heat Sources
- Line and Point Heat Sources

Predefined Variables

This section lists some predefined variables that are available to evaluate heat fluxes, sources, and integral quantities used in energy balance. All the variable names begin with the physics interface name (the prefix). By default the Heat Transfer interface prefix is `ht`. As an example, you can access the variable named `tflux` using `ht.tflux` (as long as the physics interface is named `ht`).

TABLE 14-3: HEAT FLUX VARIABLES.

VARIABLE	NAME	GEOMETRIC ENTITY LEVEL
`dEiInt`	Total Accumulated Heat Rate	Global
`ntfluxInt`	Total Net Heat Rate	Global
`QInt`	Total Heat Source	Global
`WnsInt`	Total Fluid Losses	Global
`dEiOInt`	Total Accumulated Energy Rate	Global
`ntefluxInt`	Total Net Energy Rate	Global
`tflux`	Total Heat Flux	Domains, boundaries
`dflux`	Conductive Heat Flux	Domains, boundaries
`trlflux`	Translational Heat Flux	Domains, boundaries
`teflux`	Total Energy Flux	Domains, boundaries
`ntflux`	Normal Total Heat Flux	Boundaries
`ndflux`	Normal Conductive Heat Flux	Boundaries
`ncflux`	Normal Convective Heat Flux	Boundaries
`ntrlflux`	Normal Translational Heat Flux	Boundaries
`nteflux`	Normal Total Energy Flux	Boundaries
`ndflux_u`	Internal Normal Conductive Heat Flux, Upside	Interior boundaries
`ndflux_d`	Internal Normal Conductive Heat Flux, Downside	Interior boundaries
`ncflux_u`	Internal Normal Convective Heat Flux, Upside	Interior boundaries
`ncflux_d`	Internal Normal Convective Heat Flux, Downside	Interior boundaries
`ntrlflux_u`	Internal Normal Translational Heat Flux, Upside	Interior boundaries

TABLE 14-3: HEAT FLUX VARIABLES.

VARIABLE	NAME	GEOMETRIC ENTITY LEVEL
ntrlflux_d	Internal Normal Translational Heat Flux, Downside	Interior boundaries
ntflux_u	Internal Normal Total Heat Flux, Upside	Interior boundaries
ntflux_d	Internal Normal Total Heat Flux, Downside	Interior boundaries
nteflux_u	Internal Normal Total Energy Flux, Upside	Interior boundaries
nteflux_d	Internal Normal Total Energy Flux, Downside	Interior boundaries
Qtot	Domain Heat Sources	Domains
Qbtot	Boundary Heat Sources	Boundaries
Qltot	Line heat source (Line and Point Heat Sources)	Edges, Points (2D, 2D axial symmetry)
Qptot	Point heat source (Line and Point Heat Sources)	Points

Some of these variables are only available with the Heat Transfer Module (rflux_u, rflux_d, rflux_z, q0_u, q0_d, and q0_z), or when either the CFD Module or the Heat Transfer Module is added (rflux and turbflux).

Global Variables

This section describes variables defined by integrals. A concise notation denotes the different domains of integration: Ω is the geometry domain, $\partial\Omega_{ext}$ represents the exterior boundaries, and $\partial\Omega_{int}$ represents the interior boundaries.

TOTAL ACCUMULATED HEAT RATE

The total accumulated heat rate variable, dEiInt, is the variation of internal energy per unit time in the domain:

$$\text{dEiInt} = \frac{d}{dt}\int_{\Omega} \rho E d\omega$$

TOTAL NET HEAT RATE

The total net heat rate, ntfluxInt, is the integral of Total Heat Flux over all external boundaries:

$$\text{ntfluxInt} = \int_{\partial\Omega_{ext}} (\rho \mathbf{u} E - k\nabla T + \mathbf{q}_r) \cdot \mathbf{n} d\sigma$$

This indicates the sum of incoming and outgoing total heat flux through the system.

TOTAL HEAT SOURCE

The total heat source, QInt, accounts for all domain sources, interior boundary, edge and point sources, and radiative sources at interior boundaries:

$$\text{QInt} = \int_{\Omega} Q d\omega + \int_{\partial\Omega_{int}} Q_b d\omega + \int_{\partial\Omega_{int}} Q_r d\omega$$

TOTAL FLUID LOSSES

The total fluid losses, WnsInt, correspond to the work lost by a fluid by degradation of energy. These works are transmitted to the system through pressure work and viscous dissipation:

$$\text{WnsInt} = \int_{\Omega} (\mathbf{u} \cdot \nabla p_A) d\omega + \int_{\Omega} (-\tau : \nabla \mathbf{u}) d\omega$$

TOTAL ACCUMULATED ENERGY RATE

The total accumulated energy rate, `dEi0Int`, is the variation of total internal energy per unit time in the domain:

$$\text{dEi0Int} = \frac{d}{dt}\int_{\Omega} \rho E_0 d\omega$$

where the total internal energy, E_0, is defined as

$$E_0 = E + \frac{\mathbf{u}\cdot\mathbf{u}}{2}$$

TOTAL NET ENERGY RATE

The total net energy rate, `ntefluxInt`, is the integral of Total Energy Flux over all external boundaries:

$$\text{ntefluxInt} = \int_{\partial\Omega_{\text{ext}}} (\rho\mathbf{u}H_0 - k\nabla T - \tau\mathbf{u} + \mathbf{q}_r)\cdot\mathbf{n}d\sigma$$

This indicates the sum of incoming and outgoing total energy flux through the system.

HEAT BALANCE

The following equality between COMSOL Multiphysics variables holds:

```
dEiInt + ntfluxInt = QInt - WnsInt
```

This is the most general form that can be used for time-dependent models. At steady-state the formula is simplified. The accumulated heat rate equals zero, so the total net heat rate (the sum of incoming and outgoing heat rates) should correspond to the heat and work sources:

```
ntfluxInt = QInt - WnsInt
```

The sign convention used in COMSOL Multiphysics for `QInt` is positive when energy is produced (as for a heater) and negative when energy is consumed (as for a cooler). For `WnsInt`, the losses that heat up the system are positive and the gains that cool down the system are negative.

For stationary models with convection by an incompressible flow, the heat balance becomes:

```
ntfluxInt = QInt
```

which corresponds to the conservation of convective and conductive flux as in:

$$\int_{\partial\Omega_{\text{ext}}} \rho\mathbf{u}E\cdot\mathbf{n}d\sigma - \int_{\partial\Omega_{\text{ext}}} k\nabla T\cdot\mathbf{n}d\sigma = Q_{\text{Int}}$$

ENERGY BALANCE

The following equality between COMSOL Multiphysics predefined variables holds:

```
dEi0Int + ntefluxInt = QInt
```

In stationary models, `dEi0Int` is zero so the energy balance simplifies into:

```
ntefluxInt = QInt
```

At steady state, and without any additional heat source (`QInt` equal to zero), the integral of the net energy flux on all boundaries of the flow domain, `ntefluxInt`, vanishes. However, the corresponding integral of the net heat flux does not, in general, vanish. It corresponds instead to the losses from mass and momentum equations, such as `WnsInt` for pressure work and viscous dissipation in fluids. Hence, energy is the conserved quantity, not heat.

Domain Heat Fluxes

On domains the heat fluxes are vector quantities. The definition can vary depending on the active physics nodes and selected properties.

TOTAL HEAT FLUX

On domains the total heat flux, `tflux`, corresponds to the conductive and convective heat flux. For accuracy reasons the radiative heat flux is not included.

For solid domains — for example, the heat transfer in solids and biological tissue domains—the total heat flux is defined as:

$$\text{tflux} = \text{trlflux} + \text{dflux}$$

For fluid domains (for example, Heat Transfer in Fluids), the total heat flux is defined as:

$$\text{tflux} = \text{cflux} + \text{dflux}$$

CONDUCTIVE HEAT FLUX

The conductive heat flux variable, `dflux`, is evaluated using the temperature gradient and the effective thermal conductivity:

$$\text{dflux} = -k_{\text{eff}}\nabla T$$

In the general case k_{eff} is the thermal conductivity, k.

For heat transfer in fluids with turbulent flow, $k_{\text{eff}} = k + k_{\text{T}}$, where k_{T} is the turbulent thermal conductivity.

For heat transfer in porous media, k_{eff} is the effective conductivity computed from the solid and fluid conductivities.

CONVECTIVE HEAT FLUX

The convective heat flux variable, `cflux`, is defined using the internal energy, E:

$$\text{cflux} = \rho\mathbf{u}E$$

The internal energy, E, is defined as:

- $E = C_p T$ for solid domains
- $E = H - p/\rho$ for other fluid domains

where H is the enthalpy.

TRANSLATIONAL HEAT FLUX

Similar to convective heat flux but defined for solid domains with translation. The variable name is `trlflux`.

TOTAL ENERGY FLUX

The total energy flux, `teflux`, is defined when viscous dissipation is enabled:

$$\text{teflux} = \rho\mathbf{u}H_0 + \text{dflux} + \tau\mathbf{u}$$

where the total enthalpy, H_0, is defined as

$$H_0 = H + \frac{\mathbf{u}\cdot\mathbf{u}}{2}$$

Boundary Heat Fluxes

All the domain heat fluxes (vector quantity) are also available as boundary heat fluxes. The boundary heat fluxes are then equal to the mean value of the heat fluxes on adjacent domains. In addition, normal boundary heat fluxes (scalar quantity) are available on boundaries.

NORMAL TOTAL HEAT FLUX

The variable `ntflux` is defined as:

$$\text{ntflux} = \text{ndflux} + \text{ncflux} + \text{ntrlflux}$$

NORMAL CONDUCTIVE HEAT FLUX

The variable `ndflux` is defined on exterior boundaries as:

- ndflux = –dflux_spatial(T) if the adjacent domain is on the downside,
- ndflux = –uflux_spatial(T) if the adjacent domain is on the upside,

and, on interior boundaries, as:

$$\text{ndflux} = (\text{uflux_spatial}(T) - \text{dflux_spatial}(T))/2$$

NORMAL CONVECTIVE HEAT FLUX

The variable `ncflux` is defined as:

$$\text{ncflux} = \text{mean}(\text{cflux}) \cdot \mathbf{n}$$

NORMAL TRANSLATIONAL HEAT FLUX

The variable `ntrlflux` is defined as

$$\text{ntrlflux} = \text{mean}(\text{trlflux}) \cdot \mathbf{n}$$

NORMAL TOTAL ENERGY FLUX

The variable `nteflux` is defined as:

$$\text{nteflux} = \text{mean}(\text{teflux}) \cdot \mathbf{n} - \text{mean}(\text{dflux}) \cdot \mathbf{n} + \text{ndflux}$$

Internal Boundary Heat Fluxes

The internal normal boundary heat fluxes (scalar quantity) are available on interior boundaries. They are calculated using the upside and the downside value of heat fluxes from the adjacent domains.

INTERNAL NORMAL CONDUCTIVE HEAT FLUX, UPSIDE

The variable `ndflux_u` is defined as:

$$\text{ndflux_u} = \text{uflux_spatial}(T)$$

INTERNAL NORMAL CONDUCTIVE HEAT FLUX, DOWNSIDE

The variable `ndflux_d` is defined as:

$$\text{ndflux_d} = \text{dflux_spatial}(T)$$

INTERNAL NORMAL CONVECTIVE HEAT FLUX, UPSIDE

The variable `ncflux_u` is defined as:

$$\text{ncflux_u} = \text{up}(\text{cflux}) \cdot \mathbf{un}$$

INTERNAL NORMAL CONVECTIVE HEAT FLUX, DOWNSIDE

The variable `ncflux_d` is defined as:

$$\text{ncflux_d} = \text{down}(\text{cflux}) \cdot \mathbf{dn}$$

INTERNAL NORMAL TRANSLATIONAL HEAT FLUX, UPSIDE

The variable `ntrlflux_u` is defined as:

$$\text{ntrlflux_u} = \text{up}(\text{trlflux}) \cdot \mathbf{un}$$

INTERNAL NORMAL TRANSLATIONAL HEAT FLUX, DOWNSIDE

The variable `ntrlflux_d` is defined as:

$$\text{ntrlflux_d} = \text{down}(\text{trlflux}) \cdot \mathbf{dn}$$

INTERNAL NORMAL TOTAL HEAT FLUX, UPSIDE

The variable `ntflux_u` is defined as:

$$\text{ntflux_u} = \text{ndflux_u} + \text{ncflux_u} + \text{ntrlflux_u}$$

INTERNAL NORMAL TOTAL HEAT FLUX, DOWNSIDE

The variable `ntflux_d` is defined as:

$$\text{ntflux_d} = \text{ndflux_d} + \text{ncflux_d} + \text{ntrlflux_d}$$

INTERNAL NORMAL TOTAL ENERGY FLUX, UPSIDE

The variable `nteflux_u` is defined as:

$$\text{nteflux_u} = \text{up}(\text{teflux}) \cdot \mathbf{un} - \text{up}(\text{dflux}) \cdot \mathbf{un} + \text{ndflux_u}$$

INTERNAL NORMAL TOTAL ENERGY FLUX, DOWNSIDE

The variable `nteflux_d` is defined as:

$$\text{nteflux_d} = \text{down}(\text{teflux}) \cdot \mathbf{dn} - \text{down}(\text{dflux}) \cdot \mathbf{dn} + \text{ndflux_d}$$

Domain Heat Sources

The sum of the domain heat sources added by different physics features is available in the variable `Qtot`, which is the sum of Q's, which are the heat sources added by the Heat Source (described for the Heat Transfer interface) and Electromagnetic Heating (described for the Joule Heating interface) features.

Boundary Heat Sources

The sum of the boundary heat sources added by different boundary conditions is available in the variable, $Q_{\text{b,tot}}$ (SI unit: W/m^2). This variable `Qbtot` is the sum of:

- Q_{b}, which is the boundary heat source added by the Boundary Heat Source boundary condition.
- Q_{sh}, which is the boundary heat source added by the Electromagnetic Heating feature on its boundary selection (described for the Joule Heating interface).

Line and Point Heat Sources

The sum of the line heat sources is available in a variable called `Qltot` (SI unit: W/m).

The sum of the point heat sources is available in a variable called `Qptot` (SI unit: W).

Using the Boundary Conditions for the Heat Transfer Interfaces

In this section:

- Temperature and Heat Flux Boundary Conditions
- Overriding Mechanism for Heat Transfer Boundary Conditions

Temperature and Heat Flux Boundary Conditions

The heat equation accepts two basic types of boundary conditions: specified temperature and specified heat flux. The specified condition is of constraint type and prescribes the temperature on a boundary:

$$T = T_0 \qquad \text{on } \partial\Omega$$

while the latter specifies the inward heat flux

$$-\mathbf{n} \cdot \mathbf{q} = q_0 \qquad \text{on } \partial\Omega$$

where

- $\mathbf{q}$ is the *conductive heat flux vector* (SI unit: $\mathrm{W/m^2}$), $\mathbf{q} = -k\nabla T$.
- $\mathbf{n}$ is the normal vector on the boundary.
- q_0 is the *inward heat flux* (SI unit: $\mathrm{W/m^2}$), normal to the boundary.

The inward heat flux, q_0, is often a sum of contributions from different heat transfer processes (for example, radiation and convection). The special case $q_0 = 0$ is called *thermal insulation*.

A common type of heat flux boundary conditions is one for which $q_0 = h \cdot (T_{\text{ext}} - T)$, where T_{ext} is the temperature far away from the modeled domain and the heat transfer coefficient, h, represents all the physics occurring between the boundary and "far away." It can include almost anything, but the most common situation is that h represents the effect of an exterior fluid cooling or heating the surface of a solid, a phenomenon often referred to as convective cooling or heating.

	The CFD Module and the Heat Transfer Module contain a set of correlations for convective heat flux and heating.

Overriding Mechanism for Heat Transfer Boundary Conditions

Many boundary conditions are available in heat transfer. Some of these can coexist (for example, Heat Flux and Thin Layer); others cannot (for example, Heat Flux and Thermal Insulation).

Several categories of boundary condition exist in heat transfer. Table 14-4 gives the overriding rules for these groups.

1 Temperature, Outflow

2 Thermal Insulation, Symmetry, Periodic Condition

3 Heat Flux

4 Boundary Heat Source, Line Heat Source on Axis

5 Surface-to-Ambient Radiation

6 Thin Layer

TABLE 14-4: OVERRIDING RULES FOR HEAT TRANSFER BOUNDARY CONDITIONS.

A\B	1	2	3	4	5	6
1-Temperature	X	X				X
2-Thermal Insulation	X	X			X	
3-Heat Flux	X	X				
4-Boundary heat source						
5-Radiation		X			X	
6-Thin Layer	X					X

When there is a boundary condition *A* above a boundary condition *B* in the model tree and both conditions apply to the same boundary, use Table 14-4 to determine if *A* is overridden by *B* or not:

- Locate the line that corresponds to the *A* group (see above the definition of the groups). In the table above only the first member of the group is displayed.
- Locate the column that corresponds to the group of *B*.
- If the corresponding cell is empty, *A* and *B* contribute. If it contains an X, *B* overrides A.

Group 3 and group 4 boundary conditions are always contributing. That means that they never override any other boundary condition. But they might be overridden.

Example 1

Consider a boundary where **Temperature** is applied. Then a **Surface-to-Ambient Radiation** boundary condition is applied on the same boundary afterward.

- **Temperature** belongs to group 1.
- **Surface-to-Ambient Radiation** belongs to group 5.

The cell on the line of group 1 and the column of group 5 is empty so **Temperature** and **Surface-to-Ambient Radiation** contribute.

Example 2

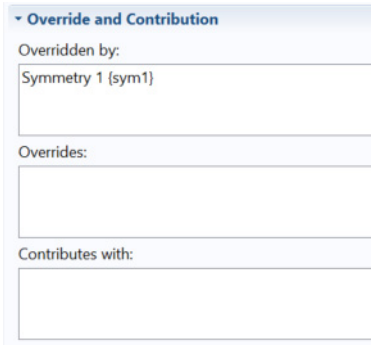
Consider a boundary where **Heat Flux** is applied. Then a **Symmetry** boundary condition is applied on the same boundary afterward.

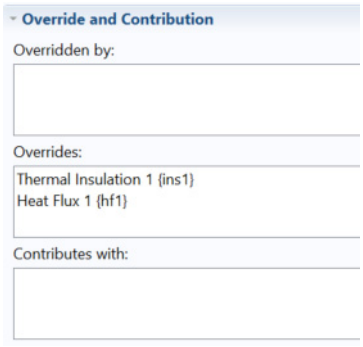
- **Heat Flux** belongs to group 3.
- **Symmetry** belongs to group 2.

The cell on the line of group 3 and the column of group 2 contains an X so **Heat Flux** is overridden by **Symmetry**.

This mechanism can be checked in the COMSOL Desktop, in the **Override and Contribution** section of each feature, as shown in the following table:

TABLE 14-5: OVERRIDE AND CONTRIBUTION SECTIONS.

HEAT FLUX	SYMMETRY
	




In Example 2 above, if **Symmetry** followed by **Heat Flux** is added, the boundary conditions contribute.

Heat Transfer Consistent and Inconsistent Stabilization Methods

The different versions of the Heat Transfer interface include the advanced option to set stabilization method parameters. This section has information about these options. To display the stabilization sections, click the **Show More Options** button ( ) and select **Stabilization** in the **Show More Options** dialog.

In this section:

- Consistent Stabilization
- Inconsistent Stabilization

Consistent Stabilization

This section contains two consistent stabilization methods: streamline diffusion and crosswind diffusion. These are consistent stabilization methods, which means that they do not perturb the original transport equation.

The consistent stabilization methods are active by default. A stabilization method is active when the corresponding checkbox is selected.

STREAMLINE DIFFUSION

Streamline diffusion is active by default and should remain active for optimal performance for heat transfer in fluids or other applications that include a convective or translational term.

CROSSWIND DIFFUSION

Streamline diffusion introduces artificial diffusion in the streamline direction. This is often enough to obtain a smooth numerical solution provided that the exact solution of the heat equation does not contain any discontinuities. At sharp gradients, however, undershoots and overshoots can occur in the numerical solution. Crosswind diffusion addresses these spurious oscillations by adding diffusion orthogonal to the streamline direction — that is, in the crosswind direction.

Inconsistent Stabilization

This section contains a single stabilization method: isotropic diffusion. Adding isotropic diffusion is equivalent to adding a term to the physical diffusion coefficient. This means that the original problem is not solved, which is why isotropic diffusion is an inconsistent stabilization method. Although the added diffusion definitely attenuates spurious oscillations, try to minimize the use of isotropic diffusion.

By default there is no isotropic diffusion. To add isotropic diffusion, select the **Isotropic diffusion** checkbox. The field for the tuning parameter δ_{id} then becomes available. The default value is 0.25; increase or decrease the value of δ_{id} to increase or decrease the amount of isotropic diffusion.

- Selection Information

Handling Frames in Heat Transfer

This section discusses heat transfer analysis with moving frames, when spatial and material frames do not coincide.

About Frames

The entire physics (equations and variables) is defined in the spatial frame. When a moving mesh is detected, the user inputs for certain features are defined in the material frame and are converted so that all the corresponding variables contain the value in the spatial frame.

This subsection contains the list of all heat transfer nodes and the corresponding definition frame:

- Physics Feature Nodes and Definition Frame
- Definition Frame of Domain Nodes
- Definition Frame of Boundary Nodes
- Definition Frame of Edge and Point Nodes

Physics Feature Nodes and Definition Frame

The following explains the different values listed in the *definition frame* column in Table 14-6, Table 14-7, and Table 14-8:

Material: The inputs are entered by the user and defined in the material frame. Because the heat transfer variables and equations are defined in the spatial frame, the inputs are internally converted to the spatial frame.

Spatial: The inputs are entered by the user and defined in the spatial frame. No conversion is done.

Material/(Spatial): For these physics nodes, select from a menu to decide if the inputs are defined in the material or spatial frame. The default definition frame is the material frame.

(Material)/Spatial: For these physics nodes, select from a menu to decide if the inputs are defined in the material or spatial frame. The default definition frame is the spatial frame.

N/A: There is no definition frame for this physics node.

Solver Settings

The Heat Transfer interfaces define an elliptic partial differential equation for the temperature, T, of the form:

$$\rho C_p \frac{\partial T}{\partial t} + \nabla \cdot \mathbf{q} = Q$$

$$\mathbf{q} = -k\nabla T$$

with Dirichlet and Neumann boundary conditions at some boundaries:

$$T = T_0$$

$$-\mathbf{n} \cdot \mathbf{q} = q_0$$

In its basic form, the density, ρ, heat capacity, C_p, thermal conductivity, k, heat sources, Q, constraint temperatures, T_0, and heat fluxes, q_0, are all constant, which leads to a linear system. Here, linear solvers described in the next paragraphs are completely suited for the resolution.

However, nonlinearities can appear in the equation in the following cases:

- The material properties — ρ, C_p, and k — have a temperature dependency.
- The heat sources are not linear in temperature.
- The Neumann boundary condition is not linear in temperature, hence
  - A convective cooling condition of type $-\mathbf{n} \cdot \mathbf{q} = h(T_{ext} - T)$ keeps the linearity of the problem when the heat transfer coefficient, h, is constant.
  - A radiative condition of type $-\mathbf{n} \cdot \mathbf{q} = \varepsilon\sigma(T_{amb}^4 - T^4)$ is strongly nonlinear.

Different nonlinear solvers are also provided for these kinds of problems.

The information about default solvers given below are specific to the Heat Transfer interfaces when the **Stationary** and **Time-Dependent** studies are used. A comprehensive description of solver settings and corresponding theory are available in the Study and Study Step Types section.

See also Studies and Solvers

Linear Solver

DEFAULT SETTINGS

The default linear solver is determined based on the number of degrees of freedom and physics interface settings.

For small number of degrees of freedom, the direct PARDISO solver is used. It is known to be robust and fast for small-sized problems.

For larger models, the linear iterative GMRES solver with multigrid preconditioner is used. In most cases, SOR is the presmoother and postsmoother. This solver is memory effective and fast for large models. When the heat transfer model contains settings that lead to a system matrix with 0 on the diagonal (for example, Lagrange multipliers for weak constraints), SOR cannot be used and is replaced by Vanka, which is usually slower and uses more memory.

TUNING LINEAR SOLVER

Tuning the linear solver may be considered in case of nonconvergence or low performance. When convergence fails you should first verify that this is not due to an ill-posed model, or inappropriate settings in the Time-Dependent study or nonlinear solver.

Several options are available to tune the linear solver settings. This paragraph focuses only on the most commonly used ones.

Switch to PARDISO

When the GMRES solver with multigrid preconditioner is set by default, using PARDISO instead can be considered provided that enough RAM is available. Indeed, PARDISO usually converges easily but uses much more memory than the default iterative solver. If PARDISO does not converge, it may indicate that there is an issue in the model definition or with other solver settings.

Optimize GMRES/Multigrid for Memory

In order to optimize further the memory needed by the iterative solver, the number of mesh elements on the coarser multigrid level can be reduced by, for instance, increasing the **Mesh coarsening factor** or the **Number of multigrid levels**. The latter strategy may also increase the resolution time.

Optimize GMRES/Multigrid for Convergence

When the linear solver has difficulties to converge, the following settings can be tuned:

- When the convergence graph of GMRES shows a slow down every 50 iterations, the **Number of iteration before restart** parameter (default value of 50) should be increased — doubled for example. This may also increase the memory consumption.
- Increasing the **Number of iteration** in the Multigrid settings, and in the presmoother and postsmoother nodes improves the quality of the preconditioner and convergence of GMRES.
- Since an excessive difference between two multigrid levels can affect the convergence, lowering the **Mesh coarsening factor** in the Multigrid settings can help convergence.
- Consider creating the multigrid level meshes manually if the automatic coarsening method fails or leads to poor quality meshes.

Choosing the Right Linear System Solver

Nonlinear Solver

DEFAULT SETTINGS

Nonlinear solver settings depend on the heat transfer model and on the study type.

Fully Coupled Solver Attribute

Heat transfer models with and without surface-to-ambient radiation use a fully coupled nonlinear solver attribute by default. The Jacobian update is set to minimal. A Newton nonlinear method is set by default with

- Automatic damping factor computation for stationary studies
- Constant damping factor for time-dependent studies

Segregated Solver Attribute

The segregated solver attribute is set by default when another physics interface is solved together with heat transfer. The dependent variables of the heat transfer interface are placed in a separate segregated group. It happens as well

for the modeling of radiation in participating media using the Discrete Ordinates Method, or for the computation of damage in biological tissue (options available with the Heat Transfer Module.

TUNING THE NONLINEAR SOLVER

Default solver settings are defined to handle efficiently classical configurations. For particular applications, the default settings may need modifications to improve the robustness and performance of the solver.

Optimize Nonlinear Solver for Robustness

When the nonlinear solver fails or converges erratically, different options can be considered:

- Using the **Automatic highly nonlinear (Newton)** option forces to start the computation with a very low damping factor and increases it carefully. Alternatively a low constant damping factor can be used. The damping factor ranges between 0 and 1. A constant damping factor equal to 0.1 is a very low value and should be robust but slow to converge. For low values of the damping factor, it is thus usually needed to increase the number of nonlinear iterations. If the nonlinear solver is unstable with such a damping factor then the automatic option should be used because it makes it possible to start with a lower damping factor and gradually increases it.
- A good initial value, as close as possible from the expected solution and consistent with the boundary conditions, helps to guide the nonlinear solver to a stable physical solution. To do that:
  - Try to ramp the temperature on the boundary from the initial to the desired value by using an auxiliary sweep — for stationary problems — or a time-dependent step function —for time-dependent problems.
  - Use results from a simplified problem, for instance with no temperature dependency, or using a one-way multiphysics coupling, as initial value.

  Note that it is sometimes easier to update the boundary conditions than the initial condition to get consistent initial settings.
- When it is not possible to provide a good initial value, the segregated solver associated with low damping factors in each segregated step helps to achieve convergence.
- Forcing the Jacobian update at every iteration ensures that the nonlinear solver iterates using optimal information from the equation system. This is needed when nonlinearities are due to the temperature itself — for example, in case of strong temperature dependency of material properties — or to another variable solved in the same segregated group as the temperature — for example, in natural convection models.

Optimize Convergence Speed

Low convergence can be improved by following ways:

- Using a constant damping factor equal to 1 for linear problems. The linearity is determined at the beginning of the resolution and indicated in the **Log** section of the solver window.
- Providing a good initial value is an asset for computational speed.
- In the convergence area, the fully coupled solver has a better convergence rate than the segregated solver.
- Using minimal Jacobian update option avoid to spend time in Jacobian computation. This is suited for linear models and models with mild nonlinearities.

Time-Dependent Study Step

DEFAULT SETTINGS FOR HEAT TRANSFER INTERFACES

The default time-stepping method for the Heat Transfer interfaces is BDF at second order. It excludes algebraic variable from the error estimate.

TUNING THE TIME-DEPENDENT SOLVER

The quality of the time-stepping influences the nonlinear solver convergence. Tiny time steps usually lead to mildly nonlinear problems at each time step whereas large time steps can result in (fewer) highly nonlinear problems.

The default solver settings for transient heat transfer defines the maximal number of nonlinear iterations to 5. If this is not sufficient, it is recommended to use smaller time steps and to verify if the model definition does not contain discontinuities in time. If so, consider using smooth step functions to model sharp variations in time.

There are several ways to control the time step size:

- An implicit way is to define a lower relative tolerance in the study settings. When the relative tolerance is lowered, the absolute tolerance should be reduced in the same proportion.
- The most explicit way is to define a maximum time step. This is an appropriate option when the same maximum time step is relevant for the entire simulation. Otherwise, it is possible to include times of interest in the **Times** field of the time-dependent study and to use the **Intermediate** option in the **Time Stepping** settings.
- Lastly you can control the time step by triggering an event when a particular condition is meet (see the documentation about The Events Interface). This advanced method can be efficient when the other simpler methods are not applicable.

It is also recommended to inspect the solver log and check the default scaling of dependent variables in case of convergence failure. In case of incorrect automatic scaling, consider using **Manual** settings in the **Dependent Variable** attribute node.

Time-Dependent Solver

Guidelines for Solving Multiphysics Problems

MULTIPHYSICS MODELS

Unless the model contains a multiphysics node that defines a coupling between a Heat Transfer interface and another interface (see Multiphysics Couplings below), each physics interface defines default solver settings that are merged.

The Heat Transfer interfaces always define a dedicated segregated group that uses a linear solver optimized for the heat transfer equations. For strongly coupled models, it may be efficient to merge two (or more) segregated steps. In this case, a unique linear solver must be chosen for the fully coupled solver or the new segregated group.

Time-dependent settings from different physics interfaces may compete. When the different settings are merged the strictest one is kept.

MULTIPHYSICS COUPLINGS

When a Heat Transfer interface is coupled with another physics interface through a multiphysics coupling feature, additional predefined default settings are loaded. The next two paragraphs describes the subtleties of the Nonisothermal Flow and Joule Heating interfaces.

Nonisothermal Flow

The **Nonisothermal Flow** multiphysics coupling controls the solver settings for the flow and the temperature dependent variables.

When it assumes a weak coupling between the flow and the heat interfaces (typically no Volume Force feature in the flow interface), the default solver contains dedicated segregated groups for heat and flow dependent variables.

Each uses the default linear solver of the corresponding interface, except that the presmoother and postsmoother in the GMRES iterative solver switches from SOR to SCGS.

When a strong coupling is assumed (at least one Volume Force feature in the flow interface), the default solver merges the temperature, pressure, and velocity. In this case, the linear solver corresponds to the default linear solver of the flow interface. The Jacobian is updated once per time step.

Joule Heating

By default, the Joule Heating multiphysics interface solves the temperature and the electric potential in segregated steps.

15

Solid Mechanics

This chapter describes the Solid Mechanics interface, which is found under the **Structural Mechanics** branch ( ) when adding a physics interface. It also describes the Fluid-Solid Interaction, Fixed Geometry multiphysics interface for FSI simulations.

For more information about solid mechanics modeling and theory, see the *Structural Mechanics Module User's Guide*, which you can install also without a license for the Structural Mechanics Module.

In this chapter:

- The Solid Mechanics Interface
- The Fluid-Solid Interaction Multiphysics Interface

The Solid Mechanics Interface

The **Solid Mechanics (solid)** interface ( ), found under the **Structural Mechanics** branch ( ) when adding a physics interface, is intended for general structural analysis of 3D, 2D, 1D, or axisymmetric bodies. In 2D, 1D, and 1D axisymmetry, plane stress or plane strain assumptions can be used. The Solid Mechanics interface is based on solving the equations of motion together with a constitutive model for a solid material. Results such as displacements, stresses, and strains are computed.

The functionality provided by the Solid Mechanics interface depends on the products you are using. The Acoustics Module, MEMS Module, and Structural Mechanics Module add several features, for example geometric nonlinearity and advanced boundary conditions such as contact, follower loads, and nonreflecting boundaries.

The default material is a Linear Elastic Material.

With either the Nonlinear Structural Materials Module or the Geomechanics Module, the physics interface is extended with more materials, for example, material models for plasticity, hyperelasticity, creep, and concrete.

	For a detailed overview of the functionality available in each product, visit https://www.comsol.com/products/specifications/

When this physics interface is added, these default nodes are also added to the **Model Builder** — **Linear Elastic Material**, **Free** (a boundary condition where boundaries are free, with no loads or constraints), and **Initial Values**. Then, from the **Physics** toolbar, you can add other nodes that implement, for example, solid mechanics material models, boundary conditions, and loads. You can also right-click **Solid Mechanics** to select physics features from the context menu.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `solid`.

2D APPROXIMATION

From the **2D approximation** list, select **Plane stress** or **Plane strain** (the default). Plane stress is relevant for structures which are thin in the out-of-plane direction, such as a thin plate. Plane strain is relevant when the 2D model can be considered as a cut through an object that is long in the out-of-plane direction. For more information see the theory section.

When modeling using plane stress, the Solid Mechanics interface solves for the out-of-plane strain displacement derivative, $\partial w/\partial Z$, in addition to the displacement field **u**.

When combining Solid Mechanics with other types of physics, there is often an assumption that the out-of-plane extension is infinitely long. This is the case in, for example, Acoustic-Structure interaction problems. In these cases, **Plane strain** is usually the correct choice.

1D APPROXIMATION

From the **y direction** and **z direction** lists, select **Plane strain** or **Plane stress**.

Plane strain is relevant when the model can be considered as a cut through an object that is infinitely long in the corresponding out-of-plane direction (y or z), or as a soft object confined between rigid walls. The strain in the out-of-plane direction is assumed to be zero.

Plane stress is relevant for structures that are thin in the corresponding out-of-plane direction, such as a thin plate. When using plane stress, the Solid Mechanics interface solves for the out-of-plane strain displacement derivatives, $\partial v/\partial Y$ or $\partial w/\partial Z$, in addition to the displacement field **u**, in order to fulfill the condition that there is no stress in the thickness direction.

For more information see the theory section.

When combining Solid Mechanics with other types of physics, there is often an assumption that the out-of-plane extension is infinitely long. This is the case in, for example, Acoustic-Structure interaction problems. In these cases, **Plane strain** is usually the correct choice.

1D AXISYMMETRIC APPROXIMATION

From the **z direction** list, select **Plane strain** or **Plane stress**.

Plane strain is relevant when the model can be considered as a cut through a cylinder, which is infinitely long in the z direction, or as a soft object confined between rigid walls. The strain in the z direction is assumed to be zero.

Plane stress is relevant for thin discs. When using plane stress, the Solid Mechanics interface solves for the displacement derivative in the z direction, $\partial w/\partial Z$, in addition to the displacement field **u**, in order to fulfill the condition that there is no stress in the thickness direction.

For more information see the theory section.

When combining Solid Mechanics with other types of physics, there is often an assumption that the out-of-plane extension is infinitely long. This is the case in, for example, Acoustic–Structure interaction problems. In these cases, **Plane strain** is usually the correct choice.

THICKNESS

For 2D and 1D axisymmetric components, enter a value or expression for the **Thickness** d. The default value of 1 m is suitable for plane strain models, where it represents a unit-depth slice, for example. For plane stress models, enter the actual thickness, which should be small compared to the size of the plate for the plane stress assumption to be valid. In Acoustic-Structure Interaction problems, the **Thickness** should be set to 1 m.

Use a Change Thickness node to change thickness in parts of the geometry if necessary.

CROSS-SECTIONAL AREA

For 1D components, enter a value or expression for the cross-section area A_c. The default value is 1 m^2, which is suitable for models where plane strain assumptions are used in both transverse directions. For plane stress models, consider entering actual cross-section data.

When combining Solid Mechanics with other physics interfaces, you must make sure that the same cross-section assumption is used everywhere. In most cases, the default settings will be correct. When using other unit systems than the default SI system, you need to pay special attention to the values of this property.

Use a Change Cross Section node to change thickness in parts of the geometry if necessary.

STRUCTURAL TRANSIENT BEHAVIOR

From the **Structural transient behavior** list, select **Include inertial terms** (the default) or **Quasistatic**. Use **Quasistatic** to treat the elastic behavior as quasi static (with no mass effects; that is, no second-order time derivatives). Selecting this option gives a more efficient solution for problems where the variation in time is slow when compared to the natural frequencies of the system. The default solver for the time stepping is changed from Generalized alpha to BDF when **Quasistatic** is selected.

For problems with creep, and sometimes viscoelasticity, the problem can be considered as quasistatic. This is also the case when the time dependence exists only in some other physics, like a transient heat transfer problem causing thermal strains.

DISCRETIZATION

In the Solid Mechanics interface, you can choose not only the order of the discretization, but also the type of shape functions: *Lagrange* or *serendipity*. For highly distorted elements, Lagrange shape functions provide better accuracy than serendipity shape functions of the same order. The serendipity shape functions will however give significant reductions of the model size for a given mesh containing hexahedral, prism, or quadrilateral elements. In 1D components there is no difference between Lagrange and serendipity shape functions.

The default is to use **Quadratic serendipity** shape functions for the **Displacement field**. Using **Linear** shape functions will give what is sometimes called *constant stress* elements. Such a formulation will for many problems make the model overly stiff, and many elements may be needed for an accurate resolution of the stresses.

To display other settings for this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

DEPENDENT VARIABLES

The physics interface uses the global spatial components of the **Displacement field** u as dependent variables. The default names for the components are (u, v, w) in 3D. In 2D the component names are (u, v), and in 2D axisymmetry they are (u, w). In 1D and 1D axisymmetry the default component name is (u). You can however not

use the ‘missing’ component names in the 2D or 1D cases as a parameter or variable name, since they are used internally.

You can change both the field name and the individual component names. If a new field name coincides with the name of another displacement field, the two fields (and the interfaces that define them) share degrees of freedom and dependent variable component names. You can use this behavior to connect a Solid Mechanics interface to a Shell directly attached to the boundaries of the solid domain, or to another Solid Mechanics interface sharing a common boundary.

A new field name must not coincide with the name of a field of another type (that is, it must contain a displacement field), or with a component name belonging to some other field. Component names must be unique within a model except when two interfaces share a common field name.

See Table 2-4 for links to common sections and Table 2-5 for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

Domain, Boundary, Edge, Point, and Pair Nodes for Solid Mechanics

The Solid Mechanics Interface has these domain, boundary, edge, point, and pair nodes and subnodes (listed in alphabetical order), which are available from the **Physics** ribbon toolbar (Windows users), **Physics** context menu (macOS or Linux users), or by right-clicking to access the context menu (all users).

In general, to add a node, go to the **Physics** toolbar, no matter what operating system you are using. Subnodes are available by clicking the parent node and selecting it from the **Attributes** menu.

FEATURES AVAILABLE FROM SUBMENUS

Many features for the Solid Mechanics interface are added from submenus in the Physics toolbar groups or context menu (when you right-click the node). The submenu name is the same in both cases.

The submenus at the **Domain** level are **Material Models**, **Volume Forces**, **Domain Constraints**, and **More**.

The submenus at the **Boundary** level are **Connections**, **Pairs, Mass, Spring, and Damper**, and **More Constraints**.

There are also the **Edges** and **Points** submenus.

Note: Some submenus are only present with certain COMSOL products.

FORCE LOADS

Note that you can add force loads acting on all levels of the geometry for the physics interface. Add a:

- Body Load to domains (to model gravity effects, for example).
- Boundary Load to boundaries (a pressure acting on a boundary, for example).

- Edge Load to edges in 3D (a force distributed along an edge, for example).
- Point Load to points (concentrated forces at points).

	If there are subsequent constraints specified on the same geometrical entity, the last one takes precedence.

	For axisymmetric components, COMSOL Multiphysics takes the axial symmetry boundaries (at $r = 0$) into account and automatically adds an **Axial Symmetry** node to the component that is valid on the axial symmetry boundaries only.

- Body Load
- Boundary Load
- Change Thickness
- Damping
- Edge Load
- Fixed Constraint
- Free
- Initial Values
- Linear Elastic Material
- Periodic Condition
- Point Load
- Point Load (on Axis)
- Prescribed Displacement
- Rigid Motion Suppression
- Ring Load
- Roller
- Symmetry
- Symmetry Plane

	See Table 2-4 for links to common sections and Table 2-5 for common feature nodes. You can also search for information: press F1 to open the **Help** window or Ctrl+F1 to open the **Documentation** window.

The Damping subnode is available from Linear Elastic Material nodes.

Initial Values

The **Initial Values** node adds initial values for the displacement field and structural velocity field that can serve as an initial condition for a transient simulation or as an initial guess for a nonlinear analysis. In addition to the default **Initial Values** node always present in the interface, you can add more **Initial Values** nodes if needed.

INITIAL VALUES

Enter values or expressions for the initial values of the **Displacement field u** (the displacement components u, v, and w in 3D), and the **Structural velocity field** $\partial\mathbf{u}/\partial t$.

Linear Elastic Material

The **Linear Elastic Material** node adds the equations for a linear elastic solid and an interface for defining the elastic material properties.

By adding the following subnode to the **Linear Elastic Material** node you can incorporate damping effects; see Damping.

COORDINATE SYSTEM SELECTION

The **Global coordinate system** is selected by default. The **Coordinate system** list contains any additional coordinate systems that the model includes (except boundary coordinate systems). The coordinate system is used for interpreting directions of orthotropic and anisotropic material data and when stresses or strains are presented in a local system. The coordinate system must have orthonormal coordinate axes, and be defined in the material frame. Many of the possible subnodes inherit the coordinate system settings.

LINEAR ELASTIC MATERIAL

Define the **Solid model** and the linear elastic material properties.

Solid Model

The **Solid model** is always **Isotropic** for a linear elastic material that has the same properties in all directions.

Density

The default **Density** ρ uses values **From material**. For **User defined** enter another value or expression.

	The density is needed for dynamic analysis and when computing mass properties.

Specification of Elastic Properties for Isotropic Materials

For an **Isotropic Solid model**, from the **Specify** list select a pair of elastic properties for an isotropic material—**Young's modulus and Poisson's ratio**, **Young's modulus and shear modulus**, **Bulk modulus and shear modulus**, **Lamé parameters**, or **Pressure-wave and shear-wave speeds**. For each pair of properties, select from the applicable list to use the value **From material** or enter a **User defined** value or expression.

	Each of these pairs define the elastic properties and it is possible to convert from one set of properties to another.

The individual property parameters are:

- **Young's modulus** (elastic modulus) E.
- **Poisson's ratio** ν.
- **Shear modulus** G.
- **Bulk modulus** K.
- **Lamé parameter** λ and **Lamé parameter** μ.
- **Pressure-wave speed** (longitudinal wave speed) c_p.
- **Shear-wave speed** (transverse wave speed) c_s. This is the wave speed for a solid continuum. In plane stress, for example, the actual speed with which a longitudinal wave travels is lower than the value given.

About Isotropic Material and Elastic Moduli

The elasticity matrix is

$$D = \frac{E}{(1+\nu)(1-2\nu)}\begin{bmatrix} 1-\nu & \nu & \nu & 0 & 0 & 0 \\ \nu & 1-\nu & \nu & 0 & 0 & 0 \\ \nu & \nu & 1-\nu & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1-2\nu}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1-2\nu}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1-2\nu}{2} \end{bmatrix}$$

Different pairs of elastic moduli can be used, and as long as two moduli are defined. The others can be computed according to Table 15-1.

TABLE 15-1: EXPRESSIONS FOR THE ELASTIC MODULI.

DESCRIPTION	VARIABLE	$D(E,\nu)$	$D(K,G)$	$D(\lambda,\mu)$
Young's modulus	E		$\frac{9KG}{3K+G}$	$\mu\frac{3\lambda+2\mu}{\lambda+\mu}$
Poisson's ratio	ν		$\frac{1}{2}\left(1-\frac{3G}{3K+G}\right)$	$\frac{\lambda}{2(\lambda+\mu)}$
Bulk modulus	K	$\frac{E}{3(1-2\nu)}$		$\lambda+\frac{2\mu}{3}$
Shear modulus	G	$\frac{E}{2(1+\nu)}$		μ
Lamé parameter λ	λ	$\frac{E\nu}{(1+\nu)(1-2\nu)}$	$K-\frac{2G}{3}$	
Lamé parameter μ	μ	$\frac{E}{2(1+\nu)}$	G	
Pressure-wave speed	c_p		$\sqrt{\frac{K+4G/3}{\rho}}$	
Shear-wave speed	c_s		$\sqrt{G/\rho}$	

According to Table 15-1, the elasticity matrix D for isotropic materials is written in terms of Lamé parameters λ and μ,

$$D = \begin{bmatrix} \lambda+2\mu & \lambda & \lambda & 0 & 0 & 0 \\ \lambda & \lambda+2\mu & \lambda & 0 & 0 & 0 \\ \lambda & \lambda & \lambda+2\mu & 0 & 0 & 0 \\ 0 & 0 & 0 & \mu & 0 & 0 \\ 0 & 0 & 0 & 0 & \mu & 0 \\ 0 & 0 & 0 & 0 & 0 & \mu \end{bmatrix}$$

or in terms of the bulk modulus K and shear modulus G:

$$D = \begin{bmatrix} K+\frac{4G}{3} & K-\frac{2G}{3} & K-\frac{2G}{3} & 0 & 0 & 0 \\ K-\frac{2G}{3} & K+\frac{4G}{3} & K-\frac{2G}{3} & 0 & 0 & 0 \\ K-\frac{2G}{3} & K-\frac{2G}{3} & K+\frac{4G}{3} & 0 & 0 & 0 \\ 0 & 0 & 0 & G & 0 & 0 \\ 0 & 0 & 0 & 0 & G & 0 \\ 0 & 0 & 0 & 0 & 0 & G \end{bmatrix}$$

Mixed Formulation

For a material with a very low compressibility, using only displacements as degrees of freedom may lead to a numerically ill-posed problem. You can then use a mixed formulation, which adds an extra dependent variable for either the pressure or for the volumetric strain. For details, see the *Mixed Formulation* section in the *Structural Mechanics Theory* chapter.

From the **Use mixed formulation** list, select **None**, **Pressure formulation**, or **Strain formulation**.

ENERGY DISSIPATION

You can select to compute and store energy dissipation variables in a time dependent analysis. Doing so will add extra degrees of freedom to the model.

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Select the **Calculate dissipated energy** checkbox as needed to compute the energy dissipated by damping.

DISCRETIZATION

If **Pressure formulation** is used, select the discretization for the **Auxiliary pressure** — **Automatic**, **Discontinuous Lagrange**, **Continuous**, **Linear**, or **Constant**. If **Strain formulation** is used, select the discretization for the **Auxiliary volumetric strain** — **Automatic**, **Discontinuous Lagrange**, **Continuous**, **Linear**, or **Constant**.

The **Discretization** section is available when **Pressure formulation** or **Strain formulation** is selected from the **Use mixed formulation** list. To display the section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

QUADRATURE SETTINGS

Select the **Reduced integration** checkbox to reduce the integration points for the weak contribution of the feature. Select a method for **Hourglass stabilization** — **Automatic**, **Manual**, or **None** to use in combination with the reduced integration scheme. The default **Automatic** stabilization technique is based on the shape function and shape order of the displacement field.

Control the hourglass stabilization scheme by using the **Manual** option. Select **Shear stabilization** (default) or **Volumetric stabilization**.

When **Shear stabilization** is selected, enter a stabilization shear modulus, G_{stb}. The value should be in the order of magnitude of the equivalent shear modulus.

When **Volumetric stabilization** is selected, enter a stabilization bulk modulus, K_{stb}. The value should be in the order of magnitude of the equivalent bulk modulus.

- Using Reduced Integration
- Reduced Integration and Hourglass Stabilization

Intercalation Strain

Intercalation strain is an internal volumetric strain that occurs as a result of the insertion of species (atoms) into interstitial sites of a host electrode material, for instance intercalation of lithium atoms in graphite in lithium-ion battery electrodes.

For small strains, the strain tensor is

$$\varepsilon_{ic} = \frac{1}{3}\frac{\Delta V}{V_0}\mathbf{I}$$

Here, ΔV is the change in volume, and V_0 is the reference volume. $\mathbf{I}$ is the identity tensor.

The **Intercalation Strain** subnode is only available with the Battery Design Module, see https://www.comsol.com/products/specifications/).

INTERCALATION STRAIN

Select how to define the **Volumetric strain**, $\Delta V/V_0$, — **From material** or **User defined**.

When **From material** is selected, the material property **Volumetric strain** is used. The dependency on the concentration is then passed to the material using the input in the **Model Input** section.

For **User defined**, enter an expression for the volumetric strain as function of a concentration variable. As the strain is given explicitly, such an expression should be a function of a concentration variable.

LOCATION IN USER INTERFACE

Context Menus

Solid Mechanics > **Linear Elastic Material** > **Intercalation Strain**

Ribbon

Physics tab with **Linear Elastic Material** node selected in the model tree:

Attributes > **Intercalation Strain**

Damping

Using the **Damping** subnode, you can add damping to the material model. Damping can be used in Time Dependent, Eigenfrequency, and Frequency Domain studies; for other study types, the settings in the **Damping** subnode are ignored.

You can add the **Damping** subnode to the Linear Elastic Material node.

DAMPING SETTINGS

The **Damping type** is always **Rayleigh damping**.

Enter the **Mass damping parameter** α_{dM} and the **Stiffness damping parameter** β_{dK}.

In this damping model, the damping parameter ξ is expressed in terms of the mass m and the stiffness k as

$$\xi = \alpha_{dM} m + \beta_{dK} k$$

That is, Rayleigh damping is proportional to a linear combination of the stiffness and mass; there is no direct physical interpretation of the *mass damping parameter* α_{dM} and the stiffness damping parameter β_{dM}.

Select **Input parameters** — **Alpha and beta** — to enter the damping parameters explicitly, or **Damping ratios** to derive the damping parameters from the damping ratio at two frequencies.

When **Alpha and beta** is selected, enter values or expressions for the **Mass damping parameter** α_{dM} and the **Stiffness damping parameter** β_{dK}.

When **Damping ratios** is selected, enter two pairs of frequencies, f_1 and f_2, and the corresponding damping ratios ζ_1 and ζ_2 at these frequencies. The Rayleigh damping parameters are then computed as

$$\alpha_{dM} = 4\pi f_1 f_2 \frac{\varsigma_1 f_2 - \varsigma_2 f_1}{f_2^2 - f_1^2}$$

$$\beta_{dK} = \frac{\varsigma_2 f_2 - \varsigma_1 f_1}{\pi(f_2^2 - f_1^2)}$$

In order to visualize the damping ratio as a function of frequency, click **Damping Ratio Preview** ( ).

Context Menus

Solid Mechanics > **Linear Elastic Material** > **Damping**

Ribbon

Physics Tab with a **Linear Elastic Material** node selected in the model tree: **Attributes** > **Damping**.

Free

The **Free** node is the default boundary condition. It means that there are no constraints and no loads acting on the boundary. When the physics interfaces is added, a default **Free** node is added. If you look at the selections for this node, it will show all boundaries which do not have any boundary conditions applied.

You can manually add **Free** nodes to override other boundary conditions. This is however seldom needed.

LOCATION IN USER INTERFACE

Context menus

Prescribed Displacement

The **Prescribed Displacement** node adds a condition where the displacements are prescribed in one or more directions to the geometric entity (domain, boundary, edge, or point).

If a displacement is prescribed in one direction, this leaves the structure free to deform in the orthogonal directions.

If a zero displacement is applied in all directions, this is the same as a Fixed Constraint.

COORDINATE SYSTEM SELECTION

The constraints are applied in the axis directions of the coordinate system selected in this section. You should only use a coordinate system that has fixed spatial directions.

PRESCRIBED DISPLACEMENT

For the displacement in each direction, select a setting from the list — **Free** or **Prescribed**. Select:

- **Free** (the default) to leave the displacement component unconstrained.
- **Prescribed** to constrain the displacement component to a given value. Enter a scalar value for the component of the prescribed displacement u_0.

In versions prior to 6.2, you could chose to formulate the constraint in two ways: standard notation or general notation. Since it was rarely used, the general notation option is no longer supported. There are more natural ways of specifying identical constraints.

If you have a model created in version 6.1 or earlier, where general notation was used, the settings for this option are visible, and are still functional. You should, however, consider to reformulate the constraints, since the general notation may no longer be supported in future versions.

For reference, the documentation for the general notation is provided below:

You can specify the displacements using a general notation that includes any linear combination of displacement components. For example, for 2D components, use the relationship

$$H\begin{bmatrix} u \\ v \end{bmatrix} = R$$

For $\mathbf{H}$ matrix H select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** and then enter values as needed in the field or matrix. Enter values or expressions for the $\mathbf{R}$ vector R.

For example, to achieve the condition $u = v$, use the settings

$$H = \begin{bmatrix} 1 & -1 \\ 0 & 0 \end{bmatrix}, \qquad R = \begin{bmatrix} 0 \\ 0 \end{bmatrix},$$

which force the domain to move only diagonally in the xy-plane.

Roller

The **Roller** node adds a roller constraint as the boundary condition; that is, the displacement is zero in the direction perpendicular (normal) to the boundary, but the boundary is free to move in the tangential direction. A **Roller** condition is similar to a Symmetry condition, but the latter has some other options. The **Roller** constraint is not available in 1D and 1D axisymmetry; use a **Fixed** constraint instead.

ROLLER CONSTRAINT

The default roller constraint acts along a normal to the selected boundaries which is computed numerically. The geometry or mesh representation of the actual boundary may however be imperfect. This can lead to unexpected locking of the deformation, since the computed normals do not have the intended directions. You can then, for some important cases, prescribe that the boundary slides on an analytical surface.

Select a **Normal orientation** — **Automatic**, **Plane**, **Cylinder**, or **Sphere**.

For **Automatic**, the constraint is applied in the direction normal to the boundary, as represented by the mesh. This orientation is not updated during the analysis.

For **Plane**, select **Orientation of normal** — **X-axis**, **Y-axis**, **Z-axis**, or **User defined** to describe the constraint direction. When **User defined** is used, enter the vector $\mathbf{e}_n$, pointing along the normal to the plane along which the boundary is sliding.

For **Cylinder**, select **Axis type**— **X-axis**, **Y-axis**, **Z-axis**, or **User defined** to describe the orientation of the cylinder. Enter the location of a **Point on axis**, $\mathbf{X}_c$, in order fix the location of the cylinder. When **User defined** is used, enter the vector $\mathbf{e}_s$, pointing along the axis of the cylinder. The constraints will act radially from the cylinder axis. If the analysis is geometrically nonlinear, each mesh node is assumed to maintain its distance from the cylinder axis.

For **Sphere**, enter the location of the **Center of sphere**, $\mathbf{X}_c$. The constraints will act radially from this point. If the analysis is geometrically nonlinear, each mesh node is assumed to maintain its distance from the center of the sphere.

Boundaries > **Solid Mechanics** > **Roller**

Symmetry

The **Symmetry** node adds a boundary condition that represents symmetry in the geometry and in the loads. A symmetry condition is free in the plane and fixed in the out-of-plane direction.

NORMAL DIRECTION CONDITION

You can allow a symmetry plane to move along its normal direction. This can be used to model some situations where you want a plane to remain strictly planar but still relax the property of it being fixed.

From the list, select **No displacement, Free Displacement**, **Prescribed force**, or **Prescribed displacement**.

The value **No displacement** gives a standard symmetry condition.

Select **Free Displacement** to allow the symmetry plane to translate in the normal direction. The displacement is determined by the criterion that there is no resulting reaction force in the normal direction.

Select **Prescribed force** to prescribe the total reaction force acting on the direction normal to the symmetry plane. Enter the **Normal force** F_n. The force is defined as positive when acting along the outward normal of the symmetry plane. Setting the prescribed force to zero gives the same effect as using **Free Displacement**.

Select **Prescribed displacement** to prescribe the displacement in the direction normal to the symmetry plane. Enter the **Normal displacement** u_{n0}. Setting the prescribed displacement to zero gives the same effect as using **No displacement**.

- Using **Free Displacement**, **Prescribed force**, or **Prescribed displacement** is only meaningful if the geometry selection corresponds to a single symmetry plane.
- When using **Free Displacement** or **Prescribed force**, an extra global degree of freedom is added for determining the displacement in the normal direction. This degree of freedom will have a name of the type `<component>.<interface>.<symmetry_tag>.un`, for example `comp1.solid.sym1.un`.

Boundaries > **More Constraints** > **Symmetry**

Symmetry Plane

The **Symmetry Plane** node adds a boundary condition that represents symmetry in the geometry and in the loads. This node is available only in 2D axisymmetry, where the only possible symmetry plane is normal to the Z-axis. A symmetry condition is free in the plane and fixed in the out-of-plane direction.

NORMAL DIRECTION CONDITION

You can allow a symmetry plane to move along its normal direction. This can be used to model some situations where you want a plane to remain strictly planar but still relax the property of it being fixed.

From the list, select **No displacement, Free Displacement**, **Prescribed force**, or **Prescribed displacement**.

The value **No displacement** gives a standard symmetry condition.

Select **Free Displacement** to allow the symmetry plane to translate in the normal direction. The displacement is determined by the criterion that there is no resulting reaction force in the normal direction.

Select **Prescribed force** to prescribe the total reaction force acting on the direction normal to the symmetry plane. Enter the **Normal force** F_n. The force is defined as positive when acting along the outward normal of the symmetry plane. Setting the prescribed force to zero gives the same effect as using **Free Displacement**.

Select **Prescribed displacement** to prescribe the displacement in the direction normal to the symmetry plane. Enter the **Normal displacement** u_{n0}. Setting the prescribed displacement to zero gives the same effect as using **No displacement**.

- Using **Free Displacement**, **Prescribed force**, or **Prescribed displacement** is only meaningful if the geometry selection corresponds to a single symmetry plane.
- When using **Free Displacement** or **Prescribed force**, an extra global degree of freedom is added for determining the displacement in the normal direction. This degree of freedom will have a name of the type `<component>.<interface>.<symmetry_tag>.un`, for example `comp1.solid.symp1.un`.

Rigid Motion Suppression

The **Rigid Motion Suppression** node adds constraints required to suppress rigid body modes. The constraints are selected so that there will be no reaction forces if the external loads are self-equilibrating.

The constraints will, depending on the physics interface and the geometrical dimension, be applied to reference points as needed. These points are automatically picked from the selected geometrical domains.

This feature must not be combined with any other types of constraints, such as prescribed displacements.

If you need to constrain several objects that are not physically connected, you must add as many **Rigid Motion Suppression** nodes as there are disconnected objects. **Rigid Motion Suppression** is available for 3D, 2D, and 2D axisymmetry.

CONTRIBUTING POINTS

By default the selectable input is **Automatic**, which corresponds to using all points in the domain. When selecting **From selection input,** a new **Point Selection** section is shown where specific points can be selected. For 3D at least three points are expected, and for 2D at least two points are expected.

Periodic Condition

Use a **Periodic Condition** to prescribe that the displacements on two different sets of boundaries with the same geometrical shape are related, as in a periodic structure.

Several different types of periodicity properties of the solution can be prescribed using this boundary condition. The **Continuity**, **Antiperiodicity**, and **User defined** periodic conditions directly prescribe relations between displacements and can be used for any type of study.

The two sets of boundaries between which there is a periodicity condition are called the *source* and *destination*, respectively. It is not required to have the same mesh on the source and destination, but the local accuracy of the solution at the boundaries will be better if you use the same mesh.

BOUNDARY SELECTION

The software usually automatically identifies the boundaries as either source boundaries or destination boundaries, as indicated in the selection list. This works fine for cases like opposing parallel boundaries. In other cases, right-click **Periodic Condition** and select **Manual Destination Selection** to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

DESTINATION SELECTION

This section is available for specifying the destination boundaries, if needed, when the **Manual Destination Selection** option is selected in the context menu for the **Periodic Condition** node. You can only select destination boundaries from the union of all source and destination boundaries.

PERIODICITY SETTINGS

With **Type of periodicity** you select the form of periodicity that your solution should have.

- For **Continuity**, the displacements on the destination are set equal to the displacements on the source: $\mathbf{u}(\mathbf{x}_d) = \mathbf{u}(\mathbf{x}_s)$. If the source and destination boundaries are rotated with respect to each other, a transformation is automatically performed, so that corresponding displacement components are connected.
- For **Antiperiodicity**, the displacements on the destination are set equal to the displacements on the source with the sign reversed $\mathbf{u}(\mathbf{x}_d) = -\mathbf{u}(\mathbf{x}_s)$. If the source and destination boundaries are rotated with respect to each other, a transformation is automatically performed, so that corresponding displacement components are connected.
- For **User defined**, select the checkbox for any of the displacement components as needed. Then for each selection, choose the **Type of periodicity**: **Continuity** or **Antiperiodicity**. Each selected displacement component will be connected by $u_i(\mathbf{x}_d) = u_i(\mathbf{x}_s)$ or $u_i(\mathbf{x}_d) = -u_i(\mathbf{x}_s)$, respectively. If the source and destination boundaries are rotated with respect to each other, a transformation is automatically performed, so that corresponding displacement components are connected.

The Fluid-Solid Interaction Multiphysics Interface

Fluid–Structure Interaction

The **Fluid–Structure Interaction** ( ) multiphysics node provides a coupling on a boundary between a fluid domain and a solid material. The solid material can be modeled either in a neighboring domain, or on the boundary itself. In the former case, the Solid Mechanics or Multibody Dynamics interface is used; in the latter one of the Layered Shell, Shell, or Membrane interfaces is used.

The effect of the coupling depends on whether a **Deforming Domain** is active in the fluid domain or not. For cases when the structural deformations are so small that the change in the geometry of the fluid can be ignored, you do not have to use a deforming domain. This is called a *fixed geometry*. Domains with a fixed geometry have fewer degrees of freedom and are less nonlinear and are thus computationally less expensive

If **Deforming Domain** is active in any domain, the **Include geometric nonlinearity** option is automatically selected in all applicable study nodes.

SETTINGS

The **Label** is the multiphysics coupling feature name. The default **Label** (for the first multiphysics coupling feature in the model) is `Fluid–Structure Interaction 1`.

The **Name** is used primarily as a scope prefix for variables defined by the coupling node. Refer to such variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different coupling nodes or physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first multiphysics coupling feature in the model) is `fsi1`.

BOUNDARY SELECTION

By default, the selection is set to **All boundaries**. However, only boundaries between fluid and solid domains are applicable. This is deduced automatically using the selections made on the coupled physics interfaces.

COUPLED INTERFACES

This section defines the physics interfaces involved in the Fluid–Structure Interaction coupling. The **Fluid** and **Structure** lists include all applicable physics interfaces.

The default values depend on how the node is created.

- If it is added from the **Physics** ribbon (Windows users), **Physics** contextual toolbar (macOS and Linux users), or context menu (all users), then the first physics interface of each type in the component is selected as the default.
- If it is added automatically when the physics interface is chosen in the **Model Wizard** or **Add Physics** window, then the two participating physics interfaces are selected.

You can also select **None** from either list to uncouple the **Fluid–Structure Interaction** node from a physics interface. If the physics interface is removed from the **Model Builder**, for example **Solid Mechanics** is deleted, then the **Structure** list defaults to **None** as there is nothing to couple to.

If a physics interface is deleted and then added to the model again, then in order to reestablish the coupling, you need to choose the physics interface again from the lists. This is applicable to all multiphysics coupling nodes that would normally default to the once present physics interface. See Multiphysics Modeling Workflow.

FIXED GEOMETRY

In the case when the coupling is of the fixed geometry type, you can select which aspect of the interaction you want to model. From the **Fixed geometry coupling type** list, select **Fully coupled** (requires a MEMS Module or Structural Mechanics Module license), **Fluid loading on structure**, or **Velocity transmission to fluid** (requires a MEMS Module or Structural Mechanics Module license).

In the case **Fluid loading on structure**, pressure and viscous forces in the fluid affect the structure, but the structure does not affect the fluid flow.

In the case **Velocity transmission to fluid**, the structural velocity acts as boundary condition for the fluid, but the fluid does not affect the structure.

For **Fully coupled**, both effects are taken into account.

When a boundary is adjacent to an active deforming domain, the settings is this section are ignored.

- Fluid–Structure Interaction

16

Equation-Based Modeling

This chapter describes the use of the interfaces for mathematics and equation-based modeling, found under the **Mathematics** branch (∆u) when adding interfaces to a model. With these interfaces, you can solve various types of PDEs using different formulations. You can also solve ODEs and other global equations as well as create events, create curvilinear coordinates, and use extra dimensions.

In this chapter:

- The Mathematics Interfaces
- Modeling with PDEs
- The PDE Interfaces
- The PDE, Boundary Elements Interface
- Theory for the Boundary Elements PDE
- The Wave Form PDE Interface
- Theory for the Wave Form PDE
- About Auxiliary Equation-Based Nodes
- Modeling with ODEs and DAEs
- The ODE and DAE Interfaces
- The Events Interface
- The Wall Distance Interface
- Theory for Wall Distance
- Curvilinear Coordinates
- Using Extra Dimensions

The Mathematics Interfaces

The mathematics interfaces are a collection of tools for equation-based modeling and for performing special tasks, rather than for modeling specific physics. These interfaces support several PDE formulations as well as general ways to add ODEs, algebraic equations, other global (space-independent) equations, and curvilinear coordinates.

For a list of the available interfaces found under **Mathematics** branch (∆u) when adding interfaces, including the Names, see Physics Interface Guide.

PDE INTERFACES

The PDE Interfaces branch contains Partial Differential Equation (PDE) interfaces for PDEs in coefficient form and general form, and for weak form PDEs on different geometry levels.

These interfaces are for entering PDEs in different forms:

- *Coefficient form*, for PDEs conforming to the template explained in The Coefficient Form PDE Interfaces.
- *General form*, for conservation laws and PDEs resulting from nonlinear material models. See The General Form PDE Interfaces.
- *Weak form*, to use the weak formulation of the PDE for maximum flexibility. See The Weak Form PDE Interfaces.
- The PDE, Boundary Elements Interface, for source-free PDEs using the boundary element method (BEM).
- About Auxiliary Equation-Based Nodes solves PDEs with first-order derivatives in time and space using optimized algorithms with respect to speed and memory consumption.

Except for the Wave Form PDE, the PDE interfaces are available in domains, on boundaries, on edges, and at points. The interfaces for the different equation forms are identical except for the default node on the top geometric entity level. Also see Modeling with PDEs.

CLASSICAL PDES

The Classical PDE Interfaces branch contains some classical PDEs that are special cases of the Coefficient Form PDE: Laplace's Equation, Poisson's Equation, Wave Equation, Heat Equation, Helmholtz Equation, Convection-Diffusion Equation, and Stabilized Convection-Diffusion Equation interfaces.

Also see Compact and Standard Notations for Classical PDEs.

ODE AND DAE INTERFACES

The ODE and DAE Interfaces are used to add global, space-independent equations that can represent additional named degrees of freedom. The equations can be ODEs, algebraic equations, DAEs, and transcendental equations, either as global equations or as distributed ODEs or DAEs (on domains, boundaries, edges, or at points). For more information about global equations and ODEs, see Modeling with ODEs and DAEs.

EVENTS INTERFACE

The Events Interface is used to create solver events. An event can be explicit or implicit, and the difference is that for explicit events, you must specify the exact time when the event occurs. When an event occurs, the solver stops and provides a possibility to reinitialize the values of states and dependent variables.

WALL DISTANCE INTERFACE

The Wall Distance Interface solves a modified eikonal equation for computing the distance to walls, which is an important quantity for turbulence modeling in fluid flow simulations.

CURVILINEAR COORDINATES INTERFACE

Use the Curvilinear Coordinates interface to create a curvilinear coordinate system for defining anisotropic material properties following the shape of a geometry object. Three different methods are available for computing the coordinate system: a diffusion method, an elasticity method, and a flow method. You can also provide user-defined coordinate directions.

Modeling with PDEs

The physics interfaces in COMSOL Multiphysics and add-on modules use *partial differential equations*, PDEs, as a mathematical model of physical reality. You can access these PDEs in the following ways:

- The PDE Interfaces allow you to specify all or part of your problem using PDEs. This approach may, for example, be suitable for modeling unusual equations from various fields of physics or for learning mathematical modeling.
- Auxiliary equation-based nodes are available in all physics interfaces. These let you add extra equation contributions and constraints to the predefined mathematical model.
- Equation View nodes display the PDEs (in weak form) and constraints underlying the physics interfaces, and allow you to modify them.

This section describes the theory behind the PDE interfaces, but also contains information useful for understanding and modifying the mathematical models implemented in the physics interfaces.

- The PDE Interfaces
- About Auxiliary Equation-Based Nodes
- Equation View

About Equation Formats

Partial differential equations may be entered into COMSOL Multiphysics on the following formats:

- The General Form PDE
- The Coefficient Form PDE
- The Weak Form PDE
- The PDE, Boundary Elements Interface
- The Wave Form PDE Interface
- About Auxiliary Equation-Based Nodes

Which one to choose is mostly a matter of convenience: Certain equations are quicker and easier to specify in one particular form. Internally, equations written in general or coefficient form are converted to weak form, which is the most fundamental form. In particular, the weak form is closely linked to the theory behind the *finite element method*, FEM. The PDE, Boundary Elements interface uses the *boundary element method*, BEM, for solving source-free PDEs. In a similar way, the wave form is linked to a *discontinuous Galerkin* version of FEM, particularly suited for solving wave-propagation problems.

Notational Conventions

The PDE interfaces use a slightly different notation, compared to other physics interfaces and the associated documentation. The difference lies in the definition of the symbol ∇, pronounced *nabla* or *del*. For the physics interface equation sections and nodes (see Showing More Options), the ∇ symbol applied to a scalar or vector variable denotes the following coordinate system-independent *gradient*, *divergence*, and *curl* operations:

$$\nabla u = \text{grad}(\text{u})$$
$$\nabla \cdot \mathbf{u} = \text{div}(\mathbf{u})$$
$$\nabla \times \mathbf{u} = \text{curl}(\mathbf{u})$$

In the PDE interfaces, *nabla/del* is interpreted as the vector of partial derivatives:

$$\nabla = \left(\frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_n}\right)$$

The spatial coordinates are denoted $x_1, \ldots, x_n$, where n represents the number of space dimensions. When applied to a scalar or vector in a Cartesian coordinate system, this definition leads to an expression that is identical in form to the gradient, divergence, or curl in the same coordinate system. The same does not apply, however, in curvilinear systems such as the one implied in an axisymmetric geometry.

For example, the divergence of a vector $\mathbf{u} = [u_r, u_z]$ in an axisymmetric cylindrical system is

$$\text{div}(\mathbf{u}) = \frac{\partial u_r}{\partial r} + \frac{u_r}{r} + \frac{\partial u_z}{\partial z} = \frac{1}{r}\frac{\partial}{\partial r}(r u_r) + \frac{\partial u_z}{\partial z}$$

while the PDE interface interpretation of *nabla/del* is:

$$\nabla \cdot \mathbf{u} = \frac{\partial u_r}{\partial r} + \frac{\partial u_z}{\partial z}$$

In practice, this means that to correctly implement equations containing the gradient, divergence, or curl in an axisymmetric geometry, you must compensate for the missing factors related to the curvature of the coordinate system. In particular, note that you must typically multiply the entire equation, as well as its boundary conditions, by a volume factor — in an axisymmetric geometry, for example, with a factor r — in order to recast it into one of the equation forms in COMSOL Multiphysics.

The following related examples follow the same principle:

- The symbol Δ is the Laplace operator

$$\frac{\partial^2}{\partial x_1^2} + \ldots + \frac{\partial^2}{\partial x_n^2}$$

- $\nabla \cdot (c\nabla u)$ means

$$\frac{\partial}{\partial x_1}\left(c\frac{\partial u}{\partial x_1}\right) + \ldots + \frac{\partial}{\partial x_n}\left(c\frac{\partial u}{\partial x_n}\right)$$

- $\beta \cdot \nabla u$ means

$$\beta_1\frac{\partial u}{\partial x_1} + \ldots + \beta_n\frac{\partial u}{\partial x_n}$$

where $\beta_1, \ldots, \beta_n$ are the components of the vector β.

The axisymmetric versions of physics interfaces take the cylindrical coordinate system into account, and no compensation is therefore needed. Also, the Stabilized Convection-Diffusion Equation interface uses a formulation that takes the cylindrical coordinate system into account for axisymmetric models.

- About Auxiliary Equation-Based Nodes

PDE Interface Variables

The following list shows symbolic expressions for quantities appearing in the definition of PDEs and the corresponding variable names, which can be used in PDE coefficients and are available for results evaluation and visualization.

EXPRESSION	NAME	DESCRIPTION
u_i	u*i*	The solution variable (dependent variable)
$\frac{\partial u_i}{\partial x_j}$	u*i*x*j*	The derivative of the solution variable u_i with respect to the spatial coordinate x_j, for example, uy
$(\nabla_T u_i)_j$	u*i*T x*j*	The x_j component of the gradient of u_i projected onto a boundary or edge, for example, uTy
$\frac{\partial^2 u_i}{\partial x_j \partial x_k}$	u*i*x*j*x*k*	The second derivative of the solution variable u_i with respect to the spatial coordinates x_j and x_k, for example, uxx, uxy
$\frac{\partial u_i}{\partial t}$	u*i*t	The derivative of the solution variable u_i with respect to time as seen from the frame chosen under Discretization
$\frac{\partial^2 u_i}{\partial t^2}$	u*i*tt	The second derivative of the solution variable u_i with respect to time as seen from the frame chosen under Discretization
$\frac{\partial^2 u_i}{\partial x_j \partial t}$	u*i*x*j*t	The mixed derivative of the solution variable u_i with respect to time and the spatial coordinate x_j as seen from the frame chosen under Discretization

Interpretation of Time Derivatives

The time derivatives appearing in the Coefficient Form and General Form PDE templates are shown in the user interface and documentation as partial derivatives of the dependent variable with respect to time. This is true only as long as the mesh on which the dependent variables are represented is fixed. When using Moving Mesh or Deformed Geometry functionality, the mesh nodes and elements may be moving relative to the frame chosen under **Discretization** in the interface settings. Time derivatives used in domain PDEs (that is, on the full dimension of the geometry) are then interpreted as a total derivative with respect to time, evaluated for fixed coordinates in the chosen frame.

The dependent variables can be seen as functions of mesh coordinates $\mathbf{X}_\mathrm{m}$ and time t. If the mesh is moving, then $\mathbf{X}_\mathrm{m}(t)$ is also a function of time when seen from a point $\mathbf{x}$ fixed in space. Therefore

$$\mathrm{ut} = \frac{du}{dt} = \frac{\partial u}{\partial t} - \nabla u \cdot \frac{d\mathbf{x}}{dt}$$

and similarly for second-order and mixed derivatives. For PDEs on lower dimensions, for example a Coefficient Form Boundary PDE, this relation cannot be used since it is in general not possible to hold the position $\mathbf{x}$ fixed in space if the mesh motion is not purely tangential. For this reason, time derivatives in PDEs on lower dimensions are defined simply as the mesh frame derivative:

$$\mathrm{ut} = \frac{\partial u}{\partial t}$$

TIME DERIVATIVES IN THE FREQUENCY DOMAIN

The equation-based interfaces have an **Equation form** setting that controls the interpretation of time derivatives, depending on whether the equation is seen as a time-domain equation, a frequency domain equation using the harmonic ansatz

$$u(t) = \hat{u}e^{i\omega t}$$

where $\omega = 2\pi f$ is the angular frequency, or an eigenvalue equation using

$$u(t) = \hat{u}e^{-\lambda t}$$

When the equation form is set to **Time domain**, then the eigenvalue ansatz is used when solving using an Eigenvalue or Eigenfrequency study step. For all other solvers, the time derivative variable `ut` evaluates based on the time derivative of the degrees of freedom, which are zero in the stationary solver used by both Stationary and Frequency Domain study steps.

When the equation form is set to **Frequency domain**, then the harmonic ansatz is always used, meaning that time derivative variables are evaluated as `ut` = $i\omega u$ for all solvers and study step types. But the angular frequency ω is still by default defined by the study step. A Frequency Domain study step sets the angular frequency to $\omega = 2\pi f$ where the frequency f is given in the study step. An Eigenvalue or Eigenfrequency study step defines $\omega = i\lambda$, turning the frequency domain problem into a corresponding eigenvalue problem. It is also possible to explicitly set the frequency in the PDE interface settings.

The default equation form setting when working from the user interface is **Study controlled**, which means that the frequency-domain interpretation of time derivatives will be used in Frequency Domain study steps with the frequency supplied by the study step. For all other study types, the time-domain interpretation will be used.

Eigenvalue problems can be solved using either equation form. The **Time domain** and **Frequency domain** interpretations of time derivatives are expected to give the same result.

The General Form PDE

The General Form PDE interface provides a general interface for specifying and solving PDEs in the general form. This format is closely related to the conservation laws that govern many areas of physics. Assuming that you are working with a single dependent variable u, the general form reads:

$$\begin{cases} e_a\dfrac{\partial^2 u}{\partial t^2} + d_a\dfrac{\partial u}{\partial t} + \nabla\cdot\Gamma = f & \text{in } \Omega \\ -\mathbf{n}\cdot\Gamma = g - qu + h^T\mu & \text{on } \partial\Omega \\ 0 = R & \text{on } \partial\Omega_c \\ u = r & \text{on } \partial\Omega_d \end{cases} \tag{16-1}$$

where

- Ω is the computational domain; the union of all domains
- $\partial\Omega$ is the domain boundary
- $\mathbf{n}$ is the outward unit normal vector on $\partial\Omega$

The first line (equation) of Equation 16-1 is the PDE, which must be satisfied in Ω. The second, third, and fourth equations are the boundary conditions, which must hold on $\partial\Omega$. The second equation is a generalization of a *Neumann* boundary condition. The third equation is a general *constraint*, of which the *Dirichlet* boundary condition on the fourth line is a special case.

The terms Γ, f, g, q, R, and r are user-defined coefficients. They can be functions of the spatial coordinates, the solution u, time, the space and time derivatives of u (see PDE Interface Variables), as well as of other predefined and user-defined variables. The coefficients f, g, q, R, and r are scalar, whereas Γ is the *flux vector*.

In practical applications, Γ typically represents the flux of a conserved quantity such as heat, charge, mass, or momentum. This flux is usually related in some empirical way, via a material law, to the gradient of the dependent variable. Therefore, Γ is usually a vector whose components are functions of derivatives of the dependent variable. The flux vector can also contain terms that are proportional to a velocity field when there is convective transport of the conserved quantity present. The structure of Equation 16-1 implies that the normal component of Γ is continuous across any surface in the interior of the domain, Ω.

BOUNDARY CONDITIONS FOR THE GENERAL FORM PDE

In finite element terminology, the boundary condition on the second line of Equation 16-2, corresponding to a Neumann boundary condition, is called a *natural boundary condition*, because it does not occur explicitly in the weak form of the PDE problem. In the PDE interfaces, the corresponding condition is called a *flux* or *source*, because it specifies the value of the numerical flux Γ at the boundary.

Constraints and Dirichlet conditions are also known as *essential boundary conditions* in finite element theory, because they impose a restriction on the trial space, which is not part of the main equation. In the PDE interfaces, a distinction is made between Dirichlet boundary conditions and *constraints*. The general constraint on line 3 of Equation 16-2 specifies that an arbitrary expression is equal to zero on the boundary: $R = 0$. The Dirichlet condition on line 4 of the same equation is a special case directly specifying the value of the dependent variable at the boundary: $u = r$. This makes the constraint a more general boundary condition.

The term $-h^{\mathrm{T}}\mu$ in the generalized Neumann condition is a reaction term enforcing the constraint $R = 0$. When reaction terms are applied symmetrically on all dependent variables,

$$h = -\frac{dR}{du}$$

but other definitions are also possible. The variable μ is a Lagrange multiplier, which is eliminated by the solvers when using standard constraints and therefore does not normally appear explicitly in equations.

For details about the time-dependent and eigenvalue formulations, see Solving Time-Dependent Problems and Solving Eigenvalue Problems.

- The General Form PDE Interfaces
- Domain, Boundary, Pair, Edge, and Point Conditions for PDEs

The Coefficient Form PDE

The Coefficient Form PDE provides a general interface for specifying and solving many well-known PDEs in the coefficient form.

Many PDEs originating from physics interfaces and other fields can be cast into a generic form containing derivatives up to second order in both time and space. In COMSOL Multiphysics, you can define a PDE of this

type by specifying coefficients for the derivatives of different orders. This results in a *coefficient form* PDE, which for one dependent variable u reads:

$$\begin{cases} e_a\dfrac{\partial^2 u}{\partial t^2} + d_a\dfrac{\partial u}{\partial t} + \nabla\cdot(-c\nabla u - \alpha u + \gamma) + \beta\cdot\nabla u + au = f & \text{in } \Omega \\ \mathbf{n}\cdot(c\nabla u + \alpha u - \gamma) = g - qu + h^T\mu & \text{on } \partial\Omega \\ 0 = R & \text{on } \partial\Omega_c \\ u = r & \text{on } \partial\Omega_d \end{cases} \tag{16-2}$$

where

- Ω is the computational domain; the union of all domains
- $\partial\Omega$ is the domain boundary
- $\mathbf{n}$ is the outward unit normal vector on $\partial\Omega$

The first line (equation) of Equation 16-2 is the PDE, which must be satisfied in Ω. The second and third equations are the boundary conditions, which must hold on $\partial\Omega$. The second equation is a generalization of a Neumann boundary condition. The third equation is a general constraint, with a Dirichlet boundary condition as a special case. For more information about the boundary conditions, see The General Form PDE.

To define a PDE on coefficient form in one of the PDE interfaces, you specify the coefficients c, α, γ, β, and a and the boundary terms f, g, R, and r. They can all be functions of the spatial coordinates as well as of dependent variables and their derivatives, time, and other predefined or user-defined variables and parameters. A PDE is guaranteed to be *linear* when the coefficients vary only with the spatial coordinates (or are constants). A PDE is *nonlinear* if the c, α, β, a, h, or q coefficients depend on u or its derivatives (for example, the components of ∇u), or if γ, f, g, R, or r are nonlinear in u.

For a single dependent variable u, all the coefficients in the above equation are scalars except α, β, and γ, which are vectors with n components. The coefficient c may be given alternatively as a scalar or an n-by-n matrix to model anisotropic materials. When the coefficient form is used for modeling a system of equations, the coefficients are extended with additional vector and matrix dimensions referring to the dependent variable index. See further Multiple Dependent Variables — Equation Systems.

COEFFICIENT FORM VERSUS GENERAL FORM

Comparing Equation 16-2 to Equation 16-1 shows that the coefficient form is just a special case of the general form. Applying the following substitutions in the general form, Equation 16-1, turns it into the coefficient form:

$$\begin{aligned} \Gamma &= -c\nabla u - \alpha u + \gamma \\ F &= f - \beta\nabla u - au \end{aligned} \tag{16-3}$$

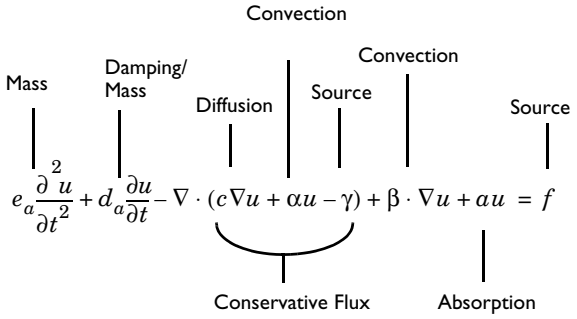
This duality lets you choose the representation in which it is easiest to implement a particular PDE. There is no difference in performance.

INTERPRETING PDE COEFFICIENTS

The PDE formulations in COMSOL Multiphysics can model a variety of problems, but this guide, as well as the interface, uses descriptive names for the coefficients that fall within the realm of continuum mechanics and mass transfer. For the coefficient form PDE:

- e_a is the mass coefficient.

- d_a is a damping coefficient or mass coefficient.
- c is the diffusion coefficient.
- α is the conservative flux convection coefficient.
- β is the convection coefficient.
- a is the absorption coefficient.
- γ is the conservative flux source term.
- f is the source term.



For the Neumann boundary condition of the coefficient form

$$\mathbf{n}\cdot(c\nabla u + \alpha u - \gamma) = g - qu + h^T\mu$$

- g is the boundary source term.
- q is the boundary absorption coefficient.

There are many interesting PDE problems to which these interpretations do not apply. For example, a time-harmonic PDE such as the Helmholtz equation represents a time-dependent phenomenon transformed into the frequency domain, making the a coefficient a mass rather than absorption term.

COMPACT AND STANDARD NOTATIONS FOR CLASSICAL PDES

Many classical PDEs are instances of the coefficient form PDE. The classical PDEs have their own interfaces, which are found under the **Mathematics** > **Classical PDEs** branch (∇^2) when adding an interface. Table 16-1 shows the available classical PDEs using two notations: the compact notation of vector analysis (used in this documentation) and an expanded component notation.

TABLE 16-1: CLASSICAL PDES IN COMPACT AND COMPONENT NOTATION.

EQUATION	COMPACT NOTATION	COMPONENT NOTATION (2D)
Laplace's equation	$-\nabla\cdot(\nabla u) = 0$	$-\frac{\partial}{\partial x}\frac{\partial u}{\partial x} - \frac{\partial}{\partial y}\frac{\partial u}{\partial y} = 0$
Poisson's equation	$-\nabla\cdot(c\nabla u) = f$	$-\frac{\partial}{\partial x}\left(c\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left(c\frac{\partial u}{\partial y}\right) = f$
Helmholtz equation	$-\nabla\cdot(c\nabla u) + au = f$	$-\frac{\partial}{\partial x}\left(c\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left(c\frac{\partial u}{\partial y}\right) + au = f$
Heat equation	$d_a\frac{\partial u}{\partial t} - \nabla\cdot(c\nabla u) = f$	$d_a\frac{\partial u}{\partial t} - \frac{\partial}{\partial x}\left(c\frac{\partial u}{\partial x}\right) - \frac{\partial}{\partial y}\left(c\frac{\partial u}{\partial y}\right) = f$

TABLE 16-1: CLASSICAL PDES IN COMPACT AND COMPONENT NOTATION.

EQUATION	COMPACT NOTATION	COMPONENT NOTATION (2D)
Wave equation	$e_a\frac{\partial^2 u}{\partial t^2}-\nabla\cdot(c\nabla u)=f$	$e_a\frac{\partial^2 u}{\partial t^2}-\frac{\partial}{\partial x}\left(c\frac{\partial u}{\partial x}\right)-\frac{\partial}{\partial y}\left(c\frac{\partial u}{\partial y}\right)=f$
Convection-diffusion equation	$d_a\frac{\partial u}{\partial t}-\nabla\cdot(c\nabla u)+\beta\cdot\nabla u=f$	$d_a\frac{\partial u}{\partial t}-\frac{\partial}{\partial x}\left(c\frac{\partial u}{\partial x}\right)-\frac{\partial}{\partial y}\left(c\frac{\partial u}{\partial y}\right)+\beta_x\frac{\partial u}{\partial x}+\beta_y\frac{\partial u}{\partial y}=f$

The default values are 1 for f and c and –1 for a, so the default Helmholtz equation, for example, is $-\Delta u-u=1$.

Multiple Dependent Variables — Equation Systems

All PDE interfaces and equation forms support multiple dependent variables — that is, a system of PDEs, which can be coupled.

THE GENERAL FORM PDE SYSTEM

In the case of several dependent variables u_1, u_2, …, u_N, a general form system of equations takes the following form:

$$\begin{cases} e_a^{lk}\frac{\partial^2 u_k}{\partial t^2}+d_a^{lk}\frac{\partial u_k}{\partial t}+\nabla\cdot\Gamma_l=F_l & \text{in } \Omega \\ -\mathbf{n}\cdot\Gamma_l=G_l+h_{ml}\mu_m & \text{on } \partial\Omega \\ 0=R_m & \text{on } \partial\Omega_c \\ u_n=r_n & \text{on } \partial\Omega_d \end{cases} \tag{16-4}$$

The equation index l and k ranges from 1 to N, while the general constraint index m ranges from 1 to M_c and the Dirichlet condition index n ranges from 1 to M_d. The total number of constraints is therefore $M=M_c+M_d$. This discussion uses the summation convention. F_l, G_l, R_m, and r_n are scalars, whereas Γ_l is a spatial vector. The mass and damping coefficients e_a and d_a are N-by-N matrices, while the constraint force Jacobian h is an M-by-N matrix. Note that there are several Lagrange multipliers: μ_1, μ_2,…, μ_M.

For a more compact form, let $\mathbf{u}$ be a vector with components u_k, let Γ be a matrix with components Γ_{lj}, and so on. Then the system of equations takes on the same form as given in Equation 16-1 for a single dependent variable.

It is also possible to write the system entirely on component form, where Γ_{lj} are components of the vector Γ_l, and n_j components of the normal vector $\mathbf{n}$. Then the system of equations becomes:

$$\begin{cases} e_a^{lk}\dfrac{\partial^2 u_k}{\partial t^2} + d_a^{lk}\dfrac{\partial u_k}{\partial t} + \dfrac{\partial}{\partial x_j}(\Gamma_{lj}) = F_l & \text{in } \Omega \\ -n_j\Gamma_{lj} = G_l + h_{ml}\mu_m & \text{on } \partial\Omega \\ 0 = R_m & \text{on } \partial\Omega_c \\ u_n = r_n & \text{on } \partial\Omega_d \end{cases}$$

System for Two Variables in the General Form

The following example of a PDE in the general form is a stationary system for $N = 2$ solution components in $n = 2$ space dimensions with $M = 2$ constraints:

$$\begin{cases} \nabla \cdot \Gamma_1 = F_1 & \text{in } \Omega \\ \nabla \cdot \Gamma_2 = F_2 & \text{in } \Omega \end{cases}$$

with the generalized Neumann boundary conditions

$$\begin{cases} -\mathbf{n} \cdot \Gamma_1 = G_1 + \dfrac{\partial R_1}{\partial u_1}\mu_1 + \dfrac{\partial R_2}{\partial u_1}\mu_2 & \text{on } \partial\Omega \\ -\mathbf{n} \cdot \Gamma_2 = G_2 + \dfrac{\partial R_1}{\partial u_2}\mu_1 + \dfrac{\partial R_2}{\partial u_2}\mu_2 & \text{on } \partial\Omega \end{cases}$$

and the Dirichlet boundary conditions

$$\begin{cases} 0 = R_1 & \text{on } \partial\Omega \\ 0 = R_2 & \text{on } \partial\Omega \end{cases}$$

- The General Form PDE
- The General Form PDE Interfaces
- Boundary Condition Types

THE COEFFICIENT FORM EQUATION SYSTEM

The coefficient form of an equation system with N dependent variables $u_1, u_2, \ldots, u_N$ can be easily obtained from the general form PDE shown in Equation 16-4 using the substitutions:

$$\begin{cases} \Gamma_{lj} = -c^{lkji}\dfrac{\partial u_k}{\partial x_i} - \alpha^{lkj}u_k + \gamma^{lj} \\ F_l = f_l - \beta^{lki}\dfrac{\partial u_k}{\partial x_i} - a^{lk}u_k \end{cases}$$

Where index k and l run over dependent variables form 1 to N, while index i and j run over space dimensions from 1 to K. This means that for the case of a system of equations with N dependent variables in K space dimensions, the coefficients have the following sizes:

- e_a is an N-by-N matrix
- d_a is an N-by-N matrix
- c is an N-by-N-by-K-by-K four-dimensional array
- α is an N-by-N-by-K three-dimensional array
- β is an N-by-N-by-K three-dimensional array
- a is an N-by-N matrix
- f is an N-vector
- g is an N-vector
- q is an N-by-N matrix

System for Two Variables in the Coefficient Form

With two dependent variables u_1 and u_2, the stationary PDE problem in coefficient form results in the following equation system:

$$e_a\frac{\partial^2 u}{\partial t^2} + d_a\frac{\partial u}{\partial t} - \nabla\cdot(c\nabla u + \alpha u - \gamma) + \beta\cdot\nabla u + au = f$$

where $u = (u_1, u_2)$. The mass term is defined as

$$e_a\frac{\partial^2 u}{\partial t^2} = \begin{bmatrix} e_{a11} & e_{a12} \\ e_{a21} & e_{a22} \end{bmatrix}\begin{bmatrix} \dfrac{\partial^2 u_1}{\partial t^2} \\ \dfrac{\partial^2 u_2}{\partial t^2} \end{bmatrix} = \begin{bmatrix} e_{a11}\dfrac{\partial^2 u_1}{\partial t^2} + e_{a12}\dfrac{\partial^2 u_2}{\partial t^2} \\ e_{a21}\dfrac{\partial^2 u_1}{\partial t^2} + e_{a22}\dfrac{\partial^2 u_2}{\partial t^2} \end{bmatrix}$$

Similarly, the damping term is

$$d_a\frac{\partial u}{\partial t} = \begin{bmatrix} d_{a11} & d_{a12} \\ d_{a21} & d_{a22} \end{bmatrix}\begin{bmatrix} \dfrac{\partial u_1}{\partial t} \\ \dfrac{\partial u_2}{\partial t} \end{bmatrix} = \begin{bmatrix} d_{a11}\dfrac{\partial u_1}{\partial t} + d_{a12}\dfrac{\partial u_2}{\partial t} \\ d_{a21}\dfrac{\partial u_1}{\partial t} + d_{a22}\dfrac{\partial u_2}{\partial t} \end{bmatrix}$$

However, if $e_a = 0$, then d_a is often called the mass coefficient.

The diffusive flux is defined as

$$c\nabla u = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} \nabla \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} \begin{bmatrix} \nabla u_1 \\ \nabla u_2 \end{bmatrix} = \begin{bmatrix} c_{11}\nabla u_1 + c_{12}\nabla u_2 \\ c_{21}\nabla u_1 + c_{22}\nabla u_2 \end{bmatrix}$$

$$= \begin{bmatrix} c_{11}\begin{bmatrix} \frac{\partial u_1}{\partial x} \\ \frac{\partial u_1}{\partial y} \end{bmatrix} + c_{12}\begin{bmatrix} \frac{\partial u_2}{\partial x} \\ \frac{\partial u_2}{\partial y} \end{bmatrix} \\ c_{21}\begin{bmatrix} \frac{\partial u_1}{\partial x} \\ \frac{\partial u_1}{\partial y} \end{bmatrix} + c_{22}\begin{bmatrix} \frac{\partial u_2}{\partial x} \\ \frac{\partial u_2}{\partial y} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} c_{11}\frac{\partial u_1}{\partial x} + c_{12}\frac{\partial u_2}{\partial x} \\ c_{11}\frac{\partial u_1}{\partial y} + c_{12}\frac{\partial u_2}{\partial y} \end{bmatrix} \\ \begin{bmatrix} c_{21}\frac{\partial u_1}{\partial x} + c_{22}\frac{\partial u_2}{\partial x} \\ c_{21}\frac{\partial u_1}{\partial y} + c_{22}\frac{\partial u_2}{\partial y} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} \texttt{cu1x} \\ \texttt{cu1y} \end{bmatrix} \\ \begin{bmatrix} \texttt{cu2x} \\ \texttt{cu2y} \end{bmatrix} \end{bmatrix}$$

where ∇u_1 and ∇u_2 are column vectors. The flux matrix or flux tensor is a column vector in this presentation. For anisotropic materials, the components c_{11}, c_{12}, c_{21}, and c_{22} can be matrices as described above for the one-variable coefficient form PDE. In this case, the diffusive flux reads

$$c\nabla u = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} \begin{bmatrix} \nabla u_1 \\ \nabla u_2 \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} c_{1111} & c_{1112} \\ c_{1121} & c_{1122} \end{bmatrix} & \begin{bmatrix} c_{1211} & c_{1212} \\ c_{1221} & c_{1222} \end{bmatrix} \\ \begin{bmatrix} c_{2111} & c_{2112} \\ c_{2121} & c_{2122} \end{bmatrix} & \begin{bmatrix} c_{2211} & c_{2212} \\ c_{2221} & c_{2222} \end{bmatrix} \end{bmatrix} \begin{bmatrix} \nabla u_1 \\ \nabla u_2 \end{bmatrix}$$

$$= \begin{bmatrix} \begin{bmatrix} c_{1111} & c_{1112} \\ c_{1121} & c_{1122} \end{bmatrix} \nabla u_1 + \begin{bmatrix} c_{1211} & c_{1212} \\ c_{1221} & c_{1222} \end{bmatrix} \nabla u_2 \\ \begin{bmatrix} c_{2111} & c_{2112} \\ c_{2121} & c_{2122} \end{bmatrix} \nabla u_1 + \begin{bmatrix} c_{2211} & c_{2212} \\ c_{2221} & c_{2222} \end{bmatrix} \nabla u_2 \end{bmatrix}$$

The conservative convective flux is defined as

$$\alpha u = \alpha \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} \alpha_{11} & \alpha_{12} \\ \alpha_{21} & \alpha_{22} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} \alpha_{111} \\ \alpha_{112} \end{bmatrix} & \begin{bmatrix} \alpha_{121} \\ \alpha_{122} \end{bmatrix} \\ \begin{bmatrix} \alpha_{211} \\ \alpha_{212} \end{bmatrix} & \begin{bmatrix} \alpha_{221} \\ \alpha_{222} \end{bmatrix} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} \alpha_{111} \\ \alpha_{112} \end{bmatrix} u_1 + \begin{bmatrix} \alpha_{121} \\ \alpha_{122} \end{bmatrix} u_2 \\ \begin{bmatrix} \alpha_{211} \\ \alpha_{212} \end{bmatrix} u_1 + \begin{bmatrix} \alpha_{221} \\ \alpha_{222} \end{bmatrix} u_2 \end{bmatrix}$$

Here the third index, k, of α_{ijk} corresponds to the space coordinate suffixes `x` and `y`.

The conservative flux source is defined as

$$\gamma = \begin{bmatrix} \begin{bmatrix} \gamma_{11} \\ \gamma_{12} \end{bmatrix} \\ \begin{bmatrix} \gamma_{21} \\ \gamma_{22} \end{bmatrix} \end{bmatrix}$$

Here the second index, j, of γ_{ij} denotes the space coordinate suffixes for `x` and `y`.

For the flux terms the divergence operator works on each row separately. To illustrate this, consider the divergence of the conservative flux source

$$\nabla \cdot \gamma = \nabla \cdot \begin{bmatrix} \begin{bmatrix} \gamma_{11} \\ \gamma_{12} \end{bmatrix} \\ \begin{bmatrix} \gamma_{21} \\ \gamma_{22} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} \nabla \cdot \begin{bmatrix} \gamma_{11} \\ \gamma_{12} \end{bmatrix} \\ \nabla \cdot \begin{bmatrix} \gamma_{21} \\ \gamma_{22} \end{bmatrix} \end{bmatrix}$$

The convection term is defined as

$$\beta \cdot \nabla u = \begin{bmatrix} \beta_{11} & \beta_{12} \\ \beta_{21} & \beta_{22} \end{bmatrix} \cdot \begin{bmatrix} \nabla u_1 \\ \nabla u_2 \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} \beta_{111} \\ \beta_{112} \end{bmatrix} & \begin{bmatrix} \beta_{121} \\ \beta_{122} \end{bmatrix} \\ \begin{bmatrix} \beta_{211} \\ \beta_{212} \end{bmatrix} & \begin{bmatrix} \beta_{221} \\ \beta_{222} \end{bmatrix} \end{bmatrix} \cdot \begin{bmatrix} \nabla u_1 \\ \nabla u_2 \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} \beta_{111} \\ \beta_{112} \end{bmatrix} \cdot \nabla u_1 + \begin{bmatrix} \beta_{121} \\ \beta_{122} \end{bmatrix} \cdot \nabla u_2 \\ \begin{bmatrix} \beta_{211} \\ \beta_{212} \end{bmatrix} \cdot \nabla u_1 + \begin{bmatrix} \beta_{221} \\ \beta_{222} \end{bmatrix} \cdot \nabla u_2 \end{bmatrix}$$

The variable names for these components are `beu1` and `beu2`.

The absorption term is defined as

$$au = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} a_{11}u_1 + a_{12}u_2 \\ a_{21}u_1 + a_{22}u_2 \end{bmatrix}$$

The variable names for these components are `au1` and `au2`.

The source term is defined as

$$f = \begin{bmatrix} f_1 \\ f_2 \end{bmatrix}$$

The variable names for these components are `f1` and `f2`.

The Boundary Condition Terms

The Dirichlet boundary condition, in expanded form, reads

$$\begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} r_1 \\ r_2 \end{bmatrix}$$

If you choose the Dirichlet condition, you also get the generalized Neumann boundary condition, which reads

$$\mathbf{n} \cdot (c\nabla u + \alpha u - \gamma) + qu = g - h^T \mu$$

The normal vector $\mathbf{n} = (n_x, n_y)$ operates on the flux vector in the same way as the divergence operator as explained earlier. If h has full rank (as in the default identity matrix, for example) only the constraints from the Dirichlet condition are active.

If you choose the Neumann condition, you get only the boundary condition

$$\mathbf{n} \cdot (c\nabla u + \alpha u - \gamma) + qu = g$$

The normal component of the diffusive flux is defined as

$$\mathbf{n} \cdot c\nabla u = \mathbf{n} \cdot \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} \begin{bmatrix} \nabla u_1 \\ \nabla u_2 \end{bmatrix} = \begin{bmatrix} \mathbf{n} \cdot (c_{11}\nabla u_1 + c_{12}\nabla u_2) \\ \mathbf{n} \cdot (c_{21}\nabla u_1 + c_{22}\nabla u_2) \end{bmatrix}$$

The normal component of the conservative convective flux is defined as

$$\mathbf{n} \cdot \alpha u = \mathbf{n} \cdot \begin{bmatrix} \begin{bmatrix} \alpha_{111} \\ \alpha_{112} \end{bmatrix} u_1 + \begin{bmatrix} \alpha_{121} \\ \alpha_{122} \end{bmatrix} u_2 \\ \begin{bmatrix} \alpha_{211} \\ \alpha_{212} \end{bmatrix} u_1 + \begin{bmatrix} \alpha_{221} \\ \alpha_{222} \end{bmatrix} u_2 \end{bmatrix} = \begin{bmatrix} (n_x, n_y) \cdot \left(\begin{bmatrix} \alpha_{111} \\ \alpha_{112} \end{bmatrix} u_1 + \begin{bmatrix} \alpha_{121} \\ \alpha_{122} \end{bmatrix} u_2 \right) \\ (n_x, n_y) \cdot \left(\begin{bmatrix} \alpha_{211} \\ \alpha_{212} \end{bmatrix} u_1 + \begin{bmatrix} \alpha_{221} \\ \alpha_{222} \end{bmatrix} u_2 \right) \end{bmatrix}$$

The normal component of the conservative flux source is defined as

$$\mathbf{n} \cdot \gamma = (n_x, n_y) \cdot \begin{bmatrix} \begin{bmatrix} \gamma_{11} \\ \gamma_{12} \end{bmatrix} \\ \begin{bmatrix} \gamma_{21} \\ \gamma_{22} \end{bmatrix} \end{bmatrix} = \begin{bmatrix} (n_x, n_y) \cdot \begin{bmatrix} \gamma_{11} \\ \gamma_{12} \end{bmatrix} \\ (n_x, n_y) \cdot \begin{bmatrix} \gamma_{21} \\ \gamma_{22} \end{bmatrix} \end{bmatrix}$$

The boundary absorption term is defined as

$$qu = \begin{bmatrix} q_{11} & q_{12} \\ q_{21} & q_{22} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} q_{11}u_1 + q_{12}u_2 \\ q_{21}u_1 + q_{22}u_2 \end{bmatrix}$$

The boundary source term is defined as

$$g = \begin{bmatrix} g_1 \\ g_2 \end{bmatrix}$$

Solving Time-Dependent Problems

The general form equation shown in Equation 16-1, as well as the coefficient form equation in Equation 16-2, contain time-derivative terms of the same form. When the interface's **Equation form** is set to **Time domain**, these time derivative terms are ignored outside of the Time-Dependent Solver or the Eigenvalue Solver. When solving a Stationary or similar study step, the solvers assume that all time derivatives are zero, so the values of the e_a and d_a coefficients do not matter. Regarding the interpretation of time derivatives for other equation forms, see Interpretation of Time Derivatives.

To activate the d_a and e_a coefficients and convert the model into a time-dependent model, select a Time Dependent study.

When solving a Time Dependent study step, the *mass coefficient*, e_a, becomes important. The name mass coefficient, or *mass matrix* in case of a system of equations, stems from the fact that in many physics applications, e_a contains the mass density. The d_a coefficient in such equations usually represents damping of wave-like phenomena. However, if $e_a = 0$, then d_a is often called the mass coefficient instead. The default settings are $e_a = 0$ and $d_a = 1$, representing a parabolic time-dependent PDE such as the heat equation. Using $e_a = 1$ and $d_a = 0$ represents an undamped wave equation.

When solving a Time Dependent study step, the time variable is called `t` and can be used anywhere in equation coefficients. For other study steps, `t` is undefined. If you want to solve a model that depends explicitly on time using a Stationary study, you must first define a model parameter called `t` and give it a suitable value.

If, for a system of equations, the e_a matrix is nonzero and singular, or if $e_a = 0$ and d_a is singular, the system becomes a *differential-algebraic equation* (DAE) system. The COMSOL Multiphysics solvers for time-dependent problems handle DAEs.

Time-Dependent Solver

USING MIXED SPACE-TIME DERIVATIVES

The coefficient forms in equation Equation 16-2 only contain coefficients for pure space and time derivatives up to second order. The only directly available time-derivative coefficients are therefore e_a and d_a, using the subscript a because they are similar to the a coefficient in the absorption term, except that they multiply $\partial^2 u/\partial t^2$ and $\partial u/\partial t$ instead of u. In analogy, it is possible to define coefficients e_c, $\mathbf{e}_\alpha$, $\mathbf{e}_\beta$ and d_c, $\mathbf{d}_\alpha$, $\mathbf{d}_\beta$ for mixed space-time derivatives, such that the equation becomes instead

$$e_a\frac{\partial^2 u}{\partial t^2} + \nabla\cdot\left(-e_c\nabla\frac{d^2 u}{dt^2} - \mathbf{e}_\alpha\frac{d^2 u}{dt^2}\right) + \mathbf{e}_\beta\cdot\nabla\frac{d^2 u}{dt^2} +$$
$$d_a\frac{\partial u}{\partial t} + \nabla\cdot\left(-d_c\nabla\frac{\partial u}{\partial t} - \mathbf{d}_\alpha\frac{\partial u}{\partial t}\right) + \mathbf{d}_\beta\cdot\nabla\frac{\partial u}{\partial t} + \nabla\cdot(-c\nabla u + \ldots) = \ldots$$

These mixed coefficients are not directly available in the general or coefficient form PDE models. Instead, enter them in the existing γ and f terms:

In 1D, add `-d_c*uxt-d_al*ut` to the γ term, and add `-d_be*uxt` to the f term, and similarly for second-order derivatives.

In 2D, add `-d_c*uxt-d_al1*ut` to the first γ component, and add `-d_c*uyt-d_al2*ut` to the second γ component. Add `-d_be1*uxt-d_be2*uyt` to the f term, and similarly for second-order derivatives.

USING TIME DERIVATIVES IN BOUNDARY CONDITIONS

To specify a flux or source boundary condition containing time-derivative terms as in

$$\mathbf{n}\cdot(c\nabla u + \ldots) = g - e_q\frac{\partial^2 u}{\partial t^2} - d_q\frac{\partial u}{\partial t} - qu + h^T\mu\,,$$

simply add the terms `-e_q*utt-d_q*ut` to the g term, and provide appropriate values or expressions for the coefficients e_q and d_q in, for example, a Global Equations Settings window.

!	Constraints and Dirichlet boundary conditions must not contain time derivatives like `ut` and `utt` in the R and r coefficients unless they are enforced weakly, using weak constraints. See Boundary Conditions.

Solving Eigenvalue Problems

THE EIGENVALUE PDE

When solving a PDE using an Eigenvalue study step, COMSOL Multiphysics assumes that all dependent variables vary with time as $u(t) = \hat{u}e^{-\lambda t}$, where $\hat{u}$ is a complex amplitude field. Therefore the time derivatives in Equation 16-1 and Equation 16-2 are interpreted as

$$\frac{\partial u}{\partial t} = -\lambda\hat{u}$$
$$\frac{\partial^2 u}{\partial t^2} = \lambda^2\hat{u}$$

which, for example, leads to the general form eigenvalue PDE

$$\begin{cases} \lambda^2\hat{u} - \lambda\hat{u} + \nabla\cdot\Gamma = f & \text{in}\,\Omega \\ -\mathbf{n}\cdot\Gamma = g - q\hat{u} + h^T\hat{\mu} & \text{on}\ \partial\Omega \\ 0 = R & \text{on}\ \partial\Omega_c \\ \hat{u} = r & \text{on}\ \partial\Omega_d \end{cases}$$

The eigenvalue solver further ignores any source or flux terms that are independent of the dependent variables.

BOUNDARY CONDITIONS IN EIGENVALUE PROBLEMS

Boundary conditions are treated as homogeneous for eigenvalue and eigenfrequency studies. It means, for example, that when using a Dirichlet boundary condition such as $u = 7$, it is treated as $u = 0$ when you use eigenvalue or eigenfrequency study steps. For nonlinear problems, the eigenvalue solver is linearizing the problem, including the constraints, around a linearization point for the dependent variables and an eigenvalue linearization point. For a nonlinear constraint (for u),

$$f(u) = 0$$

the constraint

$$f_u(u_0)\cdot u = 0$$

is used when you run eigenvalue or eigenfrequency study steps. The eigenvalue itself is not supported in constraints.

THE EIGENVALUES AND THE LAMBDA VARIABLE

As an alternative to defining eigenvalue PDEs using the time-derivative coefficients e_a and d_a, you can write the eigenvalue explicitly in the equations using the variable name `lambda`. For example, instead of specifying $e_a = 1$,

you can set a = `lambda^2` with exactly the same result. In many cases, this formulation is preferable, in particular when the eigenvalue problem does not arise from a time derivative in a time-harmonic assumption.

After solving an eigenvalue problem, the eigenvalue is always available for postprocessing under the variable name `lambda`, independently of whether the problem has been specified using the e_a and d_a coefficients or using the variable `lambda`.

Eigenfrequency studies are exactly analogous to Eigenvalue studies except that they also define the variable `freq` using the definition `freq` = $i\lambda/(2\pi)$. The variable name `freq` may be used in equations and postprocessing in the same way as `lambda`.

The eigenvalue solvers solve eigenvalue problems that are at most quadratic polynomials in the eigenvalue `lambda` exactly in one step. Therefore, damped eigenvalue solutions are easily found when both e_a and d_a are nonzero. Using the variable `lambda`, more complicated eigenvalue problems can be specified. Such problems must be solved using an iterative procedure.

Each time you run the eigenvalue solver, the PDE is expanded in a Taylor series in `lambda` around the eigenvalue linearization point λ_0. Only the linear and quadratic terms are retained, while higher order terms are dropped. Running the solver repeatedly, updating the eigenvalue linearization point to the last eigenvalue found, usually converges to an eigenvalue solving the full nonlinear eigenvalue problem.

Eigenvalue Solver and Eigenvalue.

About Weak Form Modeling

Do not be misled by the term “weak”; the weak form is very powerful and flexible. The term *weak form* is borrowed from mathematics, but in this context it has a slightly different meaning; this implementation incorporates capabilities in addition to those defined in the mathematical weak form. Moreover, knowledge of the mathematical weak form is not a prerequisite to using the COMSOL Multiphysics implementation.

The distinguishing characteristics of the weak form in COMSOL Multiphysics are that it makes it possible to:

- Enter certain equations that can be derived from an energy principle in a very compact and convenient form. Such equations arise in structural mechanics, for example.
- Add and modify nonstandard constraints, such as various contact and friction models.
- Build models with extra equations on boundaries, edges, and points.
- Use the *test operator* to conveniently work with problems in variational calculus and parametric optimization. For more information about the test operator and other operators, see Operators, Functions, and Constants.

All physics interfaces are implemented as weak form equations, which you can study and modify in the Equation View nodes. COMSOL Multiphysics also converts all equation-based models specified in The Coefficient Form PDE Interfaces and The General Form PDE Interfaces to the weak form before solving.

In addition, it is possible to add extra weak form contributions and auxiliary variables to any physics interface.

Introduction to the Weak Form

The general form and coefficient form PDEs in equations Equation 16-1 and Equation 16-2 specify PDEs in a *strong form*, in the sense that they, in principle, require the PDE to be satisfied at every point in the geometry. And for this to be possible, all terms must be sufficiently continuous for derivatives and well-defined pointwise values to exist. In many cases, the natural phenomena a PDE intends to model are best described as discontinuous and may also contain source terms that are only defined as a total over a small region, without well-defined pointwise values.

In these situations, a weak equation turns out to be a better model of the physics than can be provided by the more commonly used strong form PDEs. In addition, the weak form is particularly suitable for discretization and numerical solution using the finite element method. One reason for this is precisely the lower continuity requirement on the solution, which only needs to be sufficiently smooth on each mesh element separately.

EXAMPLE: CONVERSION FROM GENERAL FORM TO WEAK FORM

As an example, consider the general form presented in Equation 16-1, in particular the stationary form of the domain equation:

$$\nabla \cdot \Gamma = f$$

Assuming a single dependent variable u, introduce a corresponding arbitrary *test function* υ. Multiply the equation by this test function and integrate over the domain:

$$\int_\Omega \upsilon \nabla \cdot \Gamma dV = \int_\Omega \upsilon f dV \tag{16-5}$$

This integral equation is clearly a weaker statement than the original equation, in particular when Equation 16-5 is required to hold only for all test functions υ from a limited class of functions. In the finite element method, the test functions υ (and also solution u) are usually limited to the set of piecewise polynomials of a given order on each mesh element.

This polynomial can also be written as a sum of individual *shape functions*. Therefore, the original strong form PDE is transformed into a weak form equation, which must only be satisfied in a local integral sense over each shape function. When you increase the number of shape functions by refining the mesh or increasing the polynomial order, you simultaneously decrease the space of solutions u that can possibly satisfy Equation 16-5. Therefore, well-posed and consistent finite element formulations converge toward the single solution u that satisfies the original strong form PDE.

To further simplify the solution of Equation 16-5, the left-hand side integral can be integrated by parts, using Gauss law:

$$-\int_\Omega \nabla \upsilon \cdot \Gamma dV + \int_{\delta\Omega} \upsilon \mathbf{n} \cdot \Gamma dA = \int_\Omega \upsilon f dV \tag{16-6}$$

This has two main advantages. First of all, it reduces the maximum order of spatial derivatives. If Γ is a function of the gradient of u, for example $\Gamma = -c\nabla u - \alpha u + \gamma$ as in the coefficient form PDE, the transformed weak equation now contains only first-order derivatives compared to second-order derivatives in the original strong form PDE.

Secondly, it makes it clear what the *natural boundary condition* is for this equation. The second integral on the left-hand side disappears if the normal component of Γ vanishes on the boundary. Alternately, if the value of the normal component is known, for example such that

$$-\mathbf{n} \cdot \Gamma = g - qu + h^T \mu \tag{16-7}$$

on δΩ, this value can be inserted as a boundary condition into the weak form equation, which then becomes

$$-\int_{\Omega} \nabla \upsilon \cdot \Gamma dV = \int_{\Omega} \upsilon f dV + \int_{\delta\Omega} \upsilon G dA \tag{16-8}$$

This final weak formulation of the standard general form PDE therefore also explains why the Neumann boundary condition on the second line of Equation 16-1 looks the way it does.

The Weak Form PDE

The Weak Form PDE provides a general interface for specifying and solving PDEs in the weak form.

The weak form does not define any coefficients and does not even separate the different equations in a system of equations. When specifying a PDE and its boundary conditions in the weak form, you specify contributions to a generic weak-form equation, which for a 3D model reads:

$$0 = \sum_{i=1}^{N_3} \int_{\Omega_i} W^i_3 dV_i + \sum_{j=1}^{N_2} \int_{\delta\Omega_j} W^j_2 dA_j + \sum_{k=1}^{N_1} \int_{\delta^2\Omega_k} W^k_1 dL_k + \sum_{m=1}^{N_0} \sum_{\delta^3\Omega_m} W^m_0 \tag{16-9}$$

This weak equation has

- N_3 domain contributions $W^i{}_3$, each integrated over domain selection Ω_i
- N_2 boundary contributions $W^j{}_2$, each integrated over boundary selection $\delta\Omega_j$
- N_1 edge contributions $W^k{}_1$, each integrated over edge selection $\delta^2\Omega_k$
- N_0 point contributions $W^m{}_0$, each summed over point selection $\delta^3\Omega_m$

To specify Equation 16-8, in 3D, identify $N_3 = N_2 = 1$, $N_1 = N_0 = 0$, $W^1{}_3 = \nabla\upsilon\cdot\Gamma + \upsilon f$, and $W^1{}_{2=} = \upsilon G$, and get

$$0 = \int_{\Omega_1} (\nabla \upsilon \cdot \Gamma + \upsilon f) dV_1 + \int_{\delta\Omega_1} \upsilon G dA_1 \tag{16-10}$$

Note that all contributions are summed into the same integral equation without any particular order. Therefore, whether you write two equations in separate contributions or sum them into one single contribution normally does not matter. There is, however, a small caveat: the indices on dV_i, dA_j, and dL_k indicate that each contribution may be integrated in a different way. The integration can be performed with respect to either material or spatial coordinates and, in addition, using different numerical quadrature orders. But while working inside a single PDE interface, all contributions are integrated in the same way.

USING THE TEST OPERATOR

When specifying a weak contribution, you may use all variables normally available for evaluation in equation contributions and during postprocessing. This includes independent variables (coordinates), dependent variables

and their derivatives, and other predefined and user-defined variables, parameters, and constants. In addition, you must use the `test` operator to distinguish between test functions and the solution.

The `test` operator must always occur linearly in each weak form contribution. Contributions or terms without any `test` operator are ignored, while terms nonlinear in the test operator are considered an error.

In many cases, it is sufficient to let the test operator act directly on the dependent variables and their derivatives. For example, the weak form of Equation 16-10 in two dimensions is

```
test(u)*f+(Gammax*test(ux)+Gammay*test(uy))
```

on the domain level, and

```
test(u)*G
```

on the boundary level. `Gammax` and `Gammay` are variables representing the components of Γ, and `f` and `G` are variables representing f and G, respectively.

In some cases, it is more convenient to insert an expression or user-defined variable into the test function. One example of this is geometrically nonlinear solid mechanics, where the weak form can be written as a sum of terms `S_i*test(E_i)`, where `S_i` is a stress measure and `E_i` its conjugate strain measure.

When a nonlinear expression — for example, a Green–Lagrange strain — is inserted into the `test` operator, the operator acts as a linear differential operator. This means that the argument expression is effectively first differentiated with respect to each dependent variable it contains, and the results are then multiplied by the test function of the corresponding variable. Therefore, the heat equation may alternately be implemented as `q*test(u)-0.5*k*test(ux^2+uy^2)`. Using the chain rule on the second term with the `test` operator as the differential operator returns the standard weak form of the equation given above.

In another example, $\text{test}(F(u, \nabla u))$, the `test` operator is equivalent to:

$$\sum_i \text{test}(u_i)\frac{\partial}{\partial u_i}F(u_i, \nabla u_i) + \text{test}(\nabla u_i)\frac{\partial}{\partial \nabla u_i}F(u_i, \nabla u_i)$$

for all dependent variables u_i.

For more information about the test operator and other operators, see Operators, Functions, and Constants.

Specifying and Interpreting Boundary Conditions

The formulation of the boundary conditions in general form (Equation 16-1) and coefficient form (Equation 16-2) imposes both Dirichlet and Neumann conditions at the same time:

$$\begin{cases} -\mathbf{n}\cdot\Gamma = g - qu - h^T\mu & \text{on } \partial\Omega \\ 0 = R & \text{on } \partial\Omega_c \\ u = r & \text{on } \partial\Omega_d \end{cases}$$

where Γ is the *flux vector* ($\Gamma = -c\nabla u - \alpha u + \gamma$ for a coefficient form equation) and $\delta\Omega_c$ and $\delta\Omega_d$ are parts of the overall boundary, $\delta\Omega$, where general constraints and Dirichlet conditions have been specified. Combining conditions of

different types on the same boundary is possible because of a new dependent variable μ, which is defined only on the boundary. This unknown variable μ is called a *Lagrange multiplier* and usually has a physical interpretation. For example, in structural mechanics problems, the Lagrange multiplier equals the reaction forces on the boundary.

The factor h^T in the Neumann boundary condition is the *constraint force Jacobian*. It decides how the Lagrange multipliers enforcing the constraint are scaled and distributed over the equations. The default settings in a Constraint node use

$$h^T = -\left(\frac{dR}{du}\right)^T$$

while a Dirichlet Boundary Condition node by default corresponds to $h^T = -1$. For example:

- The Dirichlet condition is $u = r$ and the default constraint settings imply $h^T = -1$. The Neumann condition becomes:

  $$-\mathbf{n} \cdot \Gamma = g - qu + \mu$$

  The Lagrange multiplier, μ, adjusts so as to satisfy the requested Dirichlet condition. Specifying a nonzero g changes the value of the Lagrange multiplier on the same boundary but does not affect the actual solution u. Therefore, this equation can usually be ignored, leaving effectively a pure Dirichlet condition.
- When no constraint is applied on a boundary, the value of R is zero, or equivalently, the Dirichlet condition reads $0 = 0$. Therefore h^T is zero and the Neumann condition is:

  $$-\mathbf{n} \cdot \Gamma = g - qu$$

  This is the generalized Neumann condition without a Lagrange multiplier.

- Boundary Condition Types
- The PDE Interfaces

EXAMPLE: SYSTEM OF TWO VARIABLES IN THE GENERAL FORM

The following example demonstrates a number of possible boundary condition combinations for a stationary system with two dependent variables u_1 and u_2 and two constraints when reaction terms are applied symmetrically on all physics. This is the default, and most useful, implementation. Written in general form:

$$\begin{cases} \nabla \cdot \Gamma_1 = F_1 & \text{in } \Omega \\ \nabla \cdot \Gamma_2 = F_2 & \text{in } \Omega \end{cases}$$

with the default Neumann boundary conditions

$$\begin{cases} -\mathbf{n} \cdot \Gamma_1 = G_1 + \dfrac{\partial R_1}{\partial u_1}\mu_1 + \dfrac{\partial R_2}{\partial u_1}\mu_2 & \text{on } \partial\Omega \\ -\mathbf{n} \cdot \Gamma_2 = G_2 + \dfrac{\partial R_1}{\partial u_2}\mu_1 + \dfrac{\partial R_2}{\partial u_2}\mu_2 & \text{on } \partial\Omega \end{cases}$$

writing out the symmetric application of reaction terms on all dependent variables, and the Dirichlet boundary conditions:

$$\begin{cases} 0 = R_1 & \text{on } \partial\Omega \\ 0 = R_2 & \text{on } \partial\Omega \end{cases}$$

The same set of boundary conditions are accessible in all PDE interfaces. To illustrate the flexibility of the Constraint boundary condition $R = 0$, consider these cases:

Case 1: Let $R_1 = R_2 = 0$. Then the Dirichlet boundary conditions give $0 = 0$. In addition, the terms containing the Lagrange multipliers disappear from the Neumann boundary condition. Thus you have only the Neumann boundary conditions:

$$\begin{cases} -\mathbf{n} \cdot \Gamma_1 = G_1 & \text{on } \partial\Omega \\ -\mathbf{n} \cdot \Gamma_2 = G_2 & \text{on } \partial\Omega \end{cases}$$

Case 2: Let $R_1 = r_1 - u_1$ and $R_2 = r_2 - u_2$. Then the Dirichlet conditions are the usual $u_1 = r_1$ and $u_2 = r_2$. Using default settings for the constraint reaction terms,

$$h = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

and the Neumann boundary conditions become:

$$\begin{cases} -\mathbf{n} \cdot \Gamma_1 = G_1 - \mu_1 & \text{on } \partial\Omega \\ -\mathbf{n} \cdot \Gamma_2 = G_2 - \mu_2 & \text{on } \partial\Omega \end{cases}$$

These last equations impose no restrictions on u_1 or u_2, because the Lagrange multipliers μ_1 and μ_2 always adjust so as to fulfill the Dirichlet conditions. In this case, ignore the Neumann boundary conditions.

Case 3: Let $R_1 = r_1 - u_1$ and $R_2 = 0$. Then the Dirichlet conditions are

$$\begin{cases} 0 = r_1 - u_1 & \text{on } \partial\Omega \\ 0 = 0 & \text{on } \partial\Omega \end{cases}$$

and the default Neumann conditions including reaction terms are:

$$\begin{cases} -\mathbf{n} \cdot \Gamma_1 = G_1 - \mu_1 & \text{on } \partial\Omega \\ -\mathbf{n} \cdot \Gamma_2 = G_2 & \text{on } \partial\Omega \end{cases}$$

The first Neumann condition can be ignored because it imposes no restriction on u_1 or u_2. You effectively have only the Dirichlet condition on u_1 together with the second Neumann condition.

Case 4: The same as Case 3 but with the two PDEs interchanged (Γ_1 and Γ_2 as well as F_1 and F_2). Then the PDEs are:

$$\begin{cases} \nabla \cdot \Gamma_2 = F_2 & \text{in } \Omega \\ \nabla \cdot \Gamma_1 = F_1 & \text{in } \Omega \end{cases}$$

The Dirichlet condition is similar to that in Case 3: $u_1 = r_1$. By default, the Neumann conditions then become:

$$\begin{cases} -\mathbf{n} \cdot \Gamma_2 = G_2 - \mu_1 & \text{on } \partial\Omega \\ -\mathbf{n} \cdot \Gamma_1 = G_1 & \text{on } \partial\Omega \end{cases}$$

Effectively, you have only the Neumann condition $-\mathbf{n} \cdot \Gamma_1 = G_1$. In comparison with Case 3, the PDEs and the Dirichlet conditions are identical, while the Neumann conditions are different. Both the Dirichlet and the Neumann conditions are now applied on u_1, and nothing is specified for u_2.

This example shows that when mixing Dirichlet and Neumann conditions on Coefficient Form PDEs and General Form PDEs, the ordering of the equations and the dependent variables are important. However, the ordering of the Dirichlet conditions does not matter because the different Lagrange multipliers are for all practical purposes indistinguishable from each other.

Case 5: Finally, let $R_1 = u_2 - u_1$ and $R_2 = 0$. Also, assume that u_1 and u_2 exist on two adjacent domains rather than on the same domain. The normal vectors as seen from the two sides are then $\mathbf{n}_1 = -\mathbf{n}_2 = \mathbf{n}$. Then the Dirichlet conditions are:

$$\begin{cases} 0 = u_2 - u_1 & \text{on } \partial\Omega \\ 0 = 0 & \text{on } \partial\Omega \end{cases}$$

and the Neumann conditions using the default symmetric reaction terms are:

$$\begin{cases} -\mathbf{n}_1 \cdot \Gamma_1 = G_1 - \mu_1 & \text{on } \partial\Omega \\ -\mathbf{n}_2 \cdot \Gamma_2 = G_2 + \mu_1 & \text{on } \partial\Omega \end{cases}$$

The same Lagrange multiplier now appears in both Neumann conditions, which can have different definitions of Γ and G. Therefore, contrary to Cases 2 and 3, the Neumann conditions cannot be ignored. Instead, adding the two conditions, it becomes apparent that the solution and flux on the boundary must fulfill:

$$\begin{cases} 0 = u_2 - u_1 & \text{on } \partial\Omega \\ -\mathbf{n}_1 \cdot \Gamma_1 - \mathbf{n}_2 \cdot \Gamma_2 = G_1 + G_2 & \text{on } \partial\Omega \end{cases}$$

In particular, if $G_1 = G_2 = 0$, the last condition simplifies to:

$$-\mathbf{n} \cdot (\Gamma_1 - \Gamma_2) = 0 \text{ on } \partial\Omega$$

This means that both the variables u_1 and u_2 and the corresponding fluxes are equal at the boundary. If u_1 and u_2 represent the same quantity, this is the same continuity condition that holds implicitly at every mesh element boundary in the model, where nothing else has been specified.

In all of these examples, the values of the Lagrange multipliers do not matter. However, they often have a physical significance. In structural mechanics, the term $h^{\mathrm{T}}\mu$ in the Neumann condition is the reaction force necessary to satisfy the kinematic constraints described by the Dirichlet conditions.

Symmetric and Nonsymmetric Constraints

Constraints formulated through the coefficient R in The Coefficient Form PDE Interfaces and The General Form PDE Interfaces by default give rise to *globally symmetric bidirectional* constraints. This happens when the constraint settings specify that reaction terms are to be applied symmetrically on all physics.

A bidirectional symmetric constraint dictates exactly how the flux conditions (or Neumann boundary conditions) are influenced by the constraint force. For the coefficient form, the flux condition is

$$\mathbf{n} \cdot (c\nabla u + \alpha u - \gamma) = g - qu - \left(\frac{\partial R}{\partial u}\right)^T \mu$$

and for the general form, the flux condition is

$$-\mathbf{n} \cdot \Gamma = g - qu - \left(\frac{\partial R}{\partial u}\right)^T \mu$$

The last term on the right-hand side in both expressions is the globally symmetric constraint reaction term, or *generalized constraint force*. Thus, with symmetric constraints, a flux condition cannot be enforced independently of the constraints.

In mathematics, as well as in multiphysics modeling, it is often necessary to enforce Neumann conditions and Dirichlet conditions more freely than what is possible through symmetric constraints. As an example, consider the general form and assume that you want to enforce the boundary conditions:

$$\begin{cases} 0 = r_1 - u_1 & \text{on } \partial\Omega \\ -\mathbf{n} \cdot \Gamma_2 = G_2 & \text{on } \partial\Omega \end{cases}$$

If $r_1 = r_1(u_2)$, the first condition is fulfilled but not the second if the default reaction term definition is used. This is because the globally symmetric constraint force is not zero:

$$-\mathbf{n} \cdot \Gamma_2 = G_2 + \frac{\partial R_1}{\partial u_2}\mu_1 + \frac{\partial R_2}{\partial u_2}\mu_2 = G_2 + \frac{\partial r_1}{\partial u_2}\mu_1 \neq G_2$$

To remedy this limitation with bidirectional constraints, the **Constraint Settings** section allows you to **Apply reaction terms on** either dependent variables from **Current physics (internally symmetric)** or **Individual dependent variables**.

Both options imply a unidirectional and possibly nonsymmetric constraint in the sense that some dependent variables are considered as constants for the purpose of enforcing the constraint.

To display the **Constraint Settings** section in Constraint nodes, click the **Show More Options** button ( ) on the **Model Builder** toolbar and select **Advanced Physics Options** in the **Show More Options** dialog.

When constraint reaction terms are applied only on the current physics, flux conditions in other interfaces are left untouched by the constraint. If reaction terms are applied only to individual variables, this leaves flux conditions untouched on all but the specific variables. For the above example, both settings have the same desired effect if u_1 and u_2 belong to different interfaces. If these belong to the same interface, applying reaction terms to **Current physics (internally symmetric)** has the same effect as the default application to **All physics (symmetric)**.

In multiphysics modeling, unidirectional constraints are, for example, necessary for the following boundary conditions:

- Normal-direction constraints on a moving mesh, where the mesh motion is part of the problem. These conditions are of the type $\mathbf{n} \cdot \mathbf{u} - r = 0$ where $\mathbf{n} = \mathbf{n}(\mathbf{x})$ is the boundary normal, $\mathbf{u}$ is a vector field (displacements or velocity), and $\mathbf{x}$ is the mesh coordinate vector. Symmetric constraints give constraint forces not only on the equations for $\mathbf{u}$ but also on the equations for $\mathbf{x}$, which typically are not wanted.
- Constraints on time derivatives, such as

  $$\frac{\partial u}{\partial t} = 1$$

  on the boundary (typing `1-ut` using COMSOL syntax for R in the constraint $R = 0$). The default bidirectional symmetric constraint attempts to apply the test function on the time derivative of u, which is not supported. The solution is to apply the reaction terms on **Individual dependent variables**. Note that the constraint must also be a weak constraint because pointwise constraints for time derivatives are not supported.
- Wall boundary conditions for turbulent fluid flow. For the k-ε turbulence model, this condition is of the type $k - r(\varepsilon), -\mathbf{n} \cdot \nabla\varepsilon$, where r is a given function. Bidirectional constraints for the first relation imply that the second relation cannot hold.

Unidirectional constraints can be enforced both in a pointwise sense and in a weak sense.

Turbulent fluid flow requires the CFD Module or Heat Transfer Module.

For descriptions about how to use even more general pointwise and weak nonsymmetric constraints, see Pointwise Constraint and Weak Constraint, respectively. Also see Boundary Condition Types.

The PDE Interfaces

COMSOL Multiphysics includes different PDE interfaces for equation-based modeling, distinguished by the equation formulation used for entering the equations: Coefficient Form, General Form, and Weak Form. The interfaces are identical except for the default node added to the top geometric entity level where the interface is active. You can still use a General Form to specify equations in a Coefficient Form PDE interface, or add Weak Form contributions to a General Form PDE interface.

About Auxiliary Equation-Based Nodes and The PDE, Boundary Elements Interface are also available and described in other sections.

- Modeling with PDEs
- Notational Conventions

Adding a PDE Interface to a Component

To add a new Component and use one of the equation interfaces, start with the instructions in Creating a New Model. Then, when you are adding the physics, expand the **Mathematics** > **PDE Interfaces** node in the list of physics interfaces and select one of the PDE interfaces in the list. For PDEs on geometric entities other than domains, expand the **Lower Dimensions** node.

SPECIFYING A SYSTEM OF EQUATIONS

COMSOL Multiphysics allows the creation of equations with more than one dependent variable. To do this, on the **Add Physics** page under **Dependent variables**, enter the **Number of dependent variables** in the field. The COMSOL software then automatically assigns variable names, typically `u1`, `u2`, `u3`, and so on. You can also edit the default variable name (as long as it is valid and unique) in the **Dependent variables** table. Several scalar PDEs can also be coupled using a multiphysics approach.

For any form of PDE interface you add to a Component, additional equation nodes can be added in Coefficient Form, General Form, or Weak Form.

MODELING WITH PDES ON BOUNDARIES, EDGES, AND POINTS

The Coefficient Form PDE, General Form PDE, and Weak Form PDE are also available on boundaries, edges, and at points in the geometry.

Extra weak equations can be added by adding auxiliary dependent variables to a Weak Contribution (PDEs and Physics) node. Use such weak form equations as a way to handle thin layers; COMSOL then solves the problem by modeling rather than meshing. This approach reduces the solution time.

See *Transport and Adsorption* (Application Library path **COMSOL_Multiphysics/Chemical_Engineering/transport_and_adsorption**) to learn how to use a General Form Boundary PDE interface to model a thin adsorption layer with diffusion as a PDE on the boundary of a convection–diffusion problem.

See *Rock Fracture Flow* (Application Library path **COMSOL_Multiphysics/Geophysics/rock_fracture_flow**) to learn how to use a Coefficient Form Boundary PDE interface to solve the Reynolds equation on a boundary in a 3D model.

See *Shell Diffusion in a Tank* (Application Library path **COMSOL_Multiphysics/Equation_Based/shell_diffusion**) for an example of tangential derivative variables.

- Modeling with PDEs
- Notational Conventions
- The PDE Interfaces

Settings for the Discretization Sections

There are two categories of discretization — a section on the physics interface node's **Settings** window (described here) and adding a Discretization (Node) for global equation-based modeling. To enable the other settings beyond the element order and shape function type and to be able to add separate **Discretization** nodes, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

The settings described here are:

- Element Order and Shape Function Type
- Discretization of Fluids
- Accurate Boundary Fluxes
- Splitting Complex-Valued Variables
- Element Order and Shape Function Type

ELEMENT ORDER AND SHAPE FUNCTION TYPE

The PDE and weak form interfaces have different shape functions available with a varying choice of associated element orders (the order of the shape functions) depending on the shape function type. The element order (or, more precisely, the order of the shape function) directly affects the number of degrees of freedom in the solution and the accuracy of the solution. Increasing the order of the elements roughly corresponds to a uniform mesh refinement. Most physics interfaces use Lagrange elements, which can be of order 1 to 5 (or 1 to 7 for the PDE and weak form interfaces), with 2 being the default order in most cases. Where serendipity elements are available (in the mathematics interfaces and the Solid Mechanics interface, for example, for element orders 2, 3, and, in some cases, 4), they can be more efficient than Lagrange elements of the same order (in terms of number of degrees of freedom and the solution time) for some mesh element types (especially hexahedral meshes), but they can also be more sensitive to distorted mesh elements.

The software adapts the order of the numerical integration to the element orders for the physics in the model. Some physics interfaces use special element types or a reduced element order for some of the field variables. Select the

Shape function type and the **Element order** as, in most cases, **Linear**, **Quadratic**, **Cubic**, **Quartic**, or **Quintic** (for order 1–5, respectively).

Table 16-2 is an overview of the available shape function types and the element orders supported.

Not all shape functions are available for all space dimensions and types of equations, and not all shape functions support all orders.

TABLE 16-2: SHAPE FUNCTION TYPES.

NAME	ORDER	COMMENTS
Lagrange	1–5 or 1–7. Default: 2	The default type.
Hermite	3–7. Default: 3	
Argyris	Order 5 only.	2D only.
Discontinuous Lagrange	0–7. Default: 2	
Nodal discontinuous Lagrange	1–10 (1D and 2D); 1–7 (3D). Default: 2	Special shape functions for wave equations.
Discontinuous scalar density	0–7. Default: 2	Not available on boundaries, edges, or points.
Bubble	2 (1D); 3 (2D); 4 (3D)	Lower order on boundaries, edges, and points.
Gauss-point data	0, 2, 4, 6, 8, 10, 12, or 14. Default: 4	Discrete values associated with the quadrature points in an integration rule of the given order.
Hierarchical	1–10 (1D and 2D); 1–7 (3D). Default: 2	Hierarchical shape functions.
Nodal serendipity	2–4	In the Solid Mechanics interface, order 2 and 3 are available as Quadratic serendipity and Cubic serendipity, respectively.
Hierarchical serendipity	1–10 (1D and 2D); 1–7 (3D). Default: 2	Hierarchical serendipity shape functions.
Crouzeix–Raviart	1	Linear shape function for solving stationary Stokes equations, for example.
Divergence	1–7. Default: 2	For vector fields only (1, 2, and 3 dependent variables in 1D, 2D, and 3D, respectively).
Divergence type 2	1–7. Default: 2	For vector fields only (1, 2, and 3 dependent variables in 1D, 2D, and 3D, respectively). Available for simplex mesh elements only.
Curl	1–7. Default: 2	For vector fields only (1, 2, and 3 dependent variables in 1D, 2D, and 3D, respectively).
Curl type 2	1–7. Default: 2	For vector fields only (1, 2, and 3 dependent variables in 1D, 2D, and 3D, respectively). Available for simplex mesh elements only.

Additional information is included in Elements and Shape Functions chapter in this manual and in Elements and Shape Function Programming in the *COMSOL Multiphysics Programming Reference Manual*.

DISCRETIZATION OF FLUIDS

The following is an example of the choices of element order for Fluid Flow interfaces:

- **P1+P1** means linear elements for both the velocity components and the pressure field. Linear elements are computationally cheaper than higher-order elements and are also less prone to introducing spurious oscillations, thereby improving the numerical robustness. In other words, this can be computationally efficient but requires

streamline stabilization of the Navier–Stokes equations. This is the default element order for the Laminar Flow and Turbulent Flow single-phase flow interfaces and the discretization of fluids in the multiphase flow interfaces.

- **P2+P1** means second-order elements for the velocity components and linear elements for the pressure field. Second-order elements work well for low flow velocities. This is the default element order for the Creeping Flow interface.
- **P3+P2** means third-order elements for the velocity components and second-order elements for the pressure field. This can add additional accuracy but it also adds additional degrees of freedom compared to P2+P1 elements.

The abbreviation P_mP_n is often used to indicate the polynomial order of, in this case, the shape functions (elements) for the velocity components (m) and the pressure (n) when using tetrahedral or triangular elements. Here a corresponding nomenclature is used for all element shapes.

The theory about this is in P.M. Gresho and R.L. Sani, *Incompressible Flow and the Finite Element Method, Volume 2: Isothermal Laminar Flow*, John Wiley & Sons, 2000.

The discretization of the temperature field follows that of the fluid's velocity components, so the temperature order is 1 for **P1+P1**, 2 for **P2+P1**, and 3 for **P3+P2**.

- Numerical Stabilization

ACCURATE BOUNDARY FLUXES

Some physics can create and compute variables that accurately represent the flux across all boundaries. To enable these variables, select the **Compute boundary fluxes** checkbox. Optionally, the smoothing can provide a more well-behaved flux value close to singularities. You add smoothing by selecting the **Apply smoothing to boundary fluxes** checkbox.

Computing Accurate Fluxes

SPLITTING COMPLEX-VALUED VARIABLES

From the **Value type when using splitting of complex variables** list, you can specify the value type (**Real** or **Complex**) of dependent variables when the **Split complex variables in real and imaginary parts** setting is activated in the **Compile Equations** node of any solver sequence used. The default is the complex value type, but you can specify that the value of a dependent variable is real to make sure that it does not get affected by small imaginary contributions, which can occur, for example, when combining a Time Dependent or Stationary study with a frequency-domain study. If the split complex variables setting is not active, the value type is ignored.

For information about how to specify the splitting of complex variables, see Compile Equations.

By default, the general number formatting algorithm for complex-valued numbers in COMSOL Multiphysics ignores small real or imaginary parts. If you want to see also such small real or imaginary parts, open the **Preferences** window, and on the **User Interface** > **Precision** page, clear the **Suppress small real or imaginary part** checkbox.

The Coefficient Form PDE Interfaces

The **Coefficient Form PDE (c)** interface ( ), found under the **Mathematics** > **PDE Interfaces** branch ( ) when adding an interface, covers many well-known PDEs.

When this interface is added, these default nodes are also added to the **Model Builder**: **Coefficient Form PDE**, **Zero Flux**, and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions. You can also right-click **Coefficient Form PDE** to select features from the context menu.

The Coefficient Form PDE interface is also available in other forms from the **PDE interfaces** > **Lower Dimensions** submenu: **Coefficient Form Boundary PDE (cb)**, **Coefficient Form Edge PDE (ce)**, and **Coefficient Form Point PDE (cp)**. Also see Modeling with PDEs on Boundaries, Edges, and Points.

The Coefficient Form PDE discusses the formulation and settings pertaining to the coefficient form, as well as the general PDE terminology used in COMSOL Multiphysics.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first Coefficient Form PDE interface in the model) is `c` (in domains), `cb` (on boundaries), `ce` (on edges), or `cp` (at points).

EQUATION

From the **Equation form** list, choose **Study controlled** (the default when working in the user interface), **Time domain** (default when working in the API), or **Frequency domain**. This setting controls the interpretation of time derivatives of the interface's dependent variables. See *Interpretation of Time Derivatives* for details.

When the setting is **Study controlled**, the study decides the equation form for the physics interface. It then appears as **Automatic (Stationary)**, for example, in the **Physics and Variables Selection** section in the study step's Settings window.

If **Frequency domain** has been selected a frequency-domain interpretation of time derivatives will be used irrespective of study step type. By default the **Frequency** to be used when interpreting time derivatives is taken **From solver**. If the solver does not define a frequency, or you want to solve the Coefficient Form PDE interface for a frequency other than the one supplied by the solver, select **User defined** and specify the desired frequency **f** (SI unit: Hz).

Also, if applicable, choose which equation to display by selecting a study from the **Show equation assuming** list. The corresponding equation, which this interface will solve, appears below.

UNITS

By default, the PDE interfaces are dimensionless, but units can be defined for the dependent variable and the source term (that is, the overall left and right side of the equation). The units for these quantities — in combination with the units for length and time — fully define the units for all other terms in the equations. Select the units from a list of physical quantities or enter the unit directly.

Select the **Dependent variable quantity** that defines the unit for the dependent variable u. The default is **Dimensionless** (with **1** in the **Unit** column). Click the **Select Dependent Variable Quantity** button ( ) to open the **Physical Quantity**

dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Dependent Variable Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit to define the dependent variable quantity. The quantity column then contains **Custom unit**.

Select the **Source term quantity** that defines the unit for the source term f (the unit for the right — and left — side of the PDE). **Custom unit** is the default quantity (with **m^-2** in the **Unit** column). Click the **Select Source Term Quantity** button ( ) to open the **Physical Quantity** dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Source Term Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit (for example, `W/m^3` or `A/m^3`) to define the dependent variable quantity. The quantity column then contains **Custom unit**.

For the **Classical PDE** > **Heat Equation** interface, the **Dependent variable quantity** defaults to **Temperature** (unit: **K**), and the **Source term quantity** defaults to **Heat source** (unit: **W/m^3**).

DEPENDENT VARIABLES

Enter the **Number of dependent variables** (the default is 1) and set the field and dependent variable names. The default **Field name** and **Dependent variables** name for a single scalar PDE variable is u. If the **Field name** coincides with the name of another field of the same unit and number of components, the two fields (and the interfaces which define them) share degrees of freedom and dependent variable names.

A **Field name** must not coincide with the name of a field of another type, or with a component name belonging to some other field. Component names must be unique within a model except when two interfaces share a common field name.

DISCRETIZATION

Select a **Shape function type** (finite element type): **Lagrange** (the default), **Hermite**, **Discontinuous Lagrange**, **Nodal discontinuous Lagrange**, **Discontinuous scalar density**, **Bubble**, or **Gauss point data**.

To display additional settings in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

If you have added a Deformed Geometry or Moving Mesh interface, there is also a **Frame** list for specifying the frame for differentiation and quadrature. Choosing the frame can be needed if you want to write your own mesh smoothing or regularization equations when working with a deformed geometry. Select **Geometry**, **Mesh**, **Spatial** (the default), or **Material** from the **Frame** list.

- Modeling with PDEs
- Working with Geometric Entities
- Settings for the Discretization Sections
- Computing Accurate Fluxes
- Compile Equations

For an example of the use of units in a PDE interface, see *Shell Diffusion in a Tank*: Application Library path **COMSOL_Multiphysics/Equation_Based/shell_diffusion**.

The General Form PDE Interfaces

The **General Form PDE (g)** interface (Δu), found under the **Mathematics** > **PDE Interfaces** branch (Δu) when adding an interface, is a flexible way to specify PDEs in a general form.

When this interface is added, these default nodes are also added to the **Model Builder**: **General Form PDE**, **Zero Flux**, and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions. You can also right-click **General Form PDE** to select features from the context menu.

The General Form PDE interface is also available in other forms from the **PDE interfaces** > **Lower Dimensions** submenu: **General Form Boundary PDE (gb)**, **General Form Edge PDE (ge)**, and **General Form Point PDE (gp)**. Also see Modeling with PDEs on Boundaries, Edges, and Points.

The General Form PDE discusses the formulation and settings pertaining to the general form.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first General Form PDE interface in the model) is `g` (in domains), `gb` (on boundaries), `ge` (on edges), or `gp` (at points).

See The Coefficient Form PDE Interfaces remaining settings.

- General Form PDE
- Domain, Boundary, Pair, Edge, and Point Conditions for PDEs
- Modeling with PDEs

The Weak Form PDE Interfaces

The **Weak Form PDE (w)** interface, found under the **Mathematics** > **PDE Interfaces** branch (Δu) when adding an interface, is identical to The Coefficient Form PDE Interfaces and The General Form PDE Interfaces except for the default node on the top geometric entity level being a Weak Form PDE node.

The Weak Form PDE interface is also available in other forms from the **PDE interfaces** > **Lower Dimensions** submenu: **Weak Form Boundary PDE (wb)**, **Weak Form Edge PDE (we)**, and **Weak Form Point PDE (wp)**. Also see Modeling with PDEs on Boundaries, Edges, and Points.

In all interfaces, weak expressions can be added, which COMSOL Multiphysics adds to the overall equation. Adding one of these interfaces creates a **PDE** node ($\int du$) for PDE modeling using a weak formulation. You can also add the same type of Weak Form PDE node on the domain level to any other PDE interface.

When this interface is added, these default nodes are also added to the **Model Builder**: **Weak Form PDE**, **Zero Flux** (for a Weak Form PDE on the domain level only), and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions. On the domain level, edge level, and boundary levels, the same boundary conditions can be used as for the Coefficient Form PDE and General Form PDE. You can also right-click **Weak Form PDE** to select features from the context menu.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first Weak Form PDE interface in the model) is `w` (in domains), `wb` (on boundaries), `we` (on edges), or `wp` (at points).

See The Coefficient Form PDE Interfaces for the rest of the settings.

- Weak Form PDE
- Domain, Boundary, Pair, Edge, and Point Conditions for PDEs
- Modeling with PDEs

The Classical PDE Interfaces

Many classical PDEs are instances of Coefficient Form PDEs. The classical PDEs have their own interfaces found under the **Mathematics** > **Classical PDEs** branch (∇^2) when adding an interface. Classical PDEs, except the Stabilized Convection-Diffusion Equation, can also be added to all of the forms of PDE interfaces as domain nodes.

The following Classical PDE interfaces and nodes are available. All of these have the same settings as The Coefficient Form PDE Interfaces but adapted to a classical PDE:

- **Laplace's Equation**
- **Poisson's Equation**
- **Wave Equation**
- **Helmholtz Equation**
- **Heat Equation**
- **Convection-Diffusion Equation**
- **Stabilized Convection-Diffusion Equation**

The Stabilized Convection-Diffusion Equation is suitable for convection-dominated convection–diffusion equations and contains streamline diffusion and crosswind diffusion stabilization, active by default, in a **Consistent**

Stabilization section, and isotropic diffusion in an **Inconsistent Stabilization** section. It cannot be combined with other forms of the PDE interfaces in the same interface.

Except for the Stabilized Convection-Diffusion Equation, which is available in 2D axisymmetric geometries, the classical PDEs are not available in axisymmetric geometries. You can then use a Coefficient Form PDE instead, but note that you must compensate for missing factors related to the curvature of the coordinate system. See Notational Conventions for more information.

- Compact and Standard Notations for Classical PDEs
- Domain, Boundary, Pair, Edge, and Point Conditions for PDEs

Domain, Boundary, Pair, Edge, and Point Conditions for PDEs

The PDE interfaces have the following domain, boundary, pair, edge, and point conditions described in this section and listed in alphabetical order. Some nodes are selected from the **Classical PDEs** submenu:

- Coefficient Form PDE
- Constraint
- Convection-Diffusion Equation
- Dirichlet Boundary Condition
- Flux/Source
- General Form PDE
- Heat Equation
- Helmholtz Equation
- Initial Values
- Interior Dirichlet Boundary Condition
- Interior Flux/Source
- Laplace's Equation
- No Diffusive Flux
- No Flux
- Periodic Condition
- Poisson's Equation
- Prescribed Solution
- Source, Edge Source, and Point Source
- Wave Equation
- Weak Form PDE
- Zero Flux

There are also auxiliary equation-based nodes found under the **More**, **Edges**, and **Points** submenus. To display these submenus in the context menu, click the **Show More Options** button ( ) on the **Model Builder** toolbar and select **Equation-Based Contributions** in the **Show More Options** dialog. Then choose from the following (listed in alphabetical order):

- Auxiliary Dependent Variable
- Discretization (Node)
- Pointwise Constraint
- Weak Constraint
- Weak Contribution (PDEs and Physics)
- Weak Contribution on Mesh Boundaries

There is generally a **More** submenu for the domain level as well as one for the boundary level on a physics context menu. See Physics Interface Node Context Menu Layout for an example.

For some of the constraint nodes — Dirichlet Boundary Condition, Constraint, and Pointwise Constraint — you can add subnodes to exclude surrounding surfaces, edges, or points from the constraint. See Excluded Points, Excluded Edges, Excluded Surfaces.

- Modeling with PDEs
- Working with Geometric Entities
- The PDE Interfaces and Classical PDE Domain Nodes

Initial Values

The **Initial Values** node adds initial values for the dependent variables that can serve as an initial condition for a transient simulation or as an initial guess for a nonlinear solver. If you need to specify more than one set of initial values, you can add additional **Initial Values** nodes.

INITIAL VALUES

Enter a value or expression for the **Initial value for u**, u (dimensionless) and the **Initial time derivative of u**, $\frac{\partial u}{\partial t}$ (SI unit: 1/s). The defaults are 0 for both dependent variables.

Coefficient Form PDE

The **Coefficient Form PDE** node is the default equation for The Coefficient Form PDE Interfaces, and is available for the other forms from the context menu. Specify the coefficients for a coefficient form PDE (see The Coefficient Form PDE and Equation 16-2)

DIFFUSION COEFFICIENT

Enter a value or expression for the diffusion coefficient c. Select **Isotropic**, **Diagonal**, **Symmetric**, or **Full** and enter a c coefficient on various forms in 2D and 3D. If there are multiple dependent variables, there is a matrix of c component inputs.

ABSORPTION COEFFICIENT

Enter a value or expression for the absorption coefficient a. If there are multiple dependent variables, there is a matrix of a component inputs.

SOURCE TERM

Enter a value or expression for the source term f. If there are multiple dependent variables, there is a vector of f component inputs.

MASS COEFFICIENT

Enter a value or expression for the mass coefficient e_a. If there are multiple dependent variables, there is a matrix of e_a component inputs.

DAMPING OR MASS COEFFICIENT

Enter a value or expression for the damping or mass coefficient d_a. If there are multiple dependent variables, there is a matrix of d_a component inputs.

CONSERVATIVE FLUX CONVECTION COEFFICIENT

Enter values or expressions for the conservative flux convection coefficient α vector's components. If there are multiple dependent variables, there is a matrix of α vector component inputs.

CONVECTION COEFFICIENT

Enter values or expressions for the convection coefficient β vector's components. If there are multiple dependent variables, there is a matrix of β vector component inputs.

CONSERVATIVE FLUX SOURCE

Enter values or expressions for the conservative flux source term γ vector's components. If there are multiple dependent variables, there is a vector of γ vector component inputs.

- Specifying and Interpreting Boundary Conditions
- The PDE Interfaces
- Modeling with PDEs

General Form PDE

The **General Form PDE** node is the default equation for The General Form PDE Interfaces, and it is available for the other forms from the context menu. Specify the coefficients for a general form PDE (see The General Form PDE and Equation 16-1).

Except for Conservative Flux described in this section, see Coefficient Form PDE for the rest of the settings.

CONSERVATIVE FLUX

Enter values or expressions for the components of the conservative flux vector Γ. The default values `-ux`, `-uy`, and `-uz` (in 3D) represent the negative gradient of u and makes the left-hand side equal to the Laplace operator. If there are multiple dependent variables, there is one Γ vector for each variable.

- The PDE Interfaces
- Interpreting PDE Coefficients
- Modeling with PDEs

Weak Form PDE

The **Weak Form PDE** node is the default node on the top geometric entity level in The Weak Form PDE Interfaces and may also be added to The Coefficient Form PDE Interfaces and The General Form PDE Interfaces. It contains one weak form expression for each dependent variable in the interface (see Equation 16-9).

WEAK EXPRESSIONS

Enter the weak expressions that COMSOL Multiphysics (together with any other weak expressions on the same domain) sets equal to 0 in the **weak** field. For example, in a 2D Component model with one dependent variable, the default expression on the domain level is `-test(ux)*ux-test(uy)*uy+1[m^-2]*test(u)`. This is the weak

formulation of Poisson's equation with the right-hand side $f = 1$. On other geometric entity levels, the default weak expression is 0.

- The PDE Interfaces
- Working with Geometric Entities
- Modeling with PDEs

Source, Edge Source, and Point Source

You can add additional source term nodes on different geometry levels: **Source** on domains, **Edge Source** on edges (3D models), and **Point Source** at points.

SOURCE TERM

Enter a value or expression for the source term f. The default is 0.

Classical PDE Domain Nodes

The nodes available from the **Classical PDEs** submenu can be added to any PDE interface at the domain level. The same node is also available as its own interface from the **Mathematics** > **Classical PDEs** branch (∇^2) when adding an interface.

See Coefficient Form PDE for all the settings and Compact and Standard Notations for Classical PDEs for the equations that the Classical PDE interface solves.

The available interfaces and domain nodes are:

LAPLACE'S EQUATION

The **Laplace's Equation** is a classic PDE of elliptic type that can describe the behavior of some kind of potential or the steady-state heat equation.

POISSON'S EQUATION

The **Poisson's Equation** is a classical PDE of elliptic type that can describe, for example, electrostatics with a space charge density.

HELMHOLTZ EQUATION

The **Helmholtz Equation** is a classical PDE of elliptic type that can represent, for example, a time-independent form of the wave equation.

WAVE EQUATION

The **Wave Equation** is a classic PDE of hyperbolic type. It is a second-order PDE that describes waves, such as sound waves, light waves, and water waves.

HEAT EQUATION

The **Heat Equation** is a classical PDE of parabolic type that describes time-dependent heat transfer by diffusion or other diffusion processes.

CONVECTION-DIFFUSION EQUATION

The **Convection-Diffusion Equation** is a classical PDE that describes time-dependent transport by convection and diffusion.

STABILIZED CONVECTION-DIFFUSION EQUATION

The **Stabilized Convection-Diffusion Equation** is a classical PDE that describes time-dependent transport by convection and diffusion and includes numerical stabilization for solving convection-dominated problems.

Prescribed Solution

The **Prescribed Solution** domain condition (found under the **More** submenu) lets you specify the value of u on a set of domains. It is thus a Dirichlet condition applied at domain level that overrides the equation for u that would otherwise apply.

PRESCRIBED SOLUTION

The prescribed solution for each dependent variable (for example, u_2), has a corresponding checkbox (**Prescribed value of u2**), which is selected by default. Enter a value or expression for the prescribed value in the associated text field or clear the checkbox as needed. If cleared, no Dirichlet constraint is added for that dependent variable on the selected domains.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

You can add subnodes to exclude the constraint from any surrounding boundary, edge, or point. See Excluded Points, Excluded Edges, Excluded Surfaces.

See Coefficient Form PDE for all the settings and Compact and Standard Notations for Classical PDEs for the equations that the Classical PDE interface solves.

Dirichlet Boundary Condition

The **Dirichlet Boundary Condition** specifies a value of u on the boundary of the domain: $u = r$. By default, it is a unidirectional condition, applying reaction terms on u but not on any variables appearing in r. You can also add **Dirichlet Boundary Condition** nodes for edges in 3D components and for points in 2D and 3D components by right-clicking the main PDE interface node and choosing **Constraint** from the **Edges** and **Points** submenus.

DIRICHLET BOUNDARY CONDITION

The Dirichlet boundary condition for each dependent variable (for example, u_2), has a corresponding checkbox (**Prescribed value of u2**), which is selected by default. Enter a value or expression for the prescribed value in the associated text field or clear the checkbox as needed. If cleared, no Dirichlet constraint is added for that dependent variable, and, for example, a flux condition on the same boundary then remains as the active boundary condition.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

You can add subnodes to exclude the constraint from any surrounding edge, or point. See Excluded Points, Excluded Edges, Excluded Surfaces.

See Coefficient Form PDE for all the settings and Compact and Standard Notations for Classical PDEs for the equations that the Classical PDE interface solves.

Constraint

The **Constraint** boundary condition specifies an expression R which is constrained to be equal to zero on the selection, $R = 0$. By default, this is a bidirectional constraint, meaning that all variables in R are affected by reaction terms. You can also add **Constraint** nodes for edges in 3D components and for points in 2D and 3D components by right-clicking the main PDE interface node and choosing **Constraint** from the **Edges** and **Points** submenus.

CONSTRAINT

Enter a value or expression for the value of R in the constraint $R = 0$. For example, to constrain u to 2, enter `2-u` in the field for R. The default value, `0`, does not add any constraint.

The sign in front of u in the constraint controls the sign of the implicit Lagrange multiplier μ, as well as the sign of reaction forces computed using the `reacf()` operator. For consistency with the way predefined physics interfaces implement constraints, write `2-u` rather than `u-2` in R.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. Normally these settings do not need to be changed. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

You can add subnodes to exclude the constraint from any surrounding boundary, edge, or point. See Excluded Points, Excluded Edges, Excluded Surfaces.

See Coefficient Form PDE for all the settings and Compact and Standard Notations for Classical PDEs for the equations that the Classical PDE interfaces solve.

Excluded Points, Excluded Edges, Excluded Surfaces

Right-click a Constraint, Dirichlet Boundary Condition, or Pointwise Constraint node to add one or more **Excluded Points**, **Excluded Edges**, or **Excluded Surfaces** subnodes. Using those subnodes, you can exclude all or part of the surrounding points, edges, or surfaces from a constraint that acts on the edge, boundary, or domain inside of the excluded geometric entities. For example, the **Excluded Edges** node specifies edges where the higher-dimensional (boundary) constraint for which it is a subnode is not enforced. Excluding a constraint on a surrounding edge can be useful to avoid the constraint affecting the physics on an adjacent boundary, for example.

Flux/Source

The **Flux/Source** boundary condition adds a flux or source g on the boundary:

$$\mathbf{n} \cdot (c\nabla u + \alpha u - \gamma) = g - qu \quad \text{or} \quad -\mathbf{n} \cdot \Gamma = g - qu$$

The first equation describes this boundary condition for a Coefficient Form PDE, and the second term describes it for a General Form PDE. The g term may contain a general expression of the dependent variables. The q

coefficient simplifies the implementation of a *Robin boundary condition* by including a term on the form qu, where u is the dependent variable.

INCLUDE

This section is only available for the Stabilized Convection-Diffusion Equation interface.

By default, all checkboxes are selected for the **Diffusive flux**, **Conservative convective flux**, and **Nonconservative convective flux** to include all flux components. You can use the Flux/Source boundary condition in the Stabilized Convection-Diffusion Equation interface as an outflow condition by clearing the **Nonconservative convective flux** and **Conservative convective flux** checkboxes and as a supersonic outflow condition by clearing all checkboxes so that the flux is computed from inside the domain.

BOUNDARY FLUX/SOURCE

Enter a value or expression for the value of the boundary flux or source g in the corresponding field or fields. The default value is 0.

BOUNDARY ABSORPTION/IMPEDANCE TERM

Enter a value or expression for the value of the coefficient q in the corresponding field or fields. The default value is 0. It adds a term qu to the boundary flux or source, which can represent absorption or impedance at the boundary.

For the Stabilized Convection-Diffusion Equation, there is an additional flux term, $(\mathbf{k}\cdot\mathbf{n})u$, so, in addition, you can enter the components of the $\mathbf{k}$ vector in the corresponding text fields.

Zero Flux

The **Zero Flux** boundary condition is the default boundary condition and prescribes a zero flux (insulation) across the boundary:

$$\mathbf{n}\cdot(c\nabla u+\alpha u-\gamma)=0 \quad \text{or} \quad \mathbf{n}\cdot\Gamma=0$$

No Flux

The **No Flux** boundary condition prescribes a zero flux (insulation) across the boundary:

$$-\mathbf{n}\cdot(-c\nabla u+\alpha u+\beta u)=0$$

No Diffusive Flux

The **No Diffusive Flux** boundary condition is the default boundary condition in the Stabilized Convection-Diffusion Equation physics interface and prescribes a vanishing flux due to diffusion across the boundary:

$$-\mathbf{n}\cdot(-c\nabla u)=0$$

This is the appropriate no flux condition when the relative convective velocity with respect to the boundary velocity is zero. When the fluid velocity at the boundary is not equal to that of the boundary, it is often convenient to prescribe the total flux including convection. In this case, use the No Flux feature instead.

Interior Dirichlet Boundary Condition

The **Interior Dirichlet Boundary Condition**, which is only available for interior boundaries in the Stabilized Convection-Diffusion Equation interface, specifies values of u on the downside and upside of interior boundaries in the domain: $u_d = r_d$ and $u_u = r_u$, respectively.

The red arrows in the **Graphics** window point toward the downside from the upside.

VALUE ON BOUNDARY

Enter values or expressions for the prescribed values on the downside and upside in the associated text fields for r_d and r_u under **Downside** and **Upside**, respectively.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint. See Constraint Settings for more information.

Interior Flux/Source

The **Interior Flux/Source** boundary condition, which is only available for interior boundaries in the Stabilized Convection-Diffusion Equation interface, adds a flux or source g on the downside and upside of an interior boundary:

$$-\mathbf{n}_d \cdot (-c\nabla u + \alpha u + \beta u)_d = g_d - q_{1d}u_d - q_{2d}u_d + (\mathbf{k}_d \cdot \mathbf{n}_d)u_d$$

$$-\mathbf{n}_u \cdot (-c\nabla u + \alpha u + \beta u)_u = g_u - q_{1u}u_u - q_{2u}u_u + (\mathbf{k}_u \cdot \mathbf{n}_u)u_u$$

The g term may contain a general expression of the dependent variables. The q coefficients simplify the implementation of a *Robin boundary condition* by including a term on the form qu, where u is the dependent variable.

The red arrows in the **Graphics** window point toward the downside from the upside.

INCLUDE

By default, all checkboxes are selected for the **Diffusive flux**, **Conservative convective flux**, and **Nonconservative convective flux** to include all of the flux components. You can use the Interior Flux/Source boundary condition in the Stabilized Convection-Diffusion Equation interface as an outflow condition (from a domain) by clearing the **Nonconservative convective flux** and **Conservative convective flux** checkboxes and as a supersonic outflow condition (from a domain) by clearing all checkboxes so that the flux is computed from inside the domain.

BOUNDARY FLUX/SOURCE

Enter values or expressions for the values of the boundary flux or source g on the downside and upside in the associated text fields for g_d and g_u under **Downside** and **Upside**, respectively.

BOUNDARY ABSORPTION/IMPEDANCE TERM

Enter values or expressions for the values of the coefficient q and the components of the vector $\mathbf{k}$ on the downside and upside in the corresponding text fields under **Downside** and **Upside**, respectively. The addition of the qu terms to the boundary flux or source can represent absorption or impedance at the boundary.

Periodic Condition

The **Periodic Condition** node adds a *periodic boundary condition*. This periodicity can be continuous (the default) so that $u(x_0) = u(x_1)$ or antiperiodic so that $u(x_0) = -u(x_1)$ and can control to which dependent variables the periodic condition applies.

The software usually automatically identifies the boundaries as either source boundaries or destination boundaries, as indicated in the selection list. This works fine for cases like opposing parallel boundaries. In other cases, right-click **Periodic Condition** and select **Manual Destination Selection** to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

DESTINATION SELECTION

This section is available for specifying the destination boundaries, if needed, when the **Manual Destination Selection** option is selected in the context menu for the **Periodic Condition** node. You can only select destination boundaries from the union of all source and destination boundaries.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

ORIENTATION OF SOURCE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Orientation of Source** section, see Orientation of Source and Destination.

ORIENTATION OF DESTINATION

This section appears if the setting for **Transform to intermediate map** in the **Orientation of Source** section is changed from the default value, **Automatic**, and **Advanced Physics Options** is selected in the **Show More Options** dialog. For information about the **Orientation of Destination** section, see Orientation of Source and Destination.

The PDE, Boundary Elements Interface

About Boundary Elements Interfaces

Physics interfaces based on the boundary element method (BEM) differs from those based on the finite element method (FEM) in that they only use mesh elements on the boundaries of the modeled regions (curves in 2D and surfaces in 3D). Physics interfaces based on BEM can be used for physics modeling in three types of volumetric regions: domains, finite voids, and an infinite void. Physics interfaces based on FEM only supports the domain type. COMSOL Multiphysics uses a direct method in the BEM formulation; that is, the boundary element method directly discretizes the field and flux at the boundaries.

Domains can contain a volumetric finite element mesh; however, the physics interfaces based on BEM only utilize the boundary elements of such domains. A volumetric finite element mesh can be used for FEM-based physics in combination with BEM-based physics. Finite voids and the infinite void cannot contain a volumetric finite element mesh, and the mesh generator will only generate boundary elements adjacent to such regions. Only BEM-based physics can be defined in finite voids and the infinite void.

Unlike FEM, which produces sparse system matrices, BEM leads to filled (dense) matrices when using a direct solver. This means that even though BEM uses less degrees of freedom, as compared to the corresponding FEM discretization of the domain, the memory requirements for using a direct solver grow faster with BEM than with FEM. The problem with handling potentially large filled matrices resulting from BEM is avoided in the physics interfaces based on BEM by using iterative solvers in combination with far-field approximations. These methods avoid explicitly constructing these large matrices. Iterative solvers with far-field approximations is the default setting; however, the options of using a direct solver and no far-field approximations are also available.

Finite and Infinite Voids

For modeling with BEM, a geometry model can have multiple domains and multiple finite voids. However, there can be only one infinite void. These voids are only available for the PDE, Boundary Element interfaces and other interfaces that use BEM.

- A *domain* corresponds to a finite region where the geometry model is of the type solid. The geometry in most models based on FEM consists of domains only.
- Any other finite region is a f*inite void*. A finite void is a closed empty region, and it can be created as a geometric primitive of type curve (in 2D) or surface (in 3D), for example. You can also create it using a Boolean difference operation that subtracts a closed domain from the rest of the geometry.
- The infinite void is the single unbounded region surrounding the geometry model. The infinite void is always domain number 0. An error message, for example, that refers to `Domain 0` is then pointing to a possible problem in the infinite void.

If the model contains finite voids and an infinite void, those volumetric regions appear in the domain selection lists for BEM interfaces and in the **Selection List** window as **Finite void 1**, and so on, and as **Infinite void**. Finite voids have domain numbers –1, –2, and so on, corresponding to **Finite void 1**, **Finite void 2**, and so on. An error message, for example, that refers to `Domain -2` is then pointing to a possible problem in **Finite void 2**. The infinite void is always domain number 0. An error message, for example, that refers to `Domain 0` is then pointing to a possible problem in the **Infinite void**.

When Measuring Geometry Objects and Entities, the number of finite voids is listed among the other entities in the geometry.

For some more information, including how to visualize voids, see About Finite and Infinite Voids.

The PDE, Boundary Elements Interface Main Node

The **PDE, Boundary Elements** interface ( ), found under the **Mathematics** > **PDE Interfaces** branch ( ) when adding an interface, solves scalar stationary source-free PDEs in an unbounded domain.

This section covers the formulation and settings pertaining to those equations.

When you add this interface, these default nodes are also added to the **Model Builder**: **PDE, Boundary Elements**; **Zero Flux**; and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions. You can also right-click the main **PDE, Boundary Elements** node to select features from the context menu.

Use the *PDE, Boundary Elements* for a first-order scalar Helmholtz equation (it becomes Laplace's equation if $a = 0$). Assuming a dependent variable u, these problems take the form

$$-\nabla \cdot (c\nabla u) + au = 0$$

together with suitable initial data. c is the diffusion coefficient, and a is the absorption coefficient. They must be constant within each modeling region.

The plots can plot the boundary element field (default name: `pdebe.u`) and the normal boundary flux (default name: `pdebe.bemflux`) on boundaries and also the boundary element field in all domains and voids.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern *<name>.<variable_name>*. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first PDE, Boundary Elements interface in the model) is `pdebe`.

DOMAIN SELECTION

Define the domains and voids in which the physics interface should be active. The list can include all solid domains and finite voids. By default, it also contains the infinite void. From the **Selection** list, you can choose **All domains**, **All voids**, or **All domains and voids**. All voids include all finite voids and the infinite void.

PHYSICS SYMBOLS

Select the **Enable physics symbols** checkbox to display the symmetry lines or planes in the geometry.

SYMMETRY

In this section you can specify if you want to include symmetry or antisymmetry along out-of-plane surfaces (in 2D) or planes in (3D).

Choose an option from the **Condition for the x = x_0 plane**, **Condition for the y = y_0 plane**, or **Condition for the z = z_0 plane** lists (when applicable). In 2D, these are out-of-plane surfaces. Choose one of the following options:

- **Off**, for no symmetry (the default)

- **Symmetric**
- **Antisymmetric**

Then enter the value for the plane location x_0, y_0, or z_0 (the default is 0 m). This allows an offset of the infinite condition planes along the main coordinate axes.

UNITS

Select the **Dependent variable quantity** that defines the unit for the dependent variable u. The default is **Dimensionless** (with **1** in the **Unit** column). Click the **Select Dependent Variable Quantity** button ( ) to open the **Physical Quantity** dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Dependent Variable Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit to define the dependent variable quantity. The quantity column then contains **Custom unit**.

Select the **Source term quantity** that defines the unit for the source term f (the unit for the right — and left — side of the PDE). **Custom unit** is the default quantity (with **m^-2** in the **Unit** column). Click the **Select Source Term Quantity** button ( ) to open the **Physical Quantity** dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Source Term Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit (for example, `W/m^3` or `A/m^3`) to define the dependent variable quantity. The quantity column then contains **Custom unit**.

CONDITION AT INFINITY

In this section, you specify the condition to apply at infinity for an unbounded problem.

For the condition, choose **None** for no condition, **Laplace's equation** (the default), or **Helmholtz equation** from the **Condition type** list.

For Laplace's equation, choose to specify either a **Total flux through boundary** (the default) or an **Asymptotic value at infinity** (3D only), or **Value at reference distance** (2D only) from the **Condition at infinity** list, unless there is an antisymmetric symmetry in the model, which acts as an added infinite ground plane or line with a fixed value of the dependent variable. The value at infinity is fixed to 0 by the presence of the infinite ground plane or line, so for this case there is a fixed **Zero value at infinity** condition (3D only) or **Zero value at reference distance** condition (2D only). Depending on the condition, enter a value in the **Total flux through boundary**, **Asymptotic value**, or **Reference value** field to define the condition at infinity.

For the Helmholtz equation, choose to specify an **Outgoing wave** (the default), an **Incoming wave**, or a **General** condition from the **Condition at infinity** list. If you choose **General**, enter a condition in the **m** field. In general, it might be possible to consider any linear combination of incoming and outgoing waves, and the **m** field allows specifying such general combinations. The value of **m** should be a real number between –1 and 1, with –1 corresponding to an outgoing wave, 1 corresponding to an incoming wave, and 0 corresponding to a standing wave (this is the case for interior problems).

FAR-FIELD APPROXIMATION SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

These settings are used for matrix assembly and postprocessing. They allow characterization of interactions occurring in boundary element method into near-field and far-field interactions. While the near-field interactions are represented explicitly, the far-field interactions can be represented in an approximate way. This approach results in considerable memory and performance improvements when used in combination with iterative solvers using

matrix-free format or during postprocessing. The near-field part of stiffness matrix is used as input by the Direct and Sparse Approximate Inverse preconditioners.

The **Use far-field approximation** checkbox is selected by default in order to accelerate the solution process. If the checkbox is cleared, the solution will be slightly more accurate but the computational time and memory consumption may become prohibitively high.

The **Approximation type** can be either **ACA+** or **ACA**. These alternatives correspond to two different versions of the adaptive-cross-approximation (ACA) method, which is a fast matrix multiplication method based on far-field approximations.

When the **Use far-field approximation** checkbox is selected, the **Stationary Solver** step in the study creates an octree structure, which is a tree data structure that divides the model into 2-by-2-by-2 blocks recursively until each of the smallest boxes contains at most the number of degrees of freedom specified in the **Box size splitting limit** field. The **Far-field minimum relative distance** decides if the interaction between two boxes occurs in the near field or far field. Boxes that interact in the near field at one level may also interact with a far-field approximation at a level with smaller boxes. Boxes at the smallest level that do not fulfill the far-field minimum relative distance criteria are considered to interact in the near field. For such boxes the system matrix that is defined by the integral equation and the elements in the two boxes are explicitly computed using no approximation. For two boxes that have been classified as interacting in the far field, an approximation of the resulting matrix is computed. The algorithm for computing the approximation rewrites the matrix defined by the interaction between the two boxes using a low-rank matrix approximation. The matrix rank for the approximation is chosen so that the relative error between the approximation and the actual matrix is estimated to be smaller than the value in the **Relative tolerance** field.

The ACA+ and ACA algorithms differ in the implementation of the fast matrix multiplication. The ACA+ algorithm is more robust but slightly more computationally expensive as compared to the ACA algorithm. If the **Use SVD compression** checkbox is selected, then after the ACA+ or ACA far-field approximation, a further approximation and data compression is made based on a singular value decomposition (SVD) algorithm. This additional data compression step reduces memory usage but increases computation time.

The damping parameter is related to the near field matrix that the preconditioner sees. By default, the **Use damping** checkbox is selected. The default value in the **Damping parameter** field is 1, and increasing this value increases the numerical damping. The parameter may impact the convergence of the solver but does not change the solution it converges to.

QUADRATURE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

Select the **Thin gap handling** checkbox to increase the accuracy of the quadrature between almost-touching mesh element pairs (that is, pairs that are extremely close with respect to element size). The value in the **Threshold distance (relative to mesh size)** controls the distance at which elements are considered as almost touching (default value: 0.1). A larger value should provide more accurate results but at an increased computational cost. Under Integration order, the **Integration order, very close elements (thin gap)** option becomes active, making it possible to set a higher-order rule for such elements. In 3D, an additional variable transformation is applied to improve the accuracy even further.

The settings under **Integration order** are by default set to **Automatic**. This means that the quadrature integration order values will follow the element order selection in the **Discretization** section. Higher element orders automatically generate higher values for the quadrature integration orders.

The quadrature integration order settings determine the level of accuracy of the computation of double integrals over the singular integral kernels that need to be evaluated for solving the BEM integral equations. For contributions from overlapping mesh element pairs (identical elements, elements sharing common edge, or

elements with common vertex), specialized regularization transformations are applied before proceeding with numerical integration. For evaluation of contributions from nonoverlapping mesh element pairs, standard numerical integration is used. Due to the presence of singularities in the double integrals, higher integration order is needed for close mesh element pairs than for distant mesh element pairs. The following integration order settings are available when you select **Manual**:

- **Integration order, distant elements**: Integration order for evaluating standard double integral BEM contributions from mesh pairs separated by a large distance relative to their size.
- **Integration order, close elements**: Integration order for evaluating standard double integral BEM contributions from mesh pairs separated by a short distance relative to their size.
- **Integration order, very close elements (thin gap)** option becomes active, making it possible to set a higher-order rule for such elements when the **Thin gap handling** checkbox has been selected (see above).
- **Integration order, elements with common vertex**: Integration order for evaluating regularized double integral BEM contributions from mesh pairs with a common vertex.
- **Integration order, elements with common edge**: Integration order for evaluating regularized double integral BEM contributions from mesh pairs with a common edge.
- **Integration order, same element**: Integration order for evaluating regularized double integral BEM contributions from identical mesh pairs.
- **Integration order, weak contribution**: Integration order for evaluating standard single integral BEM contributions. This integration does not contain any singularities.

DISCRETIZATION

From the **Dependent variable/Normal boundary flux** list, choose from predefined options for the boundary element discretization order for the dependent variable and the normal boundary flux, respectively. The predefined options represent the suitable combinations of element orders such as **Quadratic/Linear** (the default).

To display additional settings in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. The settings under **Value types when using splitting of complex variables** are important for sensitivity and optimization computations. See the description of the built-in operators `fsens` and `fsensimag`.

DEPENDENT VARIABLES

Define the name of the dependent variable. The default name is u.

	The dependent variable and its name must be unique with respect to all other dependent variables in the model.

	Theory for the Boundary Elements PDE

Domain and Boundary Physics for the PDE, Boundary Elements Interface

The PDE, Boundary Elements Interface includes the following domain and boundary feature nodes:

- Dirichlet Boundary Condition
- Flux/Source
- Initial Values

- PDE, Boundary Elements
- Zero Flux

PDE, Boundary Elements

This is the equation for a **PDE, Boundary Elements** interface. Here the coefficients for the PDE using boundary elements are specified with the following equation coefficients:

$$-\nabla \cdot (c\nabla u) + au = 0$$

where c is the diffusion coefficient and a is the absorption coefficient.

COEFFICIENTS

Enter a value or expression for the **Diffusion coefficient** c and the **Absorption coefficient** a.

PHYSICS SYMBOLS

This section is visible if the **Enable physics symbols** checkbox is selected in the Settings window for the main **PDE, Boundary Elements** node. Select or clear the **Show physics symbols** checkbox to turn the display of symmetry lines or planes on and off.

Initial Values

The **Initial Values** node adds the initial value for the dependent variable to be specified. It serve as an initial condition for a nonlinear simulation.

DOMAIN SELECTION

If there is more than one type of domain, each with different initial values defined, it may be necessary to remove these domains from the selection. These are then defined in an additional **Initial Values** node.

INITIAL VALUES

Enter a value or expression for the **Dependent variable** u. The default value is 0.

Zero Flux

The **Zero Flux** boundary condition is the default boundary condition and prescribes a zero flux across the boundary:

$$-\mathbf{n} \cdot (c\nabla u) = 0\,.$$

It can be used on exterior boundaries only.

Dirichlet Boundary Condition

The **Dirichlet Boundary Condition** specifies a value of u on the boundary of the domain: $u = r$. By default, it is a unidirectional condition, applying reaction terms on u but not on any variables appearing in r.

DIRICHLET BOUNDARY CONDITION

Enter the value or expression for r to specify the condition on u on the boundary.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

Flux/Source

The **Flux/Source** boundary condition can be used on exterior boundaries only. With this node, the boundary condition is enforced according to:

$$-\mathbf{n} \cdot (c\nabla u) = g$$

where g can be specified. Here the dependent variable u in the right-hand side is evaluated on the inside (as seen from the domain where the PDE interface is defined). When the normal vector is used in expressions for curved boundaries, it is important that the mesh version of these vectors is used. The components of this vector are denoted `nxmesh`, `nymesh`, and `nzmesh`, respectively.

In this context, exterior means exterior to the PDE interface, which does not need to be an exterior boundary to the geometry. On such boundaries, the normal direction as defined by the normal vector variables does not necessarily have to be outward pointing.

BOUNDARY FLUX/SOURCE

Enter the flux term g.

Theory for the Boundary Elements PDE

About the Boundary Element Method

The *boundary element method* (BEM) is a numerical computational method of solving linear partial differential equations that have been formulated as integral equations. The boundary element method is complementary to the finite element method (FEM), which most of the other PDE interfaces are based on. The boundary element method is sometimes more efficient than other methods, including finite elements, in terms of computational resources for problems where there is a small surface-to-volume ratio. In other cases, the boundary element method is more convenient in setting up a problem. For general information about the boundary element method in addition to this section, see Ref. 1.

Physics interfaces based on the boundary element method (BEM) differs from those based on the finite element method (FEM) in that they only use mesh elements on the boundaries of the modeled regions (curves in 2D and surfaces in 3D). Physics interfaces based on BEM can be used for modeling in three types of volumetric regions: domains, finite voids, and an infinite void. Physics interfaces based on FEM only supports the domain type.

For modeling with BEM, a geometry model may have multiple domains and multiple finite voids. However, there can be only one infinite void. For more information on domains and voids, see Finite and Infinite Voids.

Unlike FEM, which produces sparse system matrices, BEM leads to filled (dense) matrices when using a direct solver. This means that even though BEM uses less degrees of freedom, as compared to the corresponding FEM discretization of the domain, the memory requirements for using a direct solver grow faster with BEM than with FEM. The problem with handling potentially large filled matrices resulting from BEM is avoided in the physics interfaces based on BEM by using iterative solvers in combination with far-field approximations. These methods avoid explicitly constructing these large matrices. Iterative solvers with far-field approximations is the default setting; however, the options of using a direct solver and no far-field approximations are also available.

The interfaces based on BEM solve the following version of Laplace's equation:

$$-\nabla \cdot (c\nabla u) = 0 \text{ in } \Omega$$

where the diffusion coefficient c has the additional requirement, as compared to FEM, that it has to be a constant within each modeling region.

To keep derivations simpler, for the remainder of this section assume that $c = 1$ and, unless otherwise specified, that Ω is a finite region (domain or finite void):

$$-\nabla \cdot (\nabla u) = 0 \text{ in } \Omega$$

The Fundamental Solution to Laplace's Equation

Consider the *fundamental solution* to the Laplace operator:

$$G(x-y) = \frac{1}{4\pi|x-y|} \text{ in 3D}$$

and

$$G(x-y) = -\frac{1}{2\pi}\log|x-y| \text{ in 2D}$$

where the variables x and y represent coordinate positions in space $x = (x_1,x_2,x_3)$ and $y = (y_1,y_2,y_3)$.

The fundamental solution has the property

$$-\nabla \cdot \nabla G(x-y) = \delta(x-y) \text{ in } \Omega$$

where the derivatives are taken with respect to x and δ is the Dirac delta distribution.

The Dirac delta has the property that when used in an integral it samples the value of a function f at y:

$$\int_{\Omega} f(x)\delta(x-y)dV = f(y)$$

Derivation of the Boundary Integral Representation of the Solution to Laplace's Equation

Similar to when deriving the weak form, multiply Laplace's equation with a test function υ and integrate by parts:

$$\int_{\Omega} (-\nabla \cdot (\nabla u))\upsilon dV = \int_{\Omega} \nabla u(\nabla \upsilon)dV - \int_{\partial\Omega} \upsilon(n \cdot \nabla u)dA$$

Repeat with the roles of u and υ reversed:

$$\int_{\Omega} (-\nabla \cdot (\nabla \upsilon))u dV = \int_{\Omega} \nabla \upsilon(\nabla u)dV - \int_{\partial\Omega} u(n \cdot \nabla \upsilon)dA$$

Now subtract the first equation from the second equation and collect terms:

$$\int_{\Omega} (-u(\nabla \cdot \nabla \upsilon) + \upsilon(\nabla \cdot \nabla u))dV = \int_{\partial\Omega} (-u(n \cdot \nabla \upsilon) + \upsilon(n \cdot \nabla u))dA$$

This relationship is known as Green's second identity.

Now, use the fundamental solution by setting

$$\upsilon(x) = G(x-y)$$

with integration over x:

$$\int_{\Omega} (-u(\nabla \cdot \nabla G(x-y)) + G(x-y)(\nabla \cdot \nabla u))dV = \int_{\partial\Omega} (-u(n \cdot \nabla G(x-y)) + G(x-y)(n \cdot \nabla u))dA$$

Using the property of the fundamental solution gives, for the first term in the volume integral:

$$\int_{\Omega} u(-\nabla \cdot \nabla G(x-y))dV = \int_{\Omega} -u\delta(x-y)dV = u(y)$$

For the second term of the volume integral, since u is assumed to be a solution to Laplace's equation $-\nabla \cdot (\nabla u) = 0$:

$$\int_{\Omega} G(x-y)\nabla \cdot \nabla u dV = \int_{\Omega} G(x-y)0dV = 0$$

The resulting relationship is known as the representation of u in terms of boundary integrals:

$$u(y) = -\int_{\partial\Omega} u(n \cdot \nabla G(x-y))dA + \int_{\partial\Omega} G(x-y)(n \cdot \nabla u)dA \text{ for } y \text{ inside } \Omega$$

The value of u over the entire domain Ω is thus determined completely by the values of u and the flux $n \cdot \nabla u$ on the boundary. The integrals are not singular anywhere inside Ω since the integral for each y is taken over x on the boundary where $x \neq y$. Furthermore, note that this relationship is not an equation but merely a representation of u

when we already know the solution and the flux on the boundary. Indeed, this representation is used to reconstruct the solution anywhere inside Ω once the field and flux are solved for and known on the boundary.

The representation of u can be written more compactly as:

$$u = -D(u) + S(\partial_n u) \text{ in } \Omega$$

where $\partial_n u = n \cdot \nabla u$.

The integral operator

$$S(\partial_n u) = \int_{\partial\Omega} G(x-y)\partial_n u dA$$

is called the single-layer volume potential.

The integral operator

$$D(u) = \int_{\partial\Omega} u\partial_n G(x-y) dA$$

is called the double-layer volume potential.

Derivation of the Boundary Integral Equations

In order to derive the ***boundary integral equations*** used in BEM, you take the limit of the volume potential operators as they approach the boundary. This limit process is nontrivial since on the boundary the integrals are evaluated for $x \neq y$. The limit process is represented by a *trace operator* γ_0. In addition, the normal derivative trace operator $\gamma_1 = \gamma_0\partial_n$ is needed.

Operating with the trace operator γ_0 on the (volume) representation for u gives

$$\gamma_0 u = -\gamma_0 D(u) + \gamma_0 S(\partial_n u) \text{ on } \partial\Omega$$

where $\gamma_0 u = u$ on $\partial\Omega$ (the trace of u is u).

The boundary integral operator V

$$V(\partial_n u) = \gamma_0 S(\partial_n u)$$

is called the *single-layer boundary potential* and has the same form as its corresponding volume potential:

$$S(\partial_n u) = \int_{\partial\Omega} G(x-y)\partial_n u dA \text{ on } \partial\Omega$$

Define the *double-layer boundary potential* operator as:

$$K(u) = \int_{\partial\Omega} u\partial_n G(x-y)\, dA \text{ on } \partial\Omega$$

The relationship between the volume and boundary versions of the double-layer potential operator is nontrivial:

$$\gamma_0 D(u) = K(u) - \frac{u}{2}$$

where the additional term comes from, roughly speaking, "cutting the singularity in half" on the boundary. This results in the following boundary integral equation for u:

$$u = \left(\frac{1}{2}I - K\right)u + V\psi \text{ on } \partial\Omega$$

where, in order to simplify the notation,

$$\psi = \partial_n u = n \cdot \nabla u$$

is used for the normal flux. In addition, operator notation is here used, for example, $K(u) = Ku$.

In the COMSOL Multiphysics implementation of BEM, the normal flux ψ is represented as a dependent variable alongside u.

To derive a boundary integral equation for ψ, operate with the trace operator $\gamma_1 = \gamma_0\partial_n$ on the representation for u:

$$\gamma_1 u = \psi = -\gamma_1 D(u) + \gamma_1 S(\psi) \text{ on } \partial\Omega$$

Define the adjoint double-layer boundary potential operator as

$$K'(\psi) = \int_{\partial\Omega} \partial_n G(x-y)\psi dA \text{ on } \partial\Omega$$

Again, the relationship between the volume and boundary potential operators is nontrivial as follows:

$$\gamma_1 S(\psi) = K'(u) + \frac{\psi}{2} \text{ on } \partial\Omega$$

Define the hypersingular integral operator as

$$W(u) = -\gamma_1 D(u) = -\partial_n \int_{\partial\Omega} \partial_n G(x-y)u dA \qquad \text{on } \partial\Omega$$

This results in the following boundary integral equation for ψ:

$$\psi = Wu + \left(K' + \frac{1}{2}I\right)\psi \text{ on } \partial\Omega$$

The Weak Form Implementation of the Boundary Integral Equations

The boundary equation system

$$u = \left(\frac{1}{2}I - K\right)u + V\psi \text{ on } \partial\Omega$$

$$\psi = Wu + \left(K' + \frac{1}{2}I\right)\psi \text{ on } \partial\Omega$$

in the unknowns u and ψ is known as the *Calderón identities*.

In order to get a systematic treatment of both the solution and the flux on the boundary, these equations are implemented using a weak formulation. This also allows for simultaneous handling of Dirichlet and Neumann boundary conditions.

To derive a weak formulation for this equation system, the boundary part of Green's second identity (see above) can be used with test function υ:

$$\int_{\partial\Omega} -u(n\cdot\nabla\upsilon)+\upsilon(n\cdot\nabla u)dA \;=\; 0$$

Focusing on the boundary equation and using the notations $\upsilon = u_{\text{test}}$, $\psi = n\cdot\nabla u$, and $\psi_{\text{test}} = n\cdot\nabla\upsilon$ gives

$$\int_{\partial\Omega} -u\psi_{\text{test}}+\psi u_{\text{test}}dA \;=\; 0$$

Using the Calderón identities gives

$$\int_{\partial\Omega} -\left(\left(\frac{1}{2}I-K\right)u+V\psi\right)\psi_{\text{test}}+\left(Wu+\left(K'+\frac{1}{2}I\right)\psi\right)u_{\text{test}}dA \;=\; 0$$

In the actual implementation the terms are rather collected in the right-hand side with the induced change of signs.

This formulation is one of several possible ways to formulate weak equations for BEM. It is known as *Costabel's symmetric coupling* and has advantages with respect to enforcing solution continuity and flux balance on boundaries for coupling BEM with FEM.

ASYMPTOTIC CONDITIONS

In the case of unbounded domains the representation of u in terms of single and double layer needs to be modified to take into account for possible contributions from the far-field boundary. For Laplace's equation these contributions will give rise to a constant additive term

$$u \;=\; -D(u)+S(\partial_n u)+u_{\text{const}} \text{ in } \Omega$$

In 3D the fundamental solution for the Laplace operator and its derivatives approaches 0 for the point approaching infinity and therefore the first two terms will vanish. Consequently u_{const} can be interpreted as an asymptotic value of the solution at infinity. In 2D the first two terms do not vanish when approaching infinity due to the logarithmic nature of fundamental solutions and therefore the value of u_{const} cannot be interpreted in the same way.

In both 2D and 3D one needs to specify this constant term either directly by specifying its value or indirectly by setting a constraint on the total flux through the boundary in order to uniquely determine the solution.

The Wave Form PDE Interface

The **Wave Form PDE (wahw)** interface ( ), found under the **Mathematics** > **PDE Interfaces** branch ( ) when adding an interface, solves wave equations formulated with first order derivatives in time and space using the discontinuous Galerkin method and is highly optimized with respect to speed and memory consumption.

This section covers the formulation and settings pertaining to those equations.

When you add this interface, these default nodes are also added to the **Model Builder**: **Wave Form PDE**, **Zero Flux**, and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions. You can also right-click **Wave Form PDE** to select features from the context menu.

Use the *wave form* for first-order hyperbolic PDEs. Assuming a scalar equation for the dependent variable u, these problems take the form

$$\begin{aligned} d_a\frac{\partial u}{\partial t} + \nabla \cdot \Gamma = f \quad & \text{in } \Omega \\ -\mathbf{n} \cdot \Gamma = gl \quad & \text{on} \partial\Omega \end{aligned}$$

together with suitable initial data. The first equation is the PDE, the second the boundary conditions.

The terms d_a, Γ, f, and g are coefficients, and l is a load factor. They can be functions of both the spatial coordinates or time, and the solution u, but not the derivatives of u. The coefficients f and g are scalar, whereas Γ is the *flux vector*. The coefficient d_a is assumed to be nonzero throughout the domain Ω, and for all times.

The **Wave Form PDE** interface also supports systems of equations. The interpretation of the coefficients are the same as for the scalar case; f and g are vectors with one component for each equation. Γ contains one flux vector for each equation, and d_a is a square (invertible) matrix.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first Wave Form PDE interface in the model) is `wahw`.

UNITS

Select the **Dependent variable quantity** that defines the unit for the dependent variable u. The default is **Dimensionless** (with **1** in the **Unit** column). Click the **Select Dependent Variable Quantity** button ( ) to open the **Physical Quantity** dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Dependent Variable Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit to define the dependent variable quantity. The quantity column then contains **Custom unit**.

Select the **Source term quantity** that defines the unit for the source term f (the unit for the right — and left — side of the PDE). **Custom unit** is the default quantity (with **m^-2** in the **Unit** column). Click the **Select Source Term Quantity** button ( ) to open the **Physical Quantity** dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of

physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Source Term Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit (for example, `W/m^3` or `A/m^3`) to define the dependent variable quantity. The quantity column then contains **Custom unit**.

DISCRETIZATION

Due to efficiency reasons, there is only one **Shape function type** (finite element type) defined for this interface — the **Nodal discontinuous Lagrange** functions. The associated element order (the order of the shape function for the element) can be chosen from the **Element order** list. The highest available order is 10 in 1D and 2D models and 7 in 3D models, and the default order is two.

To display additional settings in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

DEPENDENT VARIABLES

Define the number of the dependent variables and the variable names. The default name for a scalar PDE variable is u.

	The dependent variables and their names must be unique with respect to all other dependent variables in the model.

Add or remove dependent variables in the model and also change their names.

Enter the **Number of dependent variables**. Use the **Add dependent variable** (+) and **Remove dependent variable** ( ) buttons as needed.

Domain and Boundary Physics for the Wave Form PDE Interface

About Auxiliary Equation-Based Nodes includes the following domain and boundary feature nodes:

- Flux/Source
- Initial Values
- Interior Flux
- Interior Flux Split
- Interior Source
- Wave Form PDE
- Zero Flux

Wave Form PDE

This is the default equation for a **Wave Form PDE** interface. Here the coefficients for a wave form PDE are specified with the following equation coefficients:

$$d_a \frac{\partial u}{\partial t} + \nabla \cdot \Gamma(u) = f$$

- d_a is the mass coefficient
- $\Gamma(u)$ is the conservative flux vector
- f is the source term

DAMPING OR MASS COEFFICIENT

Enter a value or expression for the damping (or mass) coefficient d_a. The default is 1. If there are multiple dependent variables, there is a matrix of d_a component inputs.

CONSERVATIVE FLUX

Enter values or expressions for the components of the conservative flux vector $\Gamma(u)$. These components may depend on both the spatial and temporal coordinates, and the solution u, but not any derivatives of u. If there are multiple dependent variables, there is one $\Gamma(u)$ vector for each variable.

SOURCE TERM

Enter a value or expression for the source term f. If there are multiple dependent variables, there is a vector of f component inputs.

NUMERICAL FLUX

The shape functions used are discontinuous and therefore require auxiliary constraints on faces between adjacent mesh elements to yield a meaningful (that is, continuous) solution approximation. This is accomplished by specifying a so-called numerical flux on each face. The numerical flux implemented is the (global) Lax–Friedrichs flux, which is defined as the average of the fluxes on neighboring elements plus the jump of the solution times at parameter τ, which is necessary for stability. You can also specify a general numerical flux. From the **Method** list, choose **Lax–Friedrichs** (the default) to specify parameter τ, or choose General to specify a general numerical flux g^*.

For Lax-Friedrichs, enter a value or global expression for the parameter τ. Only one expression can be entered for each equation and each domain. The parameter is by default one but should be set according to the dominant eigenvalue of the flux Jacobian matrix

$$\bar{\lambda} = \max\left|\lambda\left(d_a^{-1}\left(\mathbf{n} \cdot \frac{\partial \Gamma}{\partial u}\right)\right)\right| \tag{16-11}$$

given the bound

$$0 \le \tau \le \frac{\bar{\lambda} \max|\lambda(d_a)|}{2} \tag{16-12}$$

where $\lambda(d_a)$ are the eigenvalues of the mass matrix d_a. The reason for this extra factor is that the mass matrix inverse is applied to the Lax–Friedrichs flux internally. A so-called *central flux* is obtained for $\tau = 0$. Selecting

$$\tau = \frac{\bar{\lambda} \max|\lambda(d_a)|}{2}$$

sets a maximally dissipative global Lax–Friedrichs flux.

Derivation of the Weak Form of the Wave Form PDE

ESTIMATE OF MAXIMUM WAVE SPEED

Enter a value or expression for the estimate of maximum wave speed W_s. The default is 0.

FILTER PARAMETERS

The filter provides higher-order smoothing of nodal discontinuous Galerkin formulations and is intended to be used for absorbing layers, but you can also use it to stabilize linear wave problems with highly varying coefficients. The filter is constructed by transforming the solution (in each global time step) to an orthogonal polynomial representation, multiplying with a damping factor and then transforming back to the (Lagrange) nodal basis. Select the **Activate** checkbox to use this filter.

The exponential filter can be described by the matrix formula

$$V\Lambda V^{-1}$$

where V is a Vandermonde matrix induced by the node points, and Λ is a diagonal matrix with the exponential damping factors on the diagonal:

$$\Lambda_{mm} = \sigma(\eta) = \begin{cases} 1, 0 \le \eta \le \eta_c \\ e^{-\alpha\left(\frac{\eta - \eta_c}{1 - \eta_c}\right)^{2s}}, \eta_c \le \eta \le 1 \end{cases}$$

where

$$\eta = \eta(m) = \frac{i_m}{N_p}$$

and N_p is the basis function and i_m the polynomial order for coefficient m. α (default value: 36), η_c (default value: 0.6), and s (default value: 3) are the filter parameters that you specify in the corresponding text fields. The damping is derived from a spatial dissipation operator of order $2s$. For $s = 1$, you obtain a damping that is related to the classical 2nd-order Laplacian. Higher order (larger s) gives less damping for the lower-order polynomial coefficients (a more pronounced low-pass filter), while keeping the damping property for the highest values of η, which is controlled by α. The default values 36 for α correspond to maximal damping for $\eta = 1$. It is important to realize that the effect of the filter is influenced by how much of the solution (energy) is represented by the higher-order polynomial coefficients. For a well-resolved solution this is a smaller part than for a poorly resolved solution. The effect is stronger for poorly resolved solutions than for well-resolved ones. This is one of the reasons why this filter is useful in an absorbing layer where the energy is transferred to the higher-order coefficients through a coordinate transformation. See Ref. 1 (Chapter 5) for more information.

α must be positive; $\alpha = 0$ means no dissipation, and the maximum value is related to the machine precision, $-\log(\varepsilon)$, which is approximately 36. η_c should be between 0 and 1, where $\eta_c = 0$ means maximum filtering, and $\eta_c = 1$ means no filtering, even if filtering is active.

LIMITER

If desired, you can add a WENO (weighted essentially nonoscillatory) limiter (see The WENO Limiter) to control spurious oscillations around discontinuities and stabilize the computations. From the **Limiter** list, choose **WENO** to activate the WENO limiter. You can then also activate the TVB (total variation bounded) trouble cell indicator by choosing TVB from the **Troubled cell indicator** list and specify a TVB constant (default: 10). A larger value means that a smaller number of cells will use WENO.

Initial Values

The **Initial Values** node adds the initial values for the dependent variables to be specified. These serve as an initial condition for the transient simulation.

DOMAIN SELECTION

If there is more than one type of domain, each with different initial values defined, it may be necessary to remove these domains from the selection. These are then defined in an additional **Initial Values** node.

INITIAL VALUES

Enter a value or expression for the **Initial value for u** u

Zero Flux

The **Zero Flux** boundary condition is the default boundary condition and prescribes a zero flux across the boundary:

$$-\mathbf{n} \cdot \Gamma = 0 .$$

It can be used on exterior boundaries only.

Flux/Source

The **Flux/Source** boundary condition can be used on exterior boundaries only. With this node, the boundary condition is enforced according to

$$-\mathbf{n} \cdot \Gamma = gl + qu$$

where g, q, and the load factor l can be specified. Here the dependent variable u on the right-hand side is evaluated on the inside (as seen from the domain where the PDE interface is defined). When the normal vector is used in expressions for curved boundaries, it is important that the mesh version of these vectors is used. The components of this vector are denoted `nxmesh`, `nymesh`, and `nzmesh`, respectively.

In this context, exterior means exterior to the PDE interface, which does not need to be an exterior boundary to the geometry. On such boundaries, the normal direction as defined by the normal vector variables does not necessarily have to be outward pointing.

BOUNDARY FLUX/SOURCE

Enter the flux term g.

LOAD FACTOR

In this section you can enter a load factor l (default: 1). It is multiplied with the flux term g to form a flux term gl. The use of the load factor is optional (the default of 1 means that it then has no effect), and it can be used for performance reasons. The load factor can be a scalar value or a global expression. Performance benefits are obtained when the g expression can be factorized into a constant term and a time-varying load factor. For the **Flux/Source** boundary condition this leads to the extra requirement that any flux part needs to be formulated with the q term. For constant load factors, performance benefits are still obtained when the g expression is linear in the dependent variables as long as the expression is not time dependent in other ways.

BOUNDARY ABSORPTION/IMPEDANCE TERM

Enter the absorption or impedance term q.

Interior Flux

The **Interior Flux** boundary condition can be used on interior boundaries only. With this node, the boundary condition is enforced according to

$$-\mathbf{n} \cdot \Gamma = g$$

where g can be specified. Here, $\mathbf{n}$ is outward normal seen from the downside, so it should be read as $-\mathbf{n} \cdot \Gamma = g$ for a downside of an interior boundary and as $-\mathbf{n} \cdot \Gamma = -g$ on the upside of an interior boundary. If a dependent variable is used in this expression (without `up` or `down` operators), an implicit mean operation is invoked taking the average of the up and down values.

To appreciate how this boundary condition works, consider a simple example of a one-way transport equation in 1D

$$u_t + a u_x = 0$$

with appropriate initial data and boundary conditions, and where the parameter $a > 0$ jumps (it is a discontinuous function of x) at an internal interface.

The proper upwind numerical flux condition is not obtained by using the internal Lax-Friedrichs flux. It can be shown that this is obtained by the numerical flux

$$\begin{aligned} n \cdot \Gamma^* &= \frac{1}{a^l + a^r}(a^l n \cdot \Gamma^r + a^r n \cdot \Gamma^l + a^l a^r (u^l - u^r)) \\ &= \frac{a^r a^l}{a^l + a^r} n((u^r + u^l) + (n u^l - n u^r)) \end{aligned}$$

where ^{r} and ^{l} denote the right and left side of the interface, respectively.

Since the downside coincides with the left side in 1D ($n = 1$), this condition can be expressed by setting

```
g=-2*down(a)*up(a)*down(u)/(down(a)+up(a))
```

In general and in higher dimensions, one typically needs the down (and up) versions of the mesh normal to express these conditions. For example, when the sign of the normal is unknown (that is, which side of an interface COMSOL Multiphysics considers the upside and downside), the above condition can be entered as

```
g = -down(a)*up(a)/(down(a)+up(a))*dnx*(up(u)+down(u)+dnx*(down(u)-up(u)))
```

Here `dnx` means the downside normal (`dnx=-unx`).

It is important to use the mesh version of this vector in higher dimensions on curved boundaries. For example, `dnxmesh`, `dnymesh`, and `dnzmesh` denotes the x, y, and z components of the mesh normal vector on the downside.

BOUNDARY SELECTION

Only interior boundaries can be selected. See Working with Geometric Entities.

BOUNDARY FLUX/SOURCE

Enter the flux term g (SI unit: 1/m).

Interior Flux Split

The **Interior Flux Split** boundary condition can be used on interior boundaries only. Compared to the **Interior Flux** node, the **Interior Flux Split** node makes it possible to specify the numerical flux separately on the upside and downside of the interior boundary. With this node, the boundary condition is enforced according to:

$$-\mathbf{dn} \cdot \Gamma_d = g_d$$
$$-\mathbf{du} \cdot \Gamma_u = -g_u$$

where g_d and g_u can be specified as the flux on the downside and the upside, respectively. Here, $\mathbf{dn}$ is the outward normal from the downside, and $\mathbf{du}$ is the outward normal from the upside.

BOUNDARY SELECTION

Only interior boundaries can be selected. See Working with Geometric Entities.

INTERIOR FLUX DOWNSIDE

Enter the downside flux term g_d (SI unit: 1/m).

INTERIOR FLUX UPSIDE

Enter the upside flux term g_u (SI unit: 1/m).

Interior Source

The **Interior Source** boundary condition can be used on interior boundaries only. With this node, the boundary condition is enforced according to:

$$-\mathbf{n} \cdot \Gamma = -\mathbf{n} \cdot \langle \Gamma \rangle + gl$$

where $\langle \Gamma \rangle$ is the mean flux computed internally. Here the source g and the load factor l can be specified.

BOUNDARY FLUX/SOURCE

Enter the flux term g.

LOAD FACTOR

In this section you can enter a load factor l (default: 1). It is multiplied with the flux term g to form a flux term gl. The use of the load factor is optional (the default of 1 means that it then has no effect), and it can be used for performance reasons. The load factor can be a scalar value or a global expression. Performance benefits are obtained when the g expression can be factorized into a constant term and a time-varying load factor.

Theory for the Wave Form PDE

Theory for About Auxiliary Equation-Based Nodes is described in this section.

Derivation of the Weak Form of the Wave Form PDE

Using About Auxiliary Equation-Based Nodes it is possible to solve one or several first-order wave equations; that is, PDEs of the form

$$d_a\frac{\partial u}{\partial t} + \nabla \cdot \Gamma(u) = f \tag{16-13}$$

where u is the unknown, d_a the mass coefficient, f the source, and Γ the flux vector, which generally depends on u.

The numerical method consists of a discontinuous Galerkin method in space in combination with explicit Runge–Kutta time stepping. This combination of space and time discretization is particularly well-suited for wave problems due to a favorable CFL condition. This is true even when using a high-order polynomial ansatz for u.

In order to derive the weak form underlying the DG method, let $\{\Omega^e\}$ denote a mesh of the domain $\{\Omega\}$, with Ω^e denoting a single element. On this mesh, let V be the broken space

$$V = \oplus P^s(\Omega^e)$$

with P^s denoting the space of all polynomials of degree at most s on Ω^e.

These functions are continuous in the interior of each mesh element, but generally discontinuous across the element boundaries.

A basis for V is given by the nodal discontinuous Lagrange shape functions `shhwdisc` (see Discontinuous Lagrange (shdisc) and Nodal Discontinuous Lagrange Elements (shhwdisc) in the *COMSOL Multiphysics Programming Reference Manual*. This basis is tailor made for this type of discontinuous Galerkin method and has nearly optimal interpolation properties.

The starting point for deriving a weak form is to multiply the PDE with a test function $v \subset V$ and integrate over the domain, to yield

$$\int_\Omega d_a\frac{\partial u}{\partial t} v\,dA + \int_\Omega \nabla \cdot \Gamma v\,dA = \int_\Omega f v\,dA$$

The next step is to integrate by parts. Some care must be taken, since the integrands v and u are discontinuous functions across element boundaries and only continuous in the interior of each element. Therefore, the integrals are first written as a sum over the elements and then integration by parts is done on each element, which gives

$$\sum_e \int_{\Omega^e} d_a\frac{\partial u}{\partial t} v\,dA - \sum_e \int_{\Omega^e} (\Gamma \cdot \nabla v)\,dA + \sum_e \int_{\partial\Omega^e} (\mathbf{n} \cdot \Gamma^*) v\,ds = \sum_e \int_{\Omega^e} f v\,dA$$

where $\mathbf{n}$ is the outward unit normal on the element. Further, $\Gamma*$ is the so-called numerical flux, which defines the flux vector on each element boundary. The flux vector is usually discontinuous because it depends on u.

The numerical flux defines how adjacent elements are connected and how continuous u is. Different definitions of the numerical flux lead to different variants of discontinuous Galerkin methods.

The numerical flux implemented in COMSOL Multiphysics is the global Lax–Friedrichs flux:

$$\Gamma^* = \langle \Gamma \rangle + \tau[u]$$

where the angles ⟨?⟩ and brackets [?] are the average and jump operators, respectively. Thus, on each element boundary, this flux is simply the average of the flux on the two adjacent elements sharing the face, plus a penalty on any jumps of the solution. The penalty is needed for stability and is proportional to the parameter τ, which is assumed to be constant over the whole domain Ω. The normal vector $\mathbf{n}$ is a, from the element, outward pointing normal vector. The jumps are defined as

$$[u] = \mathbf{n}_- u_- + \mathbf{n}_+ u_+ = \mathbf{n} u_- - \mathbf{n} u_+$$

where u_- is the inside values and u_+ is the outside value. So it is the element's value minus the other element's value. The multiplication is an outer product in the case of a vector quantity $\mathbf{u}$.

Using the definition of the Lax–Friedrichs flux, the weak form is obtained

$$\sum_e \int_{\Omega^e} d_a \frac{\partial u}{\partial t} v dA - \sum_e \int_{\Omega^e} (\Gamma \cdot \nabla v) dA + \sum_e \int_{\partial\Omega} (\mathbf{n} \cdot \langle \Gamma \rangle + \tau(\mathbf{n} \cdot [u])) v ds = \sum_e \int_{\Omega} f v dA$$

It is also possible to specify a general numerical flux g.

What makes this discontinuous Galerkin method particularly attractive for explicit time stepping is the fact that the term

$$d_a \frac{\partial u}{\partial t}$$

yields a block diagonal mass matrix, where each block only involves the degrees of freedom on each element. As a consequence, there is no need to invert or solve any linear system involving the global mass matrix. The inverse of the global mass matrix simply amounts to inverting the local mass matrix on each element. This is efficiently done using high performance routines such as BLAS or LAPACK.

A known drawback with explicit time stepping is the requirement on the time step, which has to be very small in order to obtain a stable numerical method. This is referred to as the CFL condition, which relates the largest possible time step k to the smallest mesh size h. For wave equations with unit wave speed, the CFL condition takes the form

$$k \leq C \frac{h}{\mathrm{p}^2}$$

where p is the order of the shape functions and C a generic constant, typically 0.25.

As implemented in COMSOL Multiphysics, the *nodal discontinuous Lagrange shape functions* are the only set of shape functions defined for this interface. The associated element order can be chosen from the **Element order** list. The highest available order is four, and the default order is two.

See Discretization as defined for About Auxiliary Equation-Based Nodes.

Time Explicit Integrator

After discretization in space, an explicit ordinary system of differential equations is obtained. The standard procedure is to integrate the DG system of equations with the explicit Runge–Kutta family of methods.

In the literature, the combination is denoted RK-DG. Often, a $p+1$-order RK method is combined with pth order shape functions. See Ref. 1 for details. The new integrator supports a CFL-based time step regulator. The stability limitation for the time step k is of the sort

$$k \leq \frac{C}{(1+2\mathrm{p})^2} \min \frac{h}{\left|\lambda\left(\frac{\partial \Gamma}{\partial u}\right)\right|}$$

where C is a moderate constant.

COMSOL Multiphysics can compute the largest time step k based on the smallest mesh size h, the order of the shape functions, and the maximum wave speed in the domain. Under **Time stepping**, select **From expressions** to automatically compute the largest stable time step k. Under **Cell time scale expressions** add `wahw.wtc` as the variable for the **Estimate of Maximum Wave Speed** when using About Auxiliary Equation-Based Nodes.

- Introduction to Solvers and Studies

Local Time Stepping

The time step restriction is directly proportional to the smallest mesh element size. The CFL condition is normally too restrictive on highly graded meshes. On such a mesh, it is common that only few elements are small, yet these dictate the overall time step for the whole problem. As an example, think of a mesh with a small geometric feature somewhere or a mesh stemming from an adaptive computation.

In these cases one option is to use local time stepping, which allows the use of a larger time step based on the size of the majority of the elements. This is possible due to the elementwise nature of the DG scheme. The larger the spread is between the smallest mesh-element size and the ideal mesh-element size dictated by a points per wavelength argument, the more beneficial this technique is.

The basic problem with local time stepping, aside from stability issues, is to obtain high accuracy. Classical results only involve second order accuracy. This is not good enough for DG methods.

In order to perform local time stepping, the third order classical Adams–Bashforth (AB) method is implemented

$$u_{n+1} = u_n + \frac{k}{12}(23R(u_n) - 16R(u_{n-1}) + 5R(u_{n-2})) \tag{16-14}$$

here, u_n is the solution at time t_n, k is the time step, and $R(u_n)$ the weak form $f - \nabla \cdot \Gamma$ of the DG scheme (compare to the weak formulation of Equation 16-13), which includes the numerical flux.

The basic idea with local time stepping is as follows. First, the elements are divided into groups, based on their size. Typically, the groups are constructed such that the time steps k, $k/2$, $k/4$, and so forth are stable time steps for each group of elements and where any coupling between groups is disregarded. This allows for easy synchronization of the solution at every full step. The right-hand-side vectors

$$R(u_n),\ R(u_{n-1}),\ \text{and}\ R(u_{n-2})$$

are expensive to compute, thus these are naturally stored from previous time steps, so for each group of DOFs, their own history of right-hand sides are stored.

The main idea with local time stepping is to match the different groups with their own time step and thus save computational resources.

About Auxiliary Equation-Based Nodes

The PDE Interfaces provide an environment for specifying a model in terms of equations. In many cases, however, you may only be interested in adding an equation term or a constraint to the PDE implemented by a physics interface.

The auxiliary equation-based nodes are found under the context submenus **More**, **Edges**, and **Points**. To display these in the context menu, click the **Show More Options** button ( ) on the **Model Builder** toolbar and select **Equation-Based Contributions** in the **Show More Options** dialog.

The following nodes (listed in alphabetical order) can be added to most physics and PDE interfaces:

- Auxiliary Dependent Variable
- Discretization (Node)
- Pointwise Constraint
- Weak Constraint
- Weak Contribution (PDEs and Physics)
- Weak Contribution on Mesh Boundaries

The following nodes can be added in the same way to most physics interfaces, but can also be added directly under Global Definitions or Component>Definitions, making it possible to set up a PDE without any physics or PDE interface:

- Constraint
- Dependent Variable Field
- Global Dependent Variables
- State Variables

- The PDE Interfaces
- Equation Contributions
- Working with Geometric Entities
- Domain, Boundary, Pair, Edge, and Point Conditions for PDEs

Weak Contribution (PDEs and Physics)

The **Weak Contribution** node is available in all interfaces and for all geometry levels, including the global level. The node adds an arbitrary contribution to the total system of equations. Its weak form expression may contain the `test()` operator acting on any dependent variable in the model and therefore add contributions to any equation.

To create an independent weak form equation rather than a weak form contribution, add extra states (dependent variables), right-click the **Weak Contribution** node, and add an Auxiliary Dependent Variable. You can then use the auxiliary dependent variables in the weak-form expression.

To add this node in any physics interface, click the **Show More Options** button ( ) and select **Equation-Based Contributions** in the **Show More Options** dialog. Then, in the **Model Builder**, right-click the main interface node and, depending on the geometric entity level, select **More** > **Weak Contribution** at the domain or boundary level, **Edges** > **Weak Contribution**, **Points** > **Weak Contribution**, or **Global** > **Weak Contribution**.

When you use a Domain Decomposition (Schwarz) solver with an absorbing boundary condition or shifted Laplace contribution with a physics interface that supports that functionality, one of the following special weak contribution nodes appears: **Absorbing Boundary Conditions Weak Contribution**, **Shifted Laplace Weak Contribution on Main Level**, or **Shifted Laplace Weak Contribution on Multigrid Levels**. They contain weak expressions generated by the solver, and those expressions should normally not be changed.

WEAK CONTRIBUTION

Enter the weak-form contribution in the **Weak expression** field. For example, `-ux*test(ux)-uy*test(uy)+1*test(u)` is the weak formulation of Poisson's equation with u as the dependent variable and 1 as the source term on the right-hand side. To add a time derivative as in the time-dependent coefficient form PDE, add `-ut*test(u)` (notice the sign and the syntax `ut` for the time derivative of u).

QUADRATURE SETTINGS

These settings affect the numerical integration, and you do not normally need to change them. The **Use automatic quadrature settings** checkbox is selected by default, meaning that the settings are taken from the main equation in the interface.

If the checkbox is cleared, the following settings become available:

Integration Order

The **Integration order** specifies the desired accuracy of integration during discretization. Polynomials of at most the given integration order are integrated without systematic errors. For smooth constraints, a sufficient integration order is typically twice the order of the shape function. For example, the default integration order for second-order Lagrange elements is 4. The integration order is a positive integer.

Integrate on Frame

The **Integrate on frame** setting determines which frame to base the integration on: **Spatial**, **Material**, **Mesh**, or **Geometry**. The default frame is the one used for the physics interface.

Multiplication by 2πr

This section is available for 2D axisymmetric and 1D axisymmetric models.

By default, the **Multiply by 2πr** checkbox is selected, which is consistent with the implementation in the physics interfaces. This convention defines all fluxes as per unit area and the natural boundary condition per length and full revolution.

- Weak Contribution (ODEs and DAEs)
- Working with Geometric Entities

Weak Contribution on Mesh Boundaries

The **Weak Contribution on Mesh Boundaries** node is available on the domain level in all physics interfaces. To add this node to any physics interface, click the **Show More Options** button ( ) and select **Equation-Based Contributions** in the **Show More Options** dialog. Then right-click the physics interface node and select **More** > **Weak Contribution on Mesh Boundaries** at the domain level.

This node is very similar to the Weak Contribution (PDEs and Physics) node on the boundary level, except that it requires a domain selection. Otherwise, the settings are identical. The domain selection is interpreted as all mesh element boundaries (edges in 2D and faces in 3D) in the interior of the selected domains.

Element edges or faces that are part of a real boundary are not included in this selection.

Use a Weak Contribution on Mesh Boundaries node to set up boundary conditions between every pair of adjacent mesh elements in its domain selection. To access values in the two adjacent elements, use the `up()` and `down()` operators. In practice, this node must be used together with discontinuous shape functions to implement a discontinuous Galerkin method. You can also right-click to add an Auxiliary Dependent Variable subnode.

up and down (operator)

Auxiliary Dependent Variable

If a complete equation is specified in weak form in a Weak Contribution (PDEs and Physics) or Weak Contribution on Mesh Boundaries node and a new dependent variable that is not part of the physics interface is used, right-click either of these nodes to add an **Auxiliary Dependent Variable** subnode.

DOMAIN, BOUNDARY, EDGE, OR POINT SELECTION

In rare cases, more than one **Auxiliary Dependent Variable** node can be used on subsets of the **Weak Contribution** node's selection (to use different initial values, for example).

AUXILIARY DEPENDENT VARIABLE

Define the name and properties of the auxiliary dependent variable. Enter the:

- **Field variable name** (the dependent variable).
- **Initial value** for the dependent variable. The default is 0.
- **Initial time derivative** for the dependent variable. The default is 0.

Under **Discretization** (if **Advanced Physics Options** is selected in the **Show More Options** dialog):

- Except for the **Compute boundary fluxes** checkbox (which is not available), the rest of the settings are the same as for The Coefficient Form PDE Interfaces.
- The value type of auxiliary dependent variables is always **Complex** when **Split complex variables in real and imaginary parts** is activated in the Compile Equations node of any solver sequence used.
- When an auxiliary dependent variable has been used with a product selection of an extra dimension, the **Shape function type** list includes a **User-defined product** option, and individual settings for every extra dimensions and the base selection are available.

About Explicit Constraint Reaction Terms

In the Weak Constraint and Pointwise Constraint nodes you specify an expression, R, which is forced equal to zero. Optionally, you may also specify how reaction terms are applied. The default setting, **All physics (symmetric)**, applies reaction terms based on the constraint expression in a way that preserves the symmetry of a symmetric unconstrained system of equations. These reaction terms are uniquely defined by the symmetry requirement.

Selecting **User defined** from the **Apply reaction terms on** list lets you specify the constraint reaction terms explicitly, using a syntax borrowed from weak form modeling.

- Constraint Reaction Terms
- About Weak Form Modeling

CONSTRAINT REACTION TERM EXAMPLE

For example, in a three-variable problem for variables u_1, u_2, and u_3, specify the constraints (using the **Constraint expression** field in two separate Weak Constraint or Pointwise Constraint nodes)

$$\begin{cases} 0 = R_1(u_1, u_2) = 2u_1 - 3u_2 & \text{on } \partial\Omega \\ 0 = R_2(u_2, u_3) = 2u_2 + 3u_3 & \text{on } \partial\Omega \end{cases}$$

Note that both constraints involve both more than one variable and that to each constraint corresponds a Lagrange multiplier variable, μ_1 and μ_2, respectively. The weak equation corresponding to these constraints is

$$\int_{\partial\Omega} \hat{\mu}_1 R_1 + \hat{\mu}_2 R_2 = \int_{\partial\Omega} \hat{\mu}_1(2u_1 - 3u_2) + \hat{\mu}_2(2u_2 + 3u_3) = 0$$

where μ_1 and μ_2 are the test functions corresponding to the Lagrange multipliers.

This integral equation must be respected for every possible value of the Lagrange multiplier test functions. The only difference between a weak constraint and a pointwise constraint in this respect is that the Lagrange multiplier test functions in a weak constraint are nonzero over the elements adjacent to each mesh node, while the pointwise constraint test functions are nonzero only at the nodes. Therefore, weak constraints are enforced in a local weighted average sense, while pointwise constraints are enforced exactly at the mesh nodes. For this discussion, the difference is not important.

The default reaction terms, applied symmetrically to all dependent variables in the model, are defined simply by switching the test operator (here denoted by the circumflex "^") from the Lagrange multipliers to the constraint expressions. Since the test operator is a linear differential operator, the weak form symmetric reaction term is

$$\int_{\partial\Omega} \mu_1 \hat{R}_1 + \mu_2 \hat{R}_2 = \int_{\partial\Omega} \mu_1 \left(\frac{\partial R_1}{\partial u_1} \hat{u}_1 + \frac{\partial R_1}{\partial u_2} \hat{u}_2 \right) + \mu_2 \left(\frac{\partial R_2}{\partial u_2} \hat{u}_2 + \frac{\partial R_2}{\partial u_3} \hat{u}_3 \right) =$$

$$\int_{\partial\Omega} \mu_1(2\hat{u}_1 - 3\hat{u}_2) + \mu_2(2\hat{u}_2 + 3\hat{u}_3)$$

The user-defined **Constraint force expression** to enter in a Weak Constraint or Pointwise Constraint node to explicitly recreate these symmetric reaction terms may be identified as the expressions multiplying the Lagrange multipliers. The test operator is denoted `test()` in weak expression syntax. Therefore, the constraint force expression for constraint $R_1 = 2u_1 - 3u_2 = 0$ is `test(2*u1-3*u2)` or, equivalently, `2*test(u1)-3*test(u2)`. The corresponding expression for R_2 is `test(2*u2+3*u3)` or, after linearization, `2*test(u2)+3*test(u3)`.

As a general rule, anything that multiplies `test(u1)` appears as a source term in the u_1 equation. Similarly, coefficients of `test(u2)` and `test(u3)` are source terms in the u_2 and u_3 equations, respectively. The symmetric reaction terms from the R_1 constraint contain both a `test(u1)` and a `test(u2)` term. Therefore, its generalized reaction force affects both these equations, while the reaction terms from R_2 affect the u_2 and u_3 equations.

Now suppose that u_1 and u_2 in reality represent components of the same vector, $\mathbf{u}$, while u_3 can be seen as an external quantity that should affect, but not be affected by, the value of $\mathbf{u}$. The symmetric reaction term from constraint R_2 violates this assumption and must be modified. In a user-defined **Constraint force expression**, write, for example, just `test(u2)` to apply reaction terms only as a generalized reaction force in the u_2 equation and leave the u_3 equation unaffected. This corresponds to a weak form integral contribution

$$\int_{\partial\Omega} \mu_1(2\hat{u_1} - 3\hat{u_2}) + \mu_2\hat{u_2}$$

Nonsymmetric reaction terms do not always lead to a well-posed problem. If, in the example above, you would also set the **Constraint force expression** for the first constraint to `test(u2)`, the Lagrange multipliers become nonunique because only their sum enters the u_2 equation. At the same time, there is no means to enforce any constraint on u_1 because that equation contains no Lagrange multiplier at all.

Pointwise Constraint

To add a **Pointwise Constraint** node on the domain, boundary, edge, or point level in any physics interface, click the **Show More Options** button ( ) and select **Equation-Based Contributions** in the **Show More Options** dialog. Then, depending on the geometric entity level, select **More** > **Pointwise Constraint** at the domain or boundary level, **Edges** > **Pointwise Constraint**, or **Points** > **Pointwise Constraint** from the context menu. There is no global pointwise constraint option.

This node adds standard pointwise constraints, similar to the ones used by boundary conditions of a constraint type in the physics interfaces.

Use **Pointwise Constraint** nodes to add extra constraints to a physics interface and to assume complete control over constraint reaction terms and points of application.

POINTWISE CONSTRAINT

These settings are similar to those for the Weak Constraint, but pointwise constraints do not need explicit, named Lagrange multipliers. Instead, implicit Lagrange multipliers are eliminated by the solvers, together with the degrees of freedom being constrained.

Select an option from the **Apply reaction terms on** list: **All physics (symmetric)** (the default) or **User defined**. For either option, enter a **Constraint expression**, which COMSOL Multiphysics constrains to 0. For example, entering `2-(u+v)` constrains $u+v$ to the value 2.

For **User defined**, also enter a **Constraint force expression**. Note that the constraint force expression must use the `test()` or `var()` operator. For example, write `test(-u)` to enforce the constraint by modifying only the u equation with reaction terms.

From the **Constraint method** list, choose **Elemental** (the default) or **Nodal**:

- Choose **Elemental** to make the software assemble the constraint on each node in each element; that is, there are usually several constraints at the same global coordinates because elements in the computational mesh overlap at nodes.
- Choose **Nodal** to make the software assemble a single constraint for each global node point. The nodal constraint method provides an averaging of the constraints from adjacent elements, which can be beneficial when the constraint has discontinuities between mesh elements (for example, due to discontinuities of the boundary normal). Another case where nodal constraints can be useful is in boundary conditions involving a coupling operator (such as continuity or periodic conditions). With elemental constraints, locking effects can sometimes

occur because the coupling operator might map to slightly different points in the source boundary when it is applied to the same node point in different mesh elements.

- About Explicit Constraint Reaction Terms
- Constraint Reaction Terms

See Coefficient Form PDE for all the settings and Compact and Standard Notations for Classical PDEs for the equations that the Classical PDE interface solve.

DISCRETIZATION

Select a **Shape function type** (finite element types): **Lagrange** (the default), **Hermite**, **Discontinuous Lagrange**, **Nodal discontinuous Lagrange**, **Discontinuous scalar density**, **Bubble**, or **Gauss point data**.

Select an associated **Element order** (the order of the shape function for the element). The default is to use **Quadratic Lagrange** elements.

In most cases, use the same shape function type and order for the pointwise constraint as for the dependent variables being constrained. If dependent variables of different order appear in the constraint expression, select the highest order for the pointwise constraint. Notable exceptions are the Hermite and Argyris shape functions, which should be constrained by Lagrange elements of the corresponding order.

The **Frame** list is available when there is more than one unique frame in the model. In this case, select **Geometry**, **Mesh**, **Spatial** (the default), or **Material** from the **Frame** list. This choice only affects how the COMSOL Multiphysics software computes derivatives of Lagrange multipliers and in general does not make any difference at all.

- Working with Geometric Entities
- Settings for the Discretization Sections

Weak Constraint

To add a **Weak Constraint** node on a domain, boundary, edge, or point in any physics interface, click the **Show More Options** button ( ) and select **Equation-Based Contributions** in the **Show More Options** dialog. Then, depending on the geometric entity level, select **More** > **Weak Constraint** at the domain or boundary level, **Edges** > **Weak Constraint**, or **Points** > **Weak Constraint** from the context menu. There is no global weak constraint option.

The **Weak Constraint** node adds an extra dependent variable, known as a Lagrange multiplier, and a weak equation, which together enforce the specified constraint.

If the weak constraint is redundant in the sense that some other weak or pointwise constraint also controls the value of the constraint expression, the Lagrange multiplier becomes under-determined. This makes the discrete system of equations singular and therefore virtually impossible to solve, even if the solution for the main dependent variables is unique.

WEAK CONSTRAINT

Select an option from the **Apply reaction terms on** list: **All physics (symmetric)** (the default) or **User defined**. For either option, enter a **Constraint expression**, which COMSOL Multiphysics constrains to 0. For example, entering `2-(u+v)` constrains $u+v$ to the value 2.

For **User defined**, also enter a **Constraint force expression**. The constraint force expression must use the `test()` or `var()` operator. For example, write `test(-u)` to enforce the constraint by modifying only the u equation with reaction terms.

- About Explicit Constraint Reaction Terms
- Constraint Reaction Terms

QUADRATURE SETTINGS

These settings affect the numerical integration, and you do normally not need to change them. The **Use automatic quadrature settings** checkbox is selected by default, meaning that the settings are taken from the main equation in the interface. If the checkbox is cleared, the following settings become available:

Integration Order

The **Integration order** is a positive integer that specifies the desired accuracy of integration during discretization. Polynomials of at most the given integration order are integrated without systematic errors. For smooth constraints, a sufficient integration order is typically twice the order of the shape function. For example, the default integration order for second-order Lagrange elements is 4.

When constraints may be discontinuous at points inside the mesh elements, raising the integration order may improve accuracy.

Integrate on Frame

The **Integrate on frame** setting determines which frame to base the integration on: **Spatial**, **Material**, **Mesh**, or **Geometry**. The default frame is the one used for the physics interface.

Multiplication by $2\pi r$

This section is available for 2D axisymmetric and 1D axisymmetric models.

By default, the **Multiply by $2\pi r$** checkbox is selected to make the Lagrange multiplier represent, for example, the flux per area rather than by length and full revolution. If the checkbox is cleared, the Lagrange multiplier is not multiplied by $2\pi r$ where it is used in the constraint equation, and therefore represents flux per length and full revolution.

When weak constraints are activated under **Constraint Settings** in other constraint-type boundary conditions, there is no automatic multiplication by $2\pi r$ for axial symmetry.

LAGRANGE MULTIPLIER

Enter a **Lagrange multiplier variable** (the default name is `lm`) and an **Initial value**. Change the name if required, for example, because a variable name conflicts.

DISCRETIZATION

Select a **Shape function type** (finite element types): **Lagrange** (the default), **Hermite**, **Discontinuous Lagrange**, **Nodal discontinuous Lagrange**, **Discontinuous scalar density**, **Bubble**, or **Gauss point data**.

Select an associated **Element order** (the order of the shape function for the element). The default is to use **Quadratic Lagrange** elements.

Always use the same shape function type for the weak constraint as for the variables that are constrained, possibly with lower-order elements for the weak constraint. In some cases (for example, when constraining derivatives) the system of equations can become singular. The reason is usually that there are redundant Lagrange multiplier degrees of freedom in the model. Try to lower the order of the Lagrange multiplier variables or use constraints on the Lagrange multiplier to remove some degrees of freedom.

The **Frame** list is available when there is more than one unique frame in the model. In this case, select **Spatial** or **Material** from the **Frame** list. This affects only how derivatives of Lagrange multipliers are computed. These are normally not used in the constraint equations, but may be of interest for postprocessing.

The value type of auxiliary dependent variables is always **Complex** when **Split complex variables in real and imaginary parts** is activated in the Compile Equations node of any solver sequence used.

- Working with Geometric Entities
- Settings for the Discretization Sections

Weak Inequality Constraint

To add a **Weak Inequality Constraint** node on a domain, boundary, edge, or point in any physics interface, click the **Show More Options** button ( ) and select **Equation-Based Contributions** in the **Show More Options** dialog. Then, depending on the geometric entity level, select **More** > **Weak Inequality Constraint** at the domain or boundary level, **Edges** > **Weak Inequality Constraint**, or **Points** > **Weak Inequality Constraint** from the context menu. There is no global weak inequality constraint option.

EQUATION AND THEORY

The **Weak Inequality Constraint** node allows specifying a complementary inequality constraint of the form

$$m_i \le 0$$
$$f_c \ge 0$$
$$m_i f_c = 0$$

where m_i is the constraint expression and f_c is the Lagrange multiplier field enforcing the constraint. The Lagrange multiplier usually has a physical interpretation as a reaction force or reaction flux. The third condition is a complementarity condition. The meaning of this condition is that the Lagrange multiplier can only be nonzero at points where the constraint is *active* ($m_i = 0$), and must be zero where the constraint is *inactive* ($m_i < 0$). For example, in a structural contact problem, the contact force (the Lagrange multiplier) must only be nonzero at points where the contact gap is zero.

This type of inequality constraint is strongly nonlinear and cannot be satisfied exactly until one knows at which points the constraint is active in the converged solution. This is a combinatorial problem that cannot be handled by the standard nonlinear solver. The **Weak Inequality Constraint** feature therefore adds a relaxed approximation to the above conditions to the overall system of equations, accepting a slight violation of the inequality constraint as well as the complementarity condition $m_i f_c = 0$.

The default approximation to the inequality constraint conditions uses a *penalty method*, also know as a *stiff spring* method. The constraint force, which is an approximation to the true Lagrange multiplier, is computed as an explicit function of the violation

$$f_c = k_s \max(m_i, 0)$$

with a user-defined spring constant k_s. Increasing the spring constant reduces the violation of active constraints, but at the same time makes the problem stiffer and more difficult for the nonlinear solver.

The discontinuous derivative of the `max()` operator may also contribute to solver nonconvergence. Therefore, the **Weak Inequality Constraint** feature can optionally replace the max( ) operator with a smoothed `ramp()` function with a user-defined transition zone size (d_t). The transition zone extends on both sides of $m_i = 0$, meaning that the Lagrange multiplier f_c can be positive also at locations where m_i is slightly negative. In a contact problem, this in practice means that the contact force will start to increase slightly before contact is made between the surfaces.

While the penalty method in many cases provides a fair approximation of the inequality constraint, its solution is inherently dependent on the unphysical spring constant k_s. You always end up in a tradeoff between constraint violations and solvability. As a way to circumvent this, the **Weak Inequality Constraint** feature optionally implements an *augmented Lagrangian* update strategy.

When the augmented Lagrangian method is used, the Lagrange multiplier is represented as a dependent variable field, λ_a, which is updated in a segregated iteration

$$f_{c,j} = k_s \max\left(m_{i,j} + \frac{\lambda_{a,j}}{k_s}, 0\right)$$

$$\lambda_{a,j+1} = f_{c,j}$$

The correction applied in each iteration, *j,* is effectively computed using the penalty method and a user-defined spring constant. This iteration can converge such that $\lambda_{a,j+1} = \lambda_{a,j}$ only when either $m_{i,j} < 0$ and $\lambda_{a,j} = 0$, or $m_{i,j} = 0$. This holds independently of the value of the spring constant k_s, which therefore now only controls the convergence rate and not the accuracy of the final solution. A higher value of the spring constant may lead to faster convergence, but also to divergence. Conversely, a lower value generally leads to a slower but more stable convergence.

INTEGRATION AND DISCRETIZATION

The Lagrange multiplier f_c is applied on the overall system of equations as an additive weak term `fc*Nf`, where `Nf` is a constraint Jacobian expression containing the `test()` or `var()` operators. The constraint Jacobian in practice controls how the constraint force affects the equations. By default, `Nf` is set to `test(fc)`, which means that active constraints are enforced in a symmetric way. The weak contribution is integrated using a specified integration order. By default the order is taken from the surrounding physics interface, based on its current discretization order.

When using the augmented Lagrangian method, the Lagrange multiplier field λ_a must be discretized using a chosen shape function and shape function order. In practice, Lagrange and Discontinuous Lagrange shape functions are the most useful. Constraints are better respected locally when using discontinuous elements or higher shape function orders, but convergence behavior may suffer. The augmented Lagrangian update equation is set up as a weak equation using an integration order matching the Lagrange multiplier shape order.

SOLVER SETTINGS FOR THE AUGMENTED LAGRANGIAN METHOD

Solution of the augmented Lagrangian system of equations requires the use of a Segregated stationary solver, where the Lagrange multiplier variable is solved for in the last step in each iteration. When constant discontinuous or first-order Lagrange shape functions are used, this update step may use a Lumped Solver. Otherwise, it should be a standard Segregated Step with default settings. If the augmented Lagrangian method is used in some Weak Inequality Constraint feature, the default solver is automatically modified in this way.

The default solver settings for other variables are not modified. In theory, the augmented Lagrangian iteration expects the remaining variables to first be solved to convergence in each segregated iteration. This means that you may have to change the **Termination technique** for these variables from the default **Iterations** to **Iterations or tolerance** with a sufficient maximum **Number of iterations**.

WEAK INEQUALITY CONSTRAINT

Select an option from the **Apply reaction terms on** list: **All physics (symmetric)** (the default) or **User defined**. For either option, enter a **Constraint expression**, which is to be set less than or equal to 0. For example, entering `2-(u+v)` constrains $u+v$ to be larger than or equal to 2.

For **User defined**, also enter a **Constraint force expression**. The constraint force expression must use the `test()` or `var()` operator. For example, write `test(u)` to enforce the constraint by modifying only the u equation with positive reaction term.

The sign of the constraint force expression is important. Changing the sign of the constraint force expression does not only change the sign of the Lagrange multiplier as is the case for a standard Weak Constraint. Instead it changes the meaning of the complementary conditions and usually leads to a diverging solution.

IMPLEMENTATION

From the **Method** list, select a method for approximating the inequality constraint: **Penalty** (the default) or **Augmented Lagrangian**. For both methods, specify a value for the **Spring constant** to be used when enforcing the constraint. The appropriate value depends both on the scale of the main system of equations (in practice the material model) and on the scale of the constraint expression. It must normally be chosen from experience or using trial and error.

Enable **Use transition zone** to relax the complementarity condition in a zone around where the constraint becomes active. This may improve convergence. Specify a **Transition zone size** which may be interpreted as in the same units as the constraint expression. For example, if the **Constraint expression** is some function `g(u)` and the **Transition zone size** is set to `0.1`, then the reaction term will start to apply already when `g(u)` becomes larger than `-0.1`.

When the selected **Method** is **Augmented Lagrangian**, specify an **Initial value** for the Lagrange multiplier. The zero default is usually appropriate, but a positive value can be used to prevent too large constraint violations during the first iterations, in particular if the **Spring constant** is chosen relatively weak.

Also select a **Shape function type**: **Lagrange** and **Discontinuous Lagrange** (the default) are the most useful types. Select an associated **Element order** (the order of the shape function for the element). The default is to use **Constant** discontinuous Lagrange elements which will enforce the inequality constraint in an integrated sense (on average) over each element.

QUADRATURE SETTINGS

These settings affect the numerical integration, and you do normally not need to change them. The **Use automatic quadrature settings** checkbox is selected by default, meaning that the settings are taken from the main equation in the interface. If the checkbox is cleared, the following settings become available:

Integration Order

The **Integration order** is a positive integer that specifies the desired accuracy of integration during discretization. Polynomials of at most the given integration order are integrated without systematic errors. For smooth constraint forces, a sufficient integration order is typically twice the order of the shape functions used in the constraint. For example, the default integration order for second-order Lagrange elements is 4.

The constraint forces generated by inequality constraints are in general continuous, but because of the presence of the `max()` operator they are not always polynomials over each element. Raising the integration order may therefore in some situations improve accuracy.

Integrate on Frame

The **Integrate on frame** setting determines which frame to base the integration on: **Spatial**, **Material**, **Mesh**, or **Geometry**. The default frame is the one used for the physics interface.

Multiplication by 2πr

This section is available for 2D axisymmetric and 1D axisymmetric models.

By default, the **Multiply by 2πr** checkbox is selected to make the Lagrange multiplier represent, for example, the constraint force per area rather than by length and a full revolution. If the checkbox is cleared, the Lagrange multiplier is not multiplied by $2\pi r$ where it is used in the weak equation, and therefore represents flux per length and a full revolution.

Discretization (Node)

To display the option, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog; then right-click the main physics interface node and select **Global** > **Discretization** to add extra **Discretization** nodes ( ).

Use **Discretization** nodes to specify multiple discretizations (shape function type and order) for the same physics, typically using different element orders. In study steps and the **Multigrid Level** subnodes, you can select among the discretizations specified for each physics interface (in the main physics interface node's **Settings** window and in any added **Discretization** nodes); see Modifying the Model Configuration and Multigrid Level. This may be used to manually create a multigrid hierarchy, or just to compare the effect of different discretizations in different studies.

The **Discretization** node's **Settings** window has one **Discretization** section, and it contains the same list of shape function types and orders for the fields in the physics as the **Discretization** section found in the main physics interface's **Settings** window.

- Settings for the Discretization Sections
- Showing More Options

If you have the Structural Mechanics Module, see *Stress Analysis of an Elliptic Membrane*: Application Library path **Structural_Mechanics_Module/Verification_Examples/elliptic_membrane**

Modeling with ODEs and DAEs

The ODE and DAE Interfaces

Adding ODEs, DAEs, and Other Global Equations

When working on complex models, single named degrees of freedom may be needed to track and update information that is not logically related to any particular point in space. The evolution of these degrees of freedom is generally governed by equations that are independent of space but often time dependent. In particular, such situations arise when modeling physics in interaction with an external system — for example, a controller or an electrical circuit built from standard components. It is often possible to describe such external systems by a system of ordinary differential equations (ODEs) with a limited number of degrees of freedom. It is also possible to create a model in COMSOL Multiphysics that only solves a set of ODEs or DAEs.

See also State Variables for information about how to define states that are updated using an update expression at the beginning or end of each completed solver step. The state variables are dependent variables in the model and stored as such in solutions.

The Global ODEs and DAEs Interface has a Global Equations node that is designed for implementing this type of external equation. Such equations are often tightly coupled to a model in a physical domain. The Global Equations node is also available for any of the physics interfaces.

To access the node, right-click the main interface in the **Model Builder** and select **Global Equations**.

Use the Global Equations node for ODEs, differential algebraic equations, purely algebraic equations and conditions, and transcendental equations, or to add degrees of freedom to a model. Possible uses include:

- Controllers
- Rigid-body mechanics
- Nonlinear eigenvalue problems
- Continuation
- Integral constraints
- Augmented or generalized equations

An example of the use of an extra degree of freedom defined using an ODE is to add a variable that indicates when a condition changes, such as temperature reaching a certain value, where it affects the material properties so that they need to change in the model. You can then add an ODE like

$$\frac{dq}{dt} = (T > T_{\text{melt}})$$

where the indicator variable q is zero as an initial value and remains at zero until T exceeds T_{melt}; it then takes on a nonzero positive value. You can then use q to switch from one set of material properties to another set that is valid when it exceeds T_{melt}.

PRESENTING RESULTS FOR GLOBAL EQUATIONS

The dependent variables in global equations are scalar values and are available globally. To view the results for an ODE, use the Line Graph, Point Graph, and Global plot types, and Global Evaluation for displaying the numerical solution.

- Plot Groups and Plots
- Derived Values, Evaluation Groups, and Tables

Solving ODEs: An Example

As an example of ODEs, the following equations are the *Lotka–Volterra equations* (also known as the *predator–prey equations*)

$$\dot{r} = ar - brf$$
$$\dot{f} = -cf + drf$$

where r is the rabbit population, and f is the population of foxes. This is an example of a system of two coupled ODEs.

Enter these equations as `a*r-b*r*f-rt` for `r` and `-c*f+d*r*f-ft` for `f`, where a, b, c, and d are scalar values defined using the **Parameters** node's **Settings** window. For this first-order ODE, specify initial values for r and f.

About Parameters, Variables, Variable Utilities, Physics Utilities, and Expressions

Solving Algebraic and Transcendental Equations: An Example

As an example of an algebraic equation, consider the equation $f(u) = 0$ for

$$f(u) = u^3 + u - 2$$

This equation has a single real-valued root at $u = 1$.

1. In the **Model Builder**, click the Global Equations node in a Global ODEs and DAEs interface.
2. In the **Settings** window for **Global Equations**, enter `u` in the **Name** column and `u^3+u-2` in the **f(u,ut,utt,t)** column (both entries on the same row).
3. Solve this using a stationary solver.
4. In the **Settings** window for **State variable u** (**Global Evaluation**), click the **Evaluate** button (=), and the value of the root displays in the **Table** window.

As an example of a transcendental equation, consider the equation $f(u) = 0$ for

$$f(u) = e^{-u} - u$$

A root to this equation is approximately 0.56714. To enter it for the node:

1. In the **Model Builder**, click the Global Equations node.
2. Enter `u` in the **Name** column and `exp(-u)-u` in the **f(u,ut,utt,t)** column (both entries on the same row).
3. Compute the solution.

4 In the Settings window for **State variable u** (**Global Evaluation**), click the **Evaluate** button (=), and the value of the root (rounded to 0.56714) displays in the **Table** window.

Derived Values, Evaluation Groups, and Tables

Distributed ODEs and DAEs

For ODEs and DAEs in domains, on boundaries and edges, and at points, The Distributed ODEs and DAEs Interfaces are available to solve the following ODE (or DAE):

$$e_a \frac{\partial^2 u}{\partial t^2} + d_a \frac{\partial u}{\partial t} = f$$

Because it is defined on a geometry but is space independent, it solves the ODE or DAE as a distributed ODE or DAE, with a solution that is defined as a field but with no space variation.

The ODE and DAE Interfaces

The Global ODEs and DAEs Interface

The **Global ODEs and DAEs (ge)** interface ($\frac{d}{dt}$), found under the **Mathematics** branch (Δu) when adding a physics interface, is used to add global space-independent equations that can represent additional degrees of freedom (scalar variables) in a model. The equations can be ODEs, algebraic equations, and DAEs. The main default node is **Global Equations**, which you use to define the global equations, including the names of the variables, the required initial values, and an optional description.

- Solving Algebraic and Transcendental Equations: An Example
- Adding ODEs, DAEs, and Other Global Equations

EQUATION

From the **Equation form** list, choose **Study controlled** (the default), **Time domain**, or **Frequency domain**. When the setting is **Study controlled**, the study controls the equation form — stationary or time dependent, for example — for the physics interface. It then appears as **Automatic (Stationary)**, for example, in the **Physics and Variables Selection** section in the study step's Settings window. For use in Frequency Domain study steps, and **Frequency domain** has been selected, select a source for the **Frequency** to be used when interpreting time derivatives in the equations: **From solver** (the default) or **User defined**. When **Frequency** is **User defined**, also specify the desired frequency **f** (SI unit: Hz).

GLOBAL ODES AND DAES TOOLBAR

The following nodes are available from the **Global ODEs and DAEs** ribbon toolbar (Windows users), **Global ODEs and DAEs** context menu (macOS or Linux users), or by right-clicking to access the context menu (all users).

For step-by-step instructions and general documentation descriptions, this is the **Global ODEs and DAEs** toolbar.

These are available:

- Global Equations
- Global Constraint
- Weak Contribution (ODEs and DAEs)

About ODEs, Initial-Value Problems, and Boundary-Value Problems

ODEs (ordinary differential equations) are often divided into these two types:

- *Initial-value problems* (IVPs), where the solution u and its derivatives (often with respect to time) are specified in one point (in time) so that $u(0)$ and $u'(0)$ are known, so the system is assumed to start at a fixed initial point. The Global Equations node in COMSOL Multiphysics supports such IVPs described with an equation in the following form: $f(u, \dot{u}, \ddot{u}, t) = 0$, including initial values for u and its derivatives.
- *Boundary-value problems* (BVPs), where the solution u has specified values at a pair of points such as $u(0)$ and $u(1)$; that is, the points 0 and 1 are regarded as boundary points of the domain for the problem. In COMSOL Multiphysics, you can specify such a BVP as a stationary 1D PDE, where the 1D interval represents the independent variable and the u is the dependent variable in the interval.

Global Equations

A default **Global Equations** node ( ) is added to The Global ODEs and DAEs Interface. To add additional **Global Equations** nodes, either right-click and select it from the context menu or click **Global Equations** in the toolbar.

In any other physics interface, click the **Show More Options** button ( ) and select **Equation-Based Contributions** in the **Show More Options** dialog. Then right-click the physics interface and select **Global** > **Global Equations** to add a node directly, without needing to add a separate Global ODEs and DAEs interface.

You can enter a suitable name for the global equations in the **Name** field. The default name (for the first **Global Equations** node) is `ODE1`. The name must be a valid variable name and is used to set the field name attribute on the ODE model entity created by the **Global Equations** node. This name is used as an identifier for the corresponding solver feature under **Dependent Variables** (`comp1.ODE1`, for example).

GLOBAL EQUATIONS

The global equations that you can solve have the following form:

$$f(u, \dot{u}, \ddot{u}, t) = 0$$

with the initial conditions $u(t_0) = u_0$ and $u_t(t_0) = u_{t,0}$ (where the subscript t indicates the time derivative). Several equations can be added and the equation can be coupled.

The first time derivative of u is written `ut`, and the second time derivative of u is `utt`. With time derivatives, this equation is an ODE (ordinary differential equation). With no time derivatives, the equation is an algebraic equation or a transcendental equation. If some equations include time derivatives and others do not, the system is a DAE (differential-algebraic equation).

Initial conditions are necessary for ODEs and DAEs. For the DAEs, it is important to specify a set of initial conditions consistent with the algebraic part of the system. Otherwise, the solvers may be forced to modify the initial values to make them consistent, or they may fail.

In the **Global Equations** table, each row corresponds to a named equation; that is, it defines a single degree of freedom and one equation.

The selected row in the table of global equations may also be edited using the **Name**, **f(u,ut,utt,t)**, **Initial value (u_0)**, **Initial value (u_t0)**, and **Description** fields underneath the table.

In each column enter as follows:

- Enter the **Name** of the equation variable. This also defines time-derivative variables. If a variable is called `u`, its first and second time derivatives are `ut` and `utt`, respectively. These variables become available in all geometries. Therefore the names must be unique.
- Use the **f(u,ut,utt,t)** column to specify the right-hand side of the equation that is to be set equal to zero.

  The software then adds this global equation to the system of equations. When solving the model, the value of the dependent variable `u` is adapted in such a way that the associated global equation is satisfied. All dependent variables and their time derivatives can be used as well as any parameters, global variables, and coupling operators with a scalar output and global domain of definition in the **f(u,ut,utt,t)** column. The variables can be functions

of the dependent variables in the global equations. Setting an equation for a dependent variable is optional. The default value of `0` means that the software does not add any additional condition to the model.

- If the time derivative of a dependent variable appears somewhere in the model during a time-dependent solution, the dependent variable needs an initial condition. Models that contain second time derivatives also require an initial value for the first time derivatives of the dependent variables. Set these conditions in the third (**Initial value (u_0)**) and fourth (**Initial value (u_t0)**) columns.
- Enter comments about the equation in the last column, **Description**.
- To add another equation, make additional entries in the first empty row.

  Move equation rows up and down using the **Move Up** (↑) and **Move Down** (↓) buttons.

  To remove an equation, select some part of that equation's row in the table and click the **Delete** button ( ).

  Save the definitions of the global equations to a text file by clicking the **Save to file** button ( ) and using the **Save to File** dialog that appears. To load a text file with global equation definitions, use the **Load from File** button ( ) and the **Load** dialog that appears. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window. Data must be separated by spaces or tabs (or be in a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ *for* Excel®).

DISCRETIZATION

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

The **Discretization** section for **Global Equations** is used to specify the **Value type** (**Real** or **Complex**) of the variables. The **Split complex variables in real and imaginary parts** setting is activated in the **Compile Equations** node of any solver sequence. The default for the split complex variables setting is to be not active and in that case you do not need to specify the value type for global equations variables (the value type specified would be ignored in such cases). The value type (complex or real) for all the variables defined by this **Global Equations** node is selected in the **Value type when using splitting of complex variables** selection. The default value type is **Complex**.

UNITS

By default, the global equations are dimensionless, but units can be defined for the dependent variable and the source term (that is, the overall left and right side of the equation). The units for these quantities — in combination with the unit for time — fully define the units for all other terms in the equations. Select the units from a list of physical quantities or enter the unit directly.

Select the **Dependent variable quantity** that defines the unit for the dependent variable u. The default is **Dimensionless** (with **1** in the **Unit** column). Click the **Select Dependent Variable Quantity** button ( ) to open the **Physical Quantity** dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Dependent Variable Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit to define the dependent variable quantity. The quantity column then contains **Custom unit**.

Select the **Source term quantity** that defines the unit for the source term f (the unit for the right — and left — side of the global equation). The default is **Dimensionless** (with **1** in the **Unit** column). Click the **Select Source Term Quantity** button ( ) to open the **Physical Quantity** dialog to browse to find a physical quantity to use. You can also type a search string in the text field at the top of the dialog and then click the **Filter** button ( ) to filter the list of physical quantities. For example, type `potential` and click the **Filter** button to only list physical quantities that represent some kind of potential. Alternatively, click the **Define Source Term Unit** button ( ) to edit the unit directly in the **Unit** column, typing a unit (for example, `W/m^3` or `A/m^3`) to define the dependent variable quantity. The quantity column then contains **Custom unit**.

Global Constraint

Use a **Global Constraint** node ( ), for example, to make the sum of some global variables (space-independent) equal to a fixed number. To add a **Global Constraint**, either right-click The Global ODEs and DAEs Interface and select it from the context menu or click **Global Constraint** in the toolbar.

In any other physics interface, click the **Show More Options** button ( ) and select **Equation-Based Contributions** in the **Show More Options** dialog. Then right-click the physics interface and select **Global** > **Global Constraint**.

GLOBAL CONSTRAINT

Choose an option from the **Apply reaction terms on** list: **All physics (symmetric)** (the default) or **User defined** to define reaction terms. For either choice, enter a **Constraint expression**. The default is 0. For example, entering `2-(u+v)` constrains $u+v$ to the value 2. For **User defined**, enter a **Constraint force expression**.

The **Constraint force expression** must use the `test()` or `var()` operator. For example, write `test(-u)` to enforce the constraint by modifying only the u equation with reaction terms. See Constraint Reaction Terms and Pointwise Constraint for more information.

Weak Contribution (ODEs and DAEs)

Another option is to enter equations in the weak form using the **Weak Contribution** node ( ). This can be convenient in advanced modeling because it controls the test variables multiplying the equations. Wherever a test function of a dependent variable appears (in the Global Equations node or elsewhere in the model), whatever it multiplies ends up in the same equation in the discrete system. To add a **Weak Contribution**, either right-click The Global ODEs and DAEs Interface and select it from the context menu or click **Weak Contribution** in the toolbar.

There can be zero or more weak expressions, regardless of the number of dependent variables.

WEAK CONTRIBUTION

Enter the expression that contains the weak formulation in the **Weak expression** field.

See The Wall Distance Interface for an example of how to write an ODE using a weak formulation.

The Distributed ODEs and DAEs Interfaces

The interfaces for distributed ODEs and DAEs ($\frac{d}{dt}$) — **Domain ODEs and DAEs (dode)**, **Boundary ODEs and DAEs (bode)**, **Edge ODEs and DAEs (eode)**, and **Point ODEs and DAEs (pode)** — are found under the **Mathematics** > **ODE and DAE Interfaces** branch ($\frac{d}{dt}$) when adding a physics interface. These interfaces provide the possibility to solve distributed ODEs and DAE in domains, on boundaries and edges, and at points.

When any of these interfaces are added, these default nodes are also added to the **Model Builder**: **Distributed ODE** and **Initial Values**. Then, from the **Physics** toolbar, add other nodes that implement, for example, other algebraic equations. You can also right-click the node to select features from the context menu.

The following sections provide information about nodes available in the distributed ODEs and DAEs interfaces.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first ODEs and DAEs interface in the model) is `dode` (in domains), `bode` (on boundaries), `eode` (on edges), or `pode` (at points).

See The Coefficient Form PDE Interfaces remaining settings. But note that the **Compute boundary fluxes** setting under **Discretization** is not available for ODEs and DAEs.

- Element Order and Shape Function Type
- Distributed ODE
- Initial Values (the same as for the PDE interfaces)

Distributed ODE

This is the default equation for a **Distributed ODE** in an interface for distributed ODEs and DAEs. Specify the coefficients for an ODE with the following equation coefficients:

$$e_a\frac{\partial^2 u}{\partial t^2} + d_a\frac{\partial u}{\partial t} = f$$

- e_a is the *mass coefficient*.
- d_a is a *damping coefficient* or a *mass coefficient*.
- f is the *source term*.

The settings are the same as for the Coefficient Form PDE.

Algebraic Equation

This node adds an **Algebraic Equation** in an interface for distributed ODEs and DAEs. Specify an algebraic equation as

$$f = 0 \tag{16-15}$$

ALGEBRAIC EQUATION

Enter an expression f for the equation $f = 0$ that defines the algebraic equation in the **f** field. If there are multiple dependent variables, there is a vector of algebraic equations for each variable.

The Events Interface

The **Events (ev)** interface ( ), found under the **Mathematics** > **ODE and DAE Interfaces** branch ( ) when adding a physics interface, is used to create solver events. An event can be explicit or implicit, and the difference is that for explicit events you must specify the exact time when the event occurs. When an event occurs, the solver stops and provides a possibility to reinitialize the values of states and dependent variables.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern *<name>.<variable_name>*. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first Events interface in the model) is `ev`.

See *Thermal Controller, Reduced-Order Model* for the use of this interface and the Discrete States, Indicator States, and Implicit Event nodes (Application Library path **COMSOL_Multiphysics/Multiphysics/thermal_controller_rom**).

EVENTS TOOLBAR

The following nodes are available from the **Events** ribbon toolbar (Windows users), **Events** context menu (macOS or Linux users), or by right-clicking to access the context menu (all users).

For step-by-step instructions and general documentation descriptions, this is the **Events** toolbar.

The following event features are available:

- Discrete States
- Indicator States
- Explicit Event
- Explicit Event List
- Implicit Event
- Event Sequence, with Sequence Member subnodes
- Global Equations

Discrete States

Use the **Discrete States** node ( ) to define discrete state variables that do not have to be continuous in time. They are often used as logical help variables that control what expression to use in a weak expression or constraint.

DISCRETE STATES

Enter values or expressions in the table for the **Name** and **Initial value (u0)**, and then enter a **Description** (optional).

Indicator States

Use the **Indicator States** node ( ) to define state variables that the solver uses to trigger implicit events, which occur at a zero crossing of an indicator state variable if the implicit event condition changes from false to true.

This behavior implies, for example, that an event of the type $z > 0$, where z is an indicator state, can be detected accurately because the zero crossing of z is found. But if the condition (in Event Conditions) is formulated as, for example, $z > 1$, the event is not triggered accurately.

INDICATOR VARIABLES

Multiple indicator state variables can be defined in the table together with corresponding g-coefficients and initial values. A state variable, u, gets its value by solving the following equation:

$$\text{nojac}(g(v, \dot{v}, \ddot{v}, t)) - u = 0$$

with the initial conditions $u(t_0) = u_0$ (where the dot notation indicates time derivatives). You use the state variables in the implicit event condition that you specify for the Implicit Event node. The g-coefficients $g(v, \dot{v}, \ddot{v}, t)$ are written similarly as when defining Global Equations; for example, any global state variables or operators in the model can be used as well as the time or discrete state variables defined by the Events interface. However, the expressions cannot contain any indicator state variables. The `nojac` operator makes sure that the state variables do not enter into the Jacobian matrix, avoiding fill-in of the matrix.

Enter values or expressions in the table for the **Name**, g-coefficients **g(v,vt,vtt,t)**, **Initial value (u0)**, and (optionally) enter a **Description**.

For both the *Initial-value based* and *Automatic* scaling methods, the *indicator states* are scaled with the average absolute DOF values (per state) obtained after the first time these are solved for. These scales are printed to the **Log** window.

Explicit Event

An **Explicit Event** node ( ) specifies an event that occurs at predefined times entered in the **Event Timings** section. When an event occurs, it is possible to specify reinitialization of global states in the **Reinitialization** section. Right-click an **Explicit Event** node to add the Reinitialization on Domains, Boundaries, Edges, or Points node.

EVENT TIMINGS

Write the first time t_i an explicit event occurs in the **Start of event** text field. It is also possible to repeatedly trigger the event by entering the period T in the **Period of event** field.

The **Use consistent initialization** checkbox is selected by default, which implies that the time-dependent solver will correct the dependent variables after reinitialization. If the provided reinitialization values lead to a consistent state, you can clear this checkbox to obtain a performance gain. See About the Reinitialization Process for more information.

REINITIALIZATION

In the table, enter information in the **Variable** and **Expression** columns for the global state variables that the event reinitializes to the given expression.

Explicit Event List

Use the **Explicit Event List** node ( ) to specify an arbitrary number of explicit events at predefined times, which all change the value of a single discrete state variable.

The state variable defined by the node can, for instance, be used in boundary condition expressions featuring multiple discrete load changes.

DISCRETE STATE VARIABLE

The node defines its own discrete state variable, with the **Variable name**, **Description**, and **Initial value** defined according to the corresponding text fields.

EXPLICIT EVENTS

Each row in the table defines an event. For each time defined by the **Time(s)** column, the value of the state variable is set to the corresponding value in the **Reinitialization expression** column.

AUXILIARY SETTINGS

See Explicit Event regarding the **Use consistent initialization** checkbox and **Period of events** settings.

Enable **Ignore consecutive identical reinitialization expressions** to only create events when the reinitialization expression is different from the previous row in the table.

Implicit Event

Use the **Implicit Event** node ( ) to specify an event that occurs when a condition involving an indicator state is fulfilled. When an event occurs, it is possible to specify reinitialization of global state variables. Right-click an **Implicit Event** node to add a Reinitialization on Domains, Boundaries, Edges, or Points node.

EVENT CONDITIONS

Enter the condition in the **Condition** field using only indicator states, comparisons operators (< or >), and logical operators (`!`, `||`, or `&&`). When the condition changes its state from false to true at the zero crossing of one of the indicator states, this triggers the implicit event.

For example, use `z>0` to trigger the event when the indicator state `z` goes from negative to positive, and use `z<0` to trigger when `z` goes from positive to negative. The condition is only evaluated at zero crossings of the indicator states, so, for example, using `z>1` as a condition never triggers the event.

The **Use consistent initialization** checkbox is selected by default, which implies that the time-dependent solver will correct the dependent variables after reinitialization. If the provided reinitialization values lead to a consistent state, you can clear this checkbox to obtain a performance gain. See About the Reinitialization Process for more information.

If a reinitialization affects some indicator variables, then it is possible for some implicit events to be triggered by a reinitialization. Such occurrences are indicated in the solver log.

REINITIALIZATION

In the table under **Variables**, enter any global dependent variable name. In the **Expression** column, enter the corresponding reinitialization expression for each variable.

Event Sequence

Use the **Event Sequence** node ( ) to specify a sequence of events that will take place in the order that you add them. This node simplifies the setup of a sequence of events by automatically defining explicit and implicit events. The individual steps in the sequence are defined under Sequence Member subnodes to an **Event Sequence** node.

SEQUENCE CONTROL

Select the **Loop** checkbox if the event sequence should repeat throughout the study.

Sequence Member

Use **Sequence Member** nodes ( ) to define the individual events in the Event Sequence. Each **Sequence Member** will be activated in turn. Right-click an **Event Sequence** node to add **Sequence Member** subnodes.

The **Discrete state name** can be used in other physics features to activate settings while that state is active. The discrete state will be set to the value of 1 when end condition of the previous sequence member in the sequence is triggered, and at the beginning of a simulation if the sequence member is the first in the sequence.

From the **End condition** list, choose **Expression** (the default) so that each step runs until a certain **End condition expression (>0)** becomes positive, or choose **Duration** to make it continue for a fixed **Duration** (default: 1 s). The **Use consistent initialization** option is the same as for Explicit Event.

REINITIALIZATION

In the table under **Variables**, enter any additional global dependent variable name (such as a discrete state) for which the value should be changed when an event occurs. In the **Expression** column, enter the corresponding reinitialization expression for each variable.

About the Reinitialization Process

Solver events make it possible to reinitialize dependent variables. This section clarifies how the provided reinitialization values are processed.

SUMMARY OF THE REINITIALIZATION PROCESS

Triggered events are processed through the following steps:

1. Dependent variables are reinitialized sequentially. If there are N triggered events, then N reinitializations are carried out.
2. The reinitializations carried out in step 1 may have led to inconsistent dependent variables (for example, boundary conditions that are not satisfied for a PDE, or a non-null residual for a DAE). By default, the solver will try to correct the reinitialized state to enforce consistency, using a small artificial time step with the backward Euler method. This can be bypassed by clearing the **Use consistent initialization** checkbox (see Enforcement of Consistency After Reinitialization below for more details). The solver log indicates whether and how consistency has been enforced.
3. If some implicit events have been triggered by steps 1–2, then steps 1–2 are carried out again, to process these events. This is indicated in the solver log.

Even if several events (explicit or implicit) are triggered simultaneously, consistency is enforced at most once in step 2.

ENFORCEMENT OF CONSISTENCY AFTER REINITIALIZATION

The **Use consistent initialization** checkbox makes it possible to control step 2 of the reinitialization process.

If the **Use consistent initialization** checkbox is deselected for all the triggered events, then consistency will not be enforced. Not enforcing consistency can yield a performance gain. However, this may lead to a solver failure if the dependent variables exhibit a significant nonconsistency after reinitialization.

If the **Use consistent initialization** checkbox is selected for at least one of the triggered events, the method used to enforce consistency is controlled by the value of the **Consistent initialization** list associated with the active time-dependent solver node (see, under Time Stepping (BDF and Generalized Alpha), the section about Algebraic Variable Settings):

- If set to **Backward Euler**, then dependent variables are corrected with the backward Euler method using a small artificial time step.
- If set to **Off**, then consistency is not enforced after reinitialization.
- If set to **On** and a **Fully Coupled** or **Segregated** solver subnode is active, then dependent variables are corrected with a backward Euler step.
- If set to **On** and the built-in nonlinear IDAS solver is used, then consistency is enforced using either IDAS or a backward Euler step, depending on the equation solved. See The Implicit Time-Dependent Solver Algorithms for instructions on how to use the built-in IDAS solver and its applicability.

Reinitialization on Domains, Boundaries, Edges, or Points

The **Reinitialization on Domains**, **Reinitialization on Boundaries**, **Reinitialization on Edges**, or **Reinitialization on Points** node can reinitialize dependent variables defined on domains, boundaries, edges, or points, respectively, when an event occurs. Right-click an Explicit Event or Implicit Event node to add this node.

REINITIALIZATION

In the table under **Variables**, enter any dependent variable name. In the **Expression** column, enter the corresponding reinitialization expression for each variable as defined on domains, boundaries, edges, or points that the event reinitializes.

The Wall Distance Interface

The **Wall Distance (wd)** interface ( ), found under the **Mathematics** branch (△∪) when adding a physics interface, has the equations and boundary conditions for calculating the distance to walls in fluid flow simulation using a modified *eikonal equation*, solving for a dependent variable G that is related to the wall distance. The main node is the **Distance Equation** node, which adds the distance equation (modified eikonal equation) and provides an interface for defining the reference length scale.

When this interface is added, these default nodes are also added to the **Model Builder**: **Wall Distance**, **Distance Equation**, and **Initial Values**. A default boundary condition is also added: a homogeneous Neumann condition that does not appear in the Model Builder. Right-click the **Wall Distance** node to add boundary conditions for walls.

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first Wall Distance interface in the model) is `wd`.

PHYSICAL MODEL

Enter a **Smoothing parameter** σ_w in Equation 16-18. The default value is 0.2.

DEPENDENT VARIABLES

The dependent variable is the **Reciprocal wall distance** G. You can change its name, which changes both the field name and the variable name. If the new name coincides with the name of another reciprocal distance field in the model, the interfaces share degrees of freedom. The new name must not coincide with the name of a field of another type, or with a component name belonging to some other field.

DISCRETIZATION

To display other settings than the element order in this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog.

- Working with Geometric Entities
- Domain and Boundary Nodes for the Wall Distance Interface and Initial Values

Domain and Boundary Nodes for the Wall Distance Interface

The Wall Distance Interface has these domain settings and boundary conditions available:

- Distance Equation
- Initial Values
- Periodic Condition
- Wall
- Wall Distance Continuity

The default boundary condition, a homogeneous Neumann condition, applies to all boundaries that are not walls:

$$\nabla G \cdot \mathbf{n} = 0$$

This node does not display in the model tree.

For axisymmetric models, COMSOL Multiphysics automatically takes the axial symmetry boundaries (at $r = 0$) into account, and prohibits the wall boundary node from being defined here.

Working with Geometric Entities

Distance Equation

The **Distance Equation** node adds to Equation 16-18, and the **Distance Equation** form contains the following sections for defining the length scale.

DISTANCE EQUATION

Select an option for the **Reference length scale** l_{ref} (SI unit: m): **Automatic** (the default) to use Equation 16-19 to compute l_{ref}, or **Manual** to enter a value in the field. The default value, when the scale is not computed automatically, is 1 m (when using SI units).

Initial Values

The **Initial Values** node adds an initial value for the reciprocal wall distance that can serve as an initial guess for a nonlinear solver.

INITIAL VALUES

Enter a value or expression for the initial value of the **Reciprocal wall distance** G (SI unit: 1/m). The default value is `wd.G0`.

Wall

The **Wall** node implements the following boundary condition for walls:

$$G = G_0 = \frac{2}{l_{\text{ref}}}$$

Wall Distance Continuity

The **Wall Distance Continuity** node implements continuity in the wall distance across a pair boundary so that the wall distance is continuous across the pair boundary instead of treating the pair boundary as a wall.

Identity, Contact, and Sector Symmetry Pairs

Periodic Condition

The **Periodic Condition** node adds a *periodic boundary condition*. This periodicity makes the selected boundaries connected so that they are not walls, and the wall distance values are continuous across the periodic boundaries.

BOUNDARY SELECTION

The software usually automatically identifies the boundaries as either source boundaries or destination boundaries, as indicated in the selection list. This works fine for cases like opposing parallel boundaries. In other cases, right-click **Periodic Condition** and select **Manual Destination Selection** to control the destination. By default it contains the selection that COMSOL Multiphysics identifies.

DESTINATION SELECTION

This section is available for specifying the destination boundaries, if needed, when the **Manual Destination Selection** option is selected in the context menu for the **Periodic Condition** node. You can only select destination boundaries from the union of all source and destination boundaries.

ORIENTATION OF SOURCE

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Orientation of Source** section, see Orientation of Source and Destination.

ORIENTATION OF DESTINATION

This section appears if the setting for **Transform to intermediate map** in the **Orientation of Source** section is changed from the default value, **Automatic**, and **Advanced Physics Options** is selected in the **Show More Options** dialog. For information about the **Orientation of Destination** section, see Orientation of Source and Destination.

MAPPING BETWEEN SOURCE AND DESTINATION

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. For information about the **Mapping Between Source and Destination** section, see Mapping Between Source and Destination.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. This section contains settings for specifying the type of constraint and whether to use a pointwise or weak constraint. See Constraint Settings for more information.

Theory for Wall Distance

The Eikonal Equation

Turbulence models often use the distance to the closest wall to approximate the mixing length or for regularization purposes. One way to compute the wall distance is to solve the eikonal equation:

$$|\nabla D| = 1 \tag{16-16}$$

with $D = 0$ on solid walls and $\nabla D \cdot \mathbf{n} = 0$ on other boundaries. The eikonal equation can be tricky to solve, and produces the exact distance to the closest wall. The modified equation described below is less computationally expensive to solve. It also uses a reference length to put more emphasis on solid objects larger than the reference length and to reduce the emphasis on smaller objects. The introduction of a reference length produces a more relevant wall distance in the following instances:

- In convex regions of small dimensions, the wall distance is reduced to reflect the close proximity of several walls.
- When a small object, such as a thin wire, is present in free flow, the wall distance is affected only in a very small region around it.

Modified Eikonal Equation

COMSOL Multiphysics uses a modified eikonal equation based on the approach in Ref. 1. This modification changes the dependent variable from D to $G = 1/D$. Equation 16-16 then transforms to

$$\nabla G \cdot \nabla G = G^4 \tag{16-17}$$

Additionally, the modification adds some diffusion and multiplies G^4 by a factor to compensate for the diffusion. The result is the following equation, which the Wall Distance interface uses:

$$\nabla G \cdot \nabla G + \sigma_w G(\nabla \cdot \nabla G) = (1 + 2\sigma_w)G^4 \tag{16-18}$$

where σ_w is a small constant. If σ_w is less than 0.5, the maximum error falls off exponentially when σ_w tends to zero. The default value of 0.2 is a good choice for both linear and quadratic elements.

The boundary conditions for Equation 16-18 is $G = G_0 = C/l_{ref}$ on solid walls and homogeneous Neumann conditions on other boundaries. The effect of C is that the solution becomes less smeared the higher the value of C. The error tends asymptotically to $0.2l_{ref}$ as C tends to infinity, but making it very large destabilizes Equation 16-18. C is 2 in the Wall Distance interface.

The effect of l_{ref} is loosely speaking that the distance to objects larger than l_{ref} is represented accurately, while objects smaller than l_{ref} appear to be further away than their exact geometrical distance. For a channel, l_{ref} should typically be set to the channel width or there about. l_{ref} has a lower bound in that it must be larger than all cells adjacent to any boundary where the boundary condition $G = G_0$ is applied; otherwise, the solution displays oscillations. l_{ref} is the only parameter in the model, and the default value is half the shortest side of the geometry bounding box. If the geometry consists of several very slender entities, or if the geometry contains very fine details, this measure can be too large. Then define l_{ref} manually.

The initial value is by default defined as $G_0 = 2/l_{ref}$, in correspondence with the boundary conditions.

The wall distance $D_w = 1/G - 1/G_0$ is a predefined variable that is used for analysis. You also have access to a vector-valued variable that represents the direction toward the nearest wall, which is defined as

$$\frac{\nabla G}{\sqrt{\max(\nabla G^2, \text{eps})}} \tag{16-19}$$

Curvilinear Coordinates

Introduction

A *curvilinear coordinate system* is a type of coordinate system where the coordinate lines can be curved. Using a curvilinear coordinate system can make it easier to, for example, define boundary conditions that follow a curved surface. The curvilinear coordinate systems in COMSOL Multiphysics can define a vector field and an associated base vector system using the following methods:

- A diffusion method, which solves Laplace's equation $\Delta u = 0$ and computes the vector field as $-\nabla u$. Solve for the vector field using a Stationary study.
- An adaptive method, which adapts the computed vector field to maintain a constant streamline density on the cross section. Solve for the vector field using a Stationary study.
- An elasticity method, which computes the vector field from the solution with the eigenvalue closest to zero for the following eigenvalue problem:

$$-\nabla \cdot (s(\nabla \cdot \mathbf{u})I + (\nabla \mathbf{u} + \nabla \mathbf{u}^T)) = \lambda \mathbf{u}$$

  Solve for the vector field using an Eigenvalue study.
- A flow method, which solves the following equation for $\mathbf{u}$ and p, and uses $\mathbf{u}$ as the vector field:

$$\nabla \cdot [-pI + (\nabla \mathbf{u} + (\nabla \mathbf{u})^T)] = 0$$
$$\nabla \cdot \mathbf{u} = 0$$

  Solve for the $\mathbf{u}$ and p using a Stationary study.
- A user-defined vector field. No study step is required.

Solve for the curvilinear coordinates (unless they are user defined) in a separate study or separate study step, which you run before the study or study step where you solve for the physics that make use of the computed curvilinear coordinates. Simultaneously solving for the curvilinear coordinates and the physics that use them does not normally work.

The Curvilinear Coordinates Interface

With the **Curvilinear Coordinates (cc)** interface ( ), you can create a vector field $\mathbf{v}$ and a base vector system (with basis vectors $\mathbf{e}_1$, $\mathbf{e}_2$, and $\mathbf{e}_3$) that can be used by other physics to specify, for example, external currents or anisotropic material properties of a bundle of wires or fibers. The resulting coordinate system can be — but does not have to be — curvilinear. Right-click the **Curvilinear Coordinates** node ( ) to add one of the available methods for computing the vector field for the curvilinear coordinates:

- Diffusion Method
- Adaptive Method
- Elasticity Method
- Flow Method
- User Defined

The first node added will be applied to all domains by default. Additional nodes will have an initially empty selection. You can use more than one vector field computation method (of the same or different types), by applying the corresponding nodes on different sets of domains.

The Curvilinear Coordinates interface is available for 2D, 2D axisymmetric, and 3D geometries. The Settings window contains the following sections:

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first Curvilinear Coordinates interface in the model) is `cc`.

EQUATION

See Physics Nodes — Equation Section.

SETTINGS

The **Normalize vector field** checkbox is selected by default because a normalized vector field simplifies the use of curvilinear coordinates and a base vector system.

Select the **Create base vector system** checkbox to add a **Curvilinear System** node under **Definitions**, which is a Base Vector System node with a name that indicates that it is created by a **Curvilinear Coordinates** interface and contains the base vectors from the curvilinear coordinate computation. Selecting this checkbox also adds a Coordinate System Settings subnode for specifying the second basis vector $\mathbf{e}_2$ (the software then forms the third basis vector as the cross product of the first and second basis vectors).

DISCRETIZATION

Select the **Element Order** of the dependent variable fields used by **Diffusion Method**, **Adaptive Method** and **Elasticity Method** nodes. The default is **Quadratic**. The **Flow Method** nodes are not affected by this setting. Those nodes always use a `P2+P1` discretization of the flow field.

Working with Geometric Entities

Anisotropic Heat Transfer Through Woven Carbon Fibers: Application Library path **COMSOL_Multiphysics/Heat_Transfer/carbon_fibers**

Diffusion Method

Add a **Diffusion Method** node to compute the vector field based on Laplace's equation $\Delta u = 0$ with the vector field $\mathbf{v}$ defined as $\mathbf{v} = -\nabla u$ (divided by $|-\nabla u|$ if normalized). This method is a scalar "potential method" resulting in an incompressible vector field and is useful for geometries that are smooth but leads to concentrations at sharp corners. To define the equation in the geometry, you can add the following boundary conditions:

- Wall (the default boundary condition)
- Inlet
- Interior Wall
- Jump
- Outlet

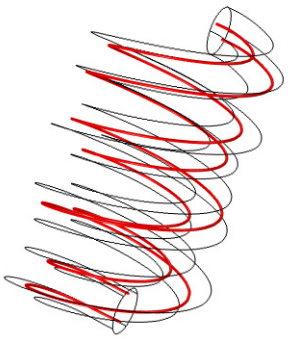

Figure 16-1: The computed velocity field in a helix using a Curvilinear Coordinates interface with a Diffusion Method.

Adaptive Method

The **Adaptive Method** node computes a vector field adapted to the shape of the geometry so that the streamline density is constant on cross sections of the geometry. When the **Normalize vector field** checkbox is not selected in the Curvilinear Coordinates node, the method also ensures conservation of the vector field, meaning that the magnitude of the field will vary as a function of the cross-section area of the domain.

This method is similar to the Coil Geometry Analysis approach used in the Multiturn Coil feature in Magnetic Fields (in the AC/DC Module).

To define the equation in the geometry, you can add the following boundary conditions:

- Inlet
- Interior Wall
- Jump
- Outlet

If the vector field must enter and exit the domain selection, add an Inlet and one or more Outlet subnodes and select respectively the inlet and outlet boundaries for the vector field. If the vector field is entirely contained in the domain selection, add a Jump subnode and select an interior boundary where the vector field must be orthogonal. Only one active Inlet or Jump subnode is allowed. Use the Interior Wall subnode to further shape the path of the vector field.

Elasticity Method

Add an **Elasticity Method** node to compute the vector field based on the solution with the eigenvalue closest to zero for the following eigenvalue problem:

$$-\nabla \cdot (s(\nabla \cdot \mathbf{u})I + (\nabla \mathbf{u} + \nabla \mathbf{u}^T)) = \lambda \mathbf{u}$$

The vector field $\mathbf{v}$ is the same as $\mathbf{u}$ but normalized if normalization is selected.

The Elasticity method requires that you use an eigenvalue study.

To define the equation in the geometry, you can add the following boundary conditions:

- Wall (the default boundary condition)
- Outlet

In addition, a default **Inlet** node is added because one inlet must be added for the geometry to define the positive direction of the vector field for the curvilinear coordinate as indicated by the arrow on the inlet boundary in the **Graphics** window.

Flow Method

Add a **Flow Method** node to solve the following equation for the vector **u** and the scalar p and use **u** as the vector field:

$$\nabla \cdot [-pI + (\nabla \mathbf{u} + (\nabla \mathbf{u})^T)] = 0$$
$$\nabla \cdot \mathbf{u} = 0$$

The vector field **v** is the same as **u** but normalized if normalization is selected. This approach is equivalent to computing the flow of an incompressible fluid — that is, creeping flow or Stokes flow. The Flow method is useful for geometries with nonconstant cross sections. To define the equation in the geometry, you can add the following boundary conditions:

- Wall (the default boundary condition)
- Inlet
- Jump
- Outlet

User Defined

Add a **User Defined** node to specify the vector field **u** as user-defined expressions for its components. In the **User Defined** section, enter the expressions for those components in the text fields under **Vector field**. The vector field **v** is the same as **u** but normalized if normalization is selected. You can select any other coordinate system in the model from the **Coordinate system** list to use as the coordinate system for defining the vector field. The **Global coordinate system** is the default.

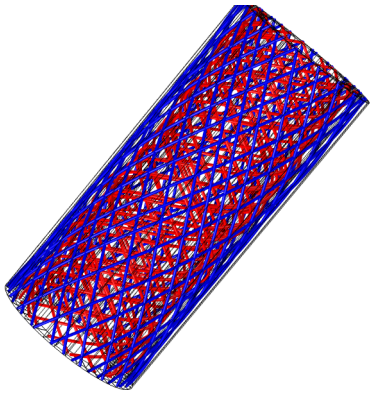

Figure 16-2: A model of arterial wall mechanics, using four user-defined Curvilinear Coordinates interfaces and a cylindrical coordinate system to define the wall pattern.

Inlet

Use an **Inlet** node to define where the vector field starts. Select the boundaries to define as the vector field's inlet in the **Boundary Selection** section.

- For the **Diffusion Method**, the **Inlet** node sets a condition on a value or a flux depending on what you choose from the **Condition on** list in the **Inlet** section:
  - Choose **Value** (the default) to specify that $U = U_0$, where $U_0 = 1$ is the default value.
  - Choose **Flux** to specify that $-\mathbf{n} \cdot \nabla U = F$, where the flux F is 1 by default. For example, if you add a Flux boundary condition, stating that the normal flux is 1, you can combine that boundary condition with an Outlet boundary condition $U = 0$. Then the potential represents the path length from the Outlet boundary.
- For the **Adaptive Method**, the **Inlet** node identifies a set of exterior boundaries where the vector field enters orthogonally the domain selection. A red arrow in the Graphics window shows the direction of the vector field on the boundary. Select the **Reverse direction** checkbox to reverse the direction of the vector field.
- For the **Elasticity Method**, an **Inlet** node with no selection is added by default. It sets $\mathbf{e} \times \mathbf{n} = 0$ at the inlet.
- For the **Flow Method** you can choose, in the **Inlet** section, to define the type of inlet using the **Type** list:
  - Choose **Normal velocity** to specify the normal velocity $\mathbf{u} \cdot \mathbf{n}$ as a velocity u_n (default value: 1, SI unit: m/s) in the **Velocity** field.
  - Choose **Velocity field** to specify the components of the velocity field $\mathbf{u}_{in}$ in the text fields under **Velocity** (default: 0, SI unit: m/s). In the **Coordinate System Selection** section, you can select any coordinate system for the Component from the **Coordinate system** list to use as the coordinate system for defining the velocity field. The **Global coordinate system** is the default.

Jump

Use a **Jump** node at a boundary to define a closed-loop vector field. You can add **Jump** nodes to interior boundaries. It is equivalent to a jump from 0 to 1 for the **Diffusion Method** and to a flow inlet and a flow outlet (with constant pressure) for the **Flow Method**; see Inlet above for the available settings. This condition is available also for the **Adaptive Method**. For the **Elasticity Method**, the jump condition is not applicable; instead, you can add an **Inlet** node to an interior boundary if needed.

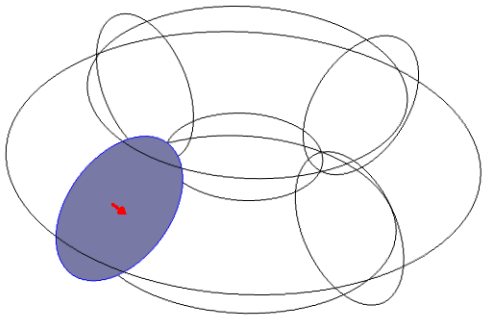

Figure 16-3: A Jump boundary condition applied to one of the interior boundaries of a torus, using a Diffusion method. The arrow indicates the direction of the vector field (the side where the value is 1).

Outlet

Use an **Outlet** node to define where the vector field ends. For the **Diffusion Method**, this means that $U = 0$; for the **Elasticity Method**, it sets $\mathbf{e} \times \mathbf{n}$ to 0. For the **Flow Method**, it is a zero pressure and no stress condition: $p = 0$ and $(\nabla u + (\nabla u)^T) \cdot \mathbf{n} = 0$. Select the boundaries to define as the vector field's outlet in the **Boundary Selection** section.

Wall

The **Wall** node is the default boundary condition and defines the walls as boundaries where the normal component of the vector field is zero. It applies to all boundaries where you do not assign any of the other boundary conditions.

Interior Wall

The **Interior Wall** subnode can be added to the Adaptive Method and Diffusion Method nodes to further shape the direction of the vector field. The subnode can be applied to interior boundaries and will force the vector field to be tangential to the boundary. When applying the Interior Wall subnode, take care to not split the domain selection in multiple nonconnected parts.

Coordinate System Settings

A **Coordinate System Settings** node is added by default if you have selected the **Create base vector system** checkbox in the **Curvilinear Coordinates** node's Settings window. You use this node to specify the second basis vector for the created base vector coordinate system. The Curvilinear Coordinates interface solves for first basis vector and then computes the third basis vector for a full orthonormal coordinate system as the cross product of the first and second basis vector:

$$\mathbf{e}_1 = \frac{\mathbf{v}}{|\mathbf{v}|}$$

$$\mathbf{e}_2 = \frac{\mathbf{v}_2 - (\mathbf{v}_2 \cdot \mathbf{e}_1)\mathbf{e}_1}{|\mathbf{v}_2 - (\mathbf{v}_2 \cdot \mathbf{e}_1)\mathbf{e}_1|}$$

$$\mathbf{e}_3 = \mathbf{e}_1 \times \mathbf{e}_2$$

The **Coordinate System Settings** node's Settings window includes the following section:

SETTINGS

Here you define the direction of the second basis vector $\mathbf{v}_2$ by selecting one of the directions from the **Second basis vector** list: **x-axis**, **y-axis**, **z-axis** (in 3D), or **User defined**. For **User defined**, enter the components of $\mathbf{v}_2$ in the corresponding text fields under **Second basis vector**. You can select any other coordinate system for the Component from the **Coordinate system** list to use as the coordinate system for defining the second basis vector. The **Global coordinate system** is the default.

Using Extra Dimensions

Extra dimensions can be used to extend a standard geometry with additional spatial dimensions. Using extra dimensions it is possible, in principle, to solve PDEs in any number of independent variables, beyond 3D and time.

- Adding Extra Dimensions to a Model
- Definitions

1 To add an extra dimension, right-click the **Global Definitions** node. See Adding Extra Dimensions to a Model. The settings for the **Extra Dimension** node are the same as for the **Component** node, except it has a unique **Name**.

2 From the Definitions node, attach the extra dimensions to a selection in the base geometry. See Attached Dimensions.

3 As required, add and define Points to Attach, Average Over Extra Dimension, and Integration Over Extra Dimension nodes.

4 Adjust the settings for these topics: Defining Equations and Variables on Extra Dimensions, Selections in the Geometry, and Plotting Results in Extra Dimensions.

DEFINING EQUATIONS AND VARIABLES ON EXTRA DIMENSIONS

To define equations in the product geometry formed by an Attached Dimensions feature, add a Weak Contribution (PDEs and Physics) feature to any physics. In the **Selection** section, select an extra dimension attachment feature in the **Extra dimensions to attach** table, and make a selection of geometric entities in the base geometry and in each attached extra dimension.

By default, there are no dependent variables defined in the extra dimensions. To define dependent variables, add an Auxiliary Dependent Variable subfeature, and then select the geometric entities in the base and extra dimension geometries where it should be defined.

Constraints in the extra dimensions can be defined by using Pointwise Constraint or Weak Constraint features with a selection in the product geometry.

SELECTIONS IN THE GEOMETRY

Whenever an extra dimension geometry has been attached using an Attached Dimensions feature, an **Extra dimensions attachment** list is available in the selection section for features that support selection in the product geometry. By default the extra dimension attachment is set to **None**.

If the **Extra dimensions attachment** setting is changed to one of the **Attached Dimensions** features, additional inputs appear for each attached extra dimension geometry. Use these to choose the geometric entity level and the geometric entities to select in each extra dimension.

Features that support selection in the product geometry are Variables, Weak Contribution (PDEs and Physics), Auxiliary Dependent Variable, Pointwise Constraint, Weak Constraint, and General Extrusion.

PLOTTING RESULTS IN EXTRA DIMENSIONS

A solution obtained by means of extra dimensions can be plotted in several ways:

- A “horizontal” section through the product geometry can be plotted by using one of the `atxd` operators. For example, if a 2D extra dimension has the tag `xdim`, the operator `xdim1.atxd2(x0,y0,expr)` evaluates `expr` at a point in the product geometry, defined by the coordinates (x0,y0) in the extra dimension geometry.

- Averages over sections through the product geometry can be computed by using operators defined by Average Over Extra Dimension features. For example, if an average operator called `xdaveop1` has been defined, `xdim1.xdaveop1(expr)` computes the average of `expr` over sections through the product geometry corresponding to the operator's selection of geometric entities in the extra dimension geometry.
- Integrals over sections through the product geometry can be computed by using operators defined by Integration Over Extra Dimension features. For example, if an integration operator called `xdintop1` has been defined, `xdim1.xdintop1(expr)` integrates `expr` over sections through the product geometry corresponding to the operator's selection of geometric entities in the extra dimension geometry.
- It is also possible to make plots to plot along "vertical" sections through the product geometry. With Datasets, select the extra dimension as Component. Then, for example, if the base geometry is in 3D and the extra dimension's name is `xdim1`, evaluate `comp1.atxd3(x0,y0,z0,expr)`, where (x_0, y_0, z_0) define the coordinates of a point in the base geometry.

EVALUATION OF VARIABLES IN EXTRA DIMENSIONS

When working with extra dimensions, variables can be defined on the base geometry, on an extra dimension, or on a product geometry formed from the base geometry and one or several extra dimensions.

When evaluating a variable v in a product geometry, the rules for resolving the correct definition of v are as follows:

- If the variable is defined in the product geometry, this definition is used.
- Otherwise, if the variable has a definition in the base geometry, the variable is evaluated in the base geometry.
- Finally, if the variable is not defined in the product geometry or base geometry, but is defined in one of the extra dimensions, then it is evaluated in this extra dimension.

NAMING OF PARTIAL DERIVATIVE IN EXTRA DIMENSIONS

Partial derivatives of dependent variables defined on a product of geometric entities of full dimension are formed by appending a coordinate name from the base geometry or one of the extra dimensions. For example, if `u` is a dependent variable, the coordinates in a 2D base geometry are called `x` and `y`; the coordinates in a 2D extra dimension are called `x1` and `y1`; and the partial derivatives with respect to those coordinates are called `ux`, `uy`, `ux1`, and `uy1`, respectively. However, if the dependent variable is defined on an entity of lower dimension in either the base geometry or the extra dimension, insert the character `T` between the dependent variable name and the coordinate name. For example, if `u` is defined on the product of a domain in the base geometry and a boundary in the extra dimension (or vice versa), the partial derivatives are called `uTx`, `uTy`, `uTx1`, and `uTy1`.

Second derivatives follow the same pattern; for example, you can use `uxx1`, if `u` is defined on a product of entities of full dimension, or `uTxx1`, if `u` is defined on a product of entities of lower dimension.

You can also use the `d` and `dtang` operators to evaluate the partial derivatives of dependent variables defined in a product geometry.

- Example: Solving Poisson's Equation in a Cylinder by Means of Extra Dimensions
- Results Analysis and Plots
- Working with Geometric Entities
- Named Selections

Attached Dimensions

An **Attached Dimensions** ( ) node forms the Cartesian product of its selection in the base geometry and the entire geometries of all selected extra dimensions. It is possible to add several Attached Dimensions features forming

Cartesian products with different sets of extra dimensions. Each such Cartesian product is called a *product geometry*.

Before Extra Dimensions can be used in physics, it must be attached on a selection in the base geometry. Under the base **Component** node, right-click **Definitions** and from the **Extra Dimensions** submenu, select **Attached Dimensions**.

Example: Solving Poisson's Equation in a Cylinder by Means of Extra Dimensions

GEOMETRIC ENTITY SELECTION

From the **Geometric entity level** list, choose **Entire geometry** (the default), **Domain**, **Boundary**, **Edge** (3D), or **Point** to determine where extra dimensions should be attached.

Click the **Active** button to toggle between turning ON and OFF selections.

ATTACHED DIMENSIONS

In the **Extra dimensions to attach** list, add the Extra Dimension features to attach. A product geometry is formed as the Cartesian product of the selection of geometric entities in the base geometry and the entire geometry in all selected extra dimensions. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the Extra Dimension features that you want to attach. See Figure 16-4.

When the **Attached Dimensions** ( ) node is used in the **Extra dimensions to attach** by some selection in the model, it is not possible to make changes in the list of attached dimensions.

To make a change in the list of attached dimensions, change the **Extra dimensions to attach** list in all selections using the **Attached Dimensions** feature to some other **Attached Dimensions** feature or to **None**.

Deleting an **Attached Dimensions** node from the model resets **Extra dimensions to attach** to **None** for all selections using this **Attached Dimension** node.

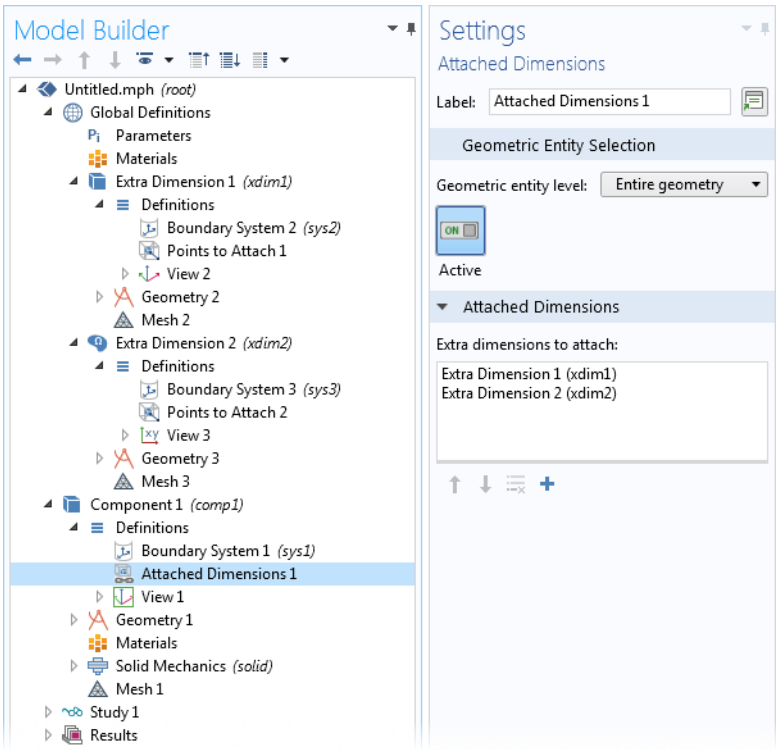

Figure 16-4: The Attached Dimension feature lists all the Extra Dimensions added to a Component. In this example, there are 3D and 2D Extra Dimensions at the Global level. Note that there is also a Definitions node under Extra Dimensions that contains a default Points to Attach feature.

Points to Attach

In each extra dimension, there is a **Points to Attach** ( ) node added by default to the **Definitions** node under Extra Dimension (See Figure 16-4). This can be used to select one or several points in the extra dimension geometry that are identified with the base geometry. In other words, the base geometry is identified with one or several sections through the product geometry.

In many cases, it is not necessary to select any points to attach.

POINTS TO ATTACH

Select a set of points in the extra dimension. These points define sections through the product geometry that are identified with the base geometry.

Example: Solving Poisson's Equation in a Cylinder by Means of Extra Dimensions

Average Over Extra Dimension

To add an **Average Over Extra Dimension** (AV) node and create an operator for computing the average over an extra dimension, under the Extra Dimension node, right-click **Definitions** and from the **Extra Dimensions** submenu, choose **Average Over Extra Dimension**.

Also, **Average** operators in other model geometries include an **Evaluate in extra dimension** checkbox in the **Advanced** section. When selected, the average operator computes the average over the extra dimension's source selection for evaluation in each coordinate of the base geometry.

OPERATOR NAME

Enter the **Operator name** of the average operator.

SOURCE SELECTION

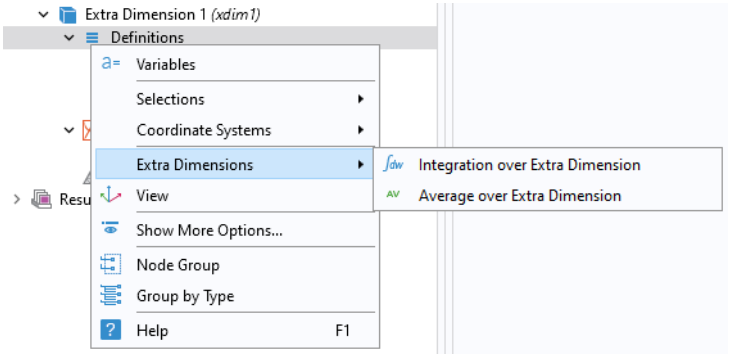
Select the geometric entities in the extra dimension geometry to compute the average for.

ADVANCED

Select the **Integration order** and the **Frame** to compute the average in. If the Extra Dimension is an axisymmetric geometry, the **Compute integral in revolved geometry** checkbox is selected by default.

Integration Over Extra Dimension

To add an **Integration Over Extra Dimension** ($\int dw$) node and create an operator for integration over an extra dimension, under the Extra Dimension node, right-click **Definitions** and from the **Extra Dimensions** submenu, choose **Integration Over Extra Dimension**.



Also, **Integration** operators in other model geometries include an **Evaluate in extra dimension** checkbox in the **Advanced** section. When selected, the integration operator computes the integration over the source selection for evaluation in each coordinate of an extra dimension geometry.

OPERATOR NAME

Enter the **Operator name** of the integration operator.

SOURCE SELECTION

Select the geometric entities in the extra dimension geometry to integrate over.

ADVANCED

Select the **Integration order** and the **Frame** to integrate in. If the Extra Dimension is an axisymmetric geometry, the **Compute integral in revolved geometry** checkbox is selected by default.

Example: Solving Poisson's Equation in a Cylinder by Means of Extra Dimensions

Example: Solving Poisson's Equation in a Cylinder by Means of Extra Dimensions

It is straightforward to solve Poisson's equation in a cylinder by setting up a 3D model in COMSOL Multiphysics. This example illustrates the use of extra dimensions by explaining how to solve the same problem by using a 2D base geometry with a 1D extra dimension.

- Creating a New Model
- Introduction to Solvers and Studies
- Creating a Geometry for Analysis

1 In the Model Wizard, create a 2D model and add a Weak Form PDE, and a **Stationary** study.

2 In the geometry, draw a **Circle** using the default settings.

3 Add an extra dimension. Right-click the **Global Definitions** node and, from the **Extra Dimensions** menu, select **1D** (requires that **Extra Dimensions** is selected in the **Show More Options** dialog).

4 In the extra dimension geometry, **Geometry 2** under **Extra Dimension 1**, draw an **Interval** using the default settings.

5 Attach the extra dimension. Under **Component 1**, right-click **Definitions** and from the **Extra Dimensions** submenu, select **Attached Dimensions** ( ).

6 In the **Settings** window for **Attached Dimensions 1**, click the **Add** button (+) and add **Extra Dimension 1 (xdim1)** to the **Extra dimensions to attach** list.

Attaching this extra dimension forms a cylinder as a Cartesian product of the circle in the base geometry and the interval in the extra dimension geometry.

7 Add an equation on the geometry formed by the Cartesian product. From the **Physics** toolbar, **Domains** menu, click **Weak Contribution**.

8 In the **Settings** window for **Weak Contribution** under **Domain Selection**, select **All domains**.

9 In the **Extra dimensions attachment** list under **Domain Selection**, select **Attached Dimensions 1**. In the **Extra Dimension 1 (xdim1)** selection, select **All domains**. This selects the entire product geometry for the weak contribution.

10 In the **Weak expression** field, enter the expression

```
-test(vx)*vx-test(vy)*vy-test(vx1)*vx1+1[m^-2]*test(v)
```

which is a weak-form expression for Poisson's equation.

11 To add a dependent variable on the product geometry, right-click **Weak Contribution 1** and select **Auxiliary Dependent Variable**.

12 In the **Domain selection** for **Auxiliary Dependent Variable 1**, select **Attached Dimensions 1** in the **Extra dimension attachment** list. In the **Extra Dimension 1 (xdim1)** selection, select **All domains**. This selects the entire product geometry for the auxiliary dependent variable. In the **Field variable name** field, enter the variable name `v`.

13 To add boundary conditions, right-click **Weak Form PDE** and select **More** > **Pointwise Constraint** (in the boundary section). In **Boundary selection** for **Pointwise Constraint 1**, select **All boundaries**, and in the **Extra dimension attachment** list, select **Attached Dimensions 1**. In the **Extra Dimension 1 (xdim1)** selection, select **All domains**. In the **Constraint expression** field, enter the expression `-v`. This applies a constraint $v = 0$ to `v` on the curved surfaces of the cylinder.

14 To add constraints also on the top and bottom of the cylinder, right click **Weak Form PDE** and select **More** > **Pointwise Constraint** (in the domain section). In **Domain Selection** for **Pointwise Constraint 2**, select **All domains**, and in the **Extra dimension attachment** list, select **Attached Dimensions 1**. In the **Extra Dimension 1 (xdim1)** selection, set **Geometric entity level** to **Boundary** and **Selection** to **All boundaries**. In the **Constraint expression** field, enter the expression `-v` to constrain v to 0.

15 Before the model can be solved, it is necessary to add suitable boundary conditions for the default dependent variable `u` (defined only in the base geometry). Right-click **Weak Form PDE**, select **Dirichlet Boundary Condition**, and in **Dirichlet Boundary Condition 1**, select **All boundaries**. By default this boundary condition sets u to 0.

16 Right-click **Study 1** and select **Compute**.

By default a plot of the dependent variable `u`, defined on the base geometry, is shown.

1 To plot `v`, go to **2D Plot Group 1** > **Surface 1** and enter the expression `xdim1.atxd1(0.4,v)`. This makes a plot of `v` on a slice through the cylinder at height 0.4. The `atxd`*`i`* operator evaluates an expression at a location in the extra dimension.

2 To make a plot of `v` along a vertical line, right-click the **Study1/Solution 1** dataset and select **Duplicate**.

3 In the new dataset **Study 1/Solution 1 (2)**, select **Extra Dimension 1 (xdim1)** from the **Component** list.

4 Right-click **Results** and select **1D Plot Group**. In **1D Plot Group 2**, select **Study1/Solution 1 (2)** from the **Dataset** list.

5 Right-click **1D Plot Group 2** and select **Line Graph**. In **Line Graph 1**, set the selection to **All domains**, and under **y-Axis Data**, enter the expression `comp1.atxd2(0.2,0.5,v)`. Also, in the **x-Axis Data** section, choose **Expression** from the **Parameter** list and enter `x1` in the **Expression** field and then click **Plot** to plot the curve versus its spatial variable. This plots `v` along a vertical line above the point with coordinates (0.2, 0.5) in the base geometry.

17

Sensitivity Analysis

This chapter describes how to perform sensitivity analysis using the Sensitivity interface, which is found under the **Mathematics** > **Optimization and Sensitivity** ( ) branch when adding an interface.

In this chapter:

- Theory for the Sensitivity Interface
- The Sensitivity Interface

Theory for the Sensitivity Interface

About Sensitivity Analysis

The Sensitivity interface is special in the sense that it does not contain any physics of its own. Instead, it is a tool for evaluating the sensitivity of a model with respect to almost any variable. The Sensitivity interface is used together with a Sensitivity study step, which in turn controls the Sensitivity solver extension. Simple cases can be handled directly in the Sensitivity study step, while more advanced cases must be set up in a Sensitivity interface prior to solving.

Simulation is a powerful tool for predicting the behavior of physical systems, particularly those that are governed by partial differential equations. However, a single simulation is often not enough to provide sufficient understanding of a system. Hence, a more exploratory process might be needed, such as *sensitivity analysis*, where one is interested in the sensitivity of a specific quantity with respect to variations in certain parameters included in the model. Such an analysis can, for example, be used for estimating modeling errors caused by uncertainties in material properties or for predicting the effect of a geometrical change.

Many times it is possible to reformulate problems of the above type as the problem of calculating derivatives, so differentiation plays a central role in solving such problems. The Sensitivity study step and corresponding physics interface can calculate derivatives of a scalar *objective function* with respect to a specified set of *control variables*. The objective function is in general a function of the solution to a multiphysics problem, which is in turn parameterized by the control variables.

Sensitivity Problem Formulation

Because the Sensitivity interface does not contain any physics, it is not intended for use on its own. When the physics interface is added to a multiphysics model, no new equations are introduced, and the set of solution variables remains the same. Instead, an objective function and a set of control variables can be specified. The Sensitivity interface can perform these distinct tasks:

- Select control variables and set their values
- Define scalar objective functions

The control variables are independent variables whose values are not affected by the solution process, but they are also degrees of freedom (DOFs) stored in the solution vector. When defining a control variable, its *initial value* must be supplied. The initial value is used to initialize the control variable DOFs, which remain fixed during the solution step.

The companion Sensitivity study step is responsible for:

- Choosing which objective functions and control variables to solve for
- Selecting a sensitivity evaluation method
- Selecting which study step to compute sensitivities for
- Setting up the Sensitivity solver extension

Theory for Stationary Sensitivity Analysis

Evaluating the sensitivity of a scalar-valued objective function $Q(\xi)$ with respect to the control variables, ξ, at a specific point, ξ_0, can be rephrased as the problem of calculating the derivative $\partial Q/\partial \xi$ at $\xi = \xi_0$. In the context of a multiphysics model, Q is usually not an explicit expression in the control variables ξ alone. Rather, $Q(u(\xi), \xi)$ is also a function of the solution variables u, which are in turn implicitly functions of ξ. Therefore, by using the chain rule, the sensitivity can be computed as

$$\frac{d}{d\xi}Q(u(\xi), \xi) = \frac{\partial Q}{\partial u}\frac{\partial u}{\partial \xi} + \frac{\partial Q}{\partial \xi} \tag{17-1}$$

The explicit partial derivative of the objective function with respect to the control variables or to the solution u are easy to compute using symbolic differentiation. In contrast, the remaining term, the partial derivative of the solution u with respect to the control variables, is more difficult to obtain. Since the multiphysics problem is a PDE, which after discretization is represented by a system of equations $L(u(\xi), \xi) = 0$, computing the total derivative of this expression with respect to ξ gives

$$0 = \frac{dL}{d\xi} = \frac{\partial L}{\partial u}\frac{\partial u}{\partial \xi} + \frac{\partial L}{\partial \xi}$$

Assuming that $L(u(\xi), \xi) = 0$ has a unique solution, the matrix $\partial L/\partial u$ is nonsingular, which implies

$$\frac{\partial u}{\partial \xi} = -\left[\frac{\partial L}{\partial u}\right]^{-1}\frac{\partial L}{\partial \xi} \tag{17-2}$$

By inserting Equation 17-2 into Equation 17-1, the sensitivity can be rewritten as

$$\frac{d}{d\xi}Q(u(\xi), \xi) = \frac{\partial Q}{\partial u}\frac{\partial u}{\partial \xi} + \frac{\partial Q}{\partial \xi} = -\frac{\partial Q}{\partial u}\left[\frac{\partial L}{\partial u}\right]^{-1}\frac{\partial L}{\partial \xi} + \frac{\partial Q}{\partial \xi} \tag{17-3}$$

Assuming that the PDE solution has N degrees of freedom and that there are n control variables ξ_i, $\partial Q/\partial u$ is an 1-by-N matrix, $\partial L/\partial u$ is an N-by-N matrix, and $\partial L/\partial \xi$ is an N-by-n matrix.

The system of equations, L, is here assumed to include any constraints present in the multiphysics model. The number of degrees of freedom, N, therefore in theory includes also Lagrange multipliers for the constraints. In practice, constraints are usually eliminated, which imposes some restrictions on the sensitivity analysis; see The Sensitivity Analysis Algorithm .

Evaluating the inverse of the N-by-N Jacobian matrix is too expensive. In order to avoid that step, an auxiliary linear problem can be introduced. This can be done in two different ways, each requiring at least one additional linear solution step (see Forward Sensitivity Methods and Adjoint Sensitivity Method below).

If an incomplete Jacobian has been detected during the sensitivity analysis, an attempt to assemble the complete Jacobian is done. If the assembly succeeds, the complete Jacobian is used in sensitivity computations in the following way:

Assume that the Jacobian $\partial L/\partial u$ in Equation 17-1 above is incomplete and denote it by $(\partial L/\partial u)_{\text{incomplete}}$.

Let the complete Jacobian be $\partial L/\partial u$. Hence, the system to solve is

$$\frac{\partial L}{\partial u}\cdot\frac{\partial u}{\partial \xi_i} = -\frac{\partial L}{\partial \xi_i} \tag{17-4}$$

Using

$$\frac{\partial L}{\partial u} = \left(\frac{\partial L}{\partial u}\right)_{\text{incomplete}} + \left(\frac{\partial L}{\partial u} - \left(\frac{\partial L}{\partial u}\right)_{\text{incomplete}}\right)$$

the previous system becomes

$$\left(\frac{\partial L}{\partial u}\right)_{\text{incomplete}} \cdot \frac{\partial u}{\partial \xi_i} = -\frac{\partial L}{\partial \xi_i} - \left(\left(\left(\frac{\partial L}{\partial u}\right)_{\text{incomplete}} - \frac{\partial L}{\partial u}\right) \cdot \frac{\partial u}{\partial \xi_i}\right)$$

Then, the solution to the system in Equation 17-4 is approximated iteratively by

$$\left(\frac{\partial L}{\partial u}\right)_{\text{incomplete}} \cdot \left(\frac{\partial u}{\partial \xi_i}\right)^n = -\frac{\partial L}{\partial \xi_i} - \left(\left(\frac{\partial L}{\partial u}\right)_{\text{incomplete}} - \frac{\partial L}{\partial u}\right) \cdot \left(\frac{\partial u}{\partial \xi_i}\right)^{n-1}$$

where n is the iteration number.

The iterations are terminated either when the estimated error is less than the relative tolerance used by the current solver (convergence), or when the number of iterations has reached the maximum number of iterations specified in the Fully Coupled or Segregated attribute node (nonconvergence).

If the previous algorithm does not converge (that is, the estimated error is larger than the given tolerance), the sensitivity computations are repeated using the incomplete Jacobian and the warning *Jacobian is incomplete. No convergence when attempting to use the complete Jacobian* is written.

If the assemble of the complete Jacobian fails, the incomplete Jacobian is used and the warning *Unable to assemble the complete Jacobian. Using incomplete Jacobian for sensitivity analysis* is written.

FORWARD SENSITIVITY METHODS

The *forward sensitivity* method explicitly computes and returns the term $\partial u/\partial \xi$ in Equation 17-2 in order to compute the sensitivity in Equation 17-1 by solving n linear systems of equations

$$\frac{\partial u}{\partial \xi_i} = -\left[\frac{\partial L}{\partial u}\right]^{-1} \cdot \frac{\partial L}{\partial \xi_i}, \qquad i = 1, \ldots, n$$

When this system is solved, a line is added to the progress window displaying the number (i) of the current sensitivity parameter being solved for.

ADJOINT SENSITIVITY METHOD

To use the *adjoint sensitivity* method, introduce the N-by-1 adjoint solution u^*, which is defined as

$$(u^*)^T = \frac{\partial Q}{\partial u} \cdot \left(\frac{\partial L}{\partial u}\right)^{-1}$$

Multiplying this relation from the right with the PDE Jacobian $\partial L/\partial u$ and transposing leads to a single linear system of equations

$$\frac{\partial L}{\partial u}^T u^* = \left[\frac{\partial Q}{\partial u}\right]^T$$

using the transpose of the original PDE Jacobian.

Specification of the Objective Function

The objective function can in general be a sum of a number of terms:

$$Q(u,\xi) = Q_{\text{global}}(u,\xi) + Q_{\text{probe}}(u,\xi) + \sum_{k=0}^{n} Q_{\text{int},k}(u,\xi)$$

where n is the space dimension of the multiphysics model and the different contributions in the sum above are defined as follows:

- Q_{global} is the *global contribution* to the objective function Q. It is given as one or more general global expressions.
- Q_{probe} is a *probe contribution* to the objective function Q. It is a *probe objective*, so its definition is restricted to a point on a given geometrical entity. The *probe point* used for the point evaluation is a point given by the user and has to be contained in the domain.
- $Q_{\text{int},k}$ is an *integral contribution* to the objective function Q. It is an *integral objective*, so its definition is restricted to a specific set of geometrical entities of the same dimension. For integral contributions on points, the integration reduces to a summation.

Several global, probe, and integral contributions can be defined. In such cases, the total global, probe, and integral contribution is given as the sum of the aforementioned global, probe, and integral contributions that are actively selected in the solver settings for the optimization.

Choosing a Sensitivity Method

To evaluate sensitivities as part of a multiphysics problem solution, an auxiliary linear problem must be solved, in addition to the original equation, using one of these methods:

- Select one of the Forward Sensitivity methods to evaluate the derivatives of all solution variables and an optional objective function.
- Select the Adjoint Sensitivity method to look only at derivatives of a scalar objective function.

FORWARD SENSITIVITY

Use the forward (or forward numeric) sensitivity method to solve for the derivatives of all dependent variables, plus an optional scalar objective function, with respect to a small number of control variables. The forward method requires one extra linear system solution for each control variable.

The linear system that must be solved is the same as the last linearization needed for solving the forward model. Thus, when using a direct solver (for example, PARDISO) the extra work amounts only to one back-substitution per control variable DOF. The forward numeric method uses numerical perturbation rather than analytical methods to calculate forward sensitivities, and can be used when the analytical method fails for some reason or as a tool to verify that the analytical method is correct. In addition, the forward numeric method requires two additional residual evaluations. The iterative linear and segregated solvers can reuse preconditioners and other data but must otherwise perform a complete solution each time. Further, the forward numeric method only differentiates the PDE problem numerically (giving a numeric method for the forward sensitivity). The objective sensitivity is still differentiated analytically (both with respect to the controls and with respect to the PDE variables). The functional sensitivity is therefore computed with a hybrid method.

ADJOINT SENSITIVITY

The adjoint method solves for the derivatives of a single scalar objective function with respect to any number of control variables, requiring only one single additional linear system solution. In addition to the objective function gradient, the discrete adjoint solution is computed. This quantity represents the sensitivity of the objective function with respect to an additional generalized force applied as a nodal force to the corresponding solution component.

The auxiliary linear system is in this case the transpose of the last linearization needed for solving the forward model. The MUMPS and PARDISO linear solvers can solve the transposed problem at the cost of a back-substitution, while the SPOOLES linear solver needs to do a new factorization if the problem is not symmetric or Hermitian. The iterative solvers can reuse most preconditioning information as can the segregated solver, which, however, loops over the segregated steps in reversed order.

Sensitivity analysis can be used together with all stationary and parametric standard solvers and with the BDF solver for transient studies. The available solvers are described in the section Studies and Solvers.

Postprocessing Sensitivities

When a multiphysics problem is solved using sensitivity analysis, the generated solution contains stored sensitivity data. You can access this data in postprocessing using the `fsens` and `sens` operators:

- `fsens(`*`<control_variable>`*`)` evaluates the sensitivity (derivative) of the objective function with respect to the specified control variable. This result is available for all sensitivity methods. The result of `fsens` can be evaluated on the geometric entities where the control variable is defined. For a global control variable, `fsens` is available everywhere. In the same way, `fsensimag(`*`<control_variable>`*`)` evaluates the sensitivity (derivative) of the objective function with respect to the imaginary part of the specified control variable.
- `sens(`*`<dependent_variable>`*`,`*`<control_variable>`*`)` or `sens(`*`<dependent_variable>`*`,`*`<control_DOF>`*`)` evaluates the sensitivity (derivative) of the specified dependent variable with respect to the specified control variable degree of freedom. This is only possible when forward sensitivity has been used, which computes and stores derivatives of the entire solution vector with respect to each control variable degree of freedom.

  Global control variables can be identified by name. Otherwise, control variable degrees of freedom are identified by their index (starting from `1`) among all control variables in the solution vector. The result of `sens` has the same geometric scope as the dependent variable argument; it can be plotted or evaluated wherever the dependent variable itself is available.

Issues to Consider Regarding the Control Variables

THE EFFECT OF DISCRETIZATION

The sensitivity analysis is always performed on the discretized system of equations. As already mentioned, the control variables can be a scalar, vector, or an element in some infinite-dimensional function space. In the latter case, it is represented on the finite element mesh, just like the solution variables, or global scalar quantities. When using a control variable field represented on the finite element mesh, the sensitivities are therefore associated with individual control variable degrees of freedom rather than with the field value at each point. This makes it difficult to interpret the result. For example, if a domain control variable is set up using a first-order Lagrange shape function representation to control the material density in a model, the solution contains the sensitivity of the objective function with respect to the discrete density value at each node point in the mesh. Because each node influences the density in a small surrounding region, the size of which varies from node to node, the individual sensitivities are not directly comparable to each other.

Displaying such domain control variables results in a plot that is not smooth due to the varying element size. It must therefore not be used to draw any conclusions about the physics and the effect of changing the physical field represented by the control variable. Some insight can, however, be gained by looking at the sensitivities divided by the mesh volume scale factor `dvol`. This makes the sensitivities in the plot comparable between different parts of

the surface but still not mathematically well defined. In particular, using discontinuous constant shape functions together with the division by `dvol` results in a plot that is proportional to the true pointwise sensitivity.

If the plan is to use the sensitivities in an automatic optimization procedure, as is done through the Optimization interface available with the Optimization Module, the discrete nature of the sensitivities causes no additional complication. The optimization solver searches for optimum values of the discrete control variables using the discrete gradient provided by the sensitivity analysis.

GEOMETRICAL SENSITIVITY

You can use the control variables directly to parameterize any aspect of the physics that is controlled by an expression. This applies to material properties, boundary conditions, loads, and sources. However, the shape, size, and position of parts of the geometry cannot be changed as easily at solution time and require special attention.

Control variables cannot be used directly in the geometry description. Instead, the model must be set up using a Deformed Geometry or Moving Mesh interface to control the shape of the geometry. Then use control variables to control the mesh movement, effectively parameterizing the geometry.

See Deformed Geometry and Moving Mesh for details about these interfaces and ALE in general.

Issues to Consider Regarding the Objective Function

THE PRINCIPLE OF VIRTUAL WORK

Potential energy has a special status among scalar objective functions because its derivatives with respect to scalar control variables can in many cases be interpreted as (true or generalized) forces.

COMPLEX-VALUED OBJECTIVE FUNCTIONS

Sensitivity analysis can be directly applied only when the objective function is a real differentiable or complex analytic function of the control variables. This is usually not a severe constraint, even for frequency-domain models where the PDE solution variables are complex valued. One reason is that physical quantities of interest to the analyst are always real valued, and if complex-valued control variables are required, it is possible to treat the real and imaginary parts separately.

Some PDE problem or the objective functions are, however, nonanalytic. This is the case, for example, when the equations or the objective function contain `real()`, `imag()`, or `abs()`. One solution in such cases is to enable **Split complex variables in real and imaginary parts** in the **Compile Equations** node corresponding to the study step for which sensitivity is computed. This converts the discretized PDE system from a complex-valued system to a real-valued system of double size, with separate degrees of freedom for the real and imaginary part. For this split system, also the nonanalytic functions are differentiable almost everywhere such that sensitivities can be computed.

One special form of nonanalytic objective functions can be treated more efficiently than splitting the variables: many common quantities of interest are harmonic time averages, which can be written in the form $Q = \mathrm{real}(a \cdot \mathrm{conj}(b))$, where a and b are complex-valued linear functions of the solution variables and therefore implicit functions of the control variables. The problem with this expression is that, while Q is indeed a real-valued differentiable function of the control variables, it is not an analytical function of a and b. This complicates matters slightly because the sensitivity solver relies on symbolic partial differentiation and the chain rule.

While the partial derivatives of Q with respect to a and b are, strictly speaking, undefined, it can be proven that if they are chosen such that

$$Q(a+\delta a, b+\delta b) \approx Q(a,b) + \text{real}\left(\frac{\partial Q}{\partial a}\delta a + \frac{\partial Q}{\partial b}\delta b\right) \tag{17-5}$$

for any small complex increments δa and δb, the final sensitivities are evaluated correctly. The special function `realdot(a,b)` is identical to `real(a*conj(b))` when evaluated but implements partial derivatives according to Equation 17-5. For that reason, use it in the definition of any time-average quantity set as objective function in a sensitivity analysis.

Issues to Consider Regarding Constraints

The theory behind sensitivity analysis as presented above (under Theory for Stationary Sensitivity Analysis) assumes that constraints on the multiphysics problem are handled in the same way as with any other equations. This is indeed the case for *weak constraints*, which are implemented as a part of the main system of equations. Standard pointwise constraints are instead eliminated from the discretized equations at an early stage in the solution process. This elimination is not visible to the sensitivity solver, which therefore may miss some symbolic derivative terms necessary for computing a correct sensitivity.

In particular, if the mixed second derivative of a standard constraint with respect to both PDE solution and control variables is nonzero, sensitivity will not be correctly computed. For example, for a solution variable u and a control variable p, a constraint:

- $u = p$ will give correct sensitivity.
- $u^2 = p^2$ will give correct sensitivity.
- $u^2 = up$ will give incorrect sensitivity.

If your multiphysics model contains constraints of the problematic type, you can still compute a correct sensitivity, provided that you enable *weak constraints* in the **Constraint Settings** section of the corresponding boundary condition node.

For technical details about the solver implementation, see The Sensitivity Analysis Algorithm.

For more about the standard versus the weak constraints, see Boundary Conditions.

The Sensitivity Interface

The **Sensitivity (sens)** interface ( ), found under the **Mathematics** > **Optimization and Sensitivity** ( ) branch when adding a physics interface, provides tools for adding advanced sensitivity evaluation to a stationary model. Basic problems defined only in terms of global scalar objective functions and model parameters can be set up directly in a Sensitivity study step and therefore do not require the use of a Sensitivity interface.

	For a more extensive introduction to the mathematics implemented by this physics interface, see the Theory for the Sensitivity Interface.

The objective functions are defined in terms of control and solution variables (the latter are given as the solution to the differential equations defined by the multiphysics model), which can be fields dependent on position in space or scalar quantities defined globally. This flexibility is reflected in the physics interface by grouping these settings according to the dimension of the domain to which they apply. In such a group of settings, the following settings can be specified, to which each corresponds a separate feature and its Settings window:

- Integral Objective
- Probe Objective
- Control Variable Field

	Note that adding a Sensitivity study step to a study makes it possible to perform a sensitivity analysis directly at the study level. See Sensitivity.

SENSITIVITY TOOLBAR

The following nodes are available from the **Sensitivity** ribbon toolbar (Windows users), **Sensitivity** context menu (Mac or Linux users), or by right-clicking to access the context menu (all users).

	For step-by-step instructions and general documentation descriptions, this is the **Sensitivity** toolbar.

TABLE 17-1: THE SENSITIVITY TOOLBAR.

BUTTON OR MENU	NAME
Physics	
	Add Physics
Global	
	Global Objective
	Global Control Variables

The main **Settings** window for the **Sensitivity** node contains the following section:

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `sens`.

- Common Physics Interface and Feature Settings and Nodes
- Global Objective
- Global Control Variables

Sensitivity Analysis of a Communication Mast Detail: Application Library path **COMSOL_Multiphysics/Structural_Mechanics/ mast_diagonal_mounting_sensitivity**

Integral Objective

An **Integral Objective** is defined as the integral of a closed form expression of control and solution variables (the latter are given as the solution to the differential equations defined by the multiphysics model) that are either global or available in the domain in question. Hence, its definition is restricted to a set of geometric entities of the same dimension. For integral objectives on points, the integration reduces to a summation.

OBJECTIVE

Enter an **Objective expression** that is integrated over the geometric entity level in the integral objective.

QUADRATURE SETTINGS

Specify the settings for the **Quadrature** used to numerically evaluate the integral in the integral objective: the integration order (default: 4) in the **Integration order** field and the frame to integrate on (default: the spatial frame), which is selected from the **Integrate on frame** list.

Probe Objective

A **Probe Objective** is defined as a point evaluation of a closed form expression of control and solution variables (the latter are given as the solution to the differential equations defined by the multiphysics model) that are either global or available in the domain in question. The point used for the point evaluation has to be contained in the domain.

OBJECTIVE

Enter an **Objective expression** that is evaluated at the point in the domain.

PROBE COORDINATES

Specify the **Probe coordinates** for the point in the domain where the expression for the objective is evaluated. After specifying the probe coordinates, select an option from the **Evaluate in frame** — **Spatial** (the default), **Material**, or **Mesh**.

Control Variable Field

Add a **Control Variable Field** node ( ) by right-clicking a **Component** node and choose it from the **Control Variables** submenu. It is also available on the **Definitions** ribbon toolbar, from the **Optimization** menu. Specify the **Control**

Variable Field to add a control variable specific to the geometric entity level (domain, edge, boundary, or point) in question. The field can be accessed via its **Name** throughout the model.

GEOMETRIC ENTITY SELECTION

Here you specify the geometric entity level and the selection of geometric entities on that level for which the control variable should be defined.

DISCRETIZATION

This section contains settings for the element used to discretize the control variable. Select a **Shape function type**: **Lagrange** (the default) or **Discontinuous Lagrange**. Also select an **Element order**: **Linear**, **Quadratic** (the default), **Cubic**, **Quartic**, or **Quintic**. For **Discontinuous Lagrange**, one can also pick **Constant** shape functions. The value type (complex or real) for all the variables defined by this **Global Equations** node is selected in the **Value type when using splitting of complex variables** selection. The default value type is **Complex**.

INITIAL VALUE

Here you specify a value of expression for the initial values of the control variable in the **Initial value** field.

BOUNDS

By default, the **Use bounds** checkbox is selected so that you can add bounds for the control variable in the **Lower bound** and **Upper bound** fields. Note that the bounds are only respected at gauss points, so local violation may occur if the **Element order** is not either **Linear** or **Constant**.

SCALING

If desired, you can scale the control variable using a scalar value that you enter in the **Scale** field (default: 1; that is, no scaling). A large scale will generally cause the optimization solvers to take longer steps (MMA without move limits is the exception).

Common Physics Interface and Feature Settings and Nodes

Global Objective

Specify the **Global Objective** contribution to the function by entering an objective expression. To add this feature, either right-click the **Sensitivity** interface node and select it from the context menu, or in the **Physics** toolbar, click **Global Objective** ( ).

OBJECTIVE

Enter an **Objective expression** that defines the contribution to the objective function. It can be an expression of those components of the control and solution variable (the solution variable is given as the solution to the differential equations defined by the multiphysics model) that are globally available.

Global Control Variables

Use the **Global Control Variables** node to specify any globally available control variables. To add this feature, either right-click the **Sensitivity** interface node and select it from the context menu, or in the **Physics** toolbar, click **Global Control Variables** ( ).

CONTROL VARIABLES

In the table, enter **Variable** names and **Initial values** of the control variables that are globally available. To add a control variable to the table, click the **Add** button (+). To remove a control variable and its values from the table, click the **Delete** button ( ).

Deformed Geometry and Moving Mesh

This chapter explains how to use the moving mesh and deformed geometry functionality for adding moving meshes to COMSOL Multiphysics models. There is also information about the dedicated interfaces that control mesh deformation, which you find under the **Mathematics** > **Deformed Mesh** branch ( ) when adding physics interfaces to a model. It also contains fundamentals about deformed meshes and information about the Eulerian and Lagrangian formulations of the physics, the frame types that support these formulations, and the arbitrary Lagrangian-Eulerian (ALE) method.

In this chapter:

- Deformed Mesh Fundamentals
- Deformed Mesh Definition Features
- The Moving Mesh Interface
- The Deformed Geometry Interface

Deformed Mesh Fundamentals

About Deformed Meshes

A deformed mesh can be useful if the boundaries of your computational domain are moving in time or deform as a function of some parameter. The deformation can also be physics-induced — for example, depending on computed velocities or solid deformation. The point is that a new mesh need not be generated for each configuration of the boundaries — instead, the software perturbs the mesh nodes so they conform with the moved boundaries.

In COMSOL Multiphysics, you can control the movement of the interior nodes in these ways:

- By propagating the moving boundary displacement throughout the domain to obtain a smooth mesh deformation everywhere. This is done by solving PDEs for the mesh displacements (a Laplace or Winslow smoothing PDE, or one borrowed from continuum mechanics) with boundary conditions given by the movement of the boundaries.
- By specifying an explicit formula for the mesh deformation. The formula can make use of other dependent variables, such as the displacement components of structural mechanics.
- By leaving the control of the mesh displacement to a Solid Mechanics interface, which has built-in deformed mesh functionality.

Deformed Geometry vs. Moving Mesh

You can set up mesh deformation in two different ways, depending on the intended behavior of the model: either the deformation represents a fundamental change in the shape of the geometry, or it represents the shape change induced by deformation of solid materials. COMSOL Multiphysics refers to the former as *Deformed Geometry* and the latter as *Moving Mesh* functionality. Technically, the difference is that Deformed Geometry functionality deforms the material frame mesh relative to the geometry frame mesh, while Moving Mesh functionality deforms the spatial frame mesh relative to the material frame mesh. Both types of deformation can be used at the same time, one on top of the other.

The features and interfaces that let you specify the deformation of the material and spatial frame meshes, respectively, are the same in both cases, but are found in different places in the Model Builder tree. You can control the mesh deformations either using features added directly to the **Moving Mesh** and **Deformed Geometry** branches in a Component, or by adding a **Deformed Geometry** ( ) or **Moving Mesh** ( ) interface from the **Mathematics** > **Deformed Mesh** branch ( ) in the **Model Wizard** or **Add Physics** window.

The features available directly in the **Moving Mesh** and **Deformed Geometry** branches in a component are slightly less general than some available in the corresponding interfaces. But the **Moving Mesh** and **Deformed Geometry** branches have the advantage that physics interfaces can be aware of and interact with them, something which is important for fluid structure interaction (FSI) and rotating machinery or mixer applications, for example.

When using Deformed Geometry functionality, the material does not follow the change in shape. Deformation of the geometry boundaries therefore corresponds to addition or removal of material. When using Moving Mesh features, solid materials follow the mesh deformation and deform in the same way as the mesh. Fluids and gases,

however, are added or removed so as to always fill the current shape of the domain — any effects of compression or expansion must be introduced explicitly into the equations.

- Use Deformed Geometry features to study the behavior of different shapes of an original object. In a model with Deformed Geometry, the material never follows a perturbation of the shape. The total mass of the first shape is not the same as the mass for the second, perturbed geometry. Any deformation can be regarded as removal or addition of material. However, it is possible to make use of the Deformed Geometry functionality to study an incremental elastic deformation of a structure using an Elastic Predeformation feature available in the Solid Mechanics interface (requires the Structural Mechanics Module or MEMS Module).
- Use Moving Mesh features to study how a solid object deforms as the results of physical load, and how fluids in adjacent domains react to displacement of the domain boundaries — for example, how a tank impeller moves a fluid, or how a MEMS switch moves under the influence of an electric field. In a model with Moving Mesh, a solid material follows the mesh deformation. A movement of a boundary can therefore be regarded as bending or punching the original object. Undeformed and deformed solid objects have the same mass, but the total amount of fluid in a domain whose boundaries deform can change.

Arbitrary Lagrangian–Eulerian Formulation (ALE)

The partial differential equations of physics are usually formulated either in a *spatial* coordinate system, with coordinate axes fixed in space, or in a *material* coordinate system, fixed to the material in its reference configuration and following the material as it deforms. The former is often referred to as an *Eulerian* formulation, while the latter is a *Lagrangian* formulation.

Structural mechanics and other fields of physics dealing with a possibly anisotropic, solid material are most conveniently simulated using material coordinates. The Lagrangian formulation makes the anisotropic material properties independent of the current spatial orientation of the material.

However, if the focus is on simulating the physical state at fixed points in space, an Eulerian formulation is usually more convenient. In particular, when liquids and gases are involved, it is often unreasonable to track the state of individual material particles. Rather, the quantities of interest are pressure, temperature, concentration, and so forth, at fixed positions in space.

An inherent problem with the pure Eulerian formulation is that it cannot handle moving domain boundaries, since physical quantities are referred to fixed points in space, while the set of spatial points inside the domain boundaries changes with time. Therefore, to allow moving boundaries, the Eulerian equations must be rewritten so as to describe all physical quantities as functions of some coordinate system in which the domain boundaries are fixed. The finite element mesh offers one such system: the *mesh* coordinates.

In the mesh coordinate system, the domain is fixed, and there is a one-to-one map from the mesh coordinates to the current spatial configuration of the domain. Otherwise, the mesh coordinate system can be defined freely and separately from both the spatial and material systems. The natural choice is to let the mesh coordinate system, at least initially, coincide with the *geometry* coordinates. This follows immediately from the way meshes are created and means that points in the domain are identified by their position in the original geometry.

As the domain and mesh deform, the map from mesh coordinates to spatial coordinates can become increasingly ill-conditioned. Before the degradation of the mesh mapping goes too far, you can, using a remeshing operation, stop the simulation, create a new mesh in the current configuration of the domain, and map all quantities to the new mesh. When you restart the simulation, points in the domain are internally identified by their new mesh coordinates, which coincide with the spatial coordinates at the state where the simulation was stopped. Therefore, the geometry and mesh coordinates of a given point differ after remeshing the deformed geometry.

Rewriting physics equations in this way, on a freely moving mesh, results in an *arbitrary Lagrangian–Eulerian* (ALE) method. In the special case when the map from mesh coordinates to spatial coordinates follows the material

deformation, a Lagrangian method is recovered. Similarly, when the map is an identity map, the ALE method becomes entirely Eulerian.

The ALE method is therefore an intermediate between the Lagrangian and Eulerian methods, and it combines the best features of both: it allows moving boundaries without the need for the mesh movement to follow the material.

About Frames

The COMSOL Multiphysics software refers to the spatial, material/reference, geometry, and mesh coordinate systems described above as *spatial frame*, *material frame* (reference frame), *geometry frame*, and *mesh frame*, respectively. Physics can be formulated in the spatial frame or in the material frame, depending on whether it is more convenient to interpret the equations as Eulerian or Lagrangian, respectively. It is not possible to use the geometry and mesh frames and their associated coordinates to formulate physics because they are neither connected to the material nor to the true Euclidean space.

Conceptually, all four frames always exist, with their own separate coordinate names:

- The spatial frame coordinates are by default `x`, `y`, `z`, or `r`, `phi`, `z` in an axisymmetric geometry.
- The material frame coordinates are by default `X`, `Y`, `Z`, or `R`, `PHI`, `Z` in an axisymmetric geometry.
- The geometry frame coordinates are by default `Xg`, `Yg`, `Zg`, or `Rg`, `PHIg`, `Zg` in an axisymmetric geometry.
- The mesh frame coordinates are by default `Xm`, `Ym`, `Zm` or `Rm`, `PHIm`, `Zm` in an axisymmetric geometry.

You can change these names in the **Settings** window of a Component. Initially, all frames coincide and their coordinates evaluate to the same value at any given point in the mesh; technically, the spatial, material, and geometry coordinates are all aliases for the mesh coordinates.

When a Moving Mesh feature is added to a component, or a structural mechanics interface is added and **Include geometric nonlinearity** is switched on in a study step, the spatial frame is separated from the material frame. From this point, spatial and material coordinates will evaluate differently at a given point in the mesh. Eulerian and Lagrangian formulations behave differently because they, among other things, define derivatives with respect to different sets of independent variables.

The geometry frame and the material frame coordinates coincide until a Deformed Geometry feature is added, or you enable shape optimization (available with the Optimization Module). From that point, the geometry frame coordinates refer to the geometry as it is represented by the Geometry Sequence, while the material frame coordinates represent the geometry seen by physics interfaces. By inserting a nontrivial transformation from geometry coordinates to material coordinates, the shape of the geometry can be effectively changed without having to create a new mesh. This can be useful as a means of parameterizing the geometry, for example, before performing optimization or sensitivity analysis.

Using Deformed Geometry features affects both Eulerian and Lagrangian physics in the same way. The reason is that the Deformed Geometry interface controls the material frame in relation to the geometry frame. Unless there is also a Moving Mesh or Solid Mechanics interface present, the material frame and spatial frame coordinates still coincide, so the spatial mesh is deformed in the same way as the material mesh. The three frames refer to three different sets of coordinates only when there is both some Deformed Geometry feature and some Moving Mesh feature active in the Component.

The geometry frame and the mesh frame coincide until a manual or automatic remeshing operation is performed. At that point, a new mesh is created in the original geometry, and mesh frame coordinates are associated with this new mesh. The original geometry coordinates are mapped and stored together with the new mesh such that any Deformed Geometry interface can still define the material frame relative to the original geometry shape.

To avoid confusion, note that:

- The *spatial frame* is the usual, fixed, global, Euclidean coordinate system with the *spatial coordinates* (*x*, *y*). In the ALE context, the spatial coordinate system as such is fixed, while the spatial coordinates (x, y) of each material point and mesh node can be functions of time. Therefore, it is correct to refer to the model as having a *moving mesh*.
- The *material frame* is a coordinate system that identifies material points by their spatial coordinates (X, Y) in some — actual or imagined — reference configuration. Think of the material coordinate system as having been printed on the material in the reference configuration such that it follows it during deformation. It is therefore in general curvilinear and cannot be used directly to measure true distances and angles. See also Figure 18-1 and Figure 18-2.
- The *geometry frame* is a coordinate system that identifies points by their spatial coordinates (X_g, Y_g) in the original geometry. It is often natural to use the original geometry also as reference state to define material coordinates. Therefore, the geometry frame and material frame usually coincide. The only exception is when some Deformed Geometry feature is used to deform or parameterize the original geometry.
- The *mesh frame* is a coordinate system used internally by the finite element method. It identifies mesh points by their spatial coordinates (X_m, Y_m) at the time the mesh was created. The original mesh is always created based on the original geometry. Therefore, the mesh frame coincides with the geometry frame until a new mesh is created in the — then current — deformed configuration.

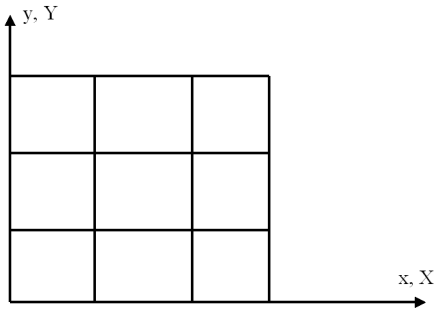

Figure 18-1: An undeformed mesh. In the reference configuration, which can be the actual configuration at a reference time or a hypothetical state, the spatial frame (x, y) and the material frame (X, Y) coincide.

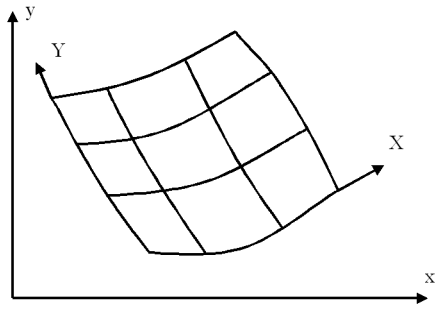

Figure 18-2: After deformation of the material, the spatial frame (x, y) remains the same, while the material coordinate system (X, Y) has been deformed, following the material. Meanwhile, the material coordinates of each material point remain the same but its spatial coordinates have changed.

Mathematical Description of the Mesh Movement

Consider a 2D geometry for simplicity, where the spatial and material frame coordinates are called (x, y) and (X, Y), respectively. Let (X_0, Y_0) be the coordinates of a mesh node in the initial material configuration. The spatial coordinates (x_0, y_0) of the same mesh node at some other time, t, are then given by the functions

$$x_0 = x(X_0, Y_0, t), \qquad y_0 = y(X_0, Y_0, t) \tag{18-1}$$

These functions can be explicit transformations (expressions) or the solution to a mesh smoothing equation. The mesh node's material coordinates (X_0, Y_0) can in turn be seen as functions of an underlying system of geometry coordinates (X_g, Y_g) and a parameter, p, such that

$$X_0 = X(X_g, Y_g, p), \qquad Y_0 = Y(X_g, Y_g, p) \tag{18-2}$$

with similar options for the transformations. The transformations can also be chained such that (x_0, y_0) are seen as functions of (X_g, Y_g), t, and p.

Introducing a vector notation for the coordinates:

- Spatial coordinates $\mathbf{x} = [x, y, z]$
- Material coordinates $\mathbf{X} = [X, Y, Z]$
- Geometry coordinates $\mathbf{X}_g = [X_g, Y_g, Z_g]$
- Mesh coordinates $\mathbf{X}_m = [X_m, Y_m, Z_m]$

The general relation between the frames can be written

$$\begin{aligned} \mathbf{x} = \mathbf{f}(\mathbf{X}, t) = \mathbf{f}(\mathbf{g}(\mathbf{X}_g, p), t) \\ \mathbf{X} = \mathbf{g}(\mathbf{X}_g, p) \\ \mathbf{X}_m = \mathbf{h}(\mathbf{X}_g, i) \end{aligned} \tag{18-3}$$

where $\mathbf{f}$, $\mathbf{g}$, and $\mathbf{h}$ are vector-valued functions, t is time, p is some set of parameters controlling Deformed Geometry features, and i is number of times the geometry has been remeshed. From the physics point of view, the domain is fixed in the geometry frame coordinates $\mathbf{X}_g$, which are therefore seen as constant in the above formulas.

From the finite elements' point of view, it is instead the mesh frame coordinates $\mathbf{X}_m$ that are constant and $\mathbf{X}_g = \mathbf{h}^{-1}(\mathbf{X}_m, i)$. Therefore when assembling the finite-element matrices, the relation actually used is

$$\mathbf{x} = \mathbf{f}(\mathbf{g}(\mathbf{h}^{-1}(\mathbf{X}_m, i), p), t)$$

where $\mathbf{f}$ is a unit map if the spatial and material frames coincide, $\mathbf{g}$ is a unit map if the material and geometry frames coincide, and the inverse mapping $\mathbf{h}^{-1}(\mathbf{X}_m, i)$ is initially a unit map and then updated by interpolation after each remeshing operation.

In addition to the different sets of coordinate variables, some other geometric variables that the software defines are available for both the spatial and material frames (see Geometric Variables, Mesh Variables, and Variables Created by Frames).

Derivatives of Dependent Variables

When solving for some physical quantity, u, COMSOL Multiphysics always stores the solution for a fixed set of mesh nodes. That is, the dependent variable u is treated internally as a function of the mesh coordinates and possibly time, $u(X_m, Y_m, t)$. The essence of the ALE system is that it allows treating the physical quantities as functions of the material or spatial coordinates, $u(X, Y, t)$ or $u(x, y, t)$, instead. This transformation is possible only if the mappings given by Equation 18-1 and Equation 18-2 are invertible.

DIFFERENTIATION IN SPACE

With respect to spatial differentiation, each dependent variable is treated as a function of one or more of the frames present in the model. Most physics interfaces are based on a formulation which is either Eulerian or Lagrangian. Their equations therefore contain derivatives of the dependent variables with respect to either the spatial or the material frame, respectively. A few physics interfaces can formulate their equations in either material or spatial frame, as set by the **Frame** setting found under **Discretization** in the physics interface node's settings.

For compactness, physics interface equations are written using derivative variables. For a dependent variable `u`, there are two basic possibilities:

- The variable is used primarily as a function of spatial coordinates. Derivatives with respect to the spatial frame are therefore defined as variables, denoted `ux` and `uy` in the software.
- The variable is used primarily as a function of material coordinates. Derivatives with respect to the material frame are therefore defined as variables, denoted `uX` and `uY` in the software.

But in many cases both sets of derivative variables exist even if they are not used by the physics interface. In addition, the built-in differentiation operator `d(`*<expr>*`,`*<var>*`)` can always compute derivatives with respect to any set of coordinates, internally using the chain rule. For example, the first component of the spatial, material, and geometry frame gradients of `u` are, respectively `d(u,x)`, `d(u,X)`, and `d(u,Xg)`.

DIFFERENTIATION IN TIME

When using ALE, there can be two kinds of time derivatives:

- The *frame time derivative*, valid for a fixed point in either the material or the spatial frame. This derivative is denoted `ut` in some physics interfaces. It is defined either as

$$u_t(x_0, y_0) = \left.\frac{\partial u}{\partial t}\right|_{x_0, y_0}$$

  in interfaces using an Eulerian formulation, or as

$$u_t(X_0, Y_0) = \left.\frac{\partial u}{\partial t}\right|_{X_0, Y_0}$$

  in interfaces using a Lagrangian formulation.
- The *mesh time derivative*, which is taken for a fixed point in the mesh:

$$u_{\mathrm{TIME}}(X_m, Y_m) = \left.\frac{\partial u}{\partial t}\right|_{X_m, Y_m}$$

  This derivative is in many cases denoted `uTIME` in the software. Since internally, everything is formulated on the mesh frame, the mesh time derivative is the one computed by the solvers and stored in the solution vector.

While the variable `t` represents the current value of the time in all frames, differentiation must be performed with respect to the symbol `TIME` only. The operator expression `d(`*<expr>*`,TIME)` is always allowed and evaluates to the mesh time derivative of *<expr>*. Because of its ambiguous meaning, the expression `d(`*<expr>*`,t)` is illegal if *<expr>* contains any variables that are functions of space.

The two derivatives are related by the chain rule. For example, for a spatial frame derivative:

$$u_t = u_{\mathrm{TIME}} - u_x x_{\mathrm{TIME}} - u_y y_{\mathrm{TIME}}$$

where $[u_x, u_y]$ is the spatial frame gradient and $(x_{\text{TIME}}, y_{\text{TIME}})$ is the spatial mesh velocity. The mesh time derivative is often less important from the user point of view because its value depends on the mesh movement, which in itself often has no physical significance. However, for the special case when the mesh follows the material's motion, the mesh time derivative is physically significant and is also called the *material time derivative*.

You can evaluate the time derivatives with respect to the different frames using frame-specific time-derivative operators `spatial.dt(<expr>)`, `material.dt(<expr>)`, `geometry.dt(<expr>)`, and `mesh.dt(<expr>)`. The two last are by definition equal to `d(<expr>,TIME)`.

Transformation Matrices and Volume Factors

The ALE machinery defines a number of variables based on the relations in Equation 18-3. The variables and component names are listed in Table 18-1, where indices i and j are 1, 2, or 3. A more detailed explanation of the variables follows below.

TABLE 18-1: GEOMETRIC VARIABLES AND MESH VARIABLES.

VARIABLE	COMPONENTS	DESCRIPTION
`spatial.F`	`spatial.F`ij	The Jacobian of spatial coordinates $\mathbf{x}$ with respect to material coordinates $\mathbf{X}$.
`spatial.invF`	`spatial.invF`ij	The Jacobian of material coordinates $\mathbf{X}$ with respect to spatial coordinates $\mathbf{x}$; the inverse of `spatial.F`.
`spatial.detF`	`spatial.detF`	The ratio of local element volume computed in the spatial frame to volume computed in the material frame; the determinant of `spatial.F` in elements of the same dimension as the geometry.
`spatial.detInvF`	`spatial.detInvF`	The ratio of local element volume computed in the material frame to volume computed in the spatial frame; the determinant of `spatial.invF` in elements of the same dimension as the geometry.
`material.F`	`material.F`ij	The Jacobian of material coordinates $\mathbf{X}$ with respect to geometry frame coordinates $\mathbf{X_g}$
`material.invF`	`material.invF`ij	The Jacobian of geometry frame coordinates $\mathbf{X_g}$ with respect to material coordinates $\mathbf{X}$; the inverse of `material.F`.
`material.detF`	`material.detF`	The ratio of local element volume computed in the material frame to volume computed in the geometry frame; the determinant of `material.F` in elements of the same dimension as the geometry.
`material.detInvF`	`material.detInvF`	The ratio of local element volume computed in the geometry frame to volume computed in the material frame; the determinant of `material.invF` in element of the same dimension as the geometry.

3D, PLANE 2D AND 1D GEOMETRIES

spatial.F The matrix `spatial.F` contains components of the Jacobian of spatial coordinates with respect to material coordinates:

$$\begin{bmatrix} \text{spatial.F11} & \text{spatial.F12} & \text{spatial.F13} \\ \text{spatial.F21} & \text{spatial.F22} & \text{spatial.F23} \\ \text{spatial.F31} & \text{spatial.F32} & \text{spatial.F33} \end{bmatrix} = \begin{bmatrix} \frac{\partial x}{\partial X} & \frac{\partial y}{\partial X} & \frac{\partial z}{\partial X} \\ \frac{\partial x}{\partial Y} & \frac{\partial y}{\partial Y} & \frac{\partial z}{\partial Y} \\ \frac{\partial x}{\partial Z} & \frac{\partial y}{\partial Z} & \frac{\partial z}{\partial Z} \end{bmatrix}$$

Rows of the matrix can be interpreted as the global material coordinate system's covariant base vectors expressed using contravariant components in the global spatial coordinate system. Conversely, columns can be interpreted as the global spatial coordinate system's contravariant base vectors expressed using covariant components in the global material coordinate system. The matrix therefore transforms contravariant material components of a vector, multiplying the matrix from the left, into contravariant spatial components. It also transforms covariant spatial components of a vector, by multiplication from the right, into covariant material components.

Note that `spatial.F` is the transpose of the deformation gradient defined by Structural Mechanics.

spatial.invF The matrix `spatial.invF` contains the inverse of `spatial.F`, which consists of components of the Jacobian of material coordinates with respect to spatial coordinates:

$$\begin{bmatrix} \text{spatial.invF11} & \text{spatial.invF12} & \text{spatial.invF13} \\ \text{spatial.invF21} & \text{spatial.invF22} & \text{spatial.invF23} \\ \text{spatial.invF31} & \text{spatial.invF32} & \text{spatial.invF33} \end{bmatrix} = \begin{bmatrix} \frac{\partial X}{\partial x} & \frac{\partial Y}{\partial x} & \frac{\partial Z}{\partial x} \\ \frac{\partial X}{\partial y} & \frac{\partial Y}{\partial y} & \frac{\partial Z}{\partial y} \\ \frac{\partial X}{\partial z} & \frac{\partial Y}{\partial z} & \frac{\partial Z}{\partial z} \end{bmatrix}$$

Rows of the matrix can be interpreted as the global spatial coordinate system's covariant base vectors expressed using contravariant components in the global material coordinate system. Conversely, columns can be interpreted as the global material coordinate system's contravariant base vectors expressed using covariant components in the global spatial coordinate system. The matrix therefore transforms contravariant spatial components of a vector, multiplying the matrix from the left, into contravariant material components. It also transforms covariant material components of a vector, by multiplication from the right, into covariant spatial components.

spatial.detF and spatial.detInvF The volume/area/length factor `spatial.detF` and its inverse `spatial.detInvF` are ratios of local element volume/area/length computed in the spatial and material frames. That is, these variables are the factors necessary to compute a spatial frame integral of quantity over a set of elements of any dimension, using material frame coordinates, or the other way around:

$$\int_D f(\mathbf{x})\mathbf{dx} = \int_D f(\mathbf{X})\text{detF}\mathbf{dX}$$

$$\int_D f(\mathbf{X})\mathbf{dX} = \int_D f(\mathbf{x})\text{detInvF}\mathbf{dx}$$

where D is a set of volume, surface, line, or point elements. This means that `spatial.detF` is a ratio of volumes in domains of 3D models, a ratio of areas in domains of plane 2D models and on boundaries of 3D models, and a ratio of lengths on boundaries of 2D models and edges in 3D models. On points, `spatial.detF` is equal to 1.

material.F, material.invF, material.detF, and material.detInvF These variables are defined in complete analogy with the corresponding `spatial` variables, but based on the relation between material frame coordinates $\mathbf{X}$ and geometry frame coordinates $\mathbf{X_g}$.

AXISYMMETRIC GEOMETRIES

Axisymmetric geometries are treated like 3-dimensional solids for the purpose of defining transformation matrices and volume factors variables. In particular, radial displacement of the mesh induces a nonunit transformation in the

azimuthal direction, in analogy with the azimuthal strain resulting from a radial displacement in an axisymmetric solid object. The transformation matrices `spatial.F` and `spatial.InvF` are:

$$\begin{bmatrix} \text{spatial.F11} & \text{spatial.F12} & \text{spatial.F13} \\ \text{spatial.F21} & \text{spatial.F22} & \text{spatial.F23} \\ \text{spatial.F31} & \text{spatial.F32} & \text{spatial.F33} \end{bmatrix} = \begin{bmatrix} \frac{\partial r}{\partial R} & 0 & \frac{\partial z}{\partial R} \\ 0 & \frac{r}{R} & 0 \\ \frac{\partial r}{\partial Z} & 0 & \frac{\partial z}{\partial Z} \end{bmatrix}$$

and

$$\begin{bmatrix} \text{spatial.invF11} & \text{spatial.invF12} & \text{spatial.invF13} \\ \text{spatial.invF21} & \text{spatial.invF22} & \text{spatial.invF23} \\ \text{spatial.invF31} & \text{spatial.invF32} & \text{spatial.invF33} \end{bmatrix} = \begin{bmatrix} \frac{\partial R}{\partial r} & 0 & \frac{\partial Z}{\partial r} \\ 0 & \frac{R}{r} & 0 \\ \frac{\partial Z}{\partial r} & 0 & \frac{\partial Z}{\partial z} \end{bmatrix}$$

The volume/area/length factors `spatial.detF` and `spatial.detInvF` also include the azimuthal strain factor r/R, such that they fulfill

$$\int_D f(r,z) r dr dz = \int_D f(R,Z) \text{detF} R dR dZ$$

$$\int_D f(R,Z) R dR dZ = \int_D f(r,z) \text{detInvF} r dr dz$$

where D is any set of surface, line, or point elements in an axisymmetric geometry. This means that `spatial.detF` is a ratio of volumes in domains, a ratio of areas on boundaries and a ratio of lengths on point entities.

Smoothing Methods

In the domains with free displacement, the Deforming Domain feature and the Free features in the Moving Mesh and Deformed Geometry interface solve an equation for the mesh displacement. This equation smoothly deforms the mesh given the constraints placed on the boundaries. Choose between *Laplace smoothing*, *Winslow smoothing*, *hyperelastic smoothing*, and *Yeoh smoothing*.

To specify the smoothing methods, use the **Mesh smoothing type** list in the **Smoothing** section of the **Deforming Domain** node or in the **Free Deformation Settings** section of the **Moving Mesh** or **Deformed Geometry** node. To see how these smoothing methods differ, let x and y be the spatial coordinates of the spatial frame, and let X and Y be the reference coordinates of the material frame.

- If Laplace smoothing is selected, the software introduces deformed mesh positions x and y as degrees of freedom in the model. In the static case, it solves the equation

$$\frac{\partial^2 x}{\partial X^2} + \frac{\partial^2 x}{\partial Y^2} = 0$$

  and in the transient case, it solves the equation

$$\frac{\partial^2}{\partial X^2}\frac{\partial x}{\partial t} + \frac{\partial^2}{\partial Y^2}\frac{\partial x}{\partial t} = 0$$

Similar equations hold for the y coordinate.

- If Winslow smoothing is selected, the software solves the equation

$$\frac{\partial^2 X}{\partial x^2} + \frac{\partial^2 X}{\partial y^2} = 0$$

and does the same for Y. Equivalently, X and Y satisfy Laplace equations as functions of the x and y coordinates.

- The hyperelastic smoothing method searches for a minimum of a mesh deformation energy inspired by neo-Hookean materials:

$$W = \int_\Omega \frac{\mu}{2}(I_1 - 3) + \frac{\kappa}{2}(J-1)^2 dV$$

where μ and κ are artificial shear and bulk moduli, respectively, and the invariants J and I_1 are given by

$$J = \det(\nabla_X x)$$
$$I_1 = J^{-2/3}\mathrm{tr}((\nabla_X x)^T \nabla_X x)$$

- The Yeoh smoothing method is also inspired by hyperelastic materials, in this case the three-term Yeoh hyperelastic model, which is a generalization of a neo-Hookean material. It uses a strain energy of the form

$$W = \frac{1}{2}\int_\Omega C_1(I_1 - 3) + C_2(I_1 - 3)^2 + C_3(I_1 - 3)^3 + \kappa(J-1)^2 dV$$

where κ is an artificial bulk modulus, as above, while C_1, C_2, and C_3 are other artificial material properties. The values of C_1 and C_3 are by default 1 and 0, respectively, and can only be changed in the Equation View subnodes under a Free Deformation node. The value of C_2 controls the nonlinear stiffening of the artificial material under deformation. It is specified in the **Stiffening factor** field, with a default value of 100.

The Laplace smoothing is the cheapest option in terms of computations because it is linear and uses one equation for each coordinate direction, which are not coupled to each other. However, there is no mechanism in Laplace smoothing that prevents inversion of elements. Therefore, this method is most suitable for small deformations in a linear regime — for example, when computing the sensitivity of some quantity to virtual deformations around the initial shape.

The Winslow, hyperelastic, and Yeoh smoothing methods are increasingly nonlinear and create a single coupled system of equations for all coordinate directions, which makes them more expensive to solve. They also share the theoretical property that continuous solutions to these equations always have positive volume everywhere. Unfortunately, this is not necessarily true for the discrete finite element solutions. In addition, a positive volume is not sufficient for maintaining element quality.

In compression, the three nonlinear methods show similar behavior, while in extension, the Winslow smoothing tends to allow elements to be stretched too far. The main difference between the simpler Hyperelastic method and the more advanced Yeoh model is that the latter responds to element distortion by sharply increasing the stiffness of distorted elements. This to some extent prevents further distortion in those regions and effectively acts to spread the mesh deformation more evenly over the domain, away from moving boundaries.

Yeoh smoothing generally produces the best results and allows the largest displacement of boundaries before mesh elements become inverted. However, because of its strong nonlinearity, it can cause convergence problems, in particular for the time-dependent and segregated solvers.

Limitations of the ALE Method

The following limitations apply to the ALE method in general and therefore to the Moving Mesh and Deformed Geometry interfaces:

- The connectivity of the mesh remains unchanged during the mesh deformation, which means that topological changes in the geometry are not allowed.
- When the mesh deformation becomes large, the quality of the mesh created by the smoothing equations can deteriorate, and the solver might then run into convergence problems. Sometimes an **Inverted mesh element** warning displays in the **Progress** window for the solver, which means that a mesh element has (partially) warped inside-out. The solver might even stop with an error for inverted mesh elements. See Inverted Mesh Elements for more information. Sometimes, introducing extra boundaries with explicit deformation inside the domains can help. You can also generate a new mesh for the region covered by the deformed mesh and let the solver continue by deforming the new mesh; see the section Remeshing a Deformed Mesh. See also Tips for Modeling Using Deformed Meshes below.
- If you use a **Geometry shape function** with an order larger than 1 in the Moving Mesh and Deformed Geometry interfaces, the mesh moving techniques often produce elements with distorted shapes. If there are warnings or errors about inverted mesh elements, consider reducing the geometry shape function order to 1. This change, however, makes the geometry representation polygonal, which might affect accuracy. The measure of mesh quality does not capture these distorted shapes because it is computed from the positions of the corners of the mesh element (ignoring midside nodes, for instance).

Tips for Modeling Using Deformed Meshes

When working with a deformed mesh to move things around, the computational mesh gets deformed. If the deformations become too large, some mesh elements might get inverted. This means that the accuracy of the solution deteriorates and eventually the solvers diverge due to an ill-conditioned system. Here are some tips on how to keep the mesh under control:

- Try a different mesh. It is often preferable to start from a reasonably uniform mesh. One way to achieve this is to first select a coarse mesh in the predefined mesh size settings and then set a small maximum element size. Also, quad meshes and mapped meshes tend to perform better than triangles.
- Try a different smoothing type. Winslow smoothing is slightly slower, more memory consuming, and usually, but not always, more stable than Laplace smoothing. Hyperelastic and Yeoh smoothing sometimes work better than the other methods (in some fluid-structure interaction problems, for example). See Smoothing Methods for more information.
- If solving a time-dependent problem, try to solve the equations more accurately by reducing the absolute and relative tolerances for the time-dependent solver.
- Help the mesh deformation by sliding the boundary elements along with the movement of the mesh. This can be achieved by adding a prescribed deformation on the boundary that moves the boundary elements according to the deformation of some point in the model. Define a coupling operator under the **Definitions** node and use it to couple the deformation from the point to the boundary mesh.
- Physics interfaces that control the coordinates of one of the frames exhibit an override behavior where a physics interface of this kind further down the list of physics interfaces in the model tree overrides the ones above, if they are active on the same domains. The Moving Mesh interface appears as not applicable where it is overridden, but physics interfaces with ALE functionality, such as the Solid Mechanics interface, only lose their control over the frame. You may need to rearrange the order of the physics interfaces in a model to avoid this behavior.

Remeshing a Deformed Mesh

When the mesh deformation has become so large that the quality of the mesh is too bad, generate a new mesh for the deformed configuration and then continue the solution process. To do so, follow these steps:

1. Add a stop condition.
2. View the deformed mesh.
3. Copy the solution.
4. Create a Deformed Configuration ( ).
5. Remesh the deformed configuration.
6. Continue solving with the new mesh.

To make the Deformed Configuration mesh represent the deformed geometry, use a Moving Mesh (ALE) interface to model the mesh deformation or, for structural mechanics models, use the option in the study to include geometric nonlinearity (requires the Structural Mechanics Module, MEMS Module, or Acoustics Module). Also, some of the physics interfaces in the Corrosion Module and Electrodeposition Module include a deformed geometry.

- Deformed Configuration
- Solution (dataset)

The following sections contain details about these steps and additional information.

ADDING A STOP CONDITION

Add a stop condition in the solver to make it stop when the mesh quality becomes too bad. If the Time-Dependent Solver is used, do this by right-clicking, for example, **Study 1** > **Solver Configurations** > **Solution 1** > **Time Dependent Solver 1** and selecting **Stop Condition** ( ) from the context menu. If the parametric stationary solver is used, right-click, for example, **Stationary Solver 1** > **Parametric 1** under **Solution 1** and select **Stop Condition** ( ) from the context menu. In the table under **Stop Expressions**, enter a Boolean expression (to stop when the expression is true) or an expression that makes the solver stop when the expression becomes negative. For example, enter `comp1.ale.I1isoMax>4` to stop before the maximum element distortion exceeds 4. Notice that you must add the component where the **Moving Mesh (ale)** interface is defined, in this case `comp1` for Component 1, to access the variable from the Study branch (see Variable Naming Convention and Namespace).

The following predefined variables are useful for defining a stop condition and for monitoring the mesh deformation: the maximum element distortion, `ale.I1isoMax`; the minimum relative element volume, `ale.relVolMin`; and the minimum mesh quality, `ale.minqual`. See Predefined Variables below.

In time-dependent simulations, you can use automatic remeshing instead of the stop condition. The software then creates new meshes when the mesh quality drops below the specified level. To do so, click the **Step 1: Time Dependent** node ( ) and then select the **Automatic remeshing** checkbox in the **Settings** window's **Study Extensions** section. To use the same condition as for the stop condition above, select **Distortion** under **Condition type**, enter `comp1.ale.I1isoMax` in the **Distortion expression** field, and enter `4` in the **Stop when distortion exceeds** field in the **Settings** window for the **Automatic Remeshing** ( ) node (under the **Time-Dependent Solver** node in the solver sequence).

VIEWING THE DEFORMED MESH

Use a Mesh plot in a 2D or 3D plot group to visualize the deformed mesh. The Mesh plot shows the element shapes, sizes, and quality corresponding to the frame selected in the underlying dataset. See Mesh (Plot) for details.

COPYING THE SOLUTION

To keep the first solution, right-click **Study 1** > **Solver Configurations** > **Solution 1** and select **Solution** > **Copy** ( ). The copied solution appears as a new solution; **Copy 2**, for example.

CREATING A DEFORMED CONFIGURATION

Create a deformed configuration by right-clicking, for example, **Results** > **Datasets** > **Solution 2** and selecting **Remesh Deformed Configuration** ( ). The deformed configuration appears as a new **Deformed Configuration** node ( ) under **Meshes**. The deformed configuration works as a new geometry but with restricted functionality. The **Settings** window of the deformed configuration indicates which solution it was constructed from. Click the **Update** button to see the corresponding deformed configuration in the graphics.

REMESHING THE DEFORMED CONFIGURATION

Expanding a **Deformed Configuration** node ( ) shows that a new meshing sequence has been added beneath it. This meshing sequence contains a **Size** node ( ) and a **Reference** node ( ) only. The reference node refers to the original meshing sequence. This means that the new meshing sequence uses the same nodes as the original meshing sequence. Build the new meshing sequence by selecting **Build All** from its context menu or pressing F8. To make changes to the new meshing sequence before building it, right-click **Reference 1** and select **Expand** ( ). Then the nodes from the original meshing sequence are copied to the new meshing sequence. You can also add and remove nodes in the new meshing sequence. If several meshes are needed on the deformed configuration (for the multigrid solver, for example), you can add an additional meshing sequence by right-clicking **Deformed Configuration** ( ) and selecting **Mesh** ( ).

CONTINUE SOLVING WITH THE NEW MESH

1. In the **Settings** window for the study step (for example, **Study 1** > **Step1: Time Dependent**), use the **Mesh** list under **Mesh Selection** to select the new meshing sequence (**Mesh 2**, for example).
2. Change the **Times** list under **Study Settings** or the **Parameter value list** under **Study Extensions** to include only the time or parameter corresponding to the deformed configuration plus the remaining times or parameters.
3. Change the initial value to be the last time or parameter of the previous solution. Do this by expanding the **Values of Dependent Variables** section in the study step settings. Under **Initial values of variables solved for**, change **Settings** to **User controlled**; then change **Method** to **Solution**, and locate the previously created solution copy. Then select the appropriate time or parameter value in the **Time** or **Parameter value** list. Usually the **Automatic (single solution)** setting, which selects the last time or parameter value, suffices. Change the settings under **Values of variables not solved for** similarly.
4. To solve for remaining times or parameters, right-click **Study 1** and select **Compute**.

REMESHING SEVERAL TIMES

You can remesh several times by iterating the above steps. For each of the solver runs, you get a copy of the solution (**Copy 2**, **Copy 3**, **Copy 4**, and so on) and a corresponding dataset (**Solution 2**, **Solution 3**, **Solution 4**, and so on). In the plot group, select one of these datasets for results analysis and visualization.

ALTERNATIVE PROCEDURE USING SEVERAL STUDIES

The above procedure uses a single study that is modified for each solver run. To recompute the whole sequence of runs, an alternative that uses one study for each run is better. To do that, add a new study after meshing each deformed configuration. The copy solution step is not needed in this case. If the settings are changed in the study or its solver sequence, make these changes also in the new study. For example, the stop condition has to be added.

Deformed Mesh Definition Features

Overview of Deformed Mesh and Moving Mesh Features

You can add deformed mesh features directly to any COMSOL Multiphysics model. The most essential ones — **Free Deformation**, **Prescribed Deformation**, and **Rotating Domain** — are available from the **Moving Mesh** and **Deformed Geometry** submenus when right-clicking a **Component** node as well as from the **Physics** toolbar when shown. After adding the first feature, the complete set of features becomes available by right-clicking the **Moving Mesh** and **Deformed Geometry** branches that appear under the component or, alternatively, from the ribbon toolbars with the same names.

You can also include deformed mesh features when setting up a model in the **Model Wizard** or add them from the **Add Physics** window. You find them under **Mathematics** > **Deformed Mesh** > **Moving Mesh** and **Mathematics** > **Deformed Mesh** > **Deformed Geometry** where they appear as if they were physics interfaces.

The same feature types are available both for Moving Mesh and Deformed Geometry; they differ only in which frame's mesh they deform.

Under **Mathematics** > **Deformed Mesh** > **Legacy Deformed Mesh** you find The Deformed Geometry Interface and The Moving Mesh Interface.

Moving Mesh Features

Features added under **Moving Mesh** control the spatial frame. They can be used to study both stationary states and time-dependent deformations where the geometry changes its shape due to motion of solid boundaries and deformation of solid domains. The same feature types are also available as Deformed Geometry Features under **Deformed Geometry** but there control the material frame. For a comparison of moving meshes and deformed geometries, see Deformed Geometry vs. Moving Mesh.

For example, a **Deforming Domain** feature can be used for fluid domain deformations in fluid-structure interaction (FSI) or electrostatic domain deformations (Electromechanics) in MEMS. The shape of the domain is then governed by the deformation or motion of its boundaries. Other features can specify that parts of the model rotate or otherwise deform in some way.

Technically, the **Moving Mesh** branch represents the spatial frame in the **Model Builder** tree. Its **Equation View** subnode displays all contributions to the spatial frame deformation, for example the mesh smoothing equations used by a Deforming Domain feature, or the boundary motion implicitly prescribed by a Solid Mechanics interface. Also, when enabling **Modify model configuration for study step** in a Study Step node, you can use the **Moving Mesh** branch to control the overall behavior of Moving Mesh features: whether they should control the spatial frame, and whether smoothing equations should be solved for.

- If you have the CFD Module, see *Laminar Flow in a Baffled Stirred Mixer*: Application Library path **CFD_Module/Fluid-Structure_Interaction/baffled_mixer**
- If you have the Structural Mechanics Module, see *Peristaltic Pump*: Application Library path **Structural_Mechanics_Module/Fluid-Structure_Interaction/peristaltic_pump**

The moving mesh features available under the **Moving Mesh** branch can be used to model moving meshes instead of adding a **Moving Mesh** interface. The Moving Mesh Interface is still available as a legacy alternative to the moving mesh functionality described here.

DOMAIN AND BOUNDARY NODES FOR MOVING MESHES

The **Moving Mesh** menu that you find when right-clicking a **Component** node includes the three domain nodes Prescribed Deformation, Rotating Domain, and Deforming Domain. The complete set of features, including boundary nodes, can be found when right-clicking the **Moving Mesh** branch in a component:

- Prescribed Deformation
- Rotating Domain
- Deforming Domain
- Fixed Boundary
- Prescribed Mesh Displacement
- Prescribed Normal Mesh Displacement
- Prescribed Normal Mesh Velocity
- Rotating Boundary
- Mesh Slip
- Symmetry/Roller

Deformed Geometry Features

Features added under **Deformed Geometry** control the material frame. They can be used to study both stationary states and time-dependent deformations where the geometry changes its shape due to addition or removal of material, whether this happens due to a physical process, or for example as part of shape optimization. The same feature types are also available as Moving Mesh Features under **Moving Mesh** but there control the spatial frame. For a comparison of moving meshes and deformed geometries, see Deformed Geometry vs. Moving Mesh.

Features added under **Deformed Geometry** define a deformation of the material frame relative to the geometry frame, and therefore potentially apply to all physics in the model. They can be used to study how physics changes when the geometry, represented by the mesh, changes due to an externally imposed geometry change. In a dynamic simulation, deformed geometry features model a deformation that represents removal or addition of material. The same feature types are also available as Moving Mesh Features under **Moving Mesh** but there control the spatial frame. For a comparison of moving meshes and deformed geometries, see Deformed Geometry vs. Moving Mesh.

Technically, the **Deformed Geometry** branch represents the material frame in the **Model Builder** tree. Its **Equation View** subnode displays all contributions to the material frame deformation, for example the mesh smoothing equations used by a Deforming Domain feature, or the boundary motion prescribed by a Polynomial Boundary feature used in shape optimization. Also, when enabling **Modify model configuration for study step** in a Study Step node, you can use the **Deformed Geometry** branch to control the overall behavior of Deformed Geometry features: whether they should control the material frame, and whether smoothing equations should be solved for.

- If you have the Heat Transfer Module, see *Tin Melting Front*: Application Library path **Heat_Transfer_Module/Phase_Change/tin_melting_front**

The deformed geometry features available in the **Deformed Geometry** branch under a component can be used to model deformed geometries instead of adding a **Deformed Geometry** interface. The Deformed Geometry Interface is still available as a legacy alternative to the deformed geometry functionality described here.

DOMAIN AND BOUNDARY NODES FOR DEFORMED GEOMETRIES

The **Deformed Geometry** menu that you find when right-clicking a **Component** node includes the three domain nodes Prescribed Deformation, Rotating Domain, and Deforming Domain. The complete set of features, including boundary nodes, can be found when right-clicking the **Deformed Geometry** branch in a component:

- Prescribed Deformation
- Rotating Domain
- Deforming Domain
- Fixed Boundary
- Prescribed Mesh Displacement
- Prescribed Mesh Velocity
- Prescribed Normal Mesh Displacement
- Prescribed Normal Mesh Velocity
- Rotating Boundary
- Mesh Slip
- Symmetry/Roller

Common Boundary Condition Feature Settings

Boundary condition features control the mesh displacement or velocity at the boundaries of deforming domains. These features have a number of common settings, controlling where and how the constraint is enforced.

EXCLUDED ENTITIES

When a boundary condition is enforced using **Pointwise constraints** or **Weak constraints**, it may come into conflict with boundary conditions at adjacent boundaries. When this happens, you can use the **Excluded Edges** or **Excluded Points** sections (collapsed by default) to exclude affected edges or points from one of the boundary conditions. This ensure that the other, remaining, condition prevails.

If the boundary condition is enforced using **Pointwise constraints**, then no constraint is added at the constraint points that belong to the excluded entities. When using **Weak constraints**, the Lagrange multiplier variable will be constrained on the excluded entities, which effectively removes the constraint. Since the **Nitsche method** is implemented as a distributed contribution on the boundary, it cannot be disabled locally at edges or points. The **Excluded Edges** or **Excluded Points** sections are therefore not available when this method is used.

CONSTRAINT SETTINGS

All moving mesh boundary conditions are of Dirichlet type, but there are a number of different ways these can be enforced:

Pointwise constraints: The mesh displacement is prescribed using a pointwise constraint at Lagrange points of the same order as the geometry representation. The default **Constraint method** is **Elemental**, which means that constraints are applied for each Lagrange point in each element separately; if the constraint is discontinuous between elements, there will be multiple separate constraints at shared points. When using the alternative **Nodal** constraints the constraint expression is first averaged over all elements sharing a constraint point, before applying a single constraint.

Pointwise constraints are stable and always respected as long as they are self-consistent, but the solvers do not allow constraining time derivatives. This option is therefore not available for velocity conditions.

Nitsche method: The mesh displacement or velocity is enforced using an incomplete Nitsche formulation, which can be seen as a modified penalty method. An equation contribution that penalizes deviation from the specified constraint is added everywhere on the boundary. The Nitsche method therefore does not satisfy the constraints exactly. You can to some extent control the accuracy by tuning the **Stabilization factor**. A higher value (default is 1) increases the penalty and therefore accuracy, but at the same time makes the system of equations increasingly ill-conditioned. The main advantage of the Nitsche method is that it does not interact with conditions at adjacent boundaries.

Weak constraints: the mesh displacement or velocity is prescribed using weak constraint equations and Lagrange multiplier variables. Where adjacent constraints meet at edges or points, it is important that the number of free Lagrange multiplier variables agree with the number of degrees of freedom to be constrained.

If a weak constraint meets at an edge or point with a pointwise constraint or another weak constraint using a different Lagrange multiplier, then one of the Lagrange multipliers will often become underdetermined. The Lagrange multiplier is then not necessary for enforcing the given boundary conditions and can take any value without violating any equations. This, in turn, leads to solvers reporting a singular system. The solution to this problem is often to use the **Excluded Edges** or **Excluded Points** selections to remove one of the constraints from the shared edges or points.

By default, the **Constraint type** is set to **Automatic**, which generally is interpreted as pointwise constraints for deformation conditions and weak constraints for velocity conditions.

Prescribed Deformation

Use the **Prescribed Deformation** node ( ) to explicitly define the deformation of the mesh in one frame relative to another. Note that the Solid Mechanics interface has built-in behavior corresponding a Prescribed Deformation node under **Moving Mesh**.

PRESCRIBED DEFORMATION

Specify expressions that define the deformation in the **Prescribed deformation** fields (dx, dy, and dz for 3D models, for example) (SI unit: m). The default gives no mesh displacement.

Rotating Domain

Add a **Rotating Domain** node ( ) to add rotation to the selected domains. You can specify the rotation type and the rotation axis.

The **Settings** window for the **Rotating Domain** node contains the following sections:

ROTATION

From the **Rotation type** list, choose a type of rotation for the domain.

- Choose **User defined** (the default) to add a user-defined expression for the rotation angle α in the **Rotation angle** field.
- Choose **Specified rotational velocity** to define a rotational velocity expression of one of the following **Rotational velocity expression** types:
  - Choose **Constant angular velocity** to specify an angular velocity ω in the **Angular velocity** field (SI unit: rad/s) using only numbers and model parameters. Specify an initial angle α_0 in the **Initial angle** field (SI unit: rad). This effectively sets the rotation angle to $\alpha = \alpha_0 + \omega t$.
  - Choose **General angular velocity** to specify a general angular velocity ω using an expression in the **Angular velocity** field (SI unit: rad/s) with an initial angle α_0 specified in the **Initial angle** field (SI unit: rad). The rotation angle is computed by solving an ODE for α, which is therefore a state variable and part of the solution.
  - Choose **Constant revolutions per time** to specify a revolution frequency f in the **Revolutions per time** field (SI unit: 1/s) using only numbers and model parameters. Specify an initial angle α_0 in the **Initial angle** field (SI unit: rad). This effectively sets the rotation angle to $\alpha = \alpha_0 + 2\pi f t$.
  - Choose **General revolutions per time** to specify a general revolution frequency f using an expression in the **Revolutions per time** field (SI unit: 1/s) with an initial angle α_0 specified in the **Initial angle** field (SI unit: rad).

The rotation angle is computed by solving an ODE for α, which is therefore a state variable and part of the solution.

- Choose **Rigid body** to specify that the rotating domain behaves as if attached to a rigid body with the following parameters:
  - Enter an **Applied moment** M (SI unit: N·m).
  - Enter a **Moment of inertia** I (SI unit: kg·m^2).
  - Enter an **Initial angle** α_0 (SI unit: rad).
  - Enter an **Initial angular velocity** ω_0 (SI unit: rad/s).

  The rotation angle is computed by solving an ODE for α, which is therefore a state variable and part of the solution.

AXIS

In this section, define the rotation axis by a base point and an axis:

Enter the base point $\mathbf{r}_{ax}$ components in the **Rotation axis base point** fields (SI unit: m).

Enter the rotation axis $\mathbf{u}_{rot}$ in the **Rotation axis** fields. In 2D, no rotation axis is specified; it is assumed to point out of the plane, toward the observer.

If you specify a **General angular velocity** or **General revolutions per time**, the Rotating Domain feature uses an ODE to integrate the rotation angle in time. This can in some situations negatively affect solver behavior. Therefore, when the rotational velocity is constant, make sure to select **Constant angular velocity** or **Constant revolutions per time**.

A Solid Mechanics interface cannot coexist with a **Rotating Domain** on the same selection. If you need to solve for solid mechanics in a rotating frame, do not add any **Rotating Domain**. Instead, add a Rotating Frame node in the Solid Mechanics interface. By selecting the **Define spatial frame rotation** checkbox in the **Rotating Frame** node you will define a rotation of the spatial frame in the domain. This rotation is also augmented by the deformations computed in the Solid Mechanics interface. This is, from the viewpoint of other physics interfaces, similar to using a **Rotating Domain** node, but with an additional deformation.

Deforming Domain

Add a **Deforming Domain** node ( ) to specify that the shape of the selected domains should be governed by the domain boundaries, which are in turn controlled either by explicit deformed mesh boundary condition nodes, or by implicit continuity constraints requiring that a deforming domain must follow the shape of adjacent domains, or stay fixed if there is no adjacent domain. Explicit boundary conditions take precedence over implicit constraints.

In the interior of the domains, the mesh is controlled by a smoothing equation. You can select the smoothing method and the initial deformation of the domain.

The **Settings** window for the **Deforming Domain** node contains the following sections:

SMOOTHING

For the mesh smoothing, choose smoothing type from the **Mesh smoothing type** list: **Laplace**, **Winslow**, **Hyperelastic**, or **Yeoh** (the default). For **Yeoh**, also enter a **Stiffening factor** C_2 (default: 10). See Smoothing Methods for more information.

INITIAL DEFORMATION

Enter expressions or values for the components of the initial deformation in the **Initial deformation** fields (SI unit: m).

Fixed Boundary

Use the **Fixed Boundary** node ( ) on boundaries of deforming domains to specify that the selected boundaries remain at their reference shape and do not move.

For common boundary condition settings, see Common Boundary Condition Feature Settings. The Fixed Boundary condition allows all constraint types.

BOUNDARY SELECTION

Here you select the boundaries that should be fixed.

Prescribed Mesh Displacement

Use the **Prescribed Mesh Displacement** node ( ) on the boundary of deforming domains to fully specify the displacement of the mesh relative to the reference mesh at the boundary.

For common boundary condition settings, see Common Boundary Condition Feature Settings. The Prescribed Mesh Displacement condition allows all constraint types.

COORDINATE SYSTEM

Select the coordinate system in which mesh displacements are prescribed. The default is the global system in the reference frame. Using a coordinate system that depends on the moving mesh is allowed, but leads to nonlinearities that the solvers may not be able to resolve.

PRESCRIBED MESH DISPLACEMENT

Enter a prescribed displacement for each coordinate direction (SI unit: m). The default settings provide a fixed boundary (zero displacements in all directions).

Prescribed Mesh Velocity

Use the **Prescribed Mesh Velocity** node ( ) on the boundary of deforming domains to fully specify the velocity of the mesh at the boundary.

For common boundary condition settings, see Common Boundary Condition Feature Settings. The Prescribed Mesh Velocity condition allows the **Nitsche method** and **Weak constraints** (the default).

COORDINATE SYSTEM

Select the coordinate system in which mesh displacements are prescribed. The default is the global system in the reference frame. Using a coordinate system that depends on the moving mesh is allowed, but leads to nonlinearities that the solvers may not be able to resolve.

PRESCRIBED MESH VELOCITY

Enter a prescribed velocity for each coordinate direction (SI unit: m/s). The default settings correspond to a fixed boundary (zero velocity in all directions) and should be avoided: use a Fixed Boundary feature instead.

Prescribed Normal Mesh Displacement

Use the **Prescribed Normal Mesh Displacement** node ( ) to specify the displacement of the boundary in the reference normal direction. The node can be used on the boundaries of deforming domains. No constraints are set on the tangential displacement.

For common boundary condition settings, see Common Boundary Condition Feature Settings. The Prescribed Normal Mesh Displacement condition allows all constraint types.

NORMAL MESH DISPLACEMENT

Enter a value or expression for the **Prescribed normal mesh displacement** d_n (SI unit: m).

Prescribing a normal displacement on a boundary which is not flat can lead to unexpected results since the normal direction is computed at the initial — reference — position. For example, prescribing a constant normal displacement on a circular boundary allows a circle of any radius as solution.

Prescribed Normal Mesh Velocity

Use the **Prescribed Normal Mesh Velocity** node ( ) to specify the velocity of the boundary in the current normal direction. The node can be used on the boundaries of deforming domains. No constraints are set on the tangential velocity.

The moving boundary smoothing option smooths the normal mesh velocity of the **Prescribed Normal Mesh Velocity** node according to the following equation:

$$\frac{\partial \mathbf{X}}{\partial t} \cdot \mathbf{n} = v_0 + v_{\text{mbs}}$$

where v_0 is the desired normal mesh velocity, and v_{mbs} is a smoothing velocity according to:

$$v_{\text{mbs}} = \delta_{\text{mbs}} |v_0| hH$$

Here δ_{mbs} is a moving boundary smoothing tuning parameter (unitless), h is the mesh element size (SI unit: m), and H is the mean surface curvature (SI unit: 1/m), defined as:

$$H = -\frac{1}{2} \nabla_T \cdot \mathbf{n}$$

where ∇_T is the surface gradient operator.

For common boundary condition settings, see Common Boundary Condition Feature Settings. The Prescribed Mesh Velocity condition allows the **Nitsche method** and **Weak constraints** (the default).

The Prescribed Normal Mesh Velocity node should only be used in Time Dependent studies. The behavior for other studies is undefined.

NORMAL MESH VELOCITY

Enter a value or expression for the **Normal mesh velocity** v_n (SI unit: m/s).

MOVING BOUNDARY SMOOTHING

By default, the **Enable moving boundary smoothing** checkbox is not selected. To enable boundary smoothing, click to select the checkbox, and then enter a value or expression for the **Moving boundary smoothing tuning parameter**, δ_{mbs} (unitless). The default value is 0.5.

Rotating Boundary

Use the **Rotating Boundary** node ( ) on boundaries of a **Deforming Domain** that is expected to be rotating. You can specify the rotation type and the rotation axis.

Rotating Boundary conditions are always enforced as pointwise constraint on the entire feature selection. There are therefore no **Excluded Edges**, **Excluded Points** or **Constraint Settings** sections. The **Settings** window for the **Rotating Boundary** node contains the following sections:

ROTATION

From the **Rotation type** list, choose a type of rotation for the domain.

- Choose **User defined** (the default) to add a user-defined expression for the rotation angle α in the **Rotation angle** field.
- Choose **Specified rotational velocity** to define a rotational velocity expression of one of the following **Rotation velocity expression** types:
  - Choose **Constant angular velocity** to specify an angular velocity ω in the **Angular velocity** field (SI unit: rad/s) using only numbers and model parameters. Specify an initial angle α_0 in the **Initial angle** field (SI unit: rad). This effectively sets the rotation angle to $\alpha = \alpha_0 + \omega t$.
  - Choose **General angular velocity** to specify a general angular velocity ω using an expression in the **Angular velocity** field (SI unit: rad/s) with an initial angle α_0 specified in the **Initial angle** field (SI unit: rad). The rotation angle is computed by solving an ODE for α, which is therefore a state variable and part of the solution.
  - Choose **Constant revolutions per time** to specify a revolution frequency f in the **Revolutions per time** field (SI unit: 1/s) using only numbers and model parameters. Specify an initial angle α_0 in the **Initial angle** field (SI unit: rad). This effectively sets the rotation angle to $\alpha = \alpha_0 + 2\pi f t$.
  - Choose **General revolutions per time** to specify a general revolution frequency f using an expression in the **Revolutions per time** field (SI unit: 1/s) with an initial angle α_0 specified in the **Initial angle** field (SI unit: rad). The rotation angle is computed by solving an ODE for α, which is therefore a state variable and part of the solution.
- Choose **Rigid body** to specify that the rotating domain behaves as if attached to a rigid body with the following parameters:
  - Enter an **Applied moment** M (SI unit: N·m).
  - Enter a **Moment of inertia** I (SI unit: kg·m^2).
  - Enter an **Initial angle** α_0 (SI unit: rad).
  - Enter an **Initial angular velocity** ω_0 (SI unit: rad/s).

  The rotation angle is computed by solving an ODE for α, which is therefore a state variable and part of the solution.

AXIS

In this section, define the rotation axis by a base point and an axis:

Enter the base point $\mathbf{r}_{ax}$ components in the **Rotation axis base point** fields (SI unit: m).

Enter the rotation axis $\mathbf{u}_{\text{rot}}$ in the **Rotation axis** fields. In 2D, no rotation axis is specified; it is assumed to point out of the plane, toward the observer.

If you specify a **General angular velocity** or **General revolutions per time**, the Rotating Domain feature uses an ODE to integrate the rotation angle in time. This can in some situations negatively affect solver behavior. Therefore, when the rotational velocity is constant, make sure to select **Constant angular velocity** or **Constant revolutions per time**.

Mesh Slip

Use the **Mesh Slip** node ( ) on boundaries of deforming domains where the mesh can slip (that is, only move in the current tangential direction). The condition is equivalent to specifying a zero normal mesh velocity in a Prescribed Normal Mesh Velocity node.

For common boundary condition settings, see Common Boundary Condition Feature Settings. The Mesh Slip condition allows the **Nitsche method** and **Weak constraints** (the default).

BOUNDARY SELECTION

Here you select the boundaries where the mesh should be able to slip.

Symmetry/Roller

Use a **Symmetry/Roller** node ( ) on flat boundaries of deforming domains which are also symmetry planes in the model, or where you otherwise want to prevent boundary nodes from moving out of the plane. This allows the mesh to move tangentially to the symmetry/roller plane, but not in its normal direction. The condition is equivalent to specifying a zero normal mesh displacement in a Prescribed Normal Mesh Displacement node.

For common boundary condition settings, see Common Boundary Condition Feature Settings. The Symmetry/Roller condition allows all constraint types.

BOUNDARY SELECTION

Here you select the boundaries where there is symmetry in the moving mesh.

The Moving Mesh Interface

The legacy **Moving Mesh (ale)** interface ( ), found under the **Mathematics** > **Deformed Mesh** > **Legacy Deformed Mesh** branch ( ) when adding a physics interface, can be used to create models where the geometry, here represented by the mesh, changes shape due to some physical phenomena without material being removed or added.

The Moving Mesh interface has been largely replaced by the moving mesh features in the **Moving Mesh** branch under a component. While the interface is slightly more general, the features under the **Moving Mesh** branch interact better with other physics interfaces.

The difference between the Deformed Geometry and Moving Mesh interfaces is that the former defines a deformation of the material frame relative to the geometry frame, while the latter defines a displacement of the spatial frame relative to the material frame. The Moving Mesh interface can be used to study both stationary states and time-dependent deformations where the geometry changes its shape due to the dynamics of the problem. For example, it can be used for fluid domain deformations in fluid-structure interaction (FSI) or electrostatic domain deformations in MEMS.

When this interface is added, these default nodes are also added to the **Model Builder**: **Fixed Mesh** and **Prescribed Mesh Displacement** (the default boundary condition). Then, from the **Physics** toolbar, add other nodes that implement, for example, boundary conditions. You can also right-click **Moving Mesh** to select features from the context menu.

Predefined Variables

The Moving Mesh interface includes the following predefined variables for the spatial frame, which can be of interest, for example, to monitor the quality of the mesh and define a stop criterion for remeshing (see Adding a Stop Condition):

- The local relative element volume, `spatial.relVol`, is a quantity that measures the local volumetric distortion of the elements. When this measure approaches zero in some part of the mesh, frame transformations become singular causing solvers to fail.
- The minimum relative element volume, `spatial.relVolMin`, must be > 0, otherwise the mesh elements are inverted. A suitable stop criterion using this variable is that the minimum relative element volume must be larger than a small positive number.
- The maximum relative element volume, `spatial.relVolMax`, is a positive scalar number that represents the maximum value of the relative element volume.
- The minimum mesh quality, `spatial.minqual`, must be > 0; an acceptable mesh quality is typically larger than 0.1 (where the quality measure is a number between 0 and 1).

- If you have the AC/DC Module, see *Electrodynamics of a Power Switch*: Application Library path **ACDC_Module/Devices,_Transducers_and_Actuators/power_switch**
- If you have the Heat Transfer Module, see *Viscous Heating in a Fluid Damper*: Application Library path **Heat_Transfer_Module/Buildings_and_Constructions/fluid_damper**

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between

variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `ale`.

DOMAIN SELECTION

You do not need to use a Moving Mesh interface in domains where a Solid Mechanics interface is active. The displacements automatically control the spatial frame when **Include geometric nonlinearity** is selected in a study step.

FRAME SETTINGS

Specify the names of the spatial coordinates of the base frame for the physics interface — the material frame — in the **Material frame coordinates** fields. The defaults are the coordinates of the spatial frame in uppercase letters (**X**, **Y**, and **Z**). You can change the names in the fields for the **First**, **Second**, and **Third** coordinate. The field labels include the default spatial coordinate names in parentheses.

The **Geometry shape function** list controls the order of the polynomials — **1** (linear), **2** (quadratic; the default), **3** (cubic), **4** (quartic), or **5** (quintic, 2D only) — used for representing the geometry shape in the spatial frame. The same order is used for Lagrange shape functions defining the mesh position in domains where **Free displacement** has been activated.

FREE DEFORMATION SETTINGS

Select the smoothing type for freely deformed domains from the **Mesh smoothing type** list. Choose between **Lagrange**, **Winslow**, **Hyperelastic**, and **Yeoh** smoothing. The default is Laplace smoothing. For Yeoh smoothing, also specify a **Stiffening factor** (default: 100).

- Domain and Boundary Nodes in the Moving Mesh Interface
- Smoothing Methods
- Common Physics Interface and Feature Settings and Nodes

Domain and Boundary Nodes in the Moving Mesh Interface

The Moving Mesh Interface includes these domain and boundary nodes:

- Fixed Mesh
- Free Deformation
- Prescribed Deformation
- Prescribed Mesh Displacement
- Prescribed Mesh Velocity
- Prescribed Normal Mesh Velocity
- Zero Normal Mesh Velocity
- Zero Normal Mesh Displacement

Fixed Mesh

Use the **Fixed Mesh** node to specify that the selected domains remain at their reference material shape and do not move. This is the default.

Prescribed Mesh Displacement

Use the **Prescribed Mesh Displacement** node on the boundary of domains with free deformation. The spatial frame in the adjacent domain moves in accordance with the displacement.

COORDINATE SYSTEM SELECTION

Select a coordinate system for the mesh displacement from the **Coordinate system** list. The default is the **Global coordinate system**.

PRESCRIBED MESH DISPLACEMENT

Select the checkbox for each coordinate direction to prescribe the displacement. The default settings provide a fixed boundary (zero displacements in all directions).

For boundaries adjacent to domains where displacement variables are defined, for example domains where a Solid Mechanics interface is active, let these variables drive the mesh displacement by typing the component field names in the corresponding fields (for example, setting **dx** to `u`, **dy** to `v`, and **dz** to `w` in 3D).

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. See Common Physics Interface and Feature Settings and Nodes for links to more information.

Free Deformation

The **Free Deformation** node constrains the mesh displacement only by the boundary conditions on the surrounding boundaries. The displacement in the domain is obtained by solving a PDE.

INITIAL DEFORMATION

Give initial values for mesh displacements, relative to the material frame, in the **Initial mesh displacement** fields.

Prescribed Deformation

Use the **Prescribed Deformation** node to define the deformation explicitly using expressions, or if you want the spatial coordinates to follow a deformation computed by, for example, a Solid Mechanics interface. (You can also achieve the latter effect by excluding the domains where the Solid Mechanics interface is defined from the domains where the Moving Mesh interface is active.)

PRESCRIBED MESH DISPLACEMENT

Specify expressions that define the deformation in the **Prescribed mesh displacement** fields (dx, dy, and dz for 3D models, for example) (SI unit: m). The default gives no mesh displacement.

Prescribed Mesh Velocity

Use the **Prescribed Mesh Velocity** node on the boundary of domains with free displacement to specify the velocity of the boundary. The spatial frame in the adjacent domains moves in accordance with the velocity.

PRESCRIBED MESH VELOCITY

Select the checkbox for each coordinate directory to prescribe a velocity. The default settings provide zero velocities in all directions.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. See Common Physics Interface and Feature Settings and Nodes for links to more information.

Prescribed Normal Mesh Velocity

Use the **Prescribed Normal Mesh Velocity** node to specify the normal velocity of the boundary. The node can be used on the boundary of domains with free displacement. No constraints are set on the tangential velocity.

Simulations using moving meshes, with a boundary moving in the normal direction, can sometimes need a stabilizing term to suppress the formation of local boundary segments of high curvature. This can be of particular importance in an automatic remeshing sequence, where the remeshing step might amplify local curvature artifacts.

The Moving Boundary Smoothing option smooths the normal mesh velocity of the Prescribed Normal Mesh Velocity node according to the following equation:

$$\frac{\partial \mathbf{X}}{\partial t} \cdot \mathbf{n} = v_0 + v_{\mathrm{mbs}}$$

where v_0 is the desired normal mesh velocity, and v_{mbs} is a smoothing velocity according to:

$$v_{\mathrm{mbs}} = \delta_{\mathrm{mbs}} |v_0| hH$$

Here δ_{mbs} is a moving boundary smoothing tuning parameter (unitless), h is the mesh element size (SI unit: m), and H the mean surface curvature (SI unit: 1/m), defined as:

$$H = -\frac{1}{2} \nabla_T \cdot \mathbf{n}$$

where ∇_T is the surface gradient operator.

NORMAL MESH VELOCITY

Enter a value or expression for the **Normal mesh velocity** v_{n} (SI unit: m/s).

MOVING BOUNDARY SMOOTHING

By default, the **Enable moving boundary smoothing** checkbox is not selected. To enable boundary smoothing, click to select the checkbox, and then enter a value or expression for the **Moving boundary smoothing tuning parameter**, δ_{mbs} (unitless). The default value is 0.5.

As the local mesh element size h at a boundary is included in the expression for v_{mbs}, a large value for δ_{mbs} can result in an uneven velocity of mesh movement along a boundary. For this reason, it is recommended to use the smallest δ_{mbs} needed to achieve a stable solution.

Zero Normal Mesh Velocity

Use the **Zero Normal Mesh Velocity** node to set the normal velocity of the boundary to zero. The node can be used on the boundary of domains with free displacement. No constraints are set on the tangential velocity.

Zero Normal Mesh Displacement

Use the **Zero Normal Mesh Displacement** node to set the displacement in the normal direction of the boundary to zero. The node can be used on the boundary of domains with free displacement. No constraints are set explicitly in the tangential direction. Note however that for curved boundaries, a zero normal mesh displacement implicitly results in a zero displacement also in the tangential direction. Only for flat parts of the undeformed mesh is the boundary free to move in the tangential direction.

The Deformed Geometry Interface

The **Deformed Geometry (dg)** interface ( ), found under the **Mathematics** > **Deformed Mesh** > **Legacy Deformed Mesh** branch ( ) when adding a physics interface, can be used to study how physics changes when the geometry, here represented by the mesh, changes due to an externally imposed geometry change.

The Deformed Geometry interface has been largely replaced by the deformed geometry features in the **Deformed Geometry** branch under a component. While the interface is slightly more general, the features under the **Deformed Geometry** branch interact better with other physics interfaces.

The difference between the Deformed Geometry and Moving Mesh interfaces is that the former defines a deformation of the material frame relative to the geometry frame, while the latter defines a displacement of the spatial frame relative to the material frame. The Deformed Geometry interface can be used in cases where the original geometry model shrinks or grows by removal or addition of material. For example, it can be used for shape optimization (geometry shrinks and grows at different places simultaneously), corrosion (geometry shrinks), or electrodeposition (geometry grows).

SETTINGS

The **Label** is the default physics interface name.

The **Name** is used primarily as a scope prefix for variables defined by the physics interface. Refer to such physics interface variables in expressions using the pattern `<name>.<variable_name>`. In order to distinguish between variables belonging to different physics interfaces, the `name` string must be unique. Only letters, numbers, and underscores (_) are permitted in the **Name** field. The first character must be a letter.

The default **Name** (for the first physics interface in the model) is `dg`.

DOMAIN SELECTION

The Deformed Geometry interface requires a domain selection which covers all domains in which some physics is active.

FRAME SETTINGS

The **Geometry shape function** list controls the order of polynomials used for representing the geometry shape in the material frame. The same order is used for Lagrange shape functions defining the mesh position in domains where **Free displacement** has been activated.

FREE DEFORMATION SETTINGS

Select the smoothing type for freely deformed domains. Choose between Lagrange, Winslow, and hyperelastic smoothing.

For detailed information about selecting geometric entities (domains, boundaries, edges, and points), see Working with Geometric Entities

For more information about deformed meshes, see The Moving Mesh Interface.

- Domain and Boundary Nodes for Deformed Geometry

Electrochemical Polishing: Application Library path
COMSOL_Multiphysics/Electromagnetics/electrochemical_polishing

Domain and Boundary Nodes for Deformed Geometry

The Deformed Geometry Interface includes these domain and boundary nodes:

- Free Deformation
- Prescribed Deformation
- Fixed Mesh
- Prescribed Mesh Displacement
- Prescribed Mesh Velocity
- Prescribed Normal Mesh Velocity
- Zero Normal Mesh Velocity
- Zero Normal Mesh Displacement

Fixed Mesh

Use the **Fixed Mesh** node to specify that the selected domains retain their original shape as defined by the geometry and original mesh. This is the default.

Prescribed Mesh Displacement

Add the **Prescribed Mesh Displacement** node on the boundaries of domains with free deformation. The material frame in the adjacent domain moves in accordance with the displacement.

PRESCRIBED MESH DISPLACEMENT

Select the checkbox for each coordinate direction where you want to prescribe the displacement. The default settings provide a fixed boundary (zero displacements in all directions).

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. See Common Physics Interface and Feature Settings and Nodes for links to more information.

Free Deformation

The **Free Deformation** node constrains the mesh displacement only by the boundary conditions on the surrounding boundaries. The material frame displacement in the domain is obtained by solving a PDE.

Smoothing Methods

INITIAL DEFORMATION

Give initial values for mesh displacements, relative to the material frame, in the **Initial mesh displacement** fields.

Prescribed Deformation

Use the **Prescribed Deformation** node to define the deformation of the material frame explicitly using expressions.

PRESCRIBED MESH DISPLACEMENT

Specify expressions that define the deformation in the **Prescribed mesh displacement** fields. Select the checkbox to enable the prescribed mesh displacement in the directions to use such a displacement condition. Use one expression per spatial coordinate.

Prescribed Mesh Velocity

Use the **Prescribed Mesh Velocity** node on the boundary of domains with free displacement. The material frame in the adjacent domains moves in accordance with the velocity.

PRESCRIBED VELOCITY

Select the checkbox for each coordinate directory to prescribe a velocity. The default settings provide zero velocities in all directions.

CONSTRAINT SETTINGS

To display this section, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog. See Common Physics Interface and Feature Settings and Nodes for links to more information.

Prescribed Normal Mesh Velocity

Use the **Prescribed Normal Mesh Velocity** node to specify the normal velocity of the boundary. The node can be used on the boundary of domains with free displacement. No constraints are set on the tangential velocity.

Simulations using moving meshes, with a boundary moving in the normal direction, can sometimes need a stabilizing term to suppress the formation of local boundary segments of high curvature. This can be of particular importance in an automatic remeshing sequence, where the remeshing step might amplify local curvature artifacts.

The moving boundary smoothing option smooths the normal mesh velocity of the **Prescribed Normal Mesh Velocity** node according to the following equation:

$$\frac{\partial \mathbf{X}}{\partial t} \cdot \mathbf{n} = v_0 + v_{\mathrm{mbs}}$$

where v_0 is the desired normal mesh velocity, and v_{mbs} is a smoothing velocity according to:

$$v_{\mathrm{mbs}} = \delta_{\mathrm{mbs}} |v_0| hH$$

Here δ_{mbs} is a moving boundary smoothing tuning parameter (unitless), h is the mesh element size (SI unit: m), and H is the mean surface curvature (SI unit: 1/m), defined as:

$$H = -\frac{1}{2} \nabla_T \cdot \mathbf{n}$$

where ∇_T is the surface gradient operator.

NORMAL MESH VELOCITY

Enter a value or expression for the **Normal mesh velocity** v_{n} (SI unit: m/s).

MOVING BOUNDARY SMOOTHING

By default, the **Enable moving boundary smoothing** checkbox is not selected. To enable boundary smoothing, click to select the checkbox, and then enter a value or expression for the **Moving boundary smoothing tuning parameter**, δ_{mbs} (unitless). The default value is 0.5.

Zero Normal Mesh Velocity

Use the **Zero Normal Mesh Velocity** node to set the normal velocity of the boundary to zero. The node can be used on the boundary of domains with free displacement. No constraints are set on the tangential velocity.

Zero Normal Mesh Displacement

Use the **Zero Normal Mesh Displacement** node to set the displacement in the normal direction of the boundary to zero. The node can be used on the boundary of domains with free displacement. No constraints are set explicitly in the tangential direction. Note, however, that for curved boundaries, a zero normal mesh displacement implicitly results in a zero displacement also in the tangential direction. Only for flat parts of the undeformed geometry is the boundary free to move in the tangential direction.

Elements and Shape Functions

This chapter contains reference information about the shape functions (elements) available in COMSOL Multiphysics and some background to the computational methods associated with those elements. See also Elements and Shape Function Programming in the *COMSOL Multiphysics Programming Reference Manual* for information about using the API for the available elements.

Shape Functions and Element Types

This section provides an overview of the finite elements and shape functions that COMSOL Multiphysics uses.

The Structural Mechanics Module contains specialized elements for modeling of beams, trusses, plates, and shells.

Finite Elements

Once you have a mesh, you can introduce approximations to the dependent variables. For this discussion, concentrate on the case of a single dependent variable, u. The idea is to approximate u with a function that you can describe with a finite number of parameters, the so-called *degrees of freedom* (DOF). Inserting this approximation into the weak form of the equation generates a system of equations for the degrees of freedom.

Start with a simple example: linear elements in 1D. Assume that a mesh consists of just two mesh intervals: $0 < x < 1$ and $1 < x < 2$. Linear elements means that on each mesh interval the continuous function u is linear (affine). Thus, the only thing you need to know in order to characterize u uniquely is its values at the *node points* $x_1 = 0$, $x_2 = 1$, and $x_3 = 2$. Denote these as $U_1 = u(0)$, $U_2 = u(1)$, $U_3 = u(2)$. These are the *degrees of freedom*.

Now you can write

$$u(x) = U_1\varphi_1(x) + U_2\varphi_2(x) + U_3\varphi_3(x)$$

where $\varphi_i(x)$ are certain piecewise linear functions. Namely, $\varphi_i(x)$ is the function that is linear on each mesh interval, equals 1 at the i^{th} node point, and equals 0 at the other node points. For example,

$$\varphi_1(x) = \begin{cases} 1-x & \text{if } 0 \le x \le 1 \\ 0 & \text{if } 1 \le x \le 2 \end{cases}$$

The $\varphi_i(x)$ are called the *basis functions*. The set of functions $u(x)$ is a linear function space called the *finite element space*.

For better accuracy, consider another finite element space corresponding to quadratic elements. Functions u in this space are second-order polynomials on each mesh interval. To characterize such a function, introduce new node points at the midpoint of each mesh interval: $x_4 = 0.5$ and $x_5 = 1.5$. You must also introduce the corresponding degrees of freedom $U_i = u(x_i)$. Then, on each mesh interval, the second-degree polynomial $u(x)$ is determined by the degrees of freedom at the endpoints and the midpoint. In fact, you get

$$u(x) = U_1\varphi_1(x) + U_2\varphi_2(x) + U_3\varphi_3(x) + U_4\varphi_4(x) + U_5\varphi_5(x)$$

where the basis functions $\varphi_i(x)$ now have a different meaning. Specifically, $\varphi_i(x)$ is the function that is quadratic on each mesh interval, equals 1 at the ith node point, and equals 0 at the other node points. For example,

$$\varphi_1(x) = \begin{cases} (1-x)(1-2x) & \text{if } 0 \le x \le 1 \\ 0 & \text{if } 1 \le x \le 2 \end{cases}$$

In general, you specify a finite element space by giving a set of basis functions. The description of the basis functions is simplified by the introduction of *local (barycentric) coordinates* (or *element coordinates*) ξ_i. Consider a mesh element of dimension d in an n-dimensional geometry (whose spatial coordinates are denoted $x_1, \ldots, x_n$). Consider also the *standard d-dimensional simplex*

$$\xi_1 \geq 0, \xi_2 \geq 0, \ldots, \xi_d \geq 0, \xi_1 + \ldots + \xi_d \leq 1$$

which resides in the local coordinate space parameterized by the local coordinates $\xi_1, \ldots, \xi_d$. If $d = 1$, then this simplex is the unit interval. If $d = 2$, it is a triangle with two 45 degree angles, and if $d = 3$ it is a tetrahedron. Now you can consider the mesh element as a linear transformation of the standard simplex. Namely, by letting the global spatial coordinates x_i be suitable linear (affine) functions of the local coordinates, you get the mesh element as the image of the standard simplex.

When described in terms of local coordinates, the basis functions assume one of a few basic shapes. These are the *shape functions*. In the example with linear elements in 1D, any basis function on any mesh element is one of the following:

$$\phi = \xi_1, \qquad \phi = 1 - \xi_1, \qquad \phi = 0$$

Thus the first two are the shape functions in this example (0 is not counted as a shape function). In the example with quadratic elements in 1D, the shape functions are

$$\phi = (1 - \xi_1)(1 - 2\xi_1), \qquad \phi = 4\xi_1(1 - \xi_1), \qquad \phi = \xi_1(2\xi_1 - 1)$$

CURVED MESH ELEMENTS

When using higher-order elements (that is, elements of an order > 1), the solution has a smaller error. The error also depends on how well the mesh approximates the true boundary of the model geometry. To keep errors in the finite element approximation and the boundary approximation at the same level, it is wise to use *curved mesh elements*. They are distorted mesh elements that can approximate a boundary better than ordinary straight elements (if the model's boundary is curved). You can get curved mesh elements by writing the global coordinates x_i as polynomials of order k (the *geometry shape function order*) in the local coordinates ξ_j (the earlier example took $k = 1$). Then the mesh element is the image of the standard simplex. It is customary to use the same order k here as for the order of the (Lagrange) element. This is referred to as using *isoparametric elements*.

The order k is determined by the geometry shape function order for the frame (coordinate system) associated with the finite element. The frame is determined by the property `frame` to the finite element (the default is the reference frame). For certain finite elements, the geometry shape function given by the frame can be overridden by the property `sorder`. In the COMSOL Desktop, the default setting is to use an automatic geometry shape function order, which means that the geometry shape function order is typically equal to the lowest order of any shape function used in the model.

If a curved mesh element becomes too distorted, it can become inverted and cause problems in the solution. The software can then reduce the geometry shape function order automatically to avoid inverted elements.

- Shape Function Variables
- Avoiding Inverted Mesh Elements
- Imported Meshes and Element Orders

LOCAL COORDINATES FOR DIFFERENT ELEMENT TYPES

The mesh element types available in COMSOL have the following representations in local coordinates $\xi_1, \ldots, \xi_d$:

MESH ELEMENT TYPE	LOCAL COORDINATES
Edge	$0 \leq \xi_1 \leq 1$
Triangle	$\xi_1 \geq 0, \xi_2 \geq 0, \xi_1 + \xi_2 \leq 1$
Quadrilateral	$0 \leq \xi_1 \leq 1, 0 \leq \xi_2 \leq 1$

MESH ELEMENT TYPE	LOCAL COORDINATES
Tetrahedron	$\xi_1 \geq 0, \xi_2 \geq 0, \xi_3 \geq 0, \xi_1 + \xi_2 + \xi_3 \leq 1$
Hexahedron	$0 \leq \xi_1 \leq 1, 0 \leq \xi_2 \leq 1, 0 \leq \xi_3 \leq 1$
Prism	$\xi_1 \geq 0, \xi_2 \geq 0, \xi_1 + \xi_2 \leq 1, 0 \leq \xi_3 \leq 1$
Pyramid	$0 \leq \xi_1 \leq 1 - \xi_3, 0 \leq \xi_2 \leq 1 - \xi_3, 0 \leq \xi_3 \leq 1$

Shape Function Types (Element Types)

This section contains information about the available shape function types (element types). See also Elements and Shape Function Programming in the *COMSOL Multiphysics Programming Reference Manual*.

THE LAGRANGE ELEMENT

The preceding examples are special cases of the *Lagrange element*. Consider a positive integer k, the *order* of the Lagrange element. For simplex mesh elements, the functions u in this finite element space are piecewise polynomials of degree k; that is, on each mesh element u is a polynomial of degree k. Also, in the following table, l, m, and n are nonnegative integers. In general, for a mesh element of type T, u belongs to the Lagrange shape function space $\mathrm{Lag}_k(T)$, which is spanned by the following monomials (or rational functions, in the case of pyramid elements):

MESH ELEMENT TYPE	BASIS FOR LAGRANGE SHAPE FUNCTION SPACE
Edge	$\xi_1^l, \quad l \leq k$
Triangle	$\xi_1^l \xi_2^m, \quad l + m \leq k$
Quadrilateral	$\xi_1^l \xi_2^m, \quad \max(l, m) \leq k$
Tetrahedron	$\xi_1^l \xi_2^m \xi_3^n, \quad l + m + n \leq k$
Hexahedron	$\xi_1^l \xi_2^m \xi_3^n, \quad \max(l, m, n) \leq k$
Prism	$\xi_1^l \xi_2^m \xi_3^n, \quad \max(l + m, n) \leq k$
Pyramid	$\left(\frac{\xi_1}{1-\xi_3}\right)^l \left(\frac{\xi_2}{1-\xi_3}\right)^m (1-\xi_3)^{k-n}, \quad \max(l, m) + n \leq k$

To describe such a function it suffices to give its values in the *Lagrange points* of order k. These are the points whose local (element) coordinates are integer multiples of $1/k$. For example, for a triangular mesh in 2D with $k = 2$, this means that you have node points at the corners and side midpoints of all mesh triangles. For each of these node points p_i, there exists a degree of freedom $U_i = u(p_i)$ and a basis function φ_i. The restriction of the basis function φ_i to a mesh element is a function in $\mathrm{Lag}_k(T)$ such that $\varphi_i = 1$ at node i, and $\varphi_i = 0$ at all other nodes. The basis functions are continuous and you have

$$u = \sum_i U_i \varphi_i$$

The Lagrange element of order 1 is called the linear element. The Lagrange element of order 2 is called the quadratic element.

The Lagrange elements are available with all types of mesh elements, and it is the most common element type in the physics interfaces. The order k can be arbitrary, but the available numerical integration formulas usually limits its usefulness to $k \leq 5$($k \leq 4$ for tetrahedral meshes).

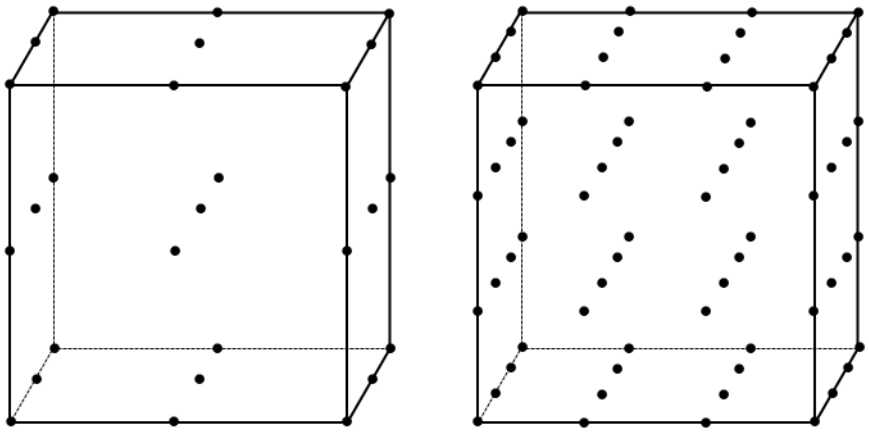

Figure 19-1: Examples of Lagrange elements: Second-order (27-node) hexahedral element (left) and third-order (64-node) hexahedral element (right).

Examples

For convenience, these examples provide explicit formulas for Lagrange shape functions for the most common element types and lowest orders.

Edge mesh elements For order $k = 1$, the Lagrange shape space has dimension 2 and has the following basis:

NODE POINT P	SHAPE FUNCTION
0	$1 - \xi_1$
1	ξ_1

For order $k = 2$ the Lagrange shape space has dimension 3 and has the following basis:

NODE POINT P	SHAPE FUNCTION
0	$(1 - \xi_1)(1 - 2\xi_1)$
1/2	$4\xi_1(1 - \xi_1)$
1	$\xi_1(2\xi_1 - 1)$

Triangular mesh elements For order $k = 1$, the Lagrange shape space has dimension 3 and has the following basis:

NODE POINT P	SHAPE FUNCTION
(0,0)	$1 - \xi_1 - \xi_2$
(1,0)	ξ_1
(0,1)	ξ_2

For order $k = 2$, the Lagrange shape space has dimension 6 and has the following basis:

NODE POINT P	SHAPE FUNCTION
(0,0)	$(1-\xi_1-\xi_2)(1-2\xi_1-2\xi_2)$
(1/2,0)	$4\xi_1(1-\xi_1-\xi_2)$
(1,0)	$\xi_1(2\xi_1-1)$
(0,1/2)	$4\xi_2(1-\xi_1-\xi_2)$
(1/2,1/2)	$4\xi_1\xi_2$
(0,1)	$\xi_2(2\xi_2-1)$

Quadrilateral mesh elements For order $k = 1$, the Lagrange shape space has dimension 4 and has the following basis:

NODE POINT P	SHAPE FUNCTION
(0,0)	$(1-\xi_1)(1-\xi_2)$
(1,0)	$\xi_1(1-\xi_2)$
(0,1)	$(1-\xi_1)\xi_2$
(1,1)	$\xi_1\xi_2$

For order $k = 2$, the Lagrange shape space has dimension 9 and has the following basis:

NODE POINT P	SHAPE FUNCTION
(0,0)	$(1-\xi_1)(1-2\xi_1)(1-\xi_2)(1-2\xi_2)$
(1/2,0)	$4\xi_1(1-\xi_1)(1-\xi_2)(1-2\xi_2)$
(1,0)	$\xi_1(2\xi_1-1)(1-\xi_2)(1-2\xi_2)$
(0,1/2)	$4(1-\xi_1)(1-2\xi_1)\xi_2(1-\xi_2)$
(1/2,1/2)	$16\xi_1(1-\xi_1)\xi_2(1-\xi_2)$
(1,1/2)	$4\xi_1(2\xi_1-1)\xi_2(1-\xi_2)$
(0,1)	$(1-\xi_1)(1-2\xi_1)\xi_2(2\xi_2-1)$
(1/2,1)	$4\xi_1(1-\xi_1)\xi_2(2\xi_2-1)$
(1,1)	$\xi_1(2\xi_1-1)\xi_2(2\xi_2-1)$

Tetrahedral mesh elements For order $k = 1$, the Lagrange shape space has dimension 4 and has the following basis:

NODE POINT P	SHAPE FUNCTION
(0,0,0)	$1-\xi_1-\xi_2-\xi_3$
(1,0,0)	ξ_1

NODE POINT P	SHAPE FUNCTION
(0,1,0)	ξ_2
(0,0,1)	ξ_3

For order $k = 2$, the Lagrange shape space has dimension 10 and has the following basis:

NODE POINT P	SHAPE FUNCTION
(0,0,0)	$(1-\xi_1-\xi_2-\xi_3)(1-2\xi_1-2\xi_2-2\xi_3)$
(1/2,0,0)	$4\xi_1(1-\xi_1-\xi_2-\xi_3)$
(1,0,0)	$\xi_1(2\xi_1-1)$
(0,1/2,0)	$4\xi_2(1-\xi_1-\xi_2-\xi_3)$
(1/2,1/2,0)	$4\xi_1\xi_2$
(0,1,0)	$\xi_2(2\xi_2-1)$
(0,0,1/2)	$4\xi_3(1-\xi_1-\xi_2-\xi_3)$
(1/2,0,1/2)	$4\xi_1\xi_3$
(0,1/2,1/2)	$4\xi_2\xi_3$
(0,0,1)	$\xi_3(2\xi_3-1)$

Hexahedral mesh elements For order $k = 1$, the Lagrange shape space has dimension 8 and has the following basis:

NODE POINT P	SHAPE FUNCTION
(0,0,0)	$(1-\xi_1)(1-\xi_2)(1-\xi_3)$
(1,0,0)	$\xi_1(1-\xi_2)(1-\xi_3)$
(0,1,0)	$(1-\xi_1)\xi_2(1-\xi_3)$
(1,1,0)	$\xi_1\xi_2(1-\xi_3)$
(0,0,1)	$(1-\xi_1)(1-\xi_2)\xi_3$
(1,0,1)	$\xi_1(1-\xi_2)\xi_3$
(0,1,1)	$(1-\xi_1)\xi_2\xi_3$
(1,1,1)	$\xi_1\xi_2\xi_3$

The Lagrange element defines the following variables. Denote `basename` with u, and let x and y denote (not necessarily distinct) spatial coordinates. The variables are (sdim = space dimension and edim = mesh element dimension):

- u
- ux, meaning the derivative of u with respect to x, defined on edim = sdim
- uxy, meaning a second derivative, defined on edim = sdim
- uTx, the tangential derivative variable, meaning the x-component of the tangential projection of the gradient, defined on edim < sdim
- $uTxy$, meaning xy-component of the tangential projection of the second derivative, defined when edim < sdim

When calculating the derivatives, the global spatial coordinates are expressed as polynomials of degree (at most) `sorder` in the local coordinates.

The use of isoparametric elements means that u is not a polynomial in the global coordinates (if $k > 1$), only in the local coordinates.

THE NODAL SERENDIPITY ELEMENT

On each mesh element, the functions in the nodal serendipity finite element space is a subset of those of the Lagrange element. For simplex mesh elements, the functions u in this finite element space are piecewise polynomials of degree k, where $k = 2$, 3, or 4; that is, on each mesh element u is a polynomial of degree k. In the following table, l, m, and n are nonnegative integers. Also, define a function $\mathrm{sl}(i)$ (for the superlinear order) such that $\mathrm{sl}(i)$ is equal to i, if $i > 1$; else $\mathrm{sl}(i) = 0$. In general, for a mesh element of type T, u belongs to the nodal serendipity shape function space $\mathrm{Ser}_k(T)$, which is spanned by the following monomials (or rational functions, in the case of pyramid elements):

MESH ELEMENT TYPE	BASIS FOR NODAL SERENDIPITY SHAPE FUNCTION SPACE
Edge	$\xi_1^l, \quad l \le k$
Triangle	$\xi_1^l \xi_2^m, \quad l + m \le k$
Quadrilateral	$\xi_1^l \xi_2^m, \quad \mathrm{sl}(l) + \mathrm{sl}(m) \le k$
Tetrahedron	$\xi_1^l \xi_2^m \xi_3^n, \quad l + m + n \le k$
Hexahedron	$\xi_1^l \xi_2^m \xi_3^n, \quad \mathrm{sl}(l) + \mathrm{sl}(m) + \mathrm{sl}(n) \le k$
Prism	$\xi_1^l \xi_2^m \xi_3^n, \quad \mathrm{sl}(l + m) + \mathrm{sl}(n) \le k$
Pyramid	$\left(\frac{\xi_1}{1-\xi_3}\right)^l \left(\frac{\xi_2}{1-\xi_3}\right)^m (1-\xi_3)^{k-n}, \quad \max(l, m, \mathrm{sl}(l) + \mathrm{sl}(m)) + n \le k$

To describe such a function it suffices to give its values in the *serendipity points* of order k, where k is 2, 3, or 4. These points are a subset of the Lagrange points (see The Lagrange Element). For each of these node points p_i, there exists a degree of freedom $U_i = u(p_i)$ and a basis function φ_i. The restriction of the basis function φ_i to a mesh element is a function in $\mathrm{Lag}_k(T)$ such that $\varphi_i = 1$ at node i, and $\varphi_i = 0$ at all other nodes. The basis functions are continuous and you have

$$u = \sum_i U_i \varphi_i$$

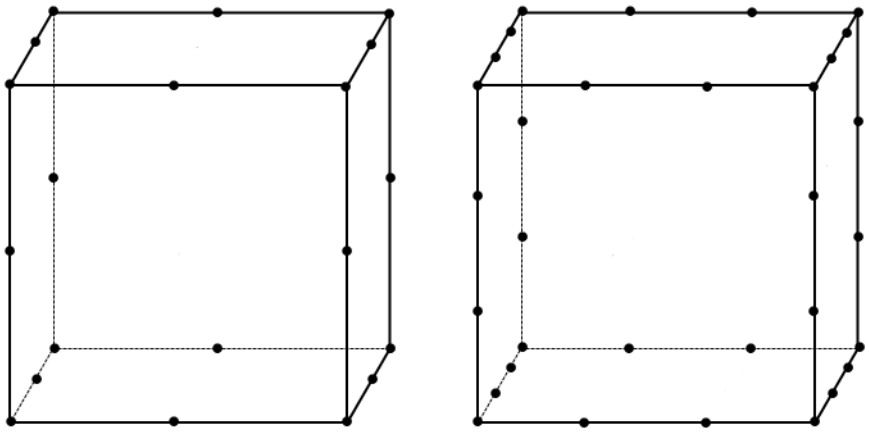

Figure 19-2: Examples of serendipity elements: Second-order (20-node) hexahedral element (left) and third-order (32-node) hexahedral element (right).

The nodal serendipity element defines the following field variables. Denote `basename` with u, and let x and y denote (not necessarily distinct) spatial coordinates. The variables are (sdim = space dimension and edim = mesh element dimension):

- u
- ux, meaning the derivative of u with respect to x, defined when edim = sdim or edim=0
- uxy, meaning a second derivative, defined when edim = sdim
- uTx, the tangential derivative variable, meaning the x-component of the tangential projection of the gradient, defined when 0 < edim < sdim
- $uTxy$, meaning xy-component of the tangential projection of the second derivative, defined when edim < sdim

When calculating the derivatives, the global spatial coordinates are expressed as polynomials of degree (at most) `sorder` in the local coordinates.

THE ARGYRIS ELEMENT

For a function represented with Lagrange elements, the first derivatives between mesh elements can be discontinuous. In certain equations (for example, the biharmonic equation) this can be a problem. The *Argyris element* has basis functions with continuous derivatives between mesh triangles (it is defined in 2D only). The second-order derivative is continuous in the triangle corners. On each triangle, a function u in the Argyris finite element space is a polynomial of degree 5 in the local coordinates.

The Argyris element is available with triangular meshes only.

When setting Dirichlet boundary conditions on a variable that has Argyris shape functions, a locking effect can occur if the boundary is curved and constraint order of 5 is used. Use a constraint order of 4 if the boundary is curved and 5 for straight boundaries.

The Argyris element defines the following degrees of freedom (where u is the base name and x and y are the spatial coordinate names):

- u at corners
- ux and uy at corners, meaning derivatives of u

- *uxx*, *uxy*, and *uyy* at corners, meaning second derivatives
- *u*n at side midpoints, meaning a normal derivative. The direction of the normal is to the right if moving along an edge from a corner with lower mesh vertex number to a corner with higher number

The Argyris element defines the following field variables (where sdim = space dimension = 2 and edim = mesh element dimension):

- *u*
- *ux*, meaning the derivative of *u* with respect to *x*
- *uxy*, meaning a second derivative, defined for edim = sdim and edim = 0
- *uxTy*, the tangential derivative variable, meaning the *y*-component of the tangential projection of the gradient of *ux*, defined for 0 < edim < sdim

When calculating the derivatives, the global spatial coordinates are always expressed with shape order 1 in the Argyris element.

THE HERMITE ELEMENT

On each mesh element, the functions in the Hermite finite element space are the same as for the Lagrange element, namely, all polynomials of degree (at most) k in the local coordinates. The difference lies in which DOFs are used. For the Hermite element, a DOF `u` exists at each Lagrange point of order k, except at those points adjacent to a corner of the mesh element. These DOFs are the values of the function. In addition, other DOFs exist for the first derivatives of the function (with respect to the global coordinates) at the corners (`ux` and `uy` in 2D). Together, these DOFs determine the polynomials completely. The functions in the Hermite finite element space have continuous derivatives between mesh elements at the mesh vertices. However, at other common points for two mesh elements, these derivatives are not continuous. You can think of the Hermite element as lying between the Lagrange and Argyris elements.

The Hermite element is available with all types of mesh elements except pyramids. The order $k \geq 3$ can be arbitrary, but the available numerical integration formulas usually limits its usefulness to $k \leq 5$ ($k \leq 4$ for tetrahedral meshes).

When setting Dirichlet boundary conditions on a variable that has Hermite shape functions, a locking effect can occur if the boundary is curved and the constraint order `cporder` is the same as the order of the Hermite element. This means that the derivative becomes overconstrained at mesh vertices at the boundary, due to the implementation of the boundary conditions. To prevent this locking, you can specify `cporder` to be the element order minus 1.

The Hermite element defines the following degrees of freedom:

- The value of the variable `basename` at each Lagrange node point that is not adjacent to a corner of the mesh element.
- The values of the first derivatives of `basename` with respect to the global spatial coordinates at each corner of the mesh element. The names of these derivatives are formed by appending the spatial coordinate names to `basename`.

The Hermite element defines the following field variables. Denote `basename` with *u*, and let *x* and *y* denote (not necessarily distinct) spatial coordinates. The variables are (sdim = space dimension and edim = mesh element dimension):

- *u*
- *ux*, meaning the derivative of *u* with respect to *x*, defined when edim = sdim or edim=0
- *uxy*, meaning a second derivative, defined when edim = sdim

- uTx, the tangential derivative variable, meaning the x-component of the tangential projection of the gradient, defined when $0 < \mathrm{edim} < \mathrm{sdim}$
- $uTxy$, meaning xy-component of the tangential projection of the second derivative, defined when $\mathrm{edim} < \mathrm{sdim}$

When calculating the derivatives, the global spatial coordinates are expressed as polynomials of degree (at most) `sorder` in the local coordinates.

BUBBLE ELEMENTS

Bubble elements have shape functions that are zero on the boundaries of the mesh element and have a maximum in the middle of the mesh element. The shape function (there is only one for each mesh element) is defined by a lowest-order polynomial that is zero on the boundary of the element.

The bubble element are available with all types of mesh elements.

The bubble element has a single degree of freedom, `basename`, at the midpoint of the mesh element.

The bubble element defines the following field variables. Denote `basename` with u, and let x and y denote (not necessarily distinct) spatial coordinates. The variables are (sdim = space dimension and edim = mesh element dimension):

- u, defined when $\mathrm{edim} \le \mathrm{mdim}$, $u = 0$ if $\mathrm{edim} < \mathrm{mdim}$.
- ux, meaning the derivative of u with respect to x, defined when $\mathrm{edim} = \mathrm{mdim} = \mathrm{sdim}$.
- $u\mathtt{T}x$, the tangential derivative variable, meaning the x-component of the tangential projection of the gradient, defined when $\mathrm{mdim} < \mathrm{sdim}$ and $\mathrm{edim} \le \mathrm{mdim}$. $u\mathtt{T}x = 0$ if $\mathrm{edim} < \mathrm{mdim}$.
- $u\mathtt{T}xy$, meaning the xy-component of the tangential projection of the second derivative, defined when $\mathrm{mdim} < \mathrm{sdim}$ and $\mathrm{edim} \le \mathrm{mdim}$. $u\mathtt{T}xy = 0$ if $\mathrm{edim} < \mathrm{mdim}$.

THE CURL ELEMENT

In electromagnetics, *curl elements* (also called *vector elements* or *Nédélec's elements of the first kind*) are widely used. Each mesh element has DOFs corresponding only to tangential components of the field. For example, in a tetrahedral mesh in 3D each of the three edges in a triangle face element has degrees of freedom that are tangential components of the vector field in the direction of the corresponding edges, and in the interior of the triangle there are degrees of freedom that correspond to vectors tangential to the triangle itself (if the element order is high enough). Finally, in the interior of the mesh tetrahedron there are degrees of freedom in all coordinate directions (if the element order is high enough). This implies that tangential components of the vector field are continuous across element boundaries, but the normal component is not necessarily continuous. This also implies that the curl of the vector field is an integrable function, so these elements are suitable for equations using the curl of the vector field.

The curl elements are available for all types of mesh elements. The polynomial order of the curl element can be at most seven in 1D, 2D, and 3D.

When postprocessing curl elements (vector elements), higher-order spatial derivatives of the fields are not available.

Detailed description of the Curl Element

The precise relation between the vector field (actually a one-form) and the DOFs of the curl element is rather complicated. We start by introducing for every mesh element T of dimension d the local vector shape function space $\mathrm{Curl}_k(T)$ consisting of vector fields $\Phi = (\Phi_1, \ldots, \Phi_d)$ satisfying the following condition:

$$\mathrm{Curl}_k(T) = \{\Phi; \Phi_i \in \mathrm{Lag}_k(T), \xi_1\Phi_1 + \ldots + \xi_d\Phi_d \in \mathrm{Lag}_k(T)\}$$

where $\mathrm{Lag}_k(T)$ is the Lagrange shape function space defined in the section on Lagrange shape functions. There is one exception; for pyramid mesh elements the definition needs to be modified as follows:

$$\mathrm{Curl}_k(T) = \{\Phi = \Psi + \nabla\psi; \Psi_i \in \mathrm{Lag}_k(T), \psi \in \mathrm{Lag}_k(T), \xi_1\Phi_1 + \ldots + \xi_d\Phi_d \in \mathrm{Lag}_k(T)\}$$

Next we introduce a transformation between local and global coordinates for a vector field in a mesh element T of dimension d embedded in space of dimension D. For a vector field in global coordinates $\varphi = (\varphi_1, \ldots, \varphi_D)$, the corresponding vector field in local coordinates is $\Phi = (\Phi_1, \ldots, \Phi_d)$ with components defined by

$$\Phi_i = \sum_{j=1}^{D} \frac{\partial x_j}{\partial \xi_i} \varphi_j$$

For mesh elements of full dimension $d = D$, this relation can be inverted to give

$$\varphi_j = \sum_{i=1}^{d} \frac{\partial \xi_i}{\partial x_j} \Phi_i$$

In particular, if T has full dimension, $\tilde{T} \subset T$ is a face or edge of T, and Φ is a vector field on T in local coordinates, then a vector field φ can be computed, and from its restriction to $\tilde{T}$ a vector field Φ in local coordinates on $\tilde{T}$.

Only the components of the global coordinate vector field φ can be directly evaluated as variables.

The relation between DOFs and vector fields is defined by specifying in each mesh element a number of pairs (p, v), where p is a point in the mesh element (given in local coordinates) and v is a vector. The DOFs are then defined as

$$\mathrm{DOF}_{(p,v)} = v \cdot \Phi(p)$$

If the number of pairs in each mesh element of type T is chosen to be equal to the dimension of $\mathrm{Curl}_k(T)$, the values of these DOFs uniquely define the vector field Φ. Typically, some of the pairs (p, v) have p in the interior of T, while others have p on some face or edge $\tilde{T} \subset T$. It is convenient to think of the DOFs corresponding to the latter points as inherited from $\tilde{T}$.

Since there might be more than one DOF in the same point p, DOF names have a suffix consisting of two integers, to distinguish different DOFs at the same point.

The choice of pairs (p, v) must take into account the orientation of each mesh element. Failing to do this would result in a vector field whose tangential component changes direction at the boundary between mesh elements. This is done by means of a global numbering of all mesh vertices.

Edge mesh elements Each edge mesh element has k DOFs. Let P_0, P_1 be the local coordinates of the endpoints of the edge, written in order of increasing mesh vertex indices (so P_0, P_1 is some permutation of the points 0 and 1 on the real line). Let v_1 be the 1-dimensional vector $\overrightarrow{P_0P_1}$. In local coordinates, the DOFs on the edge element are defined by the following pairs (p, v):

P	V	DOF NAME SUFFIX
$\frac{l}{k+1}, 1 \le l \le k$	v_1	10

Triangular mesh elements Each triangular mesh element has k DOFs on each edge (inherited from the corresponding edge elements) and $k(k-1)$ DOFs in the interior. Let P_0, P_1, P_2 be the local coordinates of the triangle vertices, in order of increasing mesh vertex indices (so P_0, P_1, P_2 is some permutation of the points $(0, 0)$,

(1, 0), (0, 1)). Let $v_1 = \overrightarrow{P_0P_1}$ and $v_2 = \overrightarrow{P_0P_2}$. Then the interior DOFs in this triangle are defined by the following pairs (p, v):

P	V	DOF NAME SUFFIX
$\left(\frac{l}{k+1}, \frac{m}{k+1}\right), 1 \le l, 1 \le m, l+m \le k$	v_1	20
$\left(\frac{l}{k+1}, \frac{m}{k+1}\right), 1 \le l, 1 \le m, l+m \le k$	v_2	21

Quadrilateral mesh elements Each quadrilateral mesh element has k DOFs on each edge (inherited from the corresponding edge elements) and $2k(k-1)$ DOFs in the interior. Let P_0 be the local coordinate of the vertex with lowest global index, P_1 the other vertex on the same horizontal edge as P_0, and P_2 the other vertex on the same vertical edge as P_0 (so P_0, P_1, P_2 is some subset of the points (0, 0), (1, 0), (0, 1), (1, 1)). Let $v_1 = \overrightarrow{P_0P_1}$ and $v_2 = \overrightarrow{P_0P_2}$. Then the interior DOFs in this quadrilateral are defined by the following pairs (p, v):

P	V	DOF NAME SUFFIX
$\left(\frac{l}{k+1}, \frac{m}{k}\right), 1 \le l \le k, 1 \le m \le k-1$	v_1	10
$\left(\frac{l}{k}, \frac{m}{k+1}\right), 1 \le l \le k-1, 1 \le m \le k$	v_2	10

Tetrahedral mesh elements Each tetrahedral mesh element has k DOFs on each edge, $k(k-1)$ DOFs on each face, and $k(k-1)(k-2)/2$ DOFs in the interior. Let P_0, P_1, P_2, P_3 be the local coordinates of the tetrahedron vertices, in order of increasing mesh vertex indices (so P_0, P_1, P_2, P_3 is some permutation of the points (0, 0, 0), (1, 0, 0), (0, 1, 0), (0, 0, 1)). Let

$$v_1 = \overrightarrow{P_0P_1},\ v_2 = \overrightarrow{P_0P_2},\ \text{and} v_3 = \overrightarrow{P_0P_3}$$

Then the interior DOFs in this tetrahedron are defined by the following pairs (p, v):

P	V	DOF NAME SUFFIX
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k+1}\right), 1 \le l, 1 \le m, 1 \le n, l+m+n \le k$	v_1	30
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k+1}\right), 1 \le l, 1 \le m, 1 \le n, l+m+n \le k$	v_2	31
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k+1}\right), 1 \le l, 1 \le m, 1 \le n, l+m+n \le k$	v_3	32

Hexahedral mesh elements Each hexahedral mesh element has k DOFs on each edge, $2k(k-1)$ DOFs on each face, and $3k(k-1)^2$ DOFs in the interior. Let P_0 be the local coordinate of the vertex with lowest global index, and let P_1, P_2, P_3 be the other vertices that differ from P_0 only in the ξ_1, ξ_2, ξ_3 coordinates respectively. Let

$$v_1 = \overrightarrow{P_0P_1},\ v_2 = \overrightarrow{P_0P_2}, v_3 = \overrightarrow{P_1P_3}$$

Then the interior DOFs in this hexahedron are defined by the following pairs (p, v):

P	V	DOF NAME SUFFIX
$\left(\frac{l}{k+1}, \frac{m}{k}, \frac{n}{k}\right), 1 \le l \le k, 1 \le m \le k-1, 1 \le n \le k-1$	v_1	10
$\left(\frac{l}{k}, \frac{m}{k+1}, \frac{n}{k}\right), 1 \le l \le k-1, 1 \le m \le k, 1 \le n \le k-1$	v_2	10
$\left(\frac{l}{k}, \frac{m}{k}, \frac{n}{k+1}\right), 1 \le l \le k-1, 1 \le m \le k-1, 1 \le n \le k$	v_3	10

Prism mesh elements Each prism mesh element has k DOFs on each edge, $k(k-1)$ DOFs on each triangular face, $2k(k-1)$ DOFs on each quadrilateral face, and $k(k-1)(3k-4)/2$ DOFs in the interior. Let P_0 be the local coordinate of the vertex with lowest global index, let P_1, P_2 be the other two vertices on the same triangular face as P_0, numbered so that P_1 has lower index than P_2, and let P_3 be the third point connected to P_0 by an edge. Let

$$v_1 = \overrightarrow{P_0P_1}, v_2 = \overrightarrow{P_0P_2}, v_3 = \overrightarrow{P_1P_3}$$

Then the interior DOFs in this prism are defined by the following pairs (p, v):

P	V	DOF NAME SUFFIX
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k}\right), 1 \le l, 1 \le m, l+m \le k, 1 \le n \le k-1$	v_1	20
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k}\right), 1 \le l, 1 \le m, l+m \le k, 1 \le n \le k-1$	v_2	21
$\left(\frac{l}{k}, \frac{m}{k}, \frac{n}{k+1}\right), 1 \le l, 1 \le m, l+m \le k-1, 1 \le n \le k$	v_3	10

Pyramid mesh elements Each pyramid mesh element has k DOFs on each edge, $k(k-1)$ DOFs on each triangular face, $2k(k-1)$ DOFs on the quadrilateral face, and $k(k-1)(2k-1)/2$ DOFs in the interior. Let $v_1 = (1, 0, 0)$, $v_2 = (0, 1, 0)$, and $v_3 = (0, 0, 1)$. Then the interior DOFs in this pyramid are defined by the following pairs (p, v):

P	V	DOF NAME SUFFIX
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k+1}\right), 1 \le l \le k-n, 1 \le m \le k-n, 1 \le n \le k$	v_1	30
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k+1}\right), 1 \le l \le k-n, 1 \le m \le k-n, 1 \le n \le k$	v_2	31
$\left(\frac{l}{k+1}, \frac{m}{k+1}, \frac{n}{k+1}\right), 1 \le l \le k-n, 1 \le m \le k-n, 1 \le n \le k$	v_3	32

Examples

For convenience we provide here explicit formulas for the Curl shape functions for the lowest orders and most common mesh elements. For each element type, the shape function corresponding to each DOF is written out in local coordinates, for a particular ordering of the mesh element vertices. For other numbers, the difference is that the vector v changes direction for some of the DOFs. For DOFs with suffix 10 this simply means that the corresponding shape functions change sign. Other shape functions might be replaced by a linear combination of the shape functions corresponding to DOFs at the same node point.

Triangular mesh elements The following formulas assume that the vertices of the triangle, in order of increasing mesh vertex index, have local coordinates (0, 0), (1, 0), (0, 1).

For order $k = 1$, the Curl shape space has dimension 3, and has the following basis:

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(1/2,0)	(1,0)	10	$(1 - \xi_2, \xi_1)$
(0,1/2)	(0,1)	10	$(\xi_2, 1 - \xi_1)$
(1/2,1/2)	(-1,1)	10	$(-\xi_2, \xi_1)$

For order $k = 2$, the Curl shape space has dimension 8, and has the following basis:

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(1/3,0)	(1,0)	10	$(2 - 3\xi_1 - 5\xi_2 + 3\xi_1\xi_2 + 3\xi_2^2, 2\xi_1 - 3\xi_1^2 - 3\xi_1\xi_2)$
(2/3,0)	(1,0)	10	$(-1 + 3\xi_1 + \xi_2 - 3\xi_1\xi_2, -\xi_1 + 3\xi_1^2)$
(0,1/3)	(0,1)	10	$(2\xi_2 - 3\xi_1\xi_2 - 3\xi_2^2, 2 - 5\xi_1 - 3\xi_2 + 3\xi_1^2 + 3\xi_1\xi_2)$
(0,2/3)	(0,1)	10	$(-\xi_2 + 3\xi_2^2, -1 + \xi_1 + 3\xi_2 - 3\xi_1\xi_2)$
(2/3,1/3)	(-1,1)	10	$(\xi_2 - 3\xi_1\xi_2, -\xi_1 + 3\xi_1^2)$
(1/3,2/3)	(-1,1)	10	$(\xi_2 - 3\xi_2^2, -\xi_1 + 3\xi_1\xi_2)$
(1/3,1/3)	(1,0)	20	$(6\xi_2 - 3\xi_1\xi_2 - 6\xi_2^2, -3\xi_1 + 3\xi_1^2 + 6\xi_1\xi_2)$
(1/3,1/3)	(0,1)	21	$(-3\xi_2 + 6\xi_1\xi_2 + 3\xi_2^2, 6\xi_1 - 6\xi_1^2 - 3\xi_1\xi_2)$

Quadrilateral mesh elements The following formulas assume that the vertices of the quadrilateral, in order of increasing mesh vertex index, have local coordinates (0, 0), (1, 0), (0, 1), (1, 1).

For order $k = 1$ the Curl shape space has dimension 4, and has the following basis:

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(1/2,0)	(1,0)	10	$(1 - \xi_2, 0)$
(1/2,1)	(1,0)	10	$(\xi_2, 0)$
(0,1/2)	(0,1)	10	$(0, 1 - \xi_1)$
(1,1/2)	(0,1)	10	$(0, \xi_1)$

For order $k = 2$ the Curl shape space has dimension 12, and has the following basis:

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(1/3,0)	(1,0)	10	$((2 - 3\xi_1)(1 - \xi_2)(1 - 2\xi_2), 0)$
(2/3,0)	(1,0)	10	$((3\xi_1 - 1)(1 - \xi_2)(1 - 2\xi_2), 0)$
(1/3,1)	(1,0)	10	$((2 - 3\xi_1)\xi_2(2\xi_2 - 1), 0)$

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(2/3,1)	(1,0)	10	$((3\xi_1 - 1)\xi_2(2\xi_2 - 1), 0)$
(0,1/3)	(0,1)	10	$(0, (2 - 3\xi_2)(1 - \xi_1)(1 - 2\xi_1))$
(0,2/3)	(0,1)	10	$(0, (3\xi_2 - 1)(1 - \xi_1)(1 - 2\xi_1))$
(1,1/3)	(0,1)	10	$(0, (2 - 3\xi_2)\xi_1(2\xi_1 - 1))$
(1,2/3)	(0,1)	10	$(0, (3\xi_2 - 1)\xi_1(2\xi_1 - 1))$
(1/3,1/2)	(1,0)	10	$(4(2 - 3\xi_1)\xi_2(1 - \xi_2), 0)$
(2/3,1/2)	(1,0)	10	$(4(3\xi_1 - 1)\xi_2(1 - \xi_2), 0)$
(1/2,1/3)	(0,1)	10	$(0, 4(2 - 3\xi_2)\xi_1(1 - \xi_1))$
(1/2,2/3)	(0,1)	10	$(0, 4(3\xi_2 - 1)\xi_1(1 - \xi_1))$

Tetrahedral mesh elements The following formulas assume that the vertices of the tetrahedron, in order of increasing mesh vertex index, have local coordinates $(0, 0, 0)$, $(1, 0, 0)$, $(0, 1, 0)$, $(0, 0, 1)$.

For order $k = 1$ the Curl shape space has dimension 6, and has the following basis:

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(1/2,0,0)	(1,0,0)	10	$(1 - \xi_2 - \xi_3, \xi_1, \xi_1)$
(0,1/2,0)	(0,1,0)	10	$(\xi_2, 1 - \xi_1 - \xi_3, \xi_2)$
(0,0,1/2)	(0,0,1)	10	$(\xi_3, \xi_3, 1 - \xi_1 - \xi_2)$
(1/2,1/2,0)	(-1,1,0)	10	$(-\xi_2, \xi_1, 0)$
(1/2,0,1/2)	(-1,0,1)	10	$(-\xi_3, 0, \xi_1)$
(0,1/2,1/2)	(0,-1,1)	10	$(0, -\xi_3, \xi_2)$

Hexahedral mesh elements The following formulas assume that the vertices of the hexahedron, in order of increasing mesh vertex index, have local coordinates $(0, 0, 0)$, $(1, 0, 0)$, $(0, 1, 0)$, $(1, 1, 0)$, $(0, 0, 1)$, $(1, 0, 1)$, $(0, 1, 1)$, $(1, 1, 1)$.

For order $k = 1$ the Curl shape space has dimension 12, and has the following basis:

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(1/2,0,0)	(1,0,0)	10	$((1 - \xi_2)(1 - \xi_3), 0, 0)$
(1/2,1,0)	(1,0,0)	10	$(\xi_2(1 - \xi_3), 0, 0)$
(1/2,0,1)	(1,0,0)	10	$((1 - \xi_2)\xi_3, 0, 0)$
(1/2,1,1)	(1,0,0)	10	$(\xi_2\xi_3, 0, 0)$
(0,1/2,0)	(0,1,0)	10	$(0, (1 - \xi_1)(1 - \xi_3), 0)$
(1,1/2,0)	(0,1,0)	10	$(0, \xi_1(1 - \xi_3), 0)$
(0,1/2,1)	(0,1,0)	10	$(0, (1 - \xi_1)\xi_3, 0)$
(1,1/2,1)	(0,1,0)	10	$(0, \xi_1\xi_3, 0)$

P	V	DOF NAME SUFFIX	LOCAL VECTOR FIELD
(0,0,1/2)	(0,0,1)	10	$(0, 0, (1-\xi_1)(1-\xi_2))$
(1,0,1/2)	(0,0,1)	10	$(0, 0, \xi_1(1-\xi_2))$
(0,1,1/2)	(0,0,1)	10	$(0, 0, (1-\xi_1)\xi_2)$
(1,1,1/2)	(0,0,1)	10	$(0, 0, \xi_1\xi_2)$

The curl element defines the following degrees of freedom: `dofbasename` d c, where $d = 1$ for DOFs in the interior of an edge, $d = 2$ for DOFs in the interior of a surface, and so forth, and c is a number between 0 and $d - 1$.

The curl element defines the following field variables (where comp is a component name from `compnames`, and dcomp is a component from `dcompnames`, sdim = space dimension and edim = mesh element dimension):

- comp, meaning a component of the vector, defined when edim = sdim.
- `t`comp, meaning one component of the tangential projection of the vector onto the mesh element, defined when edim < sdim.
- comp$x$, meaning the derivative of a component of the vector with respect to global spatial coordinate x, defined when edim = sdim.
- `tcompT`x, the tangential derivative variable, meaning the x component of the projection of the gradient of `t`comp onto the mesh element, defined when edim < sdim. Here, x is the name of a spatial coordinate.
- dcomp, meaning a component of the anti-symmetrized gradient, defined when edim = sdim.
- `t`dcomp, meaning one component of the tangential projection of the anti-symmetrized gradient onto the mesh element, defined when edim < sdim.

For performance reasons, use dcomp in expressions involving the curl rather than writing it as the difference of two gradient components.

For the computation of components, the global spatial coordinates are expressed as polynomials of degree (at most) `sorder` in the local coordinates.

THE CURL TYPE 2 ELEMENT

The *curl type 2 element* (also called *Nédélec's elements of the second kind*) is similar to the *curl element* that has DOFs corresponding to tangential components of the field. The main difference is that the curl type 2 element has full polynomial orders in all directions for each field component. The theory of curl type 2 elements is introduced in Ref. 1 and Ref. 2.

The curl type 2 element is available for simplex mesh elements only. The polynomial order of curl type 2 elements can be at most seven in 1D, 2D, and 3D. With additional DOFs introduced by the curl type 2 element, the resolution of each field component is improved, whereas the curl of the field remains unchanged compared with the curl element of the same order.

The usage of the curl type 2 element is the same as that of the curl element described above.

DISCONTINUOUS LAGRANGE ELEMENTS AND NODAL DISCONTINUOUS LAGRANGE ELEMENTS

The functions in the discontinuous Lagrange elements space are the same as for the standard Lagrange element, with the difference that the basis functions are discontinuous between the mesh elements. These elements are available in two variants: *discontinuous Lagrange* elements and *nodal discontinuous Lagrange* elements. The difference between these two is that the latter has optimal placement of degrees of freedom on triangle and tetrahedral meshes with respect to certain interpolation error estimates, whereas the former are available on all types of mesh elements with arbitrary polynomial order k.

The discontinuous element defines the following field variables. Denote `basename` with u, and let x denote the spatial coordinates. The variables are (edim is the mesh element dimension):

- u, defined when edim = mdim.
- ux, meaning the derivative of u with respect to x, defined when edim = mdim = sdim.
- uTx, the tangential derivative variable, meaning the derivative of u with respect to x, defined when edim = mdim < sdim.

DENSITY ELEMENTS

The functions in the density elements space are the same as for the discontinuous element if the mesh element is not curved. If the element is curved, the functions define a density of the given order in *local* coordinates, and the value in global coordinates depends on the transformation between local and global coordinates. The DOF values are proportional to the volume of the mesh elements.

The discontinuous elements are available with all types of mesh elements. The order k can be arbitrary, but the available numerical integration formulas usually limits its usefulness to $k \leq 5$ ($k \leq 4$ for tetrahedral meshes).

The density element defines the following field variables. Denote `basename` with u, and let x denote the spatial coordinates. The variables are (edim is the mesh element dimension):

- u, defined when edim = sdim.
- ux, meaning the derivative of u with respect to x, defined when edim = sdim.

GAUSS POINT DATA ELEMENTS

The Gauss point data elements are not shape functions in the usual sense. Instead, they define discrete degrees of freedom associated with the Gauss points used in an integration rule of a given order. To make these degrees of freedom available for evaluation and use in equations, a field variable with the same name as the degree of freedom is also defined. This field can be evaluated at any point inside the element but simply evaluates to the degree of freedom value at the closest Gauss point.

Use the Gauss point data elements to, for example, store historical values at the integration points in models with hysteresis, or to solve an implicit equation for a material property at each point. Make sure to use elements of the same order as the integration rule used for assembly of the main PDE, typically twice the discretization order of the main dependent variables. This ensures that the Gauss point data really behaves as a truly local quantity without any spatial correlation.

The Gauss point data element defines the following field variable. Denote `basename` with u and let edim be the evaluation dimension: u, defined when edim <= mdim.

DIVERGENCE ELEMENTS

For modeling the $\mathbf{B}$ (magnetic flux density) and $\mathbf{D}$ (electric displacement) fields in electromagnetics, the *divergence elements* (also called *Raviart-Thomas elements*) are useful. The DOFs on the boundary of a mesh element correspond to normal components of the field. In addition, there are DOFs corresponding to all vector field components in the interior of the mesh element of dimension sdim (if the order is high enough). This implies that the normal component of the vector field is continuous across element boundaries, but the tangential components are not necessarily continuous. This also implies that the divergence of the vector field is an integrable function, so these elements are suitable for equations using the divergence of the vector field.

The divergence element are available with all types of mesh elements. The polynomial order of the divergence element can be at most seven in 1D, 2D, and 3D.

The divergence element defines the following degrees of freedom: `dofbasename` on element boundaries, and `dofbasename` sdim c, $c = 0, \ldots, \text{sdim} - 1$ for DOFs in the interior.

The divergence element defines the following field variables (where comp is a component name from compnames, divname is the divname, sdim = space dimension and edim = mesh element dimension):

- comp, meaning a component of the vector, defined when edim = sdim.
- ncomp, meaning one component of the projection of the vector onto the normal of mesh element, defined when edim = sdim – 1.
- comp*x*, meaning the derivative of a component of the vector with respect to global spatial coordinate *x*, defined when edim = sdim.
- ncompT*x*, the tangential derivative variable, meaning the *x* component of the projection of the gradient of ncomp onto the mesh element, defined when edim < sdim. Here, *x* is the name of a spatial coordinate. ncompT*x* = 0.
- divname, means the divergence of the vector field.

For performance reasons, use divname in expressions involving the divergence rather than writing it as the sum of sdim gradient components. For the computation of components, the global spatial coordinates are expressed as polynomials of degree (at most) sorder in the local coordinates.

DIVERGENCE TYPE 2 ELEMENTS

The *divergence type 2 elements* (also called *Brezzi–Douglas–Marini elements*) are similar to the divergence elements that define DOFs on the boundary of a mesh element correspond to normal components of the field. The normal component of the vector field is continuous across element boundaries, but the tangential components are not necessarily continuous. The main difference is that divergence type 2 elements have full polynomial orders in all directions for each field component. The theory of divergence type 2 elements is introduced in Ref. 2.

The divergence type 2 elements are available for simplex mesh elements only. The polynomial order of the divergence type 2 elements can be at most seven in 1D, 2D, and 3D. Compared with divergence elements, the divergence type 2 elements introduce more DOFs to improve the resolution of each field component. However, the divergence of the field remains unchanged for these two types of divergence elements of the same order.

The usage of divergence type 2 elements is the same as that of divergence elements described above.

HIERARCHICAL BASIS ELEMENTS

For the PDE interfaces, you can choose **Hierarchical** or **Hierarchical serendipity** from the **Shape function** list. Both are available with an order from 1 to 10. The accuracy at a certain order is similar to that for a corresponding Lagrange elements or serendipity elements, respectively. With these element types, you can use different element orders in different domains in the geometry by using separate PDE interfaces for each domain. With hierarchical basis functions you get a conformal discretization without any hanging nodes.

See also The Lagrange Element and The Nodal Serendipity Element.

CROUZEIX–RAVIART ELEMENTS

The *Crouzeix–Raviart elements* are linear elements (first order only) with nodes at the midpoint of edges (2D) or the midpoint of faces (3D). The degrees of freedom are point evaluations at those midpoints. The Crouzeix–Raviart elements was devised as a technique for solving the stationary Stokes equation but have also been used for linear elasticity and Reissner–Mindlin plates. These elements consists of piecewise linear polynomials but, in contrast to linear Lagrange elements, their basis functions are not required to be continuous at every point. For more information about Crouzeix–Raviart elements, see Ref. 3.

Studies and Solvers

This chapter describes the study types and solvers available in the COMSOL Multiphysics® software.

In this chapter:

- Introduction to Solvers and Studies
- Study and Study Step Types
- Computing a Solution
- Solution Operation Nodes and Solvers
- Solution Attribute Nodes
- Solution Utility Nodes
- Job Configurations
- Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis

Introduction to Solvers and Studies

The process of solving a problem in COMSOL Multiphysics is a hierarchy. The Study node ( ) is the coarsest level (the top level). It contains the least amount of detail and defines a Study branch (see Branches and Subbranches in the Tree Structure).

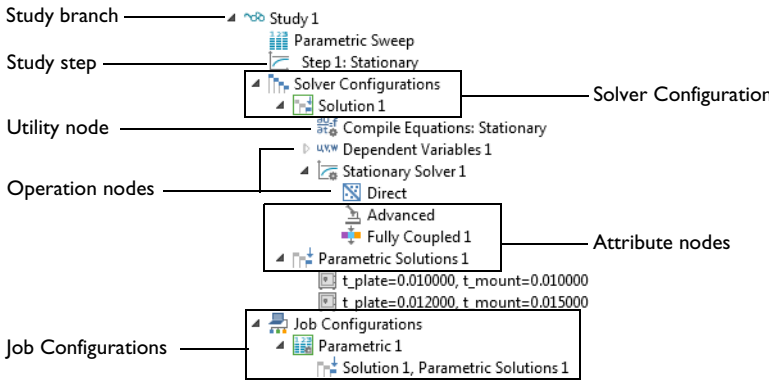

Figure 20-1: An example of the hierarchy under the Study node. This is the completed study and solver sequence for the Diagonal Mounting Detail of a Communication Mast model from the COMSOL Multiphysics Application Library. Some hierarchical categories for this sequence are shown.

ADDING A STUDY AND STUDY STEPS

When creating a new model, you can add any of the predefined Study and Study Step Types. At any time you can also add studies (see The Add Study Window). However you choose to add a study, a study node is added to The Model Builder including a corresponding *study step* (for example, **Stationary** in Figure 20-1), and in some cases, additional study steps. The study step represents the next level of detail.

DEFINING STUDY STEPS AND CREATING SOLVER CONFIGURATIONS

Most study steps are used to control the form of the equations, what physics interfaces are included in the computation, and what mesh is used. A study step **Settings** window has a Physics and Variables Selection section where inclusion and exclusion of physics interfaces and variables can be adjusted and set. There are also Common Study Step Settings for many of the study features added to a sequence.

Study steps correspond to part of a *solver configuration* (solver sequence), which is the next level of detail. There are also study steps for cluster computing, for example, which correspond to part of the Job Configurations.

Solver Configurations contain nodes that define variables to solve for, the solvers and settings, and additional sequence nodes for storing the solution, for example (see Figure 20-1). The solvers also have nodes that can control the solver settings in detail. Knowing The Relationship Between Study Steps and Solver Configurations is useful to help define and edit the settings before computing a solution. Bear in mind, however, that the default solver settings defined by the study usually provide a good starting point.

SOLVER SUGGESTIONS

Many physics interfaces suggest solver settings that are suited for the physics that you solve. The solver suggestions can also provide suitable settings for handling large 3D models, for example. See the documentation for the physics modules for more information about available solver suggestions.

You find solver suggestions in the solver configurations, when you have chosen **Show Default Solver** from the **Solver Configurations** node (see Solver Configurations). The solver suggestions are typically nodes under a solver, such as a **Time-Dependent Solver**, for example. For a 3D heat transfer simulation, for example, there can be a **Direct, heat transfer variables** solver suggestion and an iterative **AMG, heat transfer variables** suggestion. The latter is active by default, whereas the **Direct, heat transfer variables** node is disables (grayed out). To switch to the direct solver scheme instead, right-click the **Direct, heat transfer variables** node and choose **Enable**. Doing so, activates the direct solver scheme and disables the **AMG, heat transfer variables** node.

It is often best practice to use the default solver settings and possibly choose one of the other solver suggestions, if available. If you make changes to the solver settings and want to return to the default settings, right-click **Solver Configurations** node and choose **Reset Solver to Default** (see Reset Solver to Default for more information).

COMPUTING THE SOLUTION

Once the studies are added and defined, the simplest option to compute the solution is to right-click the **Study** node for a predefined study type and select **Compute** (=). This generates the default solver configuration for the corresponding study steps and computes the solution. There are a variety of techniques you can use while Computing a Solution, including many custom adjustments.

CONTROLLING AND CUSTOMIZING SOLVER SETTINGS

The settings can also be controlled at any level of detail. For example, you can add individual study steps when there is not a predefined study type that corresponds to the simulations you are interested in doing. Also, by changing the settings in the solver configuration you can, for example, control the desired tolerance for the error in the solution or which time-integration method or linear solver to use. See also Editing and Rerunning a Solver Configuration.

Solver Operation, Attribute, and Utility Nodes

There are different groups of feature types you can use to customize and fine tune the model. There are three classes of features that are subnodes to a Solution node. See Figure 20-1 for examples:

- *Operation nodes* (typically solvers) produce solutions as output. In particular, the output from the operation node that ran last is available for results analysis and visualization. See Solution Operation Nodes and Solvers.
- *Attribute nodes* hold properties that control the behavior of operation features. See Solution Attribute Nodes.
- *Utility nodes* handle special types of operations. Applicable solution utility nodes are available from the **Solver** > **Other** submenu. See Solution Utility Nodes.

Some of the settings in subnodes are synchronized with the corresponding Study setting. They are unavailable by default and can only be controlled from the subnode by changing the **Defined by study step** setting to **User defined**.

There are also advanced settings (Parametric Sweep and Optimization) and categories of Advanced Study Extension Steps (Parametric, Batch, and Cluster Computing) for additional settings customization and extensions of a study.

For some modules, more settings are available with respect to Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis.

About Solver Commands and Solution Object Data in the *COMSOL Multiphysics Programming Reference Manual*.

MULTIPLE STUDY STEPS VS. MULTIPLE STUDIES

You can create multiple studies with one or more study steps in each study. There are some aspects to consider when choosing to use multiple study steps in a single study versus multiple studies, each with a single or just a couple of study steps.

The main advantage of using multiple study steps is that initial conditions are automatically taken from the preceding step. It is also easier to run the whole sequence in one go.

When you use separate studies, you have to use more settings in the main **Study** node to point to the results in the preceding study. This approach can be useful if you need to examine the results of one study step before proceeding to the next. See Study Reference for information about referencing another study.

There are also some differences in how results are stored and shown. In a sequence with several study steps, you typically only see the results of the last step as a default. You can, however, access the results of the intermediate steps manually.

The Add Study Window

The **Add Study** window is similar to the **Select Study** window accessed through The Model Wizard. It has the same studies available and is a quick way to add a study (or studies) to models. You can have more than one study (each generating one or more solutions) for different scenarios using the same geometry and physics interface. The predefined study types correspond to the most commonly performed simulations for different physics. However, sometimes you might want to do other investigations. For example, you might want to solve a stationary problem for a physical quantity and use that solution as input to a time-dependent simulation for another physical quantity. For example, add a **Stationary** study step ( ), followed by a **Time Dependent** study step ( ) and then for each study step, choose the physics interfaces to include.

To open the **Add Study** window, right-click the root node and choose **Add Study** , or use one of the following alternatives:

Win	• In the **Home** toolbar, click **Add Study** or select **Windows** > **Add Study**. • In the **Study** toolbar, click **Add Study**.
Mac Linux	• In the Model Toolbar, click **Add Study** . • In the **Study** toolbar, click **Add Study**. • Select **Windows** > **Add Study**.
	The **Add Study** toolbar button is a toggle button: Click it again to close the **Add Study** window.

TO ADD A STUDY TO A MODEL ROOT NODE

1 In the **Add Study** window, from the branches under **Studies**, select the type of study to perform.

The available options depend on the set of physics interfaces included in the model. Some study types are applicable to all physics interfaces for which you choose to solve, while others are not, but in some way all are

available. Select one of the most common and applicable study types at the top of the list or a study type from one of the following branches:

- **General Studies** — Study types that are generally applicable, such as **Stationary** and **Time Dependent**.
- **Preset Studies for Selected Physics Interfaces** — Study types applicable to all physics interfaces that you have chosen to solve for.
- **Preset Studies for Selected Multiphysics** — Study types applicable to the multiphysics couplings that you have chosen to solve for.
- **More Studies** — This branch contains fundamental study types (**Stationary**, **Time Dependent**, **Eigenfrequency**, **Eigenvalue**, and **Frequency Domain**) that are not applicable to any of the physics interfaces being solved for.
- **Preset Studies for Some Physics Interfaces** — The study types recognized by some, but not all, of the physics interfaces being solved for.
- **Empty Study** to add a study without any study steps.

2 When there is already a physics interface in the model, the existing **Physics** are listed under **Physics interfaces in study**. Physics interfaces that are included appear with a check mark (☑) in the **Solve** column. Click in the row and column to remove the check mark (☐) and remove that physics interface from the study. If there are multiphysics couplings in the models they appear under **Multiphysics couplings in study** and can be controlled in the same way as the physics interfaces-

3 Click the **Add Study** button, press Enter, or right-click the study and choose **Add Study**. The study is added under the **Study** node in the **Model Builder**.

- Creating a New Model
- Study and Study Step Types

Study

A **Study** node (∞) holds all the nodes that define how to solve a model (see Figure 20-1). These nodes are divided into three broad categories:

- Study steps (see Study and Study Step Types), which determine overall settings suitable for a certain study type. The study steps added are based on the chosen study types. You can also add study steps to a study by right-clicking a **Study** node and choose from the available study steps or by choosing them from the **Study** ribbon.
- Solver Configurations, which contain the solvers and related configurations for dependent variables to solve for, intermediate storage of solutions, and specific solver settings. Those nodes are normally created by the study step, and you do not need to make any changes here. This branch is only initially visible if you select **Solver and Job Configurations** in the **Show More Options** dialog but appears after solving or if you choose **Show Default Solver** from the **Study** node's context menu.
- Job Configurations, which contain all jobs defined for a study (distributed parametric jobs, batch jobs, and cluster computing). This branch is only visible if you select **Solver and Job Configurations** in the **Show More Options** dialog.

Click the **Compute** button (=) (or press F8) to compute the study with its study steps (see Computing the Solution). Click the **Update Solution** button (↻) (or press F5) to update the solution for the study (see Updating a Solution).

Right-click a **Study** node and choose **Move Up** (↑), **Move Down** (↓), or **Delete** (✕) (or use the Ctrl+Up, Ctrl+Down, or Delete keys) to move a **Study** node up or down, relative to other **Study** nodes, or to remove it.

Also see Study Reference to refer to another study in the model. The main **Study** node has this section:

STUDY SETTINGS

The **Generate default plots** checkbox is selected by default so that plot groups with suitable default plots for the physics interfaces in the study are generated automatically when computing the solution. Clear this checkbox if you do not want any default plots. To restore default plots that you have removed, right-click the **Study** node and choose **Reset Default Plots**.

The **Generate convergence plots** checkbox is selected or cleared by default based on the setting for generating convergence plots on the **Results** > **Plots** > **Convergence Plots** page in the **Preferences** window. Clear this checkbox if you do not want convergence plots to be generated during the solution process.

Select the **Store solution for all intermediate study steps** checkbox to make the study add **Solution Store** nodes after all intermediate study steps in a study with multiple study steps. If this checkbox is not selected, **Solution Store** nodes are only added for some study step combinations.

Select the **Generate default plots for intermediately stored solutions** checkbox to generate a default plot group for each **Solution Store** node in the solver sequence of the study that appear after a **Compile Equations** node.

Select the **Plot the location of undefined values** checkbox (cleared by default) to create a separate window that contains a plot that shows the location of any undefined values such as Inf or NaN. Such undefined values could be the result of a division by zero, for example. For a Geometry 1, for example, the window name is **Undefined Values in Geometry 1**.

Select the **Store complete solver history** checkbox to turn on the logging of the solver history. You can also control the logging of the solver history using the **Preferences**, where you can select or clear the **Store complete solver history** checkbox under **Computing** > **Study Defaults**.

INFORMATION

In this section you find information about the computation time, date and clock time, and COMSOL version for the last run of the study.

Solver Configurations

The **Solver Configurations** node ( ) contains all solver configurations defined for a study (see Figure 20-1). It displays if it has content, or — to make the node available in the context menu — click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog.

A model is solved by computing a *solver configuration* — a scheme for computing a solution. A solver configuration is represented by a **Solution** node ( ) which stores both a sequence of subnodes, specifying how to compute the solution, and the solution itself — once it has been computed. Typically, such a solver configuration contains information about which configuration to use for physics interfaces, geometry, and mesh, which variables to solve for, and which solvers to use for the type of study to perform. You can also solve a model by directly computing a study; doing so first sets up a default solver configuration and, in some cases, one or more Job Configurations.

Right-click the node to choose one of these options from the context menu: **Show Default Solver**, **Reset Solver to Default**, **Create Custom Solver**, **Create Solution Copy**, and **Delete Configurations**.

SHOW DEFAULT SOLVER

To display the solver that corresponds to the study steps in a study and the current physics interface settings, right-click the main **Study** node ( ) (or the **Solver Configurations** or **Job Configurations** nodes) and select **Show Default Solver** ( ). See Solver Suggestions for information about physics-specific solver suggestions in the default solver.

RESET SOLVER TO DEFAULT

To reset a solver configuration to the default sequence for the current study steps and settings in the parent study, right-click the solver configuration node and select **Reset Solver to Default** ( ). The solver sequence under the solver configuration node is then reset to the default solver settings that you get when you select **Show Default Solver** and that the study uses if you have not made any changes to the solver settings. Using **Reset Solver to Default** can be useful if you have tried various solver settings and want to return to the default solvers without having to create a new solver configuration.

You can also right-click individual study step nodes and choose **Reset Solver to Default for Selected Step** to only reset the solver settings in the currently enabled solver configuration to the default for that study step.

CREATE CUSTOM SOLVER

From the main menu, click the **Show More Options** button ( ) and select **Study and Job Configurations** in the **Show More Options** dialog. Then right-click the **Solver Configurations** node and choose **Create Custom Solver** ( ). This adds a **Solution** node without any added solver settings or other nodes. Use this option if you want to create a fully user-defined custom solver scheme.

CREATE SOLUTION COPY

To create a copy of the solution dataset, right-click the main **Study** node ( ) or the **Solver Configurations** node ( ) and select **Create Solution Copy** ( ). A copy of the solution then appears as a **Solution - Copy** node ( ) under Solver Configurations and a corresponding **Solution - Copy** dataset ( ) under **Datasets** in the **Results** branch. This can be useful if you want to rerun the simulation with some changes to the model or solver settings. The first solution is then available in the **Solution - Copy** dataset so that you can postprocess and analyze multiple solutions. You can also right-click a **Solution** node ( ) under **Solver Configurations** and choose **Solution** > **Copy** ( ) to create a copy of the solution dataset for that solution.

DELETE CONFIGURATIONS

Select **Delete Configurations** ( ) to delete all solvers under the **Solver Configurations** node.

SELECTING A CLUSTER STORAGE FORMAT

Under **Solver Configurations**, right-click a **Solution** node and choose **Solution** > **Store on a Single Node** to specify that the solution should only be stored on a single cluster node. Choose **Solution** > **Store on All Nodes** if the solution should be stored on all cluster nodes. Choose **Solution** > **Store Solution Using Distributed Storage** if the solution should be stored using a distributed storage on clusters, which can improve performance using parallel I/O.

The Relationship Between Study Steps and Solver Configurations

Most studies and study steps correspond to part of a solver configuration that includes a solver for the specific problem, as listed in Table 20-1.

- Study
- Solver Configurations

TABLE 20-1: THE RELATIONSHIP BETWEEN COMMON STUDY STEPS AND SOLVERS.

STUDY STEP	DESCRIPTION	CORRESPONDS TO SOLVER
Stationary	Generates equations without time derivatives.	Stationary Solver. A parametric continuation solver can also be created by selecting an option on the study Settings window. Also see About the Stationary Solver and About the Parametric Solver.
Time Dependent	Generates equations for transient (time-dependent) simulations.	Time-Dependent Solver. Also see About the Time-Dependent Solver.
Time Discrete	Use it for performing time-dependent analysis using the projection method.	Time Discrete Solver. Also see About the Time Discrete Solver.
Time Dependent	Use the Time Explicit Solver to solve a time-dependent problem using an explicit time-stepping scheme.	References for the Solution Operation Nodes and Solvers. Also see The Time-Explicit Algorithms.
Eigenvalue	Generates equations formulated for computing eigenvalues and eigenfunctions.	Eigenvalue Solver. Also see The Eigenvalue Solver Algorithms.
Eigenfrequency	Similar to an Eigenvalue study step but computes eigenfrequencies instead of eigenvalues.	Eigenvalue Solver (set to transform eigenvalues to eigenfrequencies). Also see The Eigenvalue Solver Algorithms.
Frequency Domain	Generates stationary equations that are used for frequency sweeps.	It corresponds to a stationary parametric solver that is preset to linearize the equations (Stationary Solver with a Parametric attribute). By selecting the Use asymptotic waveform evaluation checkbox, this study step corresponds to an AWE Solver.
Time Dependent, Modal	Generates equations for time-dependent modal analysis.	Modal Solver (with Study type set to Time dependent). Also see The Modal Solver Algorithm.
Frequency Domain, Modal	Generates equations for modal analysis in the frequency domain.	Modal Solver (with Study type set to Frequency domain). Also see The Modal Solver Algorithm.

There are some study steps that do not generate equations and can only be used in combination with other study steps. These *study extension steps* do not correspond directly to any part of a solver configuration. Instead, they correspond to a part of the job configuration or modify the behavior of another study step.

STUDY EXTENSION STEPS

A Parametric Sweep is used to formulate a sequence of problems that arise when you vary some parameters in the model. The problem at a fixed parameter value is defined by the rest of the study steps in the study. It generates a Parametric Sweep (Job Configurations) node, unless the problem and parameters are such that the parametric sweep can be realized through a Stationary Solver with a Parametric node, in which case such a solver is generated in the solver configuration.

The parametric sweep can include multiple independent parameters directly, but you can also add more than one Parametric Sweep node to create nested parametric sweeps. In the **Study** branch, indentations of the node names indicate that the parametric sweeps are nested.

The Optimization study step and its variants are used to solve PDE-constrained optimization problems. These study steps allow direct definition of objective functions and selection of model parameters, including parameters that control the geometry, for optimization. They also provide control over solvers and contributions to an optimization problem defined by an Optimization interface. These study types require an Optimization Module license.

ADVANCED STUDY EXTENSION STEPS

Batch and Batch Sweep

A Batch study creates a job that can be run without the COMSOL Desktop user interface and which stores the solution on disk. It generates a Batch (Job Configurations).

A Batch Sweep is used to formulate a sequence of problems that arise when you vary some parameter in the model. Each parameter tuple generates a batch job that runs the model with the given tuple. The results are stored on file and updated into the model. It generates a Batch (Job Configurations) and a Parametric Sweep (Job Configurations). A Batch Sweep is similar to a Parametric Sweep and is useful when you want to retrieve solutions for a parametric sweep during the solution process and when the problem formulation is such that the solution for each parameter is independent of the solution of all other parameters. For example, it can be useful in the following situations where you may want to inspect the partial results during a solver sweep:

- You are basing your sweep on a table of input data and it turns out that obtaining a solution for some of those tabulated values takes an unexpectedly long time, but you do not know which values beforehand. You may still want to inspect the solution for as many parameters as possible to determine if you should terminate the solution process or start analyzing the results before the entire sweep is complete.
- You are using a mathematical expression for a certain material property or boundary condition that turns out to give unphysical results for some parameters.
- You wrote an external function (in C, for example) to define a complicated material, but you did not make it foolproof for all input data and it returns bad output data for certain parameter values.
- You are running a parametric sweep where one of the parameters is a geometric dimension, but you accidentally defined too wide of a range of dimensions. By the time you realize this, the solution has already been running for a long time and you do not want to stop it.

If you use a batch sweep in any of these cases, each parameter can be solved for in a separate process that can be started and stopped independently. The results for the parameters that have already been solved for can be stored as an MPH-file for each parameter value, and you can open and review any number of them during the solution process.

Cluster Computing and Cluster Sweep

A Cluster Computing study is used to solve the problem on a distributed-memory computer architecture. It generates a Cluster Computing (Job Configurations) and a Batch (Job Configurations).

A Cluster Sweep is used to formulate a sequence of problems that arise when you vary some parameter in the model. The program computes the solution for each parameter on a distributed-memory computer architecture. The results are stored on file and updated into the model. It generates a Cluster Computing (Job Configurations), Batch (Job Configurations), and (if applicable) Parametric Sweep (Job Configurations).

Multigrid Level

A Multigrid Level node can be added as a subnode to other study step nodes to describe a geometric multigrid level used by the study.

Sensitivity

The Sensitivity study step specifies objective functions and controls variables with respect to which sensitivity is computed. Global scalar objective functions can be specified directly in the study step, and model parameters can

be selected as control variables. In addition, the study step provides control over the sensitivity solver method and contributions to the sensitivity problem defined with a Sensitivity or Optimization interface.

BATCH SWEEPS AND CLUSTER SWEEPS VS. DISTRIBUTED SWEEPS

Batch sweeps and cluster sweeps work in a different way than distributed parametric sweeps. A distributed parametric sweep runs different parameters in parallel within an MPI job (different processes compute different parameters). A Batch Sweep or Cluster Sweep starts several processes in parallel and runs them, and it then afterward collects the result into the main process. In most cases, a distributed sweep is easier to work with. To do so, in the settings for the **Parametric Sweep** node, select the **Distribute parametric sweep** checkbox and start in distributed mode (see Distributed Parametric Sweeps). A Batch Sweep or Cluster Sweep requires that you set up a number of paths, but in cases where you want robustness and possibility for individual parameter restarts, a cluster sweep is preferred over a distributed parametric sweep. See also the following section.

BATCH SWEEPS VS. CLUSTER SWEEPS

In addition to a Parametric Sweep, you can also perform a Batch Sweep or a Cluster Sweep (see also the section above). The Batch Sweep is available for all COMSOL Multiphysics license types. If you have a floating network license, then you have access to an additional feature called Cluster Sweep. These two sweep types are similar, but the Cluster Sweep has additional settings for remote computations and cluster configurations. With a Cluster Sweep, you can distribute a large sweep on a, potentially large, cluster. The performance benefit of doing so can be very high because independent sweeps (sometimes called embarrassingly parallel computations) typically scale very well. If you know how to run batch sweeps, then the step toward running a cluster sweep is not that big.

Combine Solutions

Use a **Combine Solutions** node ( ) to combine two solutions using concatenation or summation or to remove solutions:

- You can use *concatenation* to merge (concatenate) two time-dependent solutions that cover two disjunct time intervals so that it is possible to analyze and postprocess a combined solution over both time intervals. You can also concatenate two eigenfrequency or eigenvalue solutions.
- You can use *summation* (a plain or weighted summation) to sum a number of eigensolutions, for example, for further analysis.
- You can also *remove solutions* from a time-dependent solution, for example.

This node is also available in the solver configuration as a solver utility node. It then contains a **General** section, similar to the **Combine Solutions Settings** section below but with an additional **Defined by study step** list, which includes the **Combine Solutions** study steps and the **User defined** option for combining solutions at the solver level. By default, such **Combine Solution** nodes are generated from a corresponding **Combine Solution** node at the study level. At the solver level, there is also a **Log** section.

!	Parameter and variable definitions are copied from the source solution when the **Combine Solutions** node is computed. Use **Update Solution** (see Updating a Solution) to update parameters and variables to their current values.

The **Settings** window contains the following section.

COMBINE SOLUTIONS SETTINGS

From the **Solution operation** list, choose **Concatenation** (the default), **Summation**, **Weighted summation**, **General summation**, or **Remove solutions**.

Concatenation

For a concatenation of two solutions, specify the two solutions from the **First solution** and **Second solution** lists. The lists contain all available solutions and **Solution Store** nodes (from this and other studies in the model), including **Current**, which is the default and is the output from the preceding study step.

The default for both solutions is **Current**, which is not a valid setting: the concatenation should be of two different time-dependent, parametric, or eigenvalue solutions, one of which may be the **Current** option. Stationary solutions cannot be combined.

From the **Concatenation method** list, choose **First solution has precedence** (the default) or **Include all solutions**. Use **First solution has precedence** to exclude solution numbers from the second solution whose parametric values can be found in the first solution. Use **Include all solutions** to include all solution numbers in the first solution and the second solution.

For a pure time-dependent solution with parameter size = 1, in the case of **First solution has precedence**:

- The concatenation extends the interval of the time from the **First solution** to the **Second solution**.
- For an overlapping interval, the **First solution** shadows the overlapped interval from the **Second solution**.
- If the **Add interpolated solution at intersection times** checkbox is selected (see below), an interpolation is done for the **Second solution** at the interval boundaries of the **First solution** when these boundaries are also in the interval for the second solution.

Regarding concatenation of time-parametric solutions or multiparametric solutions with one continuous parameter: For solution numbers whose values of a discontinuous parameters in the **First solution** and **Second solution** lists are the same, the concatenation follows the rule for concatenation of continuous single-parametric solutions. For solution numbers whose values of discontinuous parameters in the **First solution** and **Second solution** lists are different, solutions from both the **First solution** and **Second solution** lists are kept in the concatenated solution.

- The **Add interpolated solution at intersection points for continuous parameter intervals** checkbox is selected by default. This checkbox is only available when you have selected **First solution has precedence**, and it appears when the source solutions are parametric solutions with a continuous parameter that is not time. When selected, interpolation is done for the second solution at the intersection points for the continuous parameter. The results are always sorted for the continuous parameter values following the same order as it in the first solution.
- The **Add interpolated solution at intersection times** checkbox is selected by default. This checkbox is only available when you have selected **First solution has precedence**, and it appears when the source solutions are time-dependent solutions. When selected, interpolation is done for the second solution at the intersection times. The results are always sorted for time following the same order as it in the first solution.
- The **Sort discontinuous single-parameter values** checkbox is selected by default. This checkbox is available for both the **First solution has precedence** and **Include all solutions** methods. It appears when the source solutions are single-parametric solutions whose parameter is not continuous and is not an eigenvalue. When selected, the discontinuous parameter values are sorted in the combined solution.

If you concatenate solutions of an eigenvalue type, the following settings are available:

The **Sort eigenvalues** checkbox is selected by default. This checkbox is available for both the **First solution has precedence** and **Include all solutions** methods. It appears when the source solutions have only one parameter and are eigenvalue types of solutions like eigenvalue, eigenfrequency, or mode analysis. When selected, the relative parameter is sorted in the combined solution. The eigenvalues can be sorted in **Ascending** (the default) or **Descending** order depending on the **Ordering** setting. When the **Sorting method** is **Predefined**, you can choose to **Sort primarily**

based on the **Real part**, **Imaginary part**, **Real part magnitude**, **Imaginary part magnitude**, or **Absolute value**. The same settings are available for the **Sort secondly** option, which is used to resolve conflicts. The defaults for eigenvalues are **Real part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. For eigenfrequencies, the defaults are **Imaginary part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. Also, the **Sort based on transformed eigenvalues** checkbox is selected by default to take and eigenvalue transformation into account when sorting. Alternatively, **Manual** can be chosen for the **Sorting method** and then an arbitrary number of (ordered) custom sorting priority expressions can be defined in the table that appears. In the **Sorting priority expression** column, add expressions for the sorting, in order of priority. Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq`. For example, you can specify an expression such as `abs(freq-1)` to sort according to the distance from a given shift (1 in this case). If desired, add some descriptive text in the **Description** column for the expressions. Select the **Conjugate-pair consecutive sort** checkbox to make complex-conjugate eigenpairs appear one after the other, regardless of the sorting rules.

You can also control the solution type and select the corresponding checkboxes manually before running the combine solution operation. From the **Interpolation and sort** list, choose **Automatic** or **Manual**. The default is **Automatic**, and it determines which of the checkboxes mentioned above that appear. For the **Manual** method, all applicable checkboxes are listed for each solution type. However, only relevant checkboxes are applied when computing the combined solution. From the **Solution type** list, choose **Parametric**, **Time**, or **Eigenvalue**. When the **Solution type** is **Parametric**, it means that the source solutions are parametric solutions with or without a continuous parameter. When the **Solution type** is **Time**, it means that the source solutions are time-dependent solutions, including time–parametric solutions. When the **Solution type** is **Eigenvalue**, it means that the source solutions are eigenvalue types of solutions, including eigenvalue–parametric solutions.

Summation and Weighted Summation

For a summation of solutions, from the **Solution** list, choose the source solution to sum up all solutions in that source solution. The default is **Current**, to use the current solution.

Additionally, for a weighted summation, choose a method for the weights from the **Weights method** list: **One expression** or **List of expressions**.

Choose **One expression** to use a single expression, in the **Expression** field, to define the weights for all solutions. The expression can be, for example, a constant value like `0.1` or a parameter-based scalar value like `t`. The result of the expression has to be a scalar. **Weighted summation** with the weights method set to **One expression** and **Expression** being `1` is the same as **Summation**.

Choose **List of expressions** to define a list of expressions in the table below. The **Indices** column contains the solution numbers whose solutions are to be summed up. Solution whose solution numbers are not shown in the table will not be summed up. The expressions in the **List of expressions** column define how the weights are calculated. Different solution numbers can have their own weight expressions. Each expression should result in a scalar number. The status of the checkboxes in the **Active** column determines whether the corresponding solution number is taken into account in the summation or not.

If you only want to use the combined solution for a weighted summation, select the **Clear source solution** checkbox.

General Summation

Use this option to sum up all solutions in the source solution based on **Component expressions**, which are used to compute the corresponding DOFs in the solution vectors. You can use different expressions for different component names in the table that appears. For example, by default, the **Component expressions** are the component names themselves, in which case the general summation produces the same result as **Summation** and **Weighted summation** with weight 1. The **Component expressions** can also be the function of the component names like `(comp1.u)^2` or `abs(comp1.u)`, for which the general summation sum up the squares of all solutions or the absolute value of all solutions, respectively.

From the **Solution** list, choose the source solution of the general summation. The default is **Current**, to use the current solution.

The **General summation** option is only available for **Combine Solution** nodes that are added under a **Solution** node.

Remove Solutions

If you choose **Remove solutions**, you can remove some solutions (such as some eigenmodes, parametric solutions, or time steps) from the input solution. When using the **Remove Solutions** operation, from the **Exclude or include** list, choose **Exclude** (the default) or **Include** to use the criteria for choosing solutions as the ones to exclude or include.

From the **Exclude method** or **Include method** list, choose **Explicit** (the default) or **Implicit** to use an explicit choice of solutions or an implicit choice using Boolean expressions for the solutions to exclude or include.

For **Explicit**, choose **All**, **From list**, or **Manual** from the **Selection** list. For **From list**, choose solutions to exclude or include from the list. For **Manual**, enter solutions as indices (integers) in the **Index** field.

For **Implicit**, enter a Boolean expression in the **Exclude if** or **Include if** field. All solutions for which the expression evaluates to true are excluded or included. For example, if the source solution is a time-dependent solution, the **Exclude if** or **Include if** field can have an expression like `t>0.25`, meaning that only solutions whose parameter `t` is larger than 0.25 will be included or excluded.

If you only want to use the combined solution (a version of the input solution with some solutions removed), select the **Clear source solution** checkbox.

See *Axisymmetric Transient Heat Transfer*: Application Library path **COMSOL_Multiphysics/Heat_Transfer/heat_transient_axi**.

Study Reference

Use a **Study Reference** node ( ) to refer to another study in the model. The default name of the study reference node is the name of the study it refers to, such as **Study 2**.

You can use a **Study Reference** node to combine and nest several studies. Some examples:

- Running several studies from one study (here Study 1 runs Study 2, Study 3, and Study 4):
