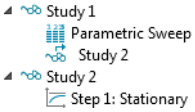
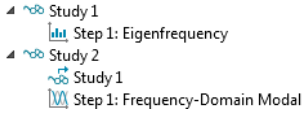
- Making a parametric sweep of another study (here the parametric sweep uses the study step in Study 2):



- Using another study as a precomputing step (here the Eigenfrequency study step in Study 1 runs as a precomputing step in Study 2):



If your license includes the Optimization Module, you can use **Study Reference** nodes to perform parameterized or nested optimization and to do derivative-free optimization where the objective and constraints are evaluated for different studies. See the *Optimization Module User's Guide* for more information.

The study reference node's **Settings** window includes the following section:

STUDY REFERENCE

From the **Study reference** list, select any available study in the model, except the one that contains the study reference node itself. The default setting, **None**, means that there is no reference to another study. Click the **Go to Source** button ( ) to move to the main **Study** node for the study that the study reference node refers to.

The **Study Reference** node is a pointer to another **Study** and triggers the execution of the study the reference points to when it is the **Study Reference** node's turn in the study sequence. However, there are no **Compile Equations**, **Dependent Variables**, or solver nodes created in the solver sequence associated with the current study. You therefore need to specify initial values to subsequent nodes or solutions to input studies explicitly if they should refer to solutions referenced by a **Study Reference**. If the target of a study reference is changed, those settings need to be reset manually.

Surrogate Model Training

Use a **Surrogate Model Training** study node ( ) to add functionality for training a data-driven *surrogate model*. A surrogate model is a simpler and computationally cheaper model, which you can use to approximate the behavior of a more complex and computationally expensive model (the full finite element model). In COMSOL apps, for example, faster model evaluation using the surrogate model provides users of the apps with a more interactive user experience. You create surrogate models by training a *deep neural network* (DNN), for example. The surrogate model training is typically based on output data from a large parametric sweep of the model for which you want to create a surrogate model. The training of a surrogate model needs a number of inputs and outputs, where the outputs are considered as functions of the inputs, which replace the full finite element solution. A large number of data points are needed in order to fully describe how the inputs map to the outputs. The outputs can be captured using domain point probes, for example.

A straightforward parametric sweep could densely and uniformly distribute input points, but such an approach would be inefficient. Random sampling is another alternative but with inherent drawbacks such as nonuniform sampling and potential failure to cover the entire input space. Instead, a more strategic approach is to use a design of experiments (DOE) method, carefully sampling within the parameter space. The **Surrogate Model Training** study uses *Latin hypercube sampling* (LHS), which is a DOE method that generates a dataset that uniformly covers the

input space without requiring an excessive number of finite element computations. This property of LHS makes it an efficient method for data generation intended for the purpose of training a surrogate model.

The more data points that are available, the more accurately the surrogate model will be able to represent the actual solution. However, generating a large number of data points requires a large number of simulations to be run, so there is a tradeoff between the time it takes to generate all the data points and the desired accuracy the surrogate model.

Tubular Reactor Surrogate Model Application: Application Library path **COMSOL_Multiphysics/Applications/tubular_reactor_surrogate**.

If you have the Battery Design Module, see *Surrogate Model Training of a Battery Rate Capability Model*: Application Library path **Battery_Design_Module/Applications/lib_rate_capability_surrogate**.

For additional information about surrogate models in connection with uncertainty quantification, see the *Uncertainty Quantification Module User's Guide*.

To add a **Surrogate Model Training** study, right-click a **Study** node and choose **Surrogate Model Training**. You can only have one **Surrogate Model Training** node in each study.

Click the **Compute** button ( ) to initiate the surrogate model training and create a surrogate model.

If you choose **Show Default Solver** from the **Study** node, the **Surrogate Model Training** study generates and sets up a **Design Of Experiments** job and its subsequence node (see the *Uncertainty Quantification Module User's Guide*). The **Design Of Experiments** job is controlled by and synchronized to the **Surrogate Model Training** study. If you click **Compute** from the **Study** node, the **Surrogate Model Training** study identifies and runs its **Design Of Experiments** job if it exists; else it first creates a **Design Of Experiments** job.

The **Settings** window for the **Surrogate Model Training** study include the following sections:

STUDY SETTINGS

From the **Compute actions** list, choose one of the following options: **Compute and build surrogate model** (the default) or **Improve and build surrogate model**. **Compute and build surrogate model** will discard data from the previous run (if the same table is used) or start a new run using a new table. **Improve and build surrogate model** will add more data to an existing table, which can be useful if you realize after having examined the trained SM function that it does not seem accurate enough. The **Surrogate Model Training** study outputs training data tables and trained surrogate models for each quantity of interest. If you choose **Design of experiments (No surrogate model)** for the surrogate model in the **Surrogate model** list below, a training data table will be the only result.

From the **Output table group** list, choose **New** to create a new output table group or choose any existing table group. All tables generated by **Surrogate Model Training** study will be grouped under this output table group.

From the **Surrogate model** list, choose **None (Design of Experiments)** (the default) to only generate training data, or choose **Gaussian process**, **Polynomial chaos expansion**, **Deep neural network**, or **Least-squares fit** to additionally set up surrogate models. **Gaussian process** and **Polynomial chaos expansion** require a license for the Uncertainty Quantification Module.

- For **Gaussian process**, also specify a covariance and a mean. From the **Covariance** list, choose **Squared exponential**, **Matérn 3/2** (the default), **Matérn 5/2**, or **Single-layer neural network**. From the **Mean** list, choose **Constant** (the default), **Linear**, or **Quadratic**.
- For **Polynomial chaos expansion**, also specify a **Settings method**. Choose **Automatic** (the default) or **Manual**. If you chose **Manual**, specify a value in the **Maximum polynomial degree** field (default value: 30), which terminates the increase of order for the PCE construction. You can also specify a value in the **q-norm** field (default: 0.5), which

determines the truncation level of the polynomial basis. If you chose **Automatic**, the training will automatically determine the required polynomial degree needed to obtain suitable accuracy.

- For **Deep neural network**, under **Layers**, define the layers in the DNN. The first layer is always the input layer of the network and specifies the number of input features of the network, which will be automatically detected. The last layer is the output layer, and the layers in between are the hidden layers. In the **Type** column, choose **Input** for the input layer (the default), and for the hidden layers and output layer, choose **Dense** (the default). In the **Settings** column for the current layer, you can see its settings. You can edit the table using the buttons under the table: Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons and the fields under tables to edit the table contents. Or right-click a table cell and select **Move Up**, **Move Down**, or **Delete**. The **Add Hidden Layer** button (+) adds a new hidden layer to the list right before the output layer. Use the **Clear Hidden Layers** button ( ) to clear all the hidden layers of the table and revert the input and output layers to their default. Underneath the table of layers, in the **Output features** field for the hidden layers, specify the number of output features, which are the number of nodes (default: 1). Choosing the number of layers and nodes in a neural network is often an iterative process that involves a combination of knowledge about the specific problem and data, empirical testing, and a bit of trial and error.

  You can also specify an activation function using the **Activation** list. An activation function in a DNN defines how the weighted sum of the input is transformed into an output from a node or nodes in a layer of the network. The default activation is **tanh**, for a hyperbolic tangent function, which is an S-shaped function. You can also choose **Linear (none)** for a linear (that is, no) activation function; **ReLU** for a rectified linear unit, an activation function defined as the positive part of its argument; **ELU** for an exponential linear unit; or **Sigmoid** for a sigmoid function. The default activation, **tanh**, is usually a good choice. **ELU** and **ReLU** are less smooth than the other functions, so avoid them if the trained function later needs to be differentiated. Choosing **Linear (none)** is only useful for the last layer.

- For **Least-squares fit**, specify the definition of the function in the **Expression** field. For example, `a1*x1+a0` for a linear function with two parameters, `a0` and `a1`, and one input parameter to the surrogate model, `x1`, defined under the **Input Parameters** section. In the table underneath, add the parameters that are used in the expression in the **Parameter** column. For the linear function example above, this would correspond to adding `a0` and `a1` in the **Parameter** column. In the **Values** column, choose the initial values (default: 0) for the parameters. The **Scale** column can be used to rescale each parameter with its specified scale. By default there is no scaling. Use the **Lower bound** and **Upper bound** columns to set lower and upper bounds on the parameters. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Clear Table** ( ) buttons underneath the table to move and remove rows and to clear the table. Use the **Load from File** ( ) and **Save to File** ( ) buttons to load or save data to or from the table. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window.

Select the **Train model automatically** checkbox if the surrogate models should also be trained after the training data has been generated and the surrogate models have been set up. By default, this checkbox is not selected.

QUANTITIES OF INTEREST

In the table under **Quantities of Interest (Outputs)**, define the outputs from the surrogate models (quantities of interest). The quantities of interest can be either global or nonglobal. Global quantities of interest can only depend on global input parameters (for example, point probe expressions). Nonglobal quantities of interest can additionally depend on space, time, and other study-dependent inputs.

In the **Expression** column, type the expression for the output (`comp1.ppb1`, for example, for a **Point Probe Expression 1** in **Component 1**). In the **Include study-dependent input** column, select **Reduce to single global output** if the quantity of interest is global or **Configure study-dependent input** if the quantity of interest is nonglobal. In the **Study-dependent input description** column you can see a small summary of the settings for each quantity of interest. If the **Surrogate model** setting is not **Design of experiments (No surrogate model)**, meaning it is either **Gaussian process**, **Polynomial chaos expansion**, **Deep neural network**, or **Least-squares fit**, there is an additional **Function name** column.

Here, you can give the name for the corresponding output in the surrogate model. To avoid name clashing, the resulting function name in the surrogate model will be the concatenation of the tag of the surrogate model and the name given in this column. For example, if the surrogate model has the tag `dnn1`, and the name provided in this table is `func1`, the resulting function name in the surrogate model corresponding to this quantity of interest will be `dnn1_func1`. If left empty, a valid default function name will be provided. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons and the fields under tables to edit the table contents. Or right-click a table cell and select **Move Up**, **Move Down**, or **Delete**. The **Add** button (+) adds a new output to the list. Use the **Clear Table** button ( ) to clear the entire table.

Underneath the table various settings are available — for each quantity of interest — based on whether the quantity of interest is global or nonglobal.

Reduce to Single Global Output

When there is a parametric sweep in the study, a selection can be made over the outer solutions (parametric solutions). From the **Individual outer solution selection** list, choose **Summation**, **Maximum**, or **Minimum**. For **Summation**, the quantity of interest is defined as the summation of the expression over all the outer solutions. For **Maximum** (or **Minimum**), the quantity of interest is defined as the maximum (or minimum) of the expression taken over all the outer solutions.

A selection can also be made over the inner solutions. First the selection is made over the outer solutions and then over the inner solutions. From the **Individual solution selection** list, choose **Automatic** (the default), **Summation**, **Minimum**, **Maximum**, **Use first**, or **Use last**. The **Automatic** solution to use will be the last solution for time-dependent and parametric solutions, while for eigenvalue and eigenfrequency solutions, it will be the first solution. You can override this mechanism by selecting any of the other methods. For **Summation**, the quantity of interest is defined as the summation of the expression over all the solutions. For **Maximum** (or **Minimum**), the quantity of interest is defined as the maximum (or minimum) of the expression taken over all the solutions. Also note that evaluation operators like `at()` and `with()` can be used in the expression, making it possible to evaluate even more general quantities from dynamic solutions.

Depending on the selection for **Surrogate model**, an additional setting will be available:

- For **Design of experiments (No surrogate model)**, select from the **Output table** list to which table the data should be written, or select **New** (the default) if a new table should be generated.
- For **Gaussian process**, **Polynomial chaos expansion**, **Deep neural network**, or **Least-squares fit**, select from the **Gaussian process function**, **PCE function**, **DNN function**, or **Least-squares fit** list, respectively, which existing surrogate model function to use or select **New** if a new surrogate model function should be created. If an existing surrogate model function is selected and a table is already attached to it, the data will be written to this table.

Configure Study-Dependent Input

Only quantities of interest evaluated with the same sampling and selection methods can be written to the same table (or file). This means that global and nonglobal quantities of interest will be separated in separate tables (or files). In the same way, not all nonglobal quantities of interest will be written to the same file. Automatically all quantities of interest evaluated with the same sampling and selection methods will be written to the same file. If **Surrogate model** is not set to **Design of experiments (No surrogate model)**, a separate surrogate model will also be created for every group.

Specify which sampling method to use from the **Geometry sampling** list to sample the quantity of interest on the geometry. Select **None** if the quantity of interest does not have spatial dependence. To create a **Geometry Sampling** node, right-click the **Surrogate Model Training** node, choose **Add Geometry Sampling to**, and then the component to which you want to add it. Or create the node directly under the **Definitions** of the **Component** using **Surrogate Model Sampling** > **Geometry Sampling**.

Specify with **Innermost parameter selection** a selection for the innermost solutions. In a time-dependent parametric simulation with an auxiliary sweep, the innermost parameter will be time. The parameters in the auxiliary sweep are

also inner parameters, but only one parameter can be the innermost parameter. For frequency-dependent simulations, the innermost parameter will be frequency, and for stationary simulations, the innermost parameter will be the continuation parameter. Choose from **Summation**, **Minimum**, **Maximum**, **Use last**, **Use first**, and **All**. For eigenvalue and eigenfrequency simulations the default is **Use first**; otherwise, the default is **All**. For **Summation**, the quantity of interest is defined as the summation of the expression over all the innermost solutions. For **Maximum** (or **Minimum**), the quantity of interest is defined as the maximum (or minimum) of the expression over all the innermost solutions. For **Use last** (or **Use first**), the quantity of interest is defined as the expression evaluated with the last (or first) innermost solution. Select all innermost solutions with **All**. If the innermost parameter is time you can also choose **Interpolation**. The quantity of interest is then defined as the expression interpolated at the times specified in **Times**. Ranges and vector-valued expressions can be used; see Entering Ranges and Vector-Valued Expressions for more on ranges and vector-valued expressions.

If there are more parameters in the study besides the innermost parameter, the **Study-dependent input configuration table** can be used to make further selections in the other parameters. In the **Study-dependent input parameter name** column all the parameters besides the innermost parameter are listed. Specify, in the **Parameter selection** column, which solutions to select for each parameter. Choose from **Last** and **All** (the default). For **Last**, the quantity of interest is defined as the expression evaluated using the last solution for that parameter. Select all solutions with **All**. **Last** can only be selected for inner parameters when the sweep type for the auxiliary sweep is **All combinations**. Select the checkbox in the **Include in training** column if the surrogate model should have an input for this parameter. By default, an input will be created for the surrogate model.

As the data generated for nonglobal quantity of interests is typically large, the data is stored on file. Specify with the **File** list if the file should be saved embedded in the model or external. Choose **Embedded file** if the file should be stored embedded in the model — the file will be attached to a table. Choose **External file** to save the file outside the model at the path specified with **Filename**. It is not possible to directly specify the filename; instead specify the **Base file path**, which is shared among all quantities of interest. It can be either a folder or a filename, and both relative and absolute paths are allowed. The file where the quantity of interest will be saved is in a file at the base file path with the name as specified in the **Filename** field. A small identifier has been added to the filename to mark which quantities of interest are in the file. Click the **Browse** button ( ) to browse the file system.

Depending on the selection for **Surrogate model**, an additional setting will be available:

- For **Design of experiments (No surrogate model)**, select from the **Output table** to which table the data should be written, or select **New** (the default) if a new table should be generated.
- For **Gaussian process**, **Polynomial chaos expansion**, **Deep neural network**, or **Least-squares fit**, select from the **Gaussian process function**, **PCE function**, **DNN function**, or **Least-squares fit** list, respectively, which existing surrogate model function to use or choose **New** if a new surrogate model function should be created. If an existing surrogate model function is selected and a table is already attached to it, the data will be written to this table.

INPUT PARAMETERS

In this section you define the input parameters for the surrogate model training.

For the input parameters, in the **Parameters** column, choose the parameter from a list of all global parameters in the model. In **Source type** column, choose **Analytic** (the default) or **Data**.

If you chose **Analytic**, you can define the following properties for the selected parameter underneath the table:

- In the **Distribution** list, choose the distribution for the input parameter: **Uniform** (the default), **Normal(μ,σ)**, **LogNormal(μ,σ)**, **Gamma(k,θ)**, **Beta(α,β)**, **Weibull(λ,k)**, or **Gumbel(μ,β)**. All distributions except the uniform distribution have two distribution parameters shown under the **Distribution** list, such as the **Mean** and **Standard deviation** for a normal distribution and **Shape** and **Scale** for a gamma distribution. You specify the distribution parameters in the corresponding text field. All distributions except the uniform distribution and beta distribution have **CDF-Lower**, **CDF-Upper** shown under the **Distribution** list.

- In the **CDF-Lower** list, choose the cumulative distribution function level for your lower bound: **30%**, **10%**, **1%**, **0.1%** (the default), **1E-4**, **1E-5**, **1E-6**, **1E-7**, or **Manual**. These bounds automatically compute a lower bound by using the inverse cumulative distribution function.
- In the **CDF-Upper** list, choose the cumulative distribution function level for your upper bound: **70%**, **90%**, **99%**, **99.9%** (the default), **1-1E-4**, **1-1E-5**, **1E-6**, **1-1E-7**, or **Manual**. These bounds automatically compute an upper bound by using the inverse cumulative distribution function.
- For Manual bounds, you can enter bounds and units for the input parameter in the **Lower bound**, **Upper bound**, and **Unit** columns. For the bounds, you can use unit syntax such as `0.45[mm]`, and for the unit, add its abbreviation, such as `Pa` for pascal.

The chosen analytic distribution appears in the **Parameter description** column.

If you chose **Data** in the **Source type** column, you can instead specify the following properties:

- From the **Data source** list, choose **Specified values** (the default), or choose **Result table** to take the data from the **Design of Experiments** results table.
- If you chose **Specified values**, specify the values to use in the **Specified values** field. Click the **Range** button ( ) to define a range of values.
- If you chose **Result table**, specify the column to use from the **Column** list.
- Specify a unit for the values in the **Unit** field. To do so, use its abbreviation, such as `Pa` for pascal.

If the source type for the parameter is **Analytic**, you can add correlations groups. Doing so allows sampling of parameters that are not statistically independent by specifying a correlation matrix. You could select a subset of all input parameters in the same correlation group and set the correlation matrix to specify the correlation between each pair of two parameters. Multiple correlation groups can be added in one study, and one parameter can only appear in one correlation group. The correlation matrix is a symmetric semidefinite matrix where all the diagonal elements are equal to 1 and all the off-diagonal elements are between [–1, 1].

Under **Sampling settings**, specify the following setting if the source type is **Analytic**:

- From the **Number of input points type** list, choose **Manual** (the default), or choose **Automatic** if the **Surrogate model** list is set to **Gaussian process** or **Polynomial chaos expansion**.
- If **Number of input points type** is set to **Manual**, then in the **Number of input points** field, if **Compute action** is set to **Compute and build surrogate model**, or **Number of input points for improve**, if **Compute action** is set to **Improve and build surrogate model**, specify the number of input points to use (default: 20 or 10). You may want to use a larger number to train the surrogate model to a sufficient degree of accuracy. The number of input points must be chosen empirically.
- From the **Random seed type** list, choose **Automatic** (the default), **Manual**, or **Current computer time**. If you chose **Manual**, enter a seed in the **Initial random seed** field. The random seed affects which sampling points you get from the Latin hypercube sampling.

You can edit the table using the buttons under the table:

- In general, use the **Move Up** ( ), **Move Down** ( ), and **Delete** ( ) buttons and the fields under tables to edit the table contents. Or right-click a table cell and select **Move Up**, **Move Down**, or **Delete**.
- The **Add** button ( ) adds a new input parameter to the list.
- Use the **Clear Table** button ( ) to clear the entire table.

ADVANCED SETTINGS

Select the **Accumulated probe table** checkbox to add accumulated probe tables for the result from the surrogate model training. From the **Output table** list, choose **New** to create a new table, or choose any existing table. The **Use**

all probes checkbox is selected by default to accumulate all the model probes in the table. If you clear this checkbox, the probes selected from the **Probes** list are used.

From the **Error handling** list, choose **Stop immediately** (the default) or **Skip problematic parameters**.

From the **Keep model evaluations in memory** list, choose **Only last** (the default) to only keep the last model evaluation in memory, or choose **All** to keep all model evaluations.

From the **Default solver sequence generation** list choose **Using global parameters** (the default) or **Using each parameter tuple**. Use this setting to control whether a solver sequence should be generated using global parameters or each parameter tuple.

Select the **Reuse the solution from the previous step** checkbox if you want the surrogate model training algorithm to reuse the solution from the previous step. It is useful if you are using an iterative solver and the solutions for different parameter values are similar enough so that it is faster to start from the previous solution instead of starting the solver from scratch.

Select the **Distribute model evaluation** checkbox if you are running the COMSOL software on a multiprocessor system and want to distribute the model evaluation to each compute node for improved performance. Using **Distribute model evaluation** is equivalent to using a **Distributed parametric sweep**.

In order for the **Distribute model evaluation** checkbox to function, you must start COMSOL with a setup for running COMSOL on clusters or other multicore system using, for example, `comsol -nn 2 -nnhost 2` on Linux® or `mpiexec -n 2 comsolcluster.exe -nnhost 2` on Windows® to start 2 compute nodes. You can also run COMSOL with a distributed parametric sweep from the command line. See Running COMSOL in Parallel on Clusters for more information.

From the **Surrogate model training log** list, choose **Minimal**, **Normal** (the default), or **Detailed** as desired.

Study and Study Step Types

To add a study or study step, see these topics:

- Creating a New Model
- The Add Study Window
- The Model Wizard

The main study step types — most of them available as a study in the **Add Study** window — are listed in Table 20-2. Some studies require add-on modules, and these are listed in Table 20-3 (in that list, the submenu under **Study Steps** in the **Study** branches appears in parentheses for the study types that are available as individual study steps).

Also see Study Extension Steps and Advanced Study Extension Steps for additional information about some study steps that do not generate equations and which can only be used in combination with other study steps. In Table 20-2, these are listed as supplemental studies and study steps.

TABLE 20-2: STANDARD STUDY TYPES, STUDY STEPS, AND STUDY EXTENSION STEPS.

ICON	STUDY OR STUDY STEP	BRIEF DESCRIPTION
	Empty Study	An Empty Study creates a Study node with no study steps.
	General Studies	Studies that are generally available, such as Stationary and Time Dependent.
	Preset Studies/Preset Studies for Selected Physics Interfaces	If you have added a single-physics interface, you find suggested studies under this node. If you have added multiple physics interfaces, you find studies applicable to all physics interfaces that you have added.
	More Studies	This branch contains study types for which the selected physics interfaces are not automatically adapted. Instead, these physics interfaces have to be adapted manually using the Model Builder.
	Preset Studies for Some Physics Interfaces	Under this node, studies applicable to all physics interfaces that you have chosen to solve for appear.
	Preset Studies for Selected Multiphysics	Under this node, studies applicable to the multiphysics couplings that you have chosen to solve for appear.
	Suggested by Some Physics Interfaces	Under this node (under Preset Studies for Selected Physics Interfaces), study types common to more than one physics interface appear if you have added more than two physics interfaces.
	Name of physics interface	Under a node with the name of a physics interface under Preset Studies for Selected Physics Interfaces, study types specific to that physics interface appears.
Stationary Studies and Study Steps		
	Stationary	For a stationary or steady-state situation where you can use a stationary solver. This study type is also used for optimization problems that are constrained with a stationary PDE. Adds a Stationary study step. You can also choose to create a parametric continuation solver.
Time-Dependent Studies and Study Steps		
	Time Dependent	For a time-dependent or transient simulation using a Time-Dependent Solver for computing the solution over time. This study type is also used for optimization problems that are constrained with a time-dependent PDE. Adds a Time Dependent study step.
	Time Discrete	Only available as a Time Dependent study step. Use it to perform time-dependent analysis using the projection method.

TABLE 20-2: STANDARD STUDY TYPES, STUDY STEPS, AND STUDY EXTENSION STEPS.

ICON	STUDY OR STUDY STEP	BRIEF DESCRIPTION
	Frequency to Time FFT	This study step performs an FFT (or nonuniform Fourier transform) from the frequency domain (the input) to the time domain for a time-dependent study.
Eigenfrequency Studies and Study Steps		
	Eigenfrequency	This study is similar to an Eigenvalue study but computes the eigenfrequencies instead of the eigenvalues. Adds an Eigenfrequency study step.
	Eigenvalue	This study uses a formulation to compute eigenvalues and eigenmodes using an eigenvalue solver. Adds an Eigenvalue study step.
	Stationary Then Eigenfrequency	This study step is for use with optimization, so that a Stationary solver can be used for the dependent variables defined by the shape optimization and topology optimization interfaces, before an Eigenvalue solver is used for the physical variables.
Frequency Domain Studies and Study Steps		
	Frequency Domain	For a study in the frequency domain such as wave equations or frequency response analysis. Adds a Frequency Domain study step.
	Frequency-Domain Perturbation	Use this study step for studies of small oscillations about a bias solution. This study step follows a study step that computes the stationary (or bias) solution and computes a perturbed solution of the linearized problem around the linearization point (or bias point) computed in the first step.
	Time-to-Frequency FFT	This study step performs an FFT from the time domain (the input) to the frequency domain (output) for a frequency-domain study.
Study Extensions Steps		
	Batch	Use this step to start a COMSOL Multiphysics batch process that solves the current study on your computer.
	Batch Sweep	Use this step to find the solution to a sequence of stationary or time-dependent simulations that arise when you vary some parameters of interest.
	Cluster Computing	Use this step when you want to submit COMSOL Multiphysics batch jobs to a job scheduler that in turn runs the batch job on a second computer or cluster.
	Cluster Sweep	Use this step to find the solution to a sequence of stationary or time-dependent simulations that arise when you vary some parameters of interest.
	Combine Solutions	Use this step to combine two solutions; for example, two time-dependent simulations over two different time spans that you want to postprocess as a single time-dependent solution.
	Function Sweep	This is a special case of Parametric Sweep study step, where the solver sweeps over functions defined under a Switch node defined under **Global Definitions** > **Functions**.
	Material Sweep	This is a special case of Parametric Sweep, where the solver sweeps over materials defined under a Switch node defined under Materials.
	Model Reduction	Use this step to create a reduced-order model from a time-dependent or frequency-domain simulation.
	Multigrid Level	This can be added as a subnode to other study step nodes to describe a geometric multigrid level used by the study.
	Parametric Sweep	Use this step to find the solution to a sequence of stationary or time-dependent problems that arise when you vary some parameters of interest. Add to a study to perform a parametric variation on other studies.
	Sensitivity	Use this step to add a sensitivity analysis to the study. Using a Sensitivity study node you can add sensitivity functions at the study level and use model parameters as global control variables.

TABLE 20-2: STANDARD STUDY TYPES, STUDY STEPS, AND STUDY EXTENSION STEPS.

ICON	STUDY OR STUDY STEP	BRIEF DESCRIPTION
	Study Reference	Use this step to refer to another study in the model.
	Surrogate Model Training	Use this step to add a surrogate model training for creating a surrogate model.

TABLE 20-3: STUDIES AND STUDY STEPS AVAILABLE WITH ADD-ON MODULES.

ICON	STUDY OR STUDY STEP	DESCRIPTION	REQUIRED MODULE
Chemical Applications			
	AC Impedance, Initial Values	The AC Impedance Initial Values study is used for electrochemical impedance spectroscopy (EIS) computations in electrochemical cells. The study consists of a single Frequency-Domain Perturbation study step, which solves for a harmonic linear perturbation.	Battery Design Module, Corrosion Module, Electrochemistry Module, or Electrodeposition Module
	AC Impedance, Stationary	Two study steps solve for a stationary problem and a harmonic perturbation in the frequency domain of the stationary solution.	Battery Design Module, Corrosion Module, Electrochemistry Module, or Electrodeposition Module
	AC Impedance, Time Dependent	Two study steps solve for a time-dependent problem and a harmonic perturbation in the frequency domain of the solution at the last time step.	Battery Design Module, Corrosion Module, Electrochemistry Module, or Electrodeposition Module
	Cyclic Voltammetry (under Time Dependent)	This study uses the Electroanalysis interface to perform transient simulations of voltammetry experiments.	Battery Design Module, Corrosion Module, Electrochemistry Module, or Electrodeposition Module
	Stationary Plug Flow (under Stationary)	This study is used for plug flow reactor models created with the Reaction Engineering interface. It is used to solve for the molar flow rate as a function of reactor volume.	Chemical Reaction Engineering Module
	Time-Dependent with Initialization	Use this study to perform transient simulations of electrochemical cells. It solves for the electrode and electrolyte potentials as well as all global ODE dependent variables. It also performs a transient simulation for all dependent variables in the model, using the result of the first study step as initial values.	Corrosion Module or Electrodeposition Module
	Time Dependent, Fixed Geometry	Use this study to exclude geometry deformation effects from a model. The study is similar to the Time-Dependent with Initialization study.	Corrosion Module or Electrodeposition Module
Electrical and Optical Applications			
	Bidirectionally Coupled Particle Tracing	This study is used to model the interactions of particle or ray trajectories with stationary fields. The study creates a Time Dependent solver that solves for all degrees of freedom related to the particles or rays. All other degrees of freedom are computed using a Stationary solver. The two solvers are repeated using a For-End For loop so that a self-consistent solution is obtained, taking the bidirectional coupling between the moving particles or rays and stationary fields into account.	Particle Tracing Module

TABLE 20-3: STUDIES AND STUDY STEPS AVAILABLE WITH ADD-ON MODULES.

ICON	STUDY OR STUDY STEP	DESCRIPTION	REQUIRED MODULE
	Bidirectionally Coupled Ray Tracing	This study is used to compute ray trajectories that are affected by external fields. This study solves for all degrees of freedom related to rays using a Time-Dependent solver. All other degrees of freedom are computed using a Stationary solver. The two solvers are repeated using a For-End For loop so that a self-consistent solution is obtained, taking the bidirectional coupling between the propagating rays and stationary fields into account.	Ray Optics Module
	Boundary Mode Analysis	Combines a mode analysis on a port (boundary) with a frequency domain study for the full geometry. Adds a Boundary Mode Analysis study step followed by a Frequency Domain study step.	RF Module, Wave Optics Module, Structural Mechanics Module, or Acoustics Module
	Coil Geometry Analysis	Use this study to solve an eigenvalue problem for the current flow in a Multiturn Coil Domain node that gives the current density likely produced by a bundle of conductive wires.	AC/DC Module
	Electrostatics Initialization	Use it to solve only the electrostatics equations of a physics interface. This study step is valuable for providing accurate and consistent initial values for subsequent study steps, particularly when there is an electric field present at time zero.	Electric Discharge Module
	Time-to-Frequency Losses	Use this study to compute the losses in a Loss Calculation Domain subnode where the loss model is set to Steinmetz or Bertotti. This study step performs an FFT from the time domain (the input) to the frequency domain that is used to compute the losses (output) based on empirical formulas or the time integral of resistive heating.	AC/DC Module
	Frequency-Stationary	This is a special case of a Stationary study and is available with the Induction Heating, Microwave Heating, and Laser Heating interfaces.	AC/DC Module, Plasma Module, RF Module, or Wave Optics Module
	Frequency-Transient	Compute electromagnetic fields in the frequency domain and the temperature (or electron temperature) in the time domain. Available with the Induction Heating, Microwave Heating, Inductively Coupled Plasma, and Microwave Plasma interfaces.	AC/DC Module, Plasma Module, RF Module, or Wave Optics Module
	Mean Energies (under Frequency Domain)	Use this study to enter an array of values for the mean electron energy. Available with the Boltzmann Equation, Two-Term Approximation interface.	Plasma Module
	Ray Tracing	Computes the trajectories of rays. This is a special case of the Time Dependent study step. The time list can either be specified directly or by entering a list of lengths and a characteristic group velocity. Built-in stop conditions can be used to stop the solver when no active rays remain, or when the intensity of active rays is negligibly small.	Ray Optics Module or Acoustics Module
	Reduced Electric Fields (under Frequency Domain)	Use this study to sweep through a range of reduced electric fields. Available with the Boltzmann Equation, Two-Term Approximation interface.	Plasma Module

TABLE 20-3: STUDIES AND STUDY STEPS AVAILABLE WITH ADD-ON MODULES.

ICON	STUDY OR STUDY STEP	DESCRIPTION	REQUIRED MODULE
	Schrödinger–Poisson	Use this study for the self-consistent solution to the Schrödinger–Poisson system.	Semiconductor Module
	Semiconductor Equilibrium	Use it to solve Poisson's equation for the case where the charge carriers are in thermal equilibrium.	Semiconductor Module
	Semiconductor Initialization	Use it to adaptively refine the mesh based on the gradient of the impurity doping concentration.	Semiconductor Module
	Frequency-Stationary, One-Way Electromagnetic Heating	First solve a frequency-domain equation for electromagnetics and then use the electromagnetic heat source as a source term when solving a subsequent stationary heat transfer equation. Available with the Induction Heating, Microwave Heating, or Laser Heating interfaces.	AC/DC Module, RF Module, or Wave Optics Module
	Frequency-Transient, One-Way Electromagnetic Heating	Sequentially compute electromagnetic fields in the frequency domain and then the temperature (or electron temperature) in the time domain. Available with the Induction Heating, Microwave Heating, and Laser Heating interfaces.	AC/DC Module, RF Module, or Wave Optics Module
	Frequency Domain, RF Adaptive Mesh	Solve a frequency-domain study that runs mesh adaptation for printed circuit boards and RF applications.	RF Module
	Frequency Domain Source Sweep	Solve a frequency-domain study that is sweeping among feedings such as ports and lumped ports, extracting automatically a full S-parameter matrix.	AC/DC Module, RF Module, or Wave Optics Module
	Stationary Source Sweep	A stationary source sweep to extract lumped matrices such as a capacitance matrix in Electrostatics.	AC/DC Module
	Stationary Source Sweep with Initialization	A combination of the source initialization study step and the stationary source sweep study step to extract lumped matrices such as an inductance matrix in Magnetic Fields, Currents Only	AC/DC Module
	Frequency Domain Source Sweep with Initialization	A combination of the source initialization study step and the frequency domain source sweep study step to extract lumped matrices such as an inductance matrix in Magnetic Fields, Currents Only.	AC/DC Module
	TEM Boundary Mode Analysis	Combines a frequency-domain analysis on port features (boundaries) with a frequency domain study for the full geometry. Adds a TEM Boundary Mode Analysis study step followed by a Frequency Domain study step.	RF Module
	Time Dependent, Modal	This study is for analyzing time-dependent wave problems using a modal solver. The Time Dependent, Modal study adds an Eigenfrequency study step followed by a Time Dependent, Modal study step.	RF Module, Acoustics Module, MEMS Module, Structural Mechanics Module, or Wave Optics Module
	EEDF Initialization	The EEDF Initialization study is used to compute the electron energy distribution function (EEDF) without solving for the other plasma degrees of freedom. It can also be used to compute the initial EEDF for a time and space dependent plasma model.	Plasma Module

TABLE 20-3: STUDIES AND STUDY STEPS AVAILABLE WITH ADD-ON MODULES.

ICON	STUDY OR STUDY STEP	DESCRIPTION	REQUIRED MODULE
	Time Periodic	This study solves for the periodic steady-state solution for models using the Plasma, Time Periodic interface.	Plasma Module
	Frequency-Time Periodic	This study is used to compute the periodic steady-state solution for models using the Plasma, Time Periodic interface together with the electromagnetic field distribution in the frequency domain.	Plasma Module
	Time Periodic to Time Dependent	This study converts a time-periodic solution to a time-dependent solution in a model using the Plasma, Time Periodic interface.	Plasma Module
	Wavelength Domain	Use this study to compute the response of a linear or linearized model subjected to electromagnetic harmonic excitation for one or several wavelengths.	Wave Optics Module
Fluid Applications			
	Frozen Rotor	This is a special case of a Stationary study. The frozen rotor approach assumes that the flow in the rotating domain, expressed in the rotating coordinate system, is fully developed. Available with the Rotating Machinery, Laminar Flow, and Turbulent Flow interfaces.	CFD Module or Mixer Module
	Frozen Rotor with Initialization	For flow in rotating machinery where the topology of the geometry does not change with rotation. You can also use it to compute the initial conditions for time-dependent simulations of flow in rotating machinery.	CFD Module or Mixer Module
	Wall Distance Initialization	A study step added to a Frozen Rotor or Stationary study to solve for the reciprocal wall distance.	CFD Module
	Mixing Plane Initialization	A study step added to a Frozen Rotor or Stationary study to perform initial mixing of flow and turbulence quantities.	Mixer Module
	Frozen Rotor with Stationary Free Surface	Two study steps, a Frozen Rotor solving for the fluid flow variables and a Stationary Free Surface one solving for the free surface deformation. Available with the Rotating Machinery, Laminar Flow, and Turbulent Flow interfaces.	CFD Module or Mixer Module
	Frozen Rotor with Initialization and Stationary Free Surface	Three study steps, a Wall Distance Initialization, followed by a Frozen Rotor solving for the fluid flow variables and a Stationary Free Surface one solving for the free surface deformation. Available with the Rotating Machinery, Turbulent Flow interfaces.	CFD Module or Mixer Module
	Stationary with Initialization	For stationary turbulent flow models that require an initialization, or for stationary electric discharges that require an initialization.	CFD Module, Heat Transfer Module, or Electric Discharge Module
	Time Dependent with Initialization	For time-dependent turbulent flow models that require an initialization, or for transient electric discharges that require an initialization.	CFD Module, Heat Transfer Module, or Electric Discharge Module

TABLE 20-3: STUDIES AND STUDY STEPS AVAILABLE WITH ADD-ON MODULES.

ICON	STUDY OR STUDY STEP	DESCRIPTION	REQUIRED MODULE
	Thermal Perturbation, Eigenfrequency	For computing the oscillations around an equilibrium steady-state temperature field using: a Stationary study step followed by an Eigenfrequency study step.	Heat Transfer Module
	Thermal Perturbation, Frequency Domain	For computing the oscillations around an equilibrium steady-state temperature field using: a Stationary study step followed by a Frequency-Domain Perturbation study step.	Heat Transfer Module
	Time Dependent with Phase Initialization	For time-dependent two-phase flow models that require an initialization of a level set function or phase field function.	CFD Module or Microfluidics Module
	Stationary, One-Way NITF	Two stationary study steps, one solving for the fluid flow variables and one solving for the heat transfer variables. Available with the Nonisothermal Flow and the Conjugate Heat Transfer interfaces.	CFD Module or Heat Transfer Module
	Time Dependent, One-Way NITF	Two time-dependent study steps, one solving for the fluid flow variables and one solving for the heat transfer variables in the time domain. Available with the Nonisothermal Flow and the Conjugate Heat Transfer interfaces.	CFD Module or Heat Transfer Module
	Frozen Rotor, One-Way NITF	Two frozen rotor study steps, one solving for the fluid flow variables and one solving for the heat transfer variables. Available with the Rotating Machinery, Nonisothermal Flow interfaces.	Mixer Module plus CFD Module
	Stationary, One-Way with Initialization NITF	A wall distance initialization followed by two stationary study steps, one solving for the fluid flow variables and one solving for the heat transfer variables. Available with the Nonisothermal Flow and the Conjugate Heat Transfer interfaces.	CFD Module or Heat Transfer Module
	Time Dependent, One-Way with Initialization NITF	A wall distance initialization followed by two time dependent study steps, one solving for the fluid flow variables and one solving for the heat transfer variables in the time domain. Available with the Nonisothermal Flow and the Conjugate Heat Transfer interfaces.	CFD Module or Heat Transfer Module
	Frozen Rotor, One-Way with Initialization NITF	Two frozen rotor study steps, one solving for the fluid flow variables and one solving for the heat transfer variables. Available with the Rotating Machinery, Nonisothermal Flow interfaces.	Mixer Module plus CFD Module
	Stationary, One-Way MF	Two study steps, one solving for the fluid flow variables and one solving for the moisture transport variables. Available with the Moisture Flow interface.	Heat Transfer Module
	Time Dependent, One-Way MF	Two study steps, one solving for the fluid flow variables and one solving for the moisture transport variables in the time domain. Available with the Moisture Flow interface.	Heat Transfer Module
Heat Applications			
	Orbit Calculation	This is a special case of a Time Dependent study, where the degrees of freedoms used for modeling the spacecraft orbit are solved for.	Heat Transfer Module

TABLE 20-3: STUDIES AND STUDY STEPS AVAILABLE WITH ADD-ON MODULES.

ICON	STUDY OR STUDY STEP	DESCRIPTION	REQUIRED MODULE
	Orbital Temperature	This is a special case of a Time Dependent study, where the external irradiation is reused on multiple orbit periods.	Heat Transfer Module
	Orbit Thermal Loads	This is a special case of a Time Dependent study, where the external irradiation is stored and the degrees of freedoms used for modeling the spacecraft orbit are solved for.	Heat Transfer Module
Mechanical and Acoustic Applications			
	Bolt Pretension	This study step is a special case of a Stationary study step, where the special degrees of freedoms used for modeling prestressed bolts are solved for.	Structural Mechanics Module
	Fatigue	Use this study for fatigue evaluation. It processes a load cycle and evaluates a fatigue criterion specified in the Fatigue interface.	Structural Mechanics Module plus Fatigue Module
	Linear Buckling	Use this study for a structural model to solve for the critical load factor using an eigenvalue solver.	Structural Mechanics Module or MEMS Module
	Eigenfrequency, Prestressed	For computing eigenfrequencies that are influenced by a prior static load.	Structural Mechanics Module, Geomechanics Module, MEMS Module, or Acoustics Module
	Frequency Domain, Prestressed	For computing the response to harmonic loads fluctuating around a static preload.	
	Frequency Domain, Prestressed, Modal	Three study steps are used to compute the response to harmonic loads fluctuating around a prior static load. The solution is performed using mode superposition.	Structural Mechanics Module, Acoustics Module, or MEMS Module
	Random Vibration (PSD)	Adds three studies and a number of nodes under Global Definitions for a random vibration analysis.	Structural Mechanics Module or MEMS Module
	Response Spectrum	Adds a Response Spectrum node under Definitions and an Eigenfrequency study step for a response-spectrum analysis.	Structural Mechanics Module or MEMS Module
	Stationary, One Way FSI	Two study steps solve for the fluid flow variables and for the solid deformation. Available with the Fluid–Multibody Interaction, Assembly interface.	Multibody Dynamics Module
	Time Dependent, One Way FSI	Two study steps solve for the fluid flow variables and for the solid deformation in the time domain. Available with the Fluid–Multibody Interaction, Assembly interface.	
	Time Dependent with FFT	Two study steps for computing a time-dependent solution using a Time Dependent study step and then applying a Time-to-Frequency FFT study step. Available with the Solid Rotor and Beam Rotor interfaces.	Rotordynamics Module
	Mapping	A dedicated study for the Background Fluid Flow Coupling multiphysics feature.	Acoustics Module
	Transient Mapping	A dedicated study for the Aeroacoustic Flow Source Coupling multiphysics feature.	Acoustics Module
Multipurpose Applications			
	Adaptive Frequency Sweep	The Adaptive Frequency Sweep study is for analyzing the frequency response of a linear or linearized model subjected to harmonic excitation in the frequency domain using an AWE solver.	Acoustics Module, MEMS Module, RF Module, or Wave Optics Module

TABLE 20-3: STUDIES AND STUDY STEPS AVAILABLE WITH ADD-ON MODULES.

ICON	STUDY OR STUDY STEP	DESCRIPTION	REQUIRED MODULE
	Frequency Domain, Modal	The Frequency Domain, Modal study is for analyzing wave problems in the frequency domain using a modal solver. It adds an Eigenfrequency study step followed by a Frequency Domain, Modal study step.	Structural Mechanics Module, MEMS Module, Acoustics Module, RF Module, or Wave Optics Module
	Mode Analysis	Computes the modes for an acoustic or electromagnetic wave using an eigenvalue solver.	Acoustics Module, RF Module, or Wave Optics Module
	Modal Reduced-Order Model	You can add a Modal Reduced-Order Model study step to export the reduced-order model matrices for time-dependent wave problems using a modal solver. Available from the **Study** node under **Study Steps** > **Time dependent**.	Structural Mechanics Module, MEMS Module, Acoustics Module, RF Module, or Wave Optics Module
	Frequency Domain, AWE Reduced-Order Model	The Frequency Domain, AWE Reduced-Order Model is an entry point which creates studies and other features which facilitates the setup of reduced-order models for frequency domain analysis using the AWE method.	Structural Mechanics Module, MEMS Module, Acoustics Module
	Frequency Domain, Modal Reduced-Order Model	The Frequency Domain, Modal Reduced-Order Model is an entry point which creates studies and other features which facilitates the setup of reduced-order models for frequency domain analysis using mode superposition.	Structural Mechanics Module, MEMS Module, Acoustics Module
	Time Dependent, Modal Reduced-Order Model	The Time Dependent, Modal Reduced-Order Model is an entry point which creates studies and other features which facilitates the setup of reduced-order models for time domain analysis using mode superposition.	Structural Mechanics Module, MEMS Module, Acoustics Module,
	Optimization	Use this study to solve PDE-constrained optimization problems. This study step allows direct definition of objective functions and selection of model parameters, including parameters that control the geometry, for optimization. It also provides detailed control over solvers and contributions to an optimization problem defined by an Optimization interface.	Optimization Module
	Curve Fitting	This study provides parameter estimation for time-dependent models.	Optimization Module
	Shape Optimization	Use this study to perform shape optimization.	Optimization Module
	Topology Optimization	Use this study to perform topology optimization.	Optimization Module
	Parameter Estimation	This study provides parameter estimation for all types of models.	Optimization Module
	Uncertainty Quantification	Add an uncertainty quantification study type.	Uncertainty Quantification Module.
	Small-Signal Analysis, Frequency Domain	For perturbed frequency domain studies of small oscillation about a bias solution. The study creates two study steps that solve for a stationary problem and for a harmonic perturbation in the frequency domain of the stationary solution.	AC/DC Module, MEMS Module, or Semiconductor Module

Common Study Step Settings

The study step nodes' **Settings** windows contain the following sections (in addition to specific study settings for each type of study step):

THE STUDY STEPS SETTINGS WINDOWS' TOOLBAR

On top of the study steps **Settings** windows, a toolbar contains the following commands:

- Click **Compute** (=) or press F8 to compute the entire study. If there is an enabled Solver node under **Solver Configurations**, that solver sequence will be executed. Otherwise a new solver sequence will first be generated. See Computing a Solution.
- Click **Update Solution** ( ) or press F5 (when applicable) to update the current study. See Updating a Solution.

STUDY SETTINGS

Include Geometric Nonlinearity Checkbox

If you have a license for the Acoustics Module, MEMS Module, or Structural Mechanics Module (including any add-on modules such as the Nonlinear Structural Materials Module) and your model involves structural mechanics, then the **Study Settings** section includes an **Include geometric nonlinearity** checkbox.

Select the **Include geometric nonlinearity** checkbox to enable a geometrically nonlinear analysis for the study step. Some physics designs force a geometrically nonlinear analysis, in which case it is not possible to clear the **Include geometric nonlinearity** checkbox. For further details, see the theory sections for the respective physics interface in the applicable modules' manuals.

Tolerance

In most stationary and frequency-domain studies, from the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field (default: 0.001).

Least-squares time/parameter method

When there are active least-squares objective functions in the model, it is possible to run an Auxiliary sweep with least-squares defined parameters if there are any. To use this possibility, choose **From least-squares objective** from the **Least-squares time/parameter method** list. Otherwise, **Least-squares time/parameter method** can be set to **Ignore**, but it is also possible to use a subset of the data using the **Merge within manual range option**. Lastly, the union between the values set in the study step can be used by selection the **Merge all** option. This option is hidden if there are no least-squares objectives in the model.

RESULTS WHILE SOLVING

This section is empty and unavailable when results while solving is not used or not applicable; for example, it is empty when there is an outer Parametric Sweep or Optimization active (and when no Auxiliary Sweep or Load Cases are used) and when you have enabled adaptive mesh refinement in the Stationary study step.

Select the **Plot** checkbox to allow plotting of results while solving. Then select what to plot from the **Plot group** list. The **Default** options creates the first default plot if it does not exist; otherwise, it uses the first default plot or the latest plot that you have added. The software plots the dataset of the selected plot group as soon as the results become available. Select **Times stored in output** (the default) or **Time steps taken by solver** from the **Update at** list when applicable.

Use the **Probes** list to select any probes to evaluate. The default is **All**, which selects all probes for plotting and tabulation of probe data. Select **Manual** to open a list with all available probes. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the probes that you want to see results from while solving. Select **None** to not evaluate any probe.

The software plots the dataset of the selected plot group and probes as soon as the results become available. Select **Steps stored in output** (the default) or **Steps taken by solver** from the **Update at** list.

You can use probes to tabulate values of interest during a large parametric simulation, for example. It can then be possible to keep only the last solution in memory during the parametric sweep, which potentially can significantly reduce memory requirements and the simulation time.

PHYSICS AND VARIABLES SELECTION

See Physics and Variables Selection for detailed information about this section. You can control and specify different cases where the physics interface to solve for is varied, or, for various analysis cases, which variables and physics features (for example, boundary conditions and sources) to use. The default is to solve for all physics interfaces that are compatible with the study step type.

VALUES OF DEPENDENT VARIABLES

When you have physics interfaces in a study step that you do not solve for but that provide degrees of freedom, you can specify how the COMSOL Multiphysics software handles the values of such degrees of freedom (dependent variables).

The settings in this section determine how the solver handles dependent variables that you do not solve for. This is applicable in, for example, a solver configuration where you only solve for a subset of the dependent variables in each step. You can also specify the initial values of variables that you do solve for.

By default, the COMSOL Multiphysics software determines these values heuristically depending on the physics as, for example, the specified initial values or a solution from an earlier study step. Under **Initial values of variables solved for**, the default value of the **Settings** list is **Physics controlled**. To specify the initial values of the dependent variables that you solve for, select **User controlled** from the **Settings** list.

The **Initial values of variables solved for** settings have no effect when using the eigenvalue solver.

Similarly, to specify the values of dependent variables that you do not solve for, select **User controlled** from the **Settings** list under **Values of variables not solved for**.

Then use the **Method** list to specify how to compute the initial values of variables solved for and the values of variables not solved for. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes for the physics interface in the model.
- **Solution** to use initial values as specified by a solution object (a solution from a study step).

Use the **Study** list to specify what study to use:

- Select **Zero solution** to initialize all variables to zero.
- Select any other available study to use it as an initial value.

Then use the **Solution** list to specify what solution object to use if **Study** has been set to a study:

- **Current** to use the current solution.
- Any other available solution object to use it as initial value.

Depending on the solution object to use, you can choose different solutions to use. If a solution has nodes for storing solutions in its sequence, you can choose which solution to use using the **Use** list. The **Current** value is the value that the solution has at the moment the value is read. The other values are the values stored in the respective nodes of the sequence. Choose **Manual** to enter the index for the solution that you want to use. The index can be a global parameter that is swept in a Parametric sweep with solution number inputs to it.

Depending on the study type of the solution that you selected, you can choose different solutions from a list underneath the **Study** list (and the **Solution** and **Use** lists, if present):

For a Stationary study, from the **Selection** list, select one of the following options:

- **Automatic (single solution)** (the default) to select one solution on the **Dependent Variables** node depending on a global evaluation to find the current value of the parameters in the input solution or, if that is not possible, the last (typically the only) solution.
- **Automatic (all solutions)** to use all (typically just one) solutions from that study (see below for more details).
- **First** to use the first (typically the only) solution.
- **Last** to use the last (typically the only) solution.
- **From list** to pick solutions from a list.
- **Manual** to use a specific solution number that you specify in the **Index** field.
- **1** to use the first (typically the only) solution. If you use a parametric continuation of the stationary study, there can be additional solutions to choose from.

For a Time Dependent study, from the **Time** list, select one of the following options:

- **Automatic (single solution)** (the default) to select one solution on the **Dependent Variables** node depending on a global evaluation to find the current value of the parameters in the input solution or, if that is not possible, the solution for the last time.
- **Automatic (all solutions)** to use all solutions from that study (see below for more details).
- **First** to use the first solution.
- **Last** to use the last solution.
- **From list** to pick solutions from a list.
- **Interpolated** to specify a time in the text field below. This option is also available for other study types for robust setup, but if the type is not time dependent when used, an error will appear.
- **Manual** to use a specific solution number that you specify in the **Index** field.
- One of the output times to use the solution at that time.

For an Eigenvalue or Eigenfrequency study, from the **Eigenvalue** list, select one of the following options:

- **Automatic (single solution)** (the default) to select one solution on the **Dependent Variables** node depending on a global evaluation to find the current value of the parameters in the input solution or, if that is not possible, to use the solution for the first eigenvalue or eigenfrequency and its associated eigensolution.
- **Automatic (all solutions)** to use all solutions from that study (see below for more details).
- **First** to use the first solution.
- **Last** to use the last solution.
- **From list** to pick solutions from a list.

- **Manual** to use a specific solution number that you specify in the **Index** field.
- One of the eigenvalues to use the solution for the corresponding eigensolution.

For a parametric or Frequency Domain study, from the **Parameter value** list, select one of the following options:

- **Automatic (single solution)** (the default) to select one solution on the **Dependent Variables** node depending on a global evaluation to find the current value of the parameters in the input solution or, if that is not possible, the solution for the last parameter value set or frequency.
- **Automatic (all solutions)** to use all solutions from that study (see below for more details).
- **First** to use the first solution.
- **Last** to use the last solution.
- **From list** to pick solutions from a list.
- **Manual** to use a specific solution number that you specify in the **Index** field.
- One of the parameter value sets or frequencies to use the corresponding solution.

For the **Automatic (all solutions)** option, all solutions are passed down to the solver, and the solver selects the initial values based on if there is a match to the current parameter tuple. This makes it possible to pass multiple initial values or guesses to the solver, which can be useful if you are doing a parametric study using multiple parameters and the convergence of each parameter tuple is dependent on a good initial guess. It can also be used together with the time-dependent parametric solver to use different initial values for each parameter tuple.

A parametric list can also appear in other studies used together with a parametric sweep.

STORE IN OUTPUT

In the **Store in Output** section, you can specify to store the field variables that you solve only for some parts of the geometry (a boundary, for example, if the solution in the domain is not of interest). You define the parts of the geometry for which to store the fields as selection nodes.

For each listed physics interface, choose one of the following options in the **Output** column:

- Choose **Physics controlled** (the default) to use the physics interface control what to store in the output.
- Choose **All** to store all fields in all parts of the geometry where they are defined.
- Choose **None** to not store any field in the output.
- Choose **Selection** to choose one or more selections that you add to the corresponding row in the **Selection** column. Then, under **Selections**, click the **Add** button (+) to open an **Add** dialog that contains all of the available selections. Select the selections that you want to add and then click **OK**. You can also delete selections from the list using the **Delete** button ( ) and move them using the **Move Up** (↑) and **Move Down** (↓) buttons.

See also the Field node, where you can also control what to store in the output, if the corresponding Dependent Variables uses user-defined settings.

If you use **For selection** and store the solution only for some parts of the geometry, it is not possible to continue with another study step.

MESH SELECTION

Specify — for each geometry — which mesh to use for the study step. For each geometry listed in the **Component** column, select a mesh from the list of meshes in the **Mesh** column. Each list of meshes contains the meshes defined for the geometry that you find on the same row.

ADAPTATION AND ERROR ESTIMATES

These are settings for mesh adaptation and error estimates, available for stationary, eigenfrequency, eigenvalue, and frequency-domain study steps. Mesh adaptation (with other settings and operation) is also available for time-dependent study steps; see Time Dependent and Adaptive Mesh Refinement (Time-Dependent Adaptation). Depending on the type of adaptation, meshing sequences for the adaptive mesh refinements, using **Adapt** or **Size Expression** nodes, and corresponding solutions are created for inspection and possible modification. Error estimates are available as variables for postprocessing (for example, `freq.errtot` for the total error estimate in a Frequency Domain study). The adaptive mesh refinement solutions become available in a separate **Solution** dataset (**Study 1/ Adaptive Mesh Refinement Solutions 1**, for example). When using that dataset for postprocessing, you can choose to use any of the available adaptive mesh refinement solutions from a **Parameter selection (Refinement level)** list. Additional settings are available in the Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation) and Error Estimation subnodes under the solver node in the solver configurations.

From the **Adaptation and error estimates** list, select **Error estimates** if you want to use error estimation or select **Adaptation and error estimates** if you want to use adaptive mesh refinement. In the latter case, error estimates that are used in the adaptation algorithm are also available for postprocessing. Choose **None** for no adaptation or error estimation. The internal name for the refinement level parameter is `adaptlevel`. It is added by the adaptation solver method to separate the solutions for the different meshes. In the case that there is a user-defined parameter with that name in the model, a unique name for the refinement level parameter is made by adding a digit to `adaptlevel`. You can use it to access the solutions from different mesh refinement levels using the `withsol()` operator with; for example, using the following syntax: `withsol('sol1',`*`expr`*`,setval(adaptlevel,2))` to evaluate an expression *`expr`* with the solution in `sol1` for the mesh adaptation level 2.

- The Adaptive Solver Algorithms and Error Estimation
- Error Estimation — Theory and Variables
- Adapt — the **Adapt** node in a meshing sequence also provides mesh adaptation. It includes a selection of geometric entities, which can be useful if you want to limit the mesh adaptation to certain geometric entities (some but not all domains, for example).

The software performs adaptive mesh refinement in one geometry only. Use the **Adaptation in geometry** list to specify that geometry. If you do not want to perform the mesh adaptation in the entire geometry, use the settings in the **Geometric Entity Selection for Adaptation** section below.

Use the **Error estimate** list to control how the error estimate is computed:

- Select **L2 norm of error squared** to use the squared L2 norm of the error. This is the only option for Eigenvalue studies. In the **Error Estimation** node under the **Stationary Solver** node, use the **Scaling factor** field to enter a space-separated list of scaling factors, one for each field variable (default: 1). The error estimate for each field variable is divided by this factor. Also, the L_2 norm error estimate is based on a stability estimate for the PDE. Also in the **Error Estimation** node, use the **Stability estimate derivative order** field to specify its order (default: 2). For certain problems, which are symmetric and where strong error estimates hold, this method is equivalent to a functional error estimation with the functional being the L2 norm squared of the solution. This method can be used also for problems where these assumptions do not hold, but then the adaptation will not be optimal. See the following for some more in-depth information about these settings.

  The **L2 norm of error squared** method estimates the error for a mesh element as a summation of contributions for the different equations solved for. It sums over

$$Ah^{2q}\frac{\rho^2}{s^2}$$

where A is the element area (volume, length), h is the element size, q is the **Stability estimate derivative order**, s is the **Scaling factor**, and ρ is an estimate of the PDE residual. The asymptotic behavior for ρ is that it is proportional to h^p, where p is the **Residual order** (see below). Even if it is possible to estimate the actual value for ρ very generally, assisting the algorithm with this order is important — for example, for the **Element selection** method **Rough global minimum** (in the **Adaptive Mesh Refinement** subnode; see Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation)), which essentially solves an optimization problem for where to refine so that the total error is reduced as much as possible (constrained by how many elements that can be added). All of the values for the **Stability estimate derivative order**, **Scaling factor**, and **Residual order** (q, s, and p, respectively, in the **Error Estimation** subnode; see Error Estimation) can all be given as vectors for the different equations. For the **Stability estimate derivative order**, the default is 2, and it is related to the stability estimate that holds for the problem at hand. If it is not of a Poisson type, then it might need adjustment. For the **Scaling factor**, the default is 1. It is mainly important to relatively weigh in the different parts of the equations solved for, which means that you need to give a space-separated array of numbers in general. Notice that when solving a multiphysics problem, the summation over different equations will not have the same unit since the different ρ will have different units. So, a first effort with scaling would be to take this into account. In fact, not even a single-physics case like fluid flow will make this summation unit consistent because the residual for momentum and mass conservation will be added up with the default scaling factors of 1. For the **Residual order**, the default is one order lower than the shape functions used for the equation. Change this only for nonstandard PDEs. Roughly speaking, the expected order is the basis order minus the highest spatial derivative order in the weak formulation. For a second-order PDE formulation with an integration by parts (lowering all second-order derivatives to first order) this will be of order one.

- Select **Functional** and specify a **Functional type**. Available functional types are **Predefined** and **Manual**. This option adapts the mesh toward improved accuracy in the expression for the functional (for example, some energy, drag, or lift). Select **Manual** to specify a globally available scalar-valued expression in the **Functional** field (for example, the name of a global variable probe). If you select **Predefined**, you can choose from a predefined list of functional from the **Solution functional** list:
  - **Integral** (the default)
  - **L2 norm**
  - **L1 norm**
  - **Approximate max norm**

  For a **Stationary** study step `stat`, a global variable is defined for the functional with the name `stat.gfunc` (and similarly for a frequency-domain study step). The functional can be evaluated under **Results** > **Derived Values** by adding a **Global Evaluation** node and, in the **Expressions** section in its Settings window, selecting **Global Definitions** > **Error estimation** > **stat.gfunc - Functional - Stationary**.

  The functional must be differentiable (or complex-valued analytic). Also, the expressions in the formulation must be differentiable. If this does not hold, the adjoint solution and its error estimate risk not being accurate, and the adaptation will then not be optimal for the functional used. The **Functional** option estimates the error for a mesh element as a summation of contributions. It sums over $A\omega_K\rho$, where ω_K is computed from the adjoint (or dual) solution. ω_K can be computed with different methods (**PPR for Lagrange** or **Interpolation error**). Equation 20-5 is about how ω_K is computed for **PPR for Lagrange**. Notice that this method is not using scaling factors or the stability estimate derivative order because they are not part of the formula (they are built into ω_K). But ρ is part of the formula and the residual order can therefore be important (for example, for the **Rough global**

minimum method; see Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation)). For the **Approximate max norm**, high order p-norm. The reason for this is that it is possible to differentiate this functional.

- Select **Error indicator** to specify an error indicator using an error expression, which you add to the **Error expression** table below using the **Add** (+) button. The error expression can be any expression, including field variables and their derivatives, defined in the domain. This method will adapt the mesh where the error expression becomes large; the adaptation is typically not optimal. Select the **Active** checkbox for the error expressions that should be part of the error indicator. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons as needed to rearrange and remove error expressions. With this setting, there are no additional settings in the **Error Estimation** subnode, which becomes unavailable.

From the **Add Error estimation variables** list (not available if you chose **Error indicator** from the **Error estimate** list above), choose which variables to store, if any:

- Select **Error estimates and residuals** to store all variables (the default).
- Select **Error estimates** to store only the variables for error estimation.
- Select **None** to not store any variables, which may lead to performance improvements.

The **Save solution on every adapted mesh** checkbox is selected per default. Clear this checkbox if you do not want to save solution on every adapted mesh. In that case, the last two solutions are saved (the finest one and the second finest) regardless of the total number of solutions.

Under **Mesh adaptation**, the following settings are available.

Use the **Adaptation method** list to control how to adaptively refine mesh elements. Select one of these methods:

- **General modification**, to use the current mesh as a starting point and modify it by refinements, coarsening, topology modification, and point smoothing. Use the **Allow coarsening** checkbox to control if mesh coarsening is used. If the mesh contains anisotropic elements (for example, a boundary layer mesh), it is best to disable mesh coarsening to preserve the anisotropic structure. If you have selected to allow coarsening, specify the **Maximum coarsening factor** (a value of 5 by default) to scale the refined mesh size in the regions where refinement is not needed.
- **Rebuild mesh**, to set up a size expression describing the error and rebuild the meshing sequence using the size expression as input. Note that structured meshes, such as mapped and swept meshes, in general are not appropriately refined. This method is not supported on imported meshes. The size of the refined mesh is the minimum of the size of the original mesh (previous refined mesh) and the size defined by the refinement. Specify the **Maximum coarsening factor** (a value of 3 by default) to scale the refined mesh size in the regions where refinement is not needed.
- **Regular refinement**, to make the solver refine elements in a regular pattern by bisecting all edges of an element that needs refinement.
- **Longest edge refinement**, to make the solver refine only the longest edge of an element by recursively bisecting the longest edge of edge elements that need refinement. This method is less suitable for models with nonsimplex elements. This is the default method.

With the settings in the **Goal-oriented termination** list you or the physics interfaces can add a number of global goal-oriented quantities so that the mesh adaptation will terminate when these are stable to a requested accuracy instead of after a fixed number of adaptation iterations. Choose **Off** (the default), **Auto**, or **Manual** to control. You, when the list is set to **Manual**, or the physics, when the list is set to **Auto**, can add a number of global goal-oriented quantities, and the mesh adaptation will terminate when these are stable to a requested accuracy. These goal-oriented quantities could, for example, for an RF simulation be the S-parameters or another quantity of interest. The goal-oriented termination can be used with any of the available error estimation methods. When the **Goal-oriented termination** list is set to **Manual**, you can add goal-oriented terminal expressions in the table at the bottom of this section. Click the **Add** button (+) to add an expression (default: 1) that you can edit in the

Goal-oriented termination expression column. If desired, adjust the tolerance (default: 0.01) in the **Tolerance** column, and the type of tolerance in the **Tolerance type** column: **Relative** (the default) or **Absolute**. Use the **Active** buttons to manage which goal-oriented termination expressions to include. The mesh adaptation will run until the relative changes for all expressions (applied individually for all expressions) go below their respective thresholds, unless the maximum number of adaptations limit is met, in which case the algorithm terminates with a warning.

Use the **Maximum number of adaptations** field to specify the maximum number of adaptive mesh refinement iterations. The default value is 5 in 1D, 2 in 2D, and 1 in 3D. With the **Goal-oriented termination** set to **Auto**, the default value is set to 20 in 1D, 15 in 2D, and 10 in 3D.

With the **Goal-oriented termination** set to **Auto** or **Manual**, you can control the display of convergence from the adaptation when the **Output goal-oriented termination increments** checkbox is selected. It is possible to choose the plot window to display the convergence as well as the table to be used by the plot from the **Plot window** — select **New window** (the default) or **Graphics** — and **Output table** lists, respectively. If you choose **New** from the **Output table** list, two new tables are created, one for the adaptation convergence plot and one for providing verbose information.

Also choose the level of detail for the log from the **Goal-oriented termination log** list: **Minimal**, **Normal** (the default), or **Detailed**. Choose **Detailed** if you want to include the evaluations for all the parameters, frequencies, or eigenvalues in the log.

For additional settings, see Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation).

Variables for Adaptation and Error Estimation

The following table includes variables that are available when adaptation and error estimates have been enabled. The variable names are for a case with a Stationary study step `stat` solving for a dependent variable `u`.

TABLE 20-4: VARIABLES FOR ADAPTATION AND ERROR ESTIMATES.

VARIABLE NAME	DESCRIPTION
stat.errEst	The total error summed over all equations and elements. A global variable.
stat.errEst.u	The total error summed over all elements for the equation or variable u. A global variable.
comp1.err.u	The error estimate for equation or variable u in component comp1. It is constant within each mesh element.
stat.errtot	The total error contribution from each element. The summation of errors is over all equations solved for. It is constant within each mesh element.

GEOMETRIC ENTITY SELECTION FOR ADAPTATION

From the **Geometric entity level** list, choose the geometric entity on which you want to do adaptive mesh refinement: **Entire geometry** (the default), **Domain**, **Boundary**, or **Edge** (3D only). For example, selecting **Boundary** can be useful if the model includes a physics interface defined on boundaries (surfaces) and you want to base the adaptation on that physics interface. For all levels except **Entire geometry**, select the geometric entities to include using the **Selection** list and selection tools below.

STUDY EXTENSIONS

These are extensions to the study's main solver, such as adaptive mesh refinement and automatic remeshing. The options vary depending on the study type.

Auxiliary Sweep

Select the **Auxiliary sweep** checkbox to enable an auxiliary parameter sweep, which corresponds to a Parametric solver attribute node. For each set of parameter values, the chosen **Sweep type** is solved for. This functionality is available for Stationary, Time Dependent, and Frequency Domain studies.

Select a **Sweep type** to specify the type of sweep to perform:

- **Specified combinations** (the default) solves for a number of given combinations of values as given for each parameter in the list. The parameter lists are combined in the order given; that is, the first combination contains the first value in each list, the second combination contains all second values, and so on.
- **All combinations** solves for all combinations of values; that is, all values for each parameter are combined with all values for the other parameters. Using all combinations can lead to a very large number of solutions (equal to the product of the lengths of the parameter lists).

In the table, specify the **Parameter name**, **Parameter value list**, and (optional) **Parameter unit** for the parametric solver. Click the **Add** button (+) to add a row to the table. When you click in the **Parameter value list** column to define the parameter values, click the **Range** button ( ) to define a range of parameter values. The parameter unit overrides the unit of the global parameter. If no parameter unit is given, parameter values without explicit dimensions are considered dimensionless.

If you choose **Specified combinations**, the lists of parameter values must have equal lengths.

An alternative to specifying parameter names and values directly in the table is to specify them in a text file. Use the **Load from File** button ( ) to browse to such a text file. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window. The read names and values are appended to the current table. The format of the text file must be such that the parameter names appear in the first column and the values for each parameter appear row-wise with a space separating the name and values and a space separating the values.

Click the **Save to File** button ( ) to save the contents of the table to a text file (or to a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ *for* Excel®).

Loading and saving the parameter table data using Excel include the units in the **Parameter unit** column. The unit column is ignored when saving and loading parameter data to *.txt, *.csv, and *.dat files.

For a Stationary or Frequency Domain study, select an option from the **Run continuation for** list: **No parameter** or one of the parameters given in the list.

- Physics and Variables Selection
- Individual study and study steps are listed in Table 20-2 and Table 20-3.

Continuation is only performed on one parameter, and the other parameters must be kept constant. If one of the secondary parameters varies, then it is considered as a new start for the continuation parameter.

Reuse Solution from Previous Step List

This option is useful for parameters not handled with continuation. Select an option from the **Reuse solution from previous step** list.

- **No** (the default for most studies) to reset the solution to the initial values before each step or continuation sweep. The initial values will not be recalculated by the parametric solver for subsequent parameter values. Parameter

dependence of the initial values can be accomplished by using parametric sweep. Set the **Reuse solution from previous step** to **Yes** to have continuation if the secondary parameters are also varying.

- **Yes** to always use the converged solution from the previous step, or the last solution from the previous continuation sweep (that is, never reset the solution).
- **Automatic** (the default for Mean Energies and Reduced Electric Field studies) to normally use the converged solution from the previous step or sweep. However, when multiple parameters are used, the solution from the first step of each parameter list is always used for the first step of the next list.

The difference between the three options is shown in Figure 20-2 for a 3-by-4 two-parameter sweep using the different choices for **Reuse solution from previous step** without continuation:

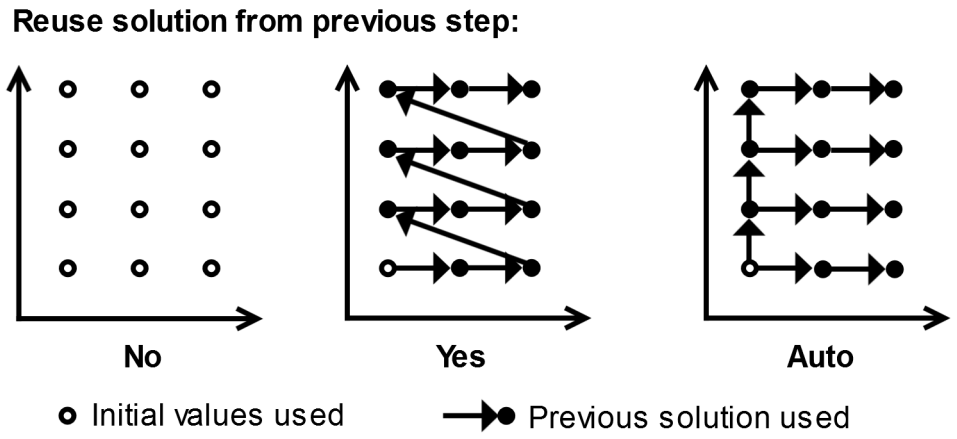


Figure 20-2: The difference between the three options for a two-parameter sweep without continuation.

When continuation is enabled by setting **Run continuation for** to one of the parameters, the converged solutions are always reused for the steps along the continuation sweep in this parameter. The setting for **Reuse solution from previous step** then determines how the solutions are reused between multiple continuation sweeps, if there are additional parameters to sweep over, as shown in Figure 20-3.

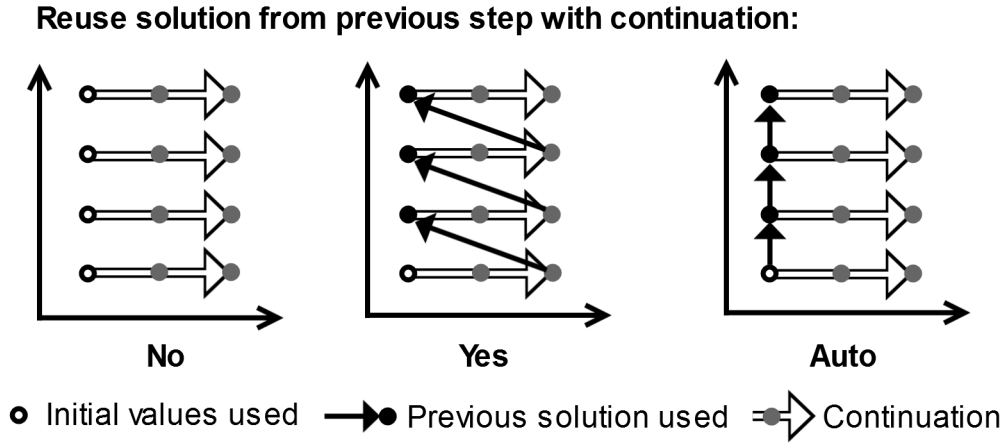

Figure 20-3: The difference between the three options for a two-parameter sweep with continuation.

For the Frequency Domain study, the auxiliary sweep is merged with the frequency sweep into a multiparameter sweep with the frequency as the parameter at the innermost level.

See About the Parametric Solver for more information.

Using a Solution from Previous Study Steps

It is sometimes useful to run one simulation for one aspect of a model and then use the output of the first simulation as input into a second simulation, covering a different aspect. You can perform such a sequential study using multiple study steps in a single study or using multiple studies in the same model:

- Use two or more study steps in a sequence in the same study if you, for example, want to use a stationary or eigenvalue solution as the initial value for a time-dependent solution. You then add an **Eigenvalue** or **Stationary** study step node followed by a **Time Dependent** study step node. By default, the COMSOL software determines the values of the dependent variables in the fields for the physics heuristically depending on the model, so normally you do not have to take specific action. To specify the initial values of the dependent variables that you solve for, select **User controlled** from the **Settings** list under **Initial values of variables solved for** in the **Values of Dependent Variables** section. Then use the **Method** list to specify how to compute the initial values. Choose **Solution** and then select the solution to the stationary or eigenvalue problem solved using the previous study step. Doing so can be useful to specify a specific eigensolution to use as the initial value, for example. You can also choose **Initial expression** to use the expressions specified on the **Initial Values** nodes for the physics interface in the model instead. For both methods, also choose the study to use (or use a zero solution) from the **Study** list.

  Another case is when you want to solve for two different physics interfaces, one at the time, but use the solution from the first study as input data for the physics interface in the second study. You then select the physics interface to solve for and the physics interface to disable in the solver under **Physics and Variables Selection** in the **Settings** windows for each study step. Typically, you solve for one physics interface (or set of physics) in the first study step and for the other physics interface in the other study step (you can also use two separate studies). To specify the values of dependent variables that you do not solve for, select **User controlled** from the **Settings** list under **Values of variables not solved for** in the **Values of Dependent Variables** section. Then use the **Method** list to specify how to compute the values of variables not solved for. Choose **Solution** and then select the study step and solution to use.

  When a model modification is required between the simulations, you can use two study steps where you use the setting available when you select the **Modify model configuration for study step** checkbox to control what physics interface the study step solves (see Modifying the Model Configuration); for example, if you want to change a boundary condition or expressions for the initial value. You then create two such nodes as separate analysis cases and use one in the first study step and the other in the second study step.
- An example when it is more practical to work with separate studies is when a study is inherently a multistep study, such as buckling in structural mechanics or modal analysis. Extending such studies with extra study steps normally becomes unnecessarily complex. A third example is when doing optimization, where the problem without optimization often needs to be solved and tested separately from another study with optimization enabled.

See Values of Dependent Variables above for details about the settings for controlling the values of the dependent variables that you solve for or exclude from the solvers. Also see Physics and Variables Selection below for information about controlling which physics interface to solve for.

Physics and Variables Selection

The **Settings** window of all study steps generating equations contains a **Physics and Variables Selection** section. Here you can control which dependent variables to solve for and also disable individual nodes for the study step. Doing so can be useful for:

- Solving physics in a sequence, with only a subset of the dependent variables active in the solvers in each step.
- Solving and comparing different configurations or "analysis cases" for a model (sharing the same geometry and material) by varying boundary conditions, sources, variables, or equation form without the need to enable and disable nodes or change settings in the physics interface.

By default, you can control, for an entire component or by physics interface, which dependent variables to solve for in the study step. Solving can be enabled or disabled for entire components or physics interfaces. To disable individual physics features and other nodes in the Model Builder, or change equation and discretization settings for physics interfaces, select the **Modify model configuration for study step** checkbox (see Modifying the Model Configuration below).

SELECTING PHYSICS INTERFACES TO SOLVE FOR

The **Node** column contains the nodes of entities defining dependent variables and which can be disabled in the solvers. These include the following types:

- Most physics interfaces.
- Moving Mesh and Deformed Geometry settings in each component where these make use of dependent variables.
- Shape Optimization and Topology Optimization settings in each component where these use filter equations.
- Reduced-order models using a stateful interface or declaring output dependent variables.

The **Node** column also includes the Component nodes under which the nodes above appear. By selecting or clearing the checkbox in the **Solve for** column for a component, you then select all applicable physics interfaces and similar features under that component, or you clear all of them.

By default, most studies solve for dependent variables for which there is a corresponding equation matching the study type. You can choose to not solve for one or more of the listed entities by clearing the ☑ checkbox in the **Solve for** column. If a physics interface cannot set up an equation matching the study step type, the checkbox will be automatically cleared and disabled unless an equation form has been explicitly selected for the interface.

The dependent variables associated with a physics interface or functionality for which the **Solve for** checkbox is cleared are not solved for but still exist in the model. Their value after solving is controlled by the separate settings for values of variables not solved for (see Values of Dependent Variables).

If you do not want to create default datasets for components where all dependent variables have been disabled in the solvers, select the **Add datasets only for components solved for** checkbox under **Dataset generation policy** on the **Results** page in the **Preferences** window.

Clearing the **Solve for** setting for a physics interface in a study does not mean that the physics interface is disregarded. The solver then does not include the DOFs in its assembled system, but all variables and shape functions in the physics interface are generated. If the values of variables not solved for are taken from the solution of another study step (see Values of Dependent Variables), then variables are generated for the equation form of that study step. Otherwise, they are generated for the physics interface's default equation form.

If the intention is to disregard the physics interface completely, removing both shape functions and variables, then disable it, either in the study step or in the Model Builder. In the study step, you must first select the **Modify model configuration for study step** checkbox.

The **Equation form** column shows the equation form that will be used when assembling equations. By default, it is decided automatically and shows **Automatic (Stationary)** for a **Stationary** study step, for example. You can change the equation form by first selecting the **Modify model configuration for study step** checkbox (see Modifying the Model Configuration below).

SELECTING MULTIPHYSICS COUPLINGS TO SOLVE FOR

In the same way, you can choose to not solve for one or more of the multiphysics couplings by clearing the checkbox in the **Solve for** column (by default, a study step solves for all coupling features that recognize the study type). If you clear the **Solve for** checkbox, any equations and dependent variables that the multiphysics coupling adds are not included, but the multiphysics coupling still affects the definition of variables.

Clearing the **Solve for** setting will for some multiphysics couplings remove the coupling effect from the model, for others it will not. This depends on whether the coupling is implemented as a separate equation added to the system — in which case it will be removed — or as a contribution to variables declared by the coupled physics interfaces — in which case it will be unaffected.

To ensure that the effect of a multiphysics coupling is completely disregarded, select the **Modify model configuration for study step** checkbox and disable it in the study step, or disable it manually in the Model Builder.

SOLVE-FOR STATE ICONS

The following icons represent the state of the corresponding component, physics interface, multiphysics coupling, or other entity:

- means that the corresponding entity is active and solved for.
- means that the corresponding entity is active but not solved for, either because of the user settings or because it is not applicable for this study step. In this case, the variables are still generated.
- means that the corresponding entity's state has been changed in some study step (see Change of States and Override and Contribution Indicators below).
- means that the corresponding entity's equation form has been changed in this study step.
- means that the corresponding entity's equation form is locked (that is, that the equation form has been set in the corresponding node in the Model Builder tree and cannot be changed in a study step).

If you have disabled an entity in the Model Builder tree it will not appear in the table.

REDUCED-ORDER MODELS AND RECONSTRUCTION

For a reduced-order model using a stateful interface, the **Solve for** setting controls whether the states declared by the reduced-order model are solved for. For a reduced-order model declaring output dependent variables, the **Solve for** setting controls whether the values of the output variables are stored in the corresponding dependent variables (for postprocessing) every time a solution vector is written to the solution.

If a physics interface is not solved for in the study step while at the same time there is at least one reduced-order model under **Global Definitions** > **Reduced-Order Modeling** capable of reconstructing the physics interface's dependent variables, then there will be an additional table allowing you to choose a reconstructing reduced-order model. The **Reconstruction** column lists all currently not solved for physics interfaces for which there is at least one reconstructing reduced-order model. The **Reduced-order model** column offers a choice for each physics interface between the available reconstructing reduced-order models, or **None**, which is the default.

By default, a selected reduced-order model applies to all fields and states in the physics interface. If desired, it is possible to use different reconstruction for different fields and states by choosing another **Reduced Model** node in the **Field** and **State** nodes.

- The Add Physics Window
- The Add Multiphysics Window
- The Add Study Window
- Model Reduction

MODIFYING THE MODEL CONFIGURATION

If the **Modify model configuration for study step** checkbox is selected, you can modify the model configuration in a number of ways in addition to specifying what to solve for. The **Physics and Variables Selection** section then contains a tree that is a copy of the main Model Builder tree but filtered to only show nodes that allow some form of modification. Depending on the type of node selected in the tree, you can:

- Choose to solve for or not solve for dependent variables associated with a component or physics interface node in the same way as when the **Modify model configuration for study step** checkbox is not selected.
- Disable or enable the node with the same effect as disabling or enabling the node in the Model Builder, available for most nodes visible in the tree (for example, physics interfaces and features and **Variables** nodes).
- Disable control over a frame implemented by a node, available for **Moving Mesh**, **Deformed Geometry**, **Shape Optimization**, and some physics interfaces.
- Change the discretization of the dependent variables in a physics interface.
- Change the equation form used by a physics interface.
- Change the frequency seen by a physics interface using a frequency-domain equation form.

Figure 20-4 contains an example of what the tree view may look like. Select one or more nodes in the tree and right-click or use the buttons at the bottom of the section (below the tree) to change their status. Click the **Go to Source** button ( ) to move to the corresponding original node in the model tree. Click the **Collapse All** ( ) and **Expand All** ( ) buttons if desired to completely collapse or expand the physics tree. Depending on the selected nodes, additional actions appear in the toolbar and context menu.

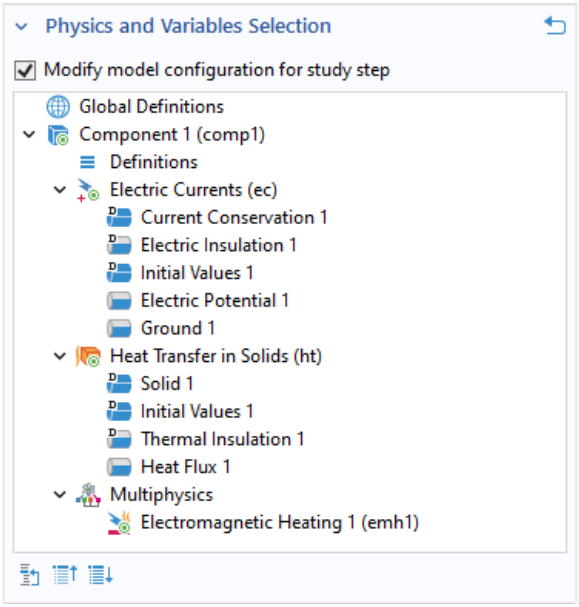

Figure 20-4: An example of a Physics and Variables Selection section tree when the Modify model configuration for study step checkbox is selected.

Disabling and Enabling Nodes

Click **Disable** (or right-click to select it from the context menu) to disable enabled nodes that are possible to disable. The contributions, conditions, or variables in a node that you disable are not included in the study when solving. A disabled node is unavailable in the tree. You can also right-click any applicable node in the model tree to select **Disable in all studies**. That node is then disabled for all studies.

Click **Enable** (or right-click to select it from the context menu) to enable disabled nodes. The contributions, conditions, or variables in a node that you enable are included in the study when solving.

When you right-click, the following context menu options mean that a node cannot be enabled or disabled:

- **Cannot be Disabled** — for default nodes in the physics interfaces.
- **Disabled in Model Builder** — for nodes that you have disabled in the Model Builder.

When solving, equations and variables are generated as if the disabled nodes in the tree were disabled in the Model Builder. This means that the nodes' selections override each other as if the nodes were disabled in the Model Builder.

Options for Discretization and Equation Form for the Main Physics Interface Nodes

The following options are available for the main physics interface nodes under the **Physics and Variables Selection** tree for modifying the discretization and the equation form:

- From the **Discretization** list, choose a discretization for the physics in the physics interface. The default (and often the only) choice is **Physics settings**, which means that the study uses the discretization from the main physics interface node's settings. Changing it affects the discretization order used by this study. To add another discretization, use a separate **Discretization** node in the physics interface.
- From the **Equation form** list, choose an applicable equation form for the study step and physics interface: **Automatic** (the default, appearing with the default equation form in parentheses such as **Automatic (Stationary)**) or any other applicable equation form. If you change the equation form, the information is updated in the table

of physics interface when you clear the **Modify model configuration for study step** checkbox. In addition to physics interfaces, the **Equation form** list is available for reduced-order models with a stateful interface.

Options and States for Nodes With Degrees of Freedom

Nodes that define dependent variables, as well as component nodes, allow, in addition to complete disabling, a choice between solving and not solving for their degrees of freedom. Right-click a node and select one of the following from the context menu, or click the button beneath the tree. Selecting these options generally affects all its children in the tree. Select:

- **Solve For** (the default setting) to fully enable the node and solve for dependent variables defined by the node and its active children. This is similar to the checkboxes in the **Solve for** columns when not using **Modify model configuration for study step**. A physics interface in this state shows a small green dot in its lower-right corner to indicate that the study step solves for the degrees of freedom (dependent variables) in the physics interface and features. This is an example of a Laminar Flow interface with the green dot: .
- **Disable in Solvers** to not solve for the physics interface but provide degrees of freedom (dependent variables) and other physics node variables using the settings for values of variables not solved for (see Values of Dependent Variables). This state is similar to when a corresponding **Solve for** column checkbox is cleared when not using **Modify model configuration for study step**. A physics node in this state shows a small orange dot in its lower-right corner to indicate that the node and its active children provide degrees of freedom but these are not solved for in the study step. For example, a Laminar Flow interface with an icon that looks like this is both showing that it provides degrees of freedom not solved for (orange dot in the lower-right corner) and has a change of state indicated by the asterisk.
- **Disable in Model** to fully disable a node and its children in the model. The node and its children do not contribute to the study, and no variables, including the degrees of freedom (dependent variables), are included. A disabled node and its children are grayed out, and the parent node shows a small red dot in its lower-right corner to indicate that the study step provides no degrees of freedom for it. For example, a Transport of Diluted Species interface with an icon is disabled (grayed out), provides no degrees of freedom (red dot in the lower-right corner), and has a change of state indicated by the asterisk.

For **Component** nodes, **Disable in Model** disables the component in the model while solving, whereas **Disable in Solvers** sets all physics interfaces in the component to disabled in the solver, in the same way as the **Solve for** checkbox works in the default view.

In addition, this type of nodes can be in the following states:

- If the node is disabled in the Model Builder, it is grayed out. If you right-click it, the context menu contains **Disabled in Model Builder**. In this case, none of the options above are available.
- If the node defines degrees of freedom but not equations applicable for the current study step type, then the **Solve For** option is grayed out and unavailable. **Disable in Solvers** is then the default option and therefore does not display any asterisk as indication of a changed state.

Change of States and Override and Contribution Indicators

An asterisk displays in the upper-right corner of nodes in the **Physics and Variables Selection** tree for which the state has been changed in some study step's settings, including being disabled in either solvers or model. This mirrors the node in the main Model Builder tree. In general, any variable or physics node in the Model Builder that is disabled in any study step gets an asterisk in the upper-right corner. For nodes defining degrees of freedom, this applies also when you have not selected the **Modify model configuration for study step** checkbox and the checkbox in a **Solve for** column in the **Physics and Variables Selection** section has been cleared.

The dynamic visual icon indicators for overridden and contributing nodes also appear in the tree in the **Settings** window for the study steps when you have selected the **Modify model configuration for study step** checkbox in a study step's **Settings** window. When you select a physics node in the tree, the override and contribution icon indicators appear in the same way as in the Model Builder when you select a physics node, but if you disable any physics node

in the study step's tree, the icon indicators then show how the physics node overrides and contributes to the model when one or more physics nodes are disabled in the study step.

Geometry Shape Functions Settings for Component Nodes

When you select a **Component** node, a **Geometry shape function** list becomes available under the tree. From that list, you can choose **Component settings** (the default), to use the settings from the corresponding **Component** node in the model tree, or choose any other available geometry shape function from the list, if desired.

- Physics Exclusive and Contributing Node Types
- Physics Node Status

Frame Control for Mesh Deformation

Multiple physics interfaces or other entities controlling the same frame are not allowed on the same selection. It is, however, possible to use multiple frame-controlling entities with overlapping selection, but you then have to explicitly disable frame control on all but one of these. You can choose different entities to control the frame in different study steps. In the **Modify model configuration for study step** tree a frame-controlling node has a label that is extended with the text **Controls spatial frame** or **Controls material frame**. Toggle the frame control on those nodes by selecting them in the tree and toggling the **Control Frame Deformation** button ( ) in the toolbar or by right-clicking the node and selecting **Control Frame Deformation** from the context menu.

If you have the AC/DC Module, see *Electric Shielding*: Application Library path **ACDC_Module/Introductory_Electric_Currents/electric_shielding**.

Error Estimation — Theory and Variables

Error estimation is available in the **Adaptation and Error Estimation** section of the Stationary, Eigenfrequency, and Frequency Domain study step types. For information about error estimation with time-dependent adaptation, see Error Indicator for the Time-Dependent Solver.

THEORY BACKGROUND

A common approach to adaptive finite elements is to use the *dual weighted residual method* (DWR). The method is based on a posteriori error estimates for a (goal) functional together with some adaptive approach for the mesh in space and time. The framework was originally developed in Ref. 1 and Ref. 2. For stationary problems or problems cast in a Galerkin formulation, the starting point is the following exact representation of the discretization error in a linear functional J:

$$J(u) - J(u_h) = \rho(u_h, z - z_h), \tag{20-1}$$

where u is the exact primal solution, u_h is the finite-element approximation of u, ρ is the weak residual of the problem, z is the exact dual solution corresponding to J, and z_h is the finite-element approximation of z. The weak residual ρ is defined by

$$\rho(v, \hat{v}) = F(\hat{v}) - A(v, \hat{v}),$$

where v and $\hat{v}$ are arbitrary elements in a function space V, F is a linear functional, and A is a bilinear functional. The exact primal solution u in V is defined by

$$A(u, \hat{u}) = F(\hat{u}), \forall \hat{u} \in V,$$

and the approximate primal solution u_h in the finite-element space V_h is thus defined by

$$A(u_h, \hat{u}_h) = F(\hat{u}_h), \forall \hat{u}_h \in V_h .$$

The exact dual solution z in V is defined by

$$A(\hat{z}, z) = J(\hat{z}), \forall \hat{z} \in V , \tag{20-2}$$

and the approximate dual solution z_h in V_h is thus defined by

$$A(\hat{z}_h, z_h) = J(\hat{z}_h), \forall \hat{z}_h \in V_h .$$

For simplicity, nonlinearity has been omitted. For nonlinear functionals and problems, the dominating part of the error can be estimated by approximating the above (dual) weighted residual. In those cases, the dual is computed for problems obtained by linearizing around the primal solution. The error representation is often taken to a local form by using integration by parts. This is straightforward when the equation form is strong but is not applicable for most physics in COMSOL Multiphysics, which is implemented using the weak form. Instead, the error estimation algorithm uses a method that can estimate the residual for the weak form directly. It works through assembling the algebraic residual for the current solution mapped to a higher-order finite-element representation. The method introduces an extension mapping $\bar{\pi}_h$ from the current finite-element space to a higher-order finite-element space. Instead of the strong form variant, it uses

$$\rho_K = \left\| \rho(\bar{\pi}_h u_h, \cdot) \right\|_K$$
$$\omega_K = \left\| z - \pi_h z \right\|_K$$

where the residual is computed by standard finite element method assembling (using numerical quadrature) for the higher-order finite-element space. This residual is then used to compute a normalized elementwise norm for each equation (here defined by the fields and their components). This technique is the same as when using mesh adaptation (see The Adaptive Solver Algorithms and Error Estimation). Also for the error estimation, the method separates the error contribution from different equations:

$$\left| J(u) - J(u_h) \right| \le \sum_K \sum_j \rho_{K,j} \omega_{K,j} ,$$

where j is an equation index and the mesh element K, and where the equations are defined from the field components.

$$\rho_{K,j} = \left\| \rho^{<j>}(\bar{\pi}_h u_h, \cdot) \right\|_K \approx |K|^{1/2} \bar{\rho}_{K,j} , \tag{20-3}$$

where $\bar{\rho}_{K,j}$ with the bar is the estimated maximum norm of the residual for the equation j and mesh element K, and $|K|$ is the mesh element volume. Furthermore,

$$\omega_{K,j} = \left\| z^{<j>} - \pi_h z^{<j>} \right\|_K \approx |K|^{1/2} \bar{\xi}_{K,j} \tag{20-4}$$

where $\bar{\xi}_{K,j}$ is the estimated maximum norm of the error for the dual solution to equation j and mesh element K. Since the exact dual solution is often not known, the weight function $z \approx \pi_h z$ must be approximated by some method. For Lagrange basis functions, the default method uses the polynomial-preserving recovery (PPR) technique (built in through the `ppr` and `pprint` operators) to estimate the dual solution and thereby the error

$$\bar{\xi}_{K,j} = \max_l \left| (\text{pprint}(z_h^{<j>}) - z_h^{<j>})(\mathbf{x}_l) \right| , \tag{20-5}$$

where $\mathbf{x}_l$ are a number of coordinates in the mesh element K. These coordinates are a union of Lagrange points and Gauss points. For both Lagrange and non-Lagrange basis functions, a different method that uses an interpolation-error estimate is supported. For basis functions of order p, this error estimate is

$$\bar{\xi}_{K,j} = \frac{h^q}{q!}\max_k \left\| (D^q z^{<j>})(\mathbf{x}_k) \right\|_2$$

where h is the mesh element diameter, q (which is related to p) is the order of the interpolation error, $D^q z^{<j>}$ is a tensor of partial derivatives of total order q, and k denotes a vertex of mesh element K. For many element types, including Lagrange, the basis functions span a complete polynomial space of order p, and thus $q = p+1$. For vector elements of type 1, $q = p$. The norm of the tensor of partial derivatives of order q is estimated as follows: For a given mesh vertex, a patch of surrounding mesh elements is formed, and a polynomial of degree q (in global coordinates, with the origin at the vertex) is fitted to the values of $z_h^{<j>}$ in a set of sampling points in these elements. In 2D, the polynomial in question is

$$\sum_{i,j} a_{i,j}(x - x_k)^i (y - y_k)^j$$

and the corresponding estimate of the norm of the tensor of partial derivatives of order q is

$$\left\| (D^q z^{<j>})(\mathbf{x}_k) \right\|_2 = \sqrt{q! \sum_{i+j=q} a_{i,j}^2 i!j!},$$

where the sum is over the coefficients of highest degree (degree q). Finally, in the case of a geometric entity with lower dimension than the space (that is, a boundary or an edge), the PPR and interpolation-error methods are not supported. In this case, a less accurate method based on the gradient of the dual solution is used:

$$\bar{\xi}_{K,j} = h \max_l \left\| (\nabla z_h^{<j>})(\mathbf{x}_l) \right\|_1. \tag{20-6}$$

ACCURACY

Ideally, since the error representation (Equation 20-1) is exact, the error estimate above has the potential of being very accurate. The method is not fail-safe, however. For example, the underlying PDE problem must be well-posed and its solution sufficiently regular. Sufficiently regular means that not only is the solution bounded in some norm, but also a number of derivatives need to be bounded in some norm. Well-posedness for the dual problem and sufficient regularity for the dual solution are also required.

Furthermore, the following guidelines should be kept in mind when using the estimates:

- The error estimate described here is the *truncation error* (also sometimes called the *Galerkin error* for the finite element method). It does not take into account:
  - The *quadrature error* made by using numerical methods to approximate the finite element integrals.
  - The *geometrical approximation error* made by representing the actual geometry by a polynomial representation (which is a sort of integration error for elements adjacent to or on a curved boundary).
  - The *algebraic error* obtained by terminating the solvers prematurely (or by using a sloppy tolerance).

  In most situations, however, the Galerkin error is the dominating error in a finite element calculation.
- Due to the independent maximum norms used for the dual error and the residual within each mesh element, the error estimate is normally an upper bound. When the error is very localized (to only a few elements) — for example, when a field value in a point is used as the functional — the discrepancy between the actual error and the estimated error tends to be larger than for cases where the error is less localized. For cases when the `ppr` method can be used, a rule-of-thumb is that the error estimate is accurate within a factor five when the error is not so localized and one order of magnitude larger when the error is very localized. When the gradient-based dual error estimation is used, the discrepancy can be much larger. This difference in accuracy occurs because this estimate does not have the correct asymptotic behavior (the correct convergence rate when the mesh size is diminished). A warning is given when the gradient method is used for a dependent variable.
- The estimates assume that the true dual solution can be approximated reasonably well with the current discretization. If this assumption is not fulfilled, the dual solution error estimates (Equation 20-5 and Equation 20-6) can underestimate the true error.

SHAPES

The residual and dual weights (Equation 20-3 and Equation 20-4) for a component `comp1.u` are stored in dependent variables called `comp1.res.u` and `comp1.dualw.u`, respectively. The error variable is defined as the product of these and is accessible as `comp1.err.u`. These variables are accessible for plotting in plot nodes using the **Expression** as, for example, for a Solid Mechanics interface) **Component 1** > **Solid Mechanics** > **Error estimation** > **err.u - Error estimate u**.

ERROR VARIABLES AND ERROR EVALUATION

You can access the residual and dual weights directly through the dependent variable names. For a Stationary study step called `stat` (and similarly for a Frequency Domain study step), the total global error summed over all mesh elements is `stat.errEst`, and the error contribution from a variable `comp1.q` is `comp1.stat.errEst.q`. The error contribution from `comp1.q` can be evaluated under **Results** > **Derived Values** by adding a **Global Evaluation** node, and then under **Expression** selecting **Global Definitions** > **Error estimation** > **stat.errEst - Error estimate global - Stationary**. The error contribution from `comp1.q` can be evaluated by selecting **Component 1** > **Global Definitions** > **Error estimation** > **stat.errEst.q - Error estimate q**. For fields using vector elements, the error estimates are done fieldwise and have a suffix `_field` in the variable name for the error (for example, `err.E_field`). For other cases, the estimates are done componentwise.

Stationary

The **Stationary** ( ) study and study step are used when field variables do not change over time, such as in stationary problems.

In electromagnetics, it is used to compute static electric or magnetic fields, as well as direct currents. In heat transfer, it is used to compute the temperature field at thermal equilibrium. In solid mechanics, it is used to compute deformations, stresses, and strains at static equilibrium. In fluid flow, it is used to compute the steady flow and pressure fields. In chemical species transport, it is used to compute steady-state chemical composition in steady flows. In chemical reactions, it is used to compute the chemical composition at equilibrium of a reacting system.

It is also possible to compute several solutions, such as a number of load cases or to track the nonlinear response to a slowly varying load.

A stationary study does not depend on time. If you use the time `t` in any physics settings (for a subsequent time-dependent study step, for example), you can replace it for the stationary study with a global parameter or local solver constant `t`, to give it a fixed value.

A **Stationary** study step node corresponds to a Stationary Solver (the default) or a parametric solver.

There is also an option to run a Stationary study with an Auxiliary sweep, with or without a continuation parameter. When a continuation parameter is selected, the continuation algorithm is run, which assumes that the sought solution is continuous in these parameters. If no continuation parameter is given, a plain sweep is performed where a solution is sought for each value of the parameters. In both cases, a **Stationary Solver** node plus a **Parametric** attribute is used. The parametric solver is the algorithm that is run when a **Parametric** attribute node is active under a **Stationary Solver** node. Similarly, when the mesh adaptation solver is the algorithm that is run, an **Adaptive Mesh Refinement** subnode is added under a **Stationary Solver** node.

The **Study Settings**, **Physics and Variables Selection**, **Values of Dependent Variables**, **Mesh Selection**, **Adaptation and Error Estimates**, and **Geometric Entity Selection for Adaptation** sections are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections. Note that the **Study Settings** section is empty if there is no **Include geometric nonlinearity** checkbox or **Parameter list method** list.

RESULTS WHILE SOLVING

See Results While Solving in the Common Study Step Settings section.

STUDY EXTENSIONS

This section contains some optional extensions of the study, such as Auxiliary Sweep (including continuation), automatic remeshing, and load cases.

Automatic Remeshing

Select the **Automatic remeshing** checkbox if the **Auxiliary sweep** checkbox is selected and you want the solver to remesh automatically when the quality of the mesh becomes poor in a Stationary study. Select the geometry to use for the automatic remeshing from the **Remesh in geometry** list. With automatic remeshing active, the solver adds an **Automatic Remeshing** subnode under the **Parametric** node under the **Stationary Solver** node. In that subnode, you specify the mesh quality expression that determines when to remesh.

Load Cases

Select the **Define load cases** checkbox to define load cases as combinations of defined load groups, multiplied with optional weights (load factors), and constraint groups. When this checkbox is selected, and a Parametric attribute node is also used, the load cases are also displayed under the **Load Cases** section for the **Parametric** node.

Load cases are useful for efficiently solving for a number of cases with varying loads (and constraints) in the same model without the need to reassemble the stiffness matrix. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the load cases that you want to solve for. For each load case, click in the column for the load groups and constraint groups that you want to include in the load case. By default, no load groups and constraint groups are included ( ). Load groups and constraint groups that are included appear with a check mark ( ). Optionally, change the default weights for the load groups from 1.0 to another value in the corresponding **Weight** column (which is to the right of the load group that it is acting on). A weight of 1.5, for

example, adds an extra 50% to the magnitude of the loads in the load group; a weight of –1 reverses the direction of the loads.

- Load Group and Constraint Group
- About the Parametric Solver
- Using Load Cases

Distribute Parametric Solver

If you are running a parametric sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric solver** checkbox. This requires that your study includes a parametric sweep. To enable this option, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

Time Dependent

The **Time Dependent** ( ) study and study step are used when field variables change over time.

For example, in electromagnetics, it is used to compute transient electromagnetic fields, including electromagnetic wave propagation in the time domain. In heat transfer, it is used to compute temperature changes over time. In solid mechanics, it is used to compute the time-varying deformation and motion of solids subject to transient loads. In acoustics, it is used to compute the time-varying propagation of pressure waves. In fluid flow, it is used to compute unsteady flow and pressure fields. In chemical species transport, it is used to compute chemical composition over time. In chemical reactions, it is used to compute the reaction kinetics and the chemical composition of a reacting system.

Selecting a Time Dependent study adds a **Time Dependent** study step node and sets up a solver with a Time-Dependent Solver. Use this study for a time-dependent or transient simulation using a Time-Dependent Solver for computing the solution over time. Also see The Relationship Between Study Steps and Solver Configurations. You do not need to consider the settings in the Time-Dependent Solver unless the simulation does not behave as expected. For example, the simulation behaves in an unexpected way when changing the end time, in case you may need to adjust the default settings for the time stepping and the tolerances. You may also need to output more time steps and use a strict time stepping and tolerance to fully resolve fast dynamics and to avoid aliasing effects.

For time-dependent simulations, check that the initial conditions and the boundary conditions match at the start time. If they do not match, the model setup is likely unphysical, and the time-dependent solver can take very small time steps trying to reconcile inconsistent initial values.

The **Physics and Variables Selection**, **Values of Dependent Variables**, and **Mesh Selection** sections, and the **Include geometric nonlinearity** checkbox, **Auxiliary sweep** settings, and **Adaptive mesh refinement** settings in the **Study Extensions** section are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

STUDY SETTINGS

Select a **Time/parameter list method**. This option only appears if there are active least-squares objective functions defined in the model. The default is **Manual**, which means that the time list defined in the **Times** field is used. The

other possibility is **From least-squares objective**, which means that the time list defined by least-squares objectives is used. If you use the latter possibility, you specify the **Initial time** instead (the default is 0).

Select a **Time unit** from the list (default: s) to use a time unit that is convenient for the time span of the simulation. Then specify the time interval for the output from the simulation in the **Times** field using the selected time unit. You can type a monotonically increasing list of individual values, for example, `0 1 2 5 10 20`; use the `range` operator, for example, `range(0,0.1,1.5)`, which (using seconds as the time unit) gives time steps from 0 to 1.5 s with a step size of 0.1 s; or use any combinations of such input.

When plotting the results from a time-dependent simulation, you can choose to plot the solution at any of the times specified in the **Output times** field. You can also plot an interpolated solution at any intermediate time. The interpolation used between times is a cubic Hermite spline; that is, the interpolation uses both the solution values and their time derivatives at two points: the closest output times before and after the time for which the interpolated solution is computed.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field. The tolerance settings control the internal time steps taken by the solver, so selecting large time steps for the output times does not affect the accuracy in the time stepping.

RESULTS WHILE SOLVING

See Results While Solving in the Common Study Step Settings section.

ADAPTATION

Select **Adaptive mesh refinement** from the **Adaptive mesh refinement** list to activate time-dependent mesh adaptation. Then choose the geometry in which you want to use adaptive mesh refinement from the **Adaptation in geometry** list. If you want to use adaptive mesh refinement in only part of that geometry, select the geometric entities for the adaptation in the Geometric Entity Selection for Adaptation that becomes available below this section.

Under **Time-interval control**, choose **Automatic** (the default) or **Manual** from the **Time-interval length** list.

Under **Mesh element control**, choose a method from the **Adaptation method** list:

- **Longest edge refinement** (the default)
- **Regular refinement**
- **General modification**
- **Rebuild mesh**

Depending on the choices for these settings, see Adaptive Mesh Refinement (Time-Dependent Adaptation) for additional settings for adaptive mesh refinement in the **Adaptive Mesh Refinement** subnode under the **Time-Dependent Solver** node in the generated solver configuration.

GEOMETRIC ENTITY SELECTION FOR ADAPTATION

From the **Geometric entity level** list, choose the geometric entity on which you want to do adaptive mesh refinement: **Entire geometry** (the default), **Domain**, **Boundary**, or **Edge** (3D only). For example, selecting **Boundary** can be useful if the model includes a physics interface defined on boundaries (surfaces) and you want to base the adaptation on that physics interface. For all levels except **Entire geometry**, select the geometric entities to include using the **Selection** list and selection tools below.

STUDY EXTENSIONS

This section contains some optional extensions of the study. The options are mutually exclusive and only one of the checkboxes can be selected. See Auxiliary Sweep for its settings. Auxiliary sweeps are not available when the **Time/parameter list method** in the **Study Settings** section is set to **From least-squares objective**.

Automatic Remeshing

Select the **Automatic remeshing** checkbox if you want the solver to remesh automatically when the quality of the mesh becomes poor in a Time Dependent study. Select the geometry to use for the automatic remeshing from the **Remesh in geometry** list. With automatic remeshing active, the solver adds an **Automatic Remeshing** subnode under the **Time-Dependent Solver** node. In that subnode, you specify the mesh quality expression that determines when to remesh.

Time Discrete

The **Time Discrete** ( ) study step adds a Time Discrete Solver. Use it for performing time-dependent analysis using the projection method. The settings for this study node are the same as for the Time Dependent node. Also see The Relationship Between Study Steps and Solver Configurations.

Time Dependent, Modal

The **Time Dependent, Modal** ( ) study and study step are used to compute the dynamic structural deformation of an object subject to a transient force.

The study consists of two study steps: one Eigenfrequency study step for computing the eigenfrequencies and eigenmodes of the structure, and a second **Time Dependent, Modal** study step for computing the modal response. In the mode superposition analysis, the deformation of the structure is represented by a linear combination of the structure's eigenmodes. This means that the frequency content of the loads is limited by the frequencies of the computed eigenmodes. All loads are assumed to have the same variation with time. A Time Dependent, Modal study usually results in a faster computation than a direct solution using the Time Dependent study.

Selecting a **Time Dependent, Modal** study step gives a **Time Dependent, Modal** study step with a Modal Solver. Use it for performing transient response analyses. The settings are the same as for the Time Dependent study step for the sections that they share (the Time Dependent study step includes some additional settings), with the following added setting:

Use a scalar-valued expression for the value in the **Load factor** field (default: 1). The solver uses this expression as a load factor that is multiplied with the residual.

Also see The Relationship Between Study Steps and Solver Configurations.

	With the Structural Mechanics Module, see *Bracket — General Periodic Dynamic Analysis*, Application Library path **Structural_Mechanics_Module/Tutorials/bracket_general_periodic**.

EEDF Initialization

The **EEDF Initialization** ( ) study is available for the Plasma, Time Periodic, Inductively Coupled Plasma and Microwave Plasma and Plasma interfaces. You can also add it from the **Study Steps** > **Stationary** submenu. It acts almost identically to the **Stationary** study and is used to initialize the electron energy distribution function (EEDF) for cases when the EEDF is computed using the two-term approximation to the Boltzmann equation. See Stationary for information about the settings for the **EEDF Initialization** study step's **Settings** window.

Time Periodic

The **Time Periodic** ( ) study is available for the Plasma, Time Periodic interface. You can also add it from the **Study Steps** > **Stationary** submenu. It acts almost identically to the **Stationary** study and is used to compute a periodic

steady-state solution. See Stationary for information about the settings for the **Time Periodic** study step's **Settings** window.

Frequency-Time Periodic

The **Frequency-Time Periodic** ( ) study is available for the Inductively Coupled Plasma with RF Bias interface. It acts almost identically to the **Frequency-Stationary** study and is used to compute a periodic steady-state solution of the plasma equations while the electromagnetic fields are computed in the frequency domain. See Stationary for information about the settings for the **Frequency-Time Periodic** study step's **Settings** window.

Time Periodic to Time Dependent

The **Time Periodic to Time Dependent** ( ) study is available for the Plasma, Time Periodic interface. You can also add it from the **Study Steps** > **Time Dependent** submenu. It is identical to the **Time Dependent** study and is used to convert a periodic steady-state solution to a time-dependent solution. See Time Dependent for information about the settings for the **Time Periodic to Time Dependent** study step's **Settings** window.

Frequency to Time FFT

The **Frequency to Time FFT** ( ) study step, which you can add to a study where the last study step is typically a frequency-domain study, performs an inverse FFT (or, alternatively, the nonuniform Fourier transform) from the frequency domain (input) to the time domain (output). As the default solver it adds an FFT solver. The **Settings** window has the following special section:

STUDY SETTINGS

From the **Input study** list, choose the study from which the FFT takes its input data (the list contains frequency-domain studies and the name of the Time Dependent study that correlates to **Current**). You can also choose **Current** to take it from the same study as the one that includes the **Frequency to Time FFT** study step. For the remaining settings, see FFT Solver, which takes the settings from this study step by default.

VALUES OF DEPENDENT VARIABLES

The contents of this section are similar to other **Values of Dependent Variables** sections, but it does not include any settings for the initial values of variables solved for.

Eigenfrequency

The **Eigenfrequency** ( ) study and study step are used to compute eigenmodes and eigenfrequencies of a linear or linearized model.

For example, in electromagnetics, the eigenfrequencies correspond to the resonant frequencies and the eigenmodes correspond to the normalized electromagnetic field at the eigenfrequencies. In solid mechanics, the eigenfrequencies correspond to the natural frequencies of vibrations and the eigenmodes correspond to the normalized deformed shapes at the eigenfrequencies. In acoustics, the eigenfrequencies correspond to the resonant frequencies and the eigenmodes correspond to the normalized acoustic field at the eigenfrequencies.

Selecting an Eigenfrequency study gives a solver with an Eigenvalue Solver. Use this study to solve an eigenvalue problem for a set of eigenmodes and associated eigenfrequencies. Also see The Relationship Between Study Steps and Solver Configurations.

The **Physics and Variables Selection**, **Values of Dependent Variables**, **Mesh Selection**, **Adaptation and Error Estimates**, and **Geometric Entity Selection for Adaptation** sections and the **Include geometric nonlinearity** checkbox are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

STUDY SETTINGS

From the **Eigenfrequency solver** list, choose **ARPACK** (the default), **FEAST**, **LAPACK (filled matrix)**, or **ARPACK nonlinear**:

The ARPACK algorithm is based on an algorithmic variant of an Arnoldi process When the matrix A is symmetric it reduces to a variant of the Lanczos process. For its settings, see Study Settings for ARPACK and ARPACK Nonlinear below.

The FEAST algorithm uses an inverse residual iteration algorithm and seeks to accelerate the convergence of the subspace eigenfrequency problem. It can be effective for finding clustered eigenfrequencies by using an ellipse to search within. For its settings, see Study Settings for FEAST.

The LAPACK algorithm is useful for finding all eigenfrequencies for a filled matrix. This option is only applicable for small eigenfrequency problems. For its settings, see Study Settings for LAPACK (Filled Matrix).

The ARPACK nonlinear algorithm is capable of solving eigenfrequency problems that are nonlinear with respect to the eigenvalue. For its settings, see Study Settings for ARPACK and ARPACK Nonlinear below.

For more information about these eigenfrequency solvers, see The Eigenvalue Solver Algorithms.

STUDY SETTINGS FOR ARPACK AND ARPACK NONLINEAR

From the **Eigenfrequency search method** list, select a search method:

- **Around shift** (the default), to specify some search criteria manually. See Manual Eigenfrequency Search Settings (Around Shift) below.
- **Rectangular**, to define a rectangular eigenfrequency search region in a complex plane. See Rectangular Eigenfrequency Search Region Settings below and The Eigenvalue Solver Algorithms.

From the **Unit** list, choose a suitable unit (default: Hz).

Manual Eigenfrequency Search Settings (Around Shift)

By default, the physics interfaces suggest a suitable number of eigenfrequencies to search for. To specify the number of eigenfrequencies, select the checkbox in front of the **Desired number of eigenfrequencies** field to specify the number of eigenfrequencies you want the solver to return (default: 6).

In a 3D model, the first six eigenfrequencies are typically zero and correspond to the rigid-body modes of a 3D geometry. You may therefore need to specify a larger number of eigenfrequencies. The largest number of eigenfrequencies that the solver can compute is equal to the number of unconstrained degrees of freedom minus two.

By default, the physics interfaces suggest a suitable value around which to search for eigenvalues. To specify the value to search for eigenvalues around (shift), select the checkbox in front of the **Search for eigenvalues around shift** field; you can then specify a value (as an eigenfrequency) around which the eigenvalue solver should look for solutions to the eigenvalue equation (default: 0).

Use the **Search method around shift** list to control how the eigenvalue solver searches for eigenfrequencies around the specified shift value:

- Select **Closest in absolute value** (the default value) to search for eigenfrequencies that are closest to the shift value when measuring the distance as an absolute value.
- Select **Larger real part** to search for eigenfrequencies with a larger real part than the shift value.
- Select **Smaller real part** to search for eigenfrequencies with a smaller real part than the shift value.
- Select **Larger imaginary part** to search for eigenfrequencies with a larger imaginary part than the shift value.
- Select **Smaller imaginary part** to search for eigenfrequencies with a smaller imaginary part than the shift value.

When using a search for eigenfrequencies, the nonsymmetric eigenvalue solver is always used, even when the problem to solve is symmetric.

Rectangular Eigenfrequency Search Region Settings

Use the **Approximate number of eigenfrequencies** field to specify the approximate number of eigenfrequencies you want the solver to return (default: 20). The value of the **Approximate number of eigenfrequencies** will affect the **Dimension of Krylov space** used by the algorithm; see the **Advanced** section of the Eigenvalue Solver. It means that increasing the value of the **Approximate number of eigenfrequencies** will increase the memory requirement and the computational time. If the solver indicates that the value of the **Approximate number of eigenfrequencies** is smaller than the actual number of eigenfrequencies in the given region, it will perform a search for more eigenfrequencies, which increases the computational time; see The Eigenvalue Region Algorithm. Within limits it is often more efficient to provide a too large value of **Approximate number of eigenfrequencies** than a too small.

In the **Maximum number of eigenfrequencies** field, you can specify a maximum number of eigenfrequencies to limit the eigenvalue solver's search for additional eigenfrequencies (default: 200).

Under **Rectangle search region**, you define the size of the search region for eigenfrequencies as a rectangle in the complex plane by specifying the **Smallest real part (eigenfrequency)**, **Largest real part (eigenfrequency)**, **Smallest imaginary part (eigenfrequency)**, and **Largest imaginary part (eigenfrequency)** in the respective text fields. The search region also works as an interval method if the **Smallest imaginary part** and **Largest imaginary part** are equal; the eigenvalue solver then only considers the real axis and vice versa.

The **Perform consistency check** checkbox is selected by default to increase confidence that the solver finds all eigenvalues in the search region. The work required for performing the consistency check constitutes a significant part of the total work of the eigenvalue computation.

Additional Settings for ARPACK Nonlinear

The following settings are only available when you have chosen **ARPACK nonlinear** from the **Eigenfrequency solver** list.

Use the **Taylor expansion truncation** list to specify in which way to truncate the Taylor expansion in order to approximate the nonlinear dependence in λ with a polynomial. There are two options: **Tolerance** and **Fixed truncation**.

With the **Tolerance** option, specifying a **Maximum degree of the Taylor expansion** (default: 5), all the latest Taylor coefficients that are smaller then the specified **Tolerance** (default: $1 \cdot e^{-12}$) will be disregarded.

With the **Fixed truncation** option, the number of Taylor coefficients to keep is specified in **Degree of the Taylor expansion** (default: 3), and no further approximation is performed.

The eigenvalue scaling factor is useful in certain applications where the nonlinear dependence has a small scale in the equations but not in the solution. In this case, the eigenvalue scaling factor is changing λ with $c \cdot \lambda$ where c is

specified in the **Eigenvalue scaling factor** field (default: 1). This scaling is only done for internal computation, and the output is scaled back.

The eigenvalue solver can in some cases return more than the desired number of eigenfrequencies (up to twice the desired number). These are eigenfrequencies that the eigenvalue solver finds without additional computational effort.

STUDY SETTINGS FOR FEAST

Using the FEAST eigenfrequency solver, you can define an ellipse to explicitly exclude the eigenfrequencies outside the ellipse. Choosing a suitable search region determines which eigenfrequencies that will be returned for results analysis.

For an eigenfrequency problem for which you know how many eigenfrequencies there are, the solver can compute the eigenfrequencies directly. For that case, choose **Manual** from the **Number of eigenfrequencies** list and enter the desired number of eigenfrequencies in the **Approximate number of eigenfrequencies** field. If you do not know the number of eigenfrequencies in the defined region, there are two cases: You can just estimate the number of eigenfrequencies without computing them, or you can let the software estimate the number of eigenfrequencies and then compute them automatically afterward. The former is achieved by clicking the **Stochastic Estimation** button ( ) at the top right of the **Study Settings** section. The latter is achieved by choosing **Stochastic estimation** from the **Number of eigenvalues** list, and then click **Compute**. Both cases require doing stochastic estimation, which needs the setting of a value in the **Approximate number of eigenfrequencies** field (default: 6).

There is an option to select the **Store linear system factorization** checkbox. If selected, linear system factorizations are stored from the first FEAST iteration and reused in later iterations.

If the **Study** > **Batch and Cluster** checkbox is selected in the **Show More Options** dialog, select the **Distribute linear system solution** checkbox to run the FEAST eigenvalue solver in parallel. See Running FEAST in a Parallel MPI Mode for more information.

From the **Unit** list, choose a suitable unit (default: Hz).

Ellipse Search Region

You define the **Ellipse** by specifying the **Center**, **Real semiaxis (eigenfrequency)**, **Imaginary semiaxis (eigenfrequency)**, and **Rotation angle** in the respective text fields. It is important that the real semiaxis that you specify in the **Real semiaxis** field is large enough to enclose the eigenvalues of interest. In the **Imaginary semiaxis** field, you specify the imaginary semiaxis in a similar way. In the **Rotation angle** field, specify the rotation angle in degrees from the vertical axis in the range of –180 degrees to 180 degrees.

The **Stochastic Estimation** works as a **Compute to Selected** step. Because the **Stochastic Estimation** action does not solve the eigenvalue problem, there will not be any valid solution from this action. So, if the **Stochastic Estimation** action is done for a single step or the first step in a multistep study, there will not be any solution that can be used for postprocessing and results analysis. If the action is done for a step after the first step in a multistep study, the main solution of the sequence corresponds to the study step right before the eigenstep for which the estimation is done.

STUDY SETTINGS FOR LAPACK (FILLED MATRIX)

To specify a shift to use in the modes computation, select the **Shift used in the modes computation** checkbox and then enter a shift (in Hz) in the associated text field.

In the **Maximum matrix size** field, enter an upper limit on the matrix size (default: 2000).

From the **Unit** list, choose a suitable unit (default: Hz).

VALUES OF LINEARIZATION POINT

Use the settings in this section to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

FILTERING AND SORTING

Filtering

The eigenvalues can be excluded if there is a filter expression that they do not satisfy. In the table below, in the **Filter expression (store if true or >0)** column, add expressions for the filtering Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq` and can be logical expressions such as `lambda>10`. If desired, add some descriptive text in the **Description** column for the expressions.

The **Store solutions** list is always available: Choose **All converged solutions** (the default) or **First Nth** for the first *N*th solutions. Then specify that number in the **Maximum number of stored solutions** field (default: 1000).

Sorting

The eigenvalues can be sorted in **Ascending** (the default) or **Descending** order depending on the **Ordering** setting. When the **Sorting method** is **Predefined**, you can choose to **Sort primarily** based on the **Real part**, **Imaginary part**, **Real part magnitude**, **Imaginary part magnitude**, or **Absolute value**. The same settings are available for the **Sort secondly** option, which is used to resolve conflicts. The defaults for eigenvalues are **Real part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. For eigenfrequencies, the defaults are **Imaginary part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. Also, the **Sort based on transformed eigenvalues** checkbox is selected by default to take and eigenvalue transformation into account when sorting.

Alternatively, **Manual** can be chosen for the **Sorting method** and then an arbitrary number of (ordered) custom sorting priority expressions can be defined in the table that appears. In the **Sorting priority expression** column, add expressions for the sorting, in order of priority. Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq`. For example, you can specify an expression such as `abs(freq-1)` to sort according to the distance from a given shift (1 in this case). If desired, add some descriptive text in the **Description** column for the expressions.

The **Conjugate-pair consecutive sort** checkbox is selected by default to make sure that complex-conjugate eigenpairs appear one after the other, regardless of the sorting rules. For example, (λ, υ) and (μ, ω) are complex-conjugate solutions if $\lambda = \text{conj}(\mu)$ and $\upsilon = \text{conj}(\omega)$.

STUDY EXTENSIONS

This section contains some optional extensions of the study, such as auxiliary sweeps (see Common Study Step Settings). Adding an auxiliary parametric sweep adds an Eigenvalue Parametric attribute node to the Eigenvalue Solver.

ARPACK Settings

If you have selected **ARPACK** as the **Eigenfrequency solver** and selected the **Auxiliary sweep** checkbox, these additional settings are available:

With the ARPACK eigenvalue solver, you can supply a starting vector for the eigenvalue computation. Doing so can accelerate convergence if a series of closely related problems are to be solved. More precisely, the convergence and the computation time can be reduced if an approximation of the solution is given. In this case, the starting vector should be a linear combination of the given approximation of the eigenvectors, and the shift should be located close to the given approximation of the eigenvalues. The following settings are related to ARPACK:

From the **ARPACK starting vector** list, choose **Default**, giving a random starting vector, or **From previous eigenvectors**. If you chose **From previous eigenvectors**, a **From previous eigenvectors** list appears, where you can choose **Summation of all eigenvectors** (the default) or **Eigenvector with eigenfrequency closest to the shift** as the new starting vector. These options can always be used without compromising the convergence. Use **Summation of all eigenvectors** when more than one eigenpair is requested. Use **Eigenvector with eigenfrequency closest to the shift** when only one eigenpair is requested.

From the **ARPACK shift** list, choose **As specified** (the default) or **Based on eigenfrequencies for last parameter**. If you chose **Based on eigenfrequencies for last parameter**, also choose an option from the **From previous eigenvalues** list that appears: Choose **Average of converged eigenfrequencies** (the default) or **Eigenfrequency closest to the previous shift**. In the case where the eigenfrequency shift value has not been parameterized, these options could be useful, but use them only if the eigenfrequencies are expected to have a small variation between two consecutive parameters. If this is not the case, ARPACK may converge to unwanted eigenpairs. Use **Average of converged eigenfrequencies** when the wanted eigenfrequencies are "around" the shift. More precisely, when the shift is an "internal point" of the convex hull of the wanted eigenfrequencies. Use **Eigenfrequency closest to previous shift** if the shift is an "external point" of the convex hull of the wanted eigenfrequencies. For example, if the eigenfrequencies are known to have positive real part and the shift is set to zero.

The shift corresponds to the value of the **Search for eigenfrequencies around** field in the **Study Settings** section. The eigenpairs, computed with respect to the previous parameter, are ordered from the closest to the shift to the one farthest from the shift.

Distribute Parametric Solver

If you are running an auxiliary sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric solver** checkbox. To enable this option, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

	Tuning Fork: Application Library path **COMSOL_Multiphysics/Structural_Mechanics/tuning_fork**. For a model that uses a search region for the eigenfrequencies, with the Acoustics Module, see *Helmholtz Resonator Analyzed with Different Frequency Domain Solvers*: Application Library path **Acoustics_Module/Tutorials,_Pressure_Acoustics/helmholtz_resonator_solvers**.

Eigenvalue

The **Eigenvalue** ( ) study and study step are used to compute the eigenvalues and eigenmodes of a linear or linearized model in a generic eigenvalue formulation where the eigenvalues are not necessarily frequencies. The Eigenvalue study gives you full control of the eigenvalue formulation, in contrast to the eigenfrequency study that is adapted for specific physics interfaces. The Eigenvalue study is typically used for equation-based modeling.

Selecting an Eigenvalue study gives a solver configuration with an Eigenvalue Solver.

The **Results While Solving**, **Physics and Variables Selection**, **Values of Dependent Variables**, **Store in Output**, **Mesh Selection**, **Adaptation and Error Estimates**, and **Geometric Entity Selection for Adaptation** sections and the **Include geometric nonlinearity** checkbox are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

STUDY SETTINGS

From the **Eigenvalue solver** list, choose **ARPACK** (the default), **FEAST**, **LAPACK (filled matrix)**, or **ARPACK nonlinear**:

The ARPACK algorithm is based on an algorithmic variant of an Arnoldi process When the matrix A is symmetric it reduces to a variant of the Lanczos process. For its settings, see Study Settings for ARPACK and ARPACK Nonlinear below.

The FEAST algorithm uses an inverse residual iteration algorithm and seeks to accelerate the convergence of the subspace eigenvalue problem. It can be effective for finding clustered eigenvalues by using an ellipse to search within. For its settings, see Study Settings for FEAST.

The LAPACK algorithm is useful for finding all eigenvalues for a filled matrix. This option is only applicable for small eigenvalue problems. For its settings, see Study Settings for LAPACK (Filled Matrix).

The ARPACK nonlinear algorithm is capable of solving eigenvalue problems that are nonlinear with respect to the eigenvalue. For its settings, see Study Settings for ARPACK and ARPACK Nonlinear below.

For more information about these eigenvalue solvers, see The Eigenvalue Solver Algorithms.

STUDY SETTINGS FOR ARPACK AND ARPACK NONLINEAR

From the **Eigenvalue search method** list, select a search method:

- **Around shift** (the default), to specify some search criteria manually. See Around Shift Eigenvalue Search Settings below.
- **Rectangle**, to define an eigenvalue search region in a complex plane. See Rectangular Eigenvalue Search Region Settings below and The Eigenvalue Solver Algorithms.

From the **Unit** list, choose a suitable unit (default rad/s).

Around Shift Eigenvalue Search Settings

By default, the physics interfaces suggest a suitable number of eigenvalues to search for. To specify the number of eigenvalues, select the checkbox in front of the **Desired number of eigenvalues** field to specify the number of eigenvalues you want the solver to return (default: 6).

In a solid 3D model, the first six eigenvalues are typically zero and correspond to the rigid-body modes of a 3D geometry. You may therefore need to specify a larger number of eigenvalues. The largest number of eigenvalues that the solver can compute is equal to the number of unconstrained degrees of freedom minus two.

By default, the physics interfaces suggest a suitable value around which to search for eigenvalues. To specify the value to search for eigenvalues around (shift), select the checkbox in front of the **Search for eigenvalues around shift** field; you can then specify a value or expression around which the eigenvalue solver should look for solutions to the eigenvalue equation (default: 0).

Use the **Search method around shift** list to control how the eigenvalue solver searches for eigenvalues around the specified shift value:

- Select **Closest in absolute value** (the default value) to search for eigenvalues that are closest to the shift value when measuring the distance as an absolute value.
- Select **Larger real part** to search for eigenvalues with a larger real part than the shift value.
- Select **Smaller real part** to search for eigenvalues with a smaller real part than the shift value.
- Select **Larger imaginary part** to search for eigenvalues with a larger imaginary part than the shift value.
- Select **Smaller imaginary part** to search for eigenvalues with a smaller imaginary part than the shift value.

Rectangular Eigenvalue Search Region Settings

Use the **Approximate number of eigenvalues** field to specify the approximate number of eigenvalues you want the solver to return (default: 20). The value of the **Approximate number of eigenvalues** will affect the **Dimension of Krylov space** used by the algorithm; see the **Advanced** section of the Eigenvalue Solver. It means that increasing the value of the **Approximate number of eigenvalues** will increase the memory requirement and the computational time. If the solver indicates that the value of the **Approximate number of eigenvalues** is smaller than the actual number of eigenvalues in the given region, it will perform a search for more eigenvalues, which increases the computational time; see The Eigenvalue Region Algorithm. Within limits it is often more efficient to provide a too large value of **Approximate number of eigenvalues** than a too small.

In the **Maximum number of eigenvalues** field, you can specify a maximum number of eigenvalues to limit the eigenvalue solver's search for additional eigenvalues (default: 200).

Under **Rectangle search region**, you define the size of the search region for eigenvalues as a rectangle in the complex plane by specifying the **Smallest real part**, **Largest real part**, **Smallest imaginary part**, and **Largest imaginary part** in the respective text fields. The search region also works as an interval method if the **Smallest imaginary part** and **Largest imaginary part** are equal; the eigenvalue solver then only considers the real axis and vice versa.

The **Perform consistency check** checkbox is available and selected by default to increase confidence that the solver finds all eigenvalues in the search region. The work required for performing the consistency check constitutes a significant part of the total work of the eigenvalue computation

Symmetry and Consistency Settings

Eigenvalue computations can be performed with a nonsymmetric solver or, if applicable, a real symmetric solver. From the **Use real symmetric eigenvalue solver** list, choose **Automatic** (the default) or **Off**. For the **Automatic** option there is the option to select the **Real symmetric eigenvalue solver consistency check** checkbox. This consistency check increases the computational time and memory requirements but provides a rigorous check of the applicability of the real symmetric solver.

Additional Settings for ARPACK Nonlinear

The following settings are only available when you have chosen **ARPACK nonlinear** from the **Eigenvalue solver** list.

Use the **Taylor expansion truncation** list to specify in which way to truncate the Taylor expansion in order to approximate the nonlinear dependence in λ with a polynomial. There are two options: **Tolerance** and **Fixed truncation**.

With the **Tolerance** option, specifying a **Maximum degree of the Taylor expansion** (default: 5), all the latest Taylor coefficients that are smaller then the specified **Tolerance** (default: $1 \cdot e^{-12}$) will be disregarded.

With the **Fixed truncation** option, the number of Taylor coefficients to keep is specified in **Degree of the Taylor expansion** (default: 3), and no further approximation is performed.

The eigenvalue scaling factor is useful in certain applications where the nonlinear dependence has a small scale in the equations but not in the solution. In this case, the eigenvalue scaling factor is changing λ with $c \cdot \lambda$ where c is

specified in the **Eigenvalue scaling factor** field (default: 1). This scaling is only done for internal computation, and the output is scaled back.

	When using a search for eigenvalues, the nonsymmetric eigenvalue solver is always used, even when the problem to solve is symmetric.

	The eigenvalue solver can in some cases return more than the desired number of eigenvalues (up to twice the desired number). These are eigenvalues that the eigenvalue solver finds without additional computational effort.

STUDY SETTINGS FOR FEAST

Using the FEAST eigenvalue solver, you can define an ellipse to explicitly exclude the eigenvalues outside the ellipse. Choosing a suitable search region determines which eigenvalues that will be returned for results analysis.

From the **Eigenvalue search method** list, select a search method:

- **Ellipse** (the default), to define an eigenvalue search contour as an ellipse in a complex plane. See Ellipse Search Region settings below.
- **Half ellipse (Hermitian problem)**, to define an eigenvalue search contour by half of the whole ellipse. See Half Ellipse Search Region below.

For an eigenvalue problem for which you know how many eigenvalues there are, the solver can compute the eigenvalues directly. For that case, choose **Manual** from the **Number of eigenvalues** list and enter the desired number of eigenvalues in the **Approximate number of eigenvalues** field. If you do not know the number of eigenvalues in the defined region, there are two cases: You can just estimate the number of eigenvalues without computing them, or you can let the software estimate the number of eigenvalues and then compute them automatically afterward. The former is achieved by clicking the **Stochastic Estimation** button ( ) at the top right of the **Study Settings** section. The latter is achieved by choosing **Stochastic estimation** from the **Number of eigenvalues** list, and then click **Compute**. Both cases require doing stochastic estimation, which needs the setting of an **Approximate number of eigenvalues** field as an initial guess in the estimation stage.

There is an option to select the **Store linear system factorization** checkbox. If selected, linear system factorizations are stored from the first FEAST iteration and reused in later iterations.

If the **Study** > **Batch and Cluster** checkbox is selected in the **Show More Options** dialog, select the **Distribute linear system solution** checkbox to run the FEAST eigenvalue solver in parallel. See Running FEAST in a Parallel MPI Mode for more information.

From the **Unit** list, choose a suitable unit (default rad/s).

Ellipse Search Region

You define the **Ellipse** by specifying the **Center**, **Real semiaxis**, **Imaginary semiaxis**, and **Rotation angle** in the respective text fields. It is important that the real semiaxis that you specify in the **Real semiaxis** field is large enough to enclose the eigenvalues of interest. In the **Imaginary semiaxis** field, you specify the imaginary semiaxis in a similar way. In

the **Rotation angle** field, specify the rotation angle in degrees from the vertical axis in the range of –180 degrees to 180 degrees.

The **Stochastic Estimation** works as a **Compute to Selected** step. Because the **Stochastic Estimation** action does not solve the eigenvalue problem, there will not be any valid solution from this action. So, if the **Stochastic Estimation** action is done for a single step or the first step in a multistep study, there will not be any solution that can be used for postprocessing and results analysis. If the action is done for a step after the first step in a multistep study, the main solution of the sequence corresponds to the study step right before the eigenstep for which the estimation is done.

Half Ellipse Search Region

You define the **Half ellipse (Hermitian problem)** by specifying the **Smallest real part**, **Largest real part**, and **Imaginary semiaxis** in the respective text fields.

Symmetry and Consistency Settings

For the **Ellipse** eigenvalue search method, eigenvalue computations can be performed with a nonsymmetric solver or, if applicable, a real symmetric solver. From the **Use real symmetric or Hermitian eigenvalue solver** list, choose **Automatic** (the default) or **Off**. For the **Automatic** option there is the option to select the **Real symmetric or Hermitian eigenvalue solver consistency check** checkbox. This consistency check increases the computational time and memory requirements but provides a rigorous check of the applicability of the real symmetric solver.

STUDY SETTINGS FOR LAPACK (FILLED MATRIX)

To specify a shift to use in the modes computation, select the **Shift used in the modes computation** checkbox and then enter a shift (in rad/s) in the associated text field.

In the **Maximum matrix size** field, enter an upper limit on the matrix size (default: 2000).

From the **Unit** list, choose a suitable unit (default: rad/s).

VALUES OF LINEARIZATION POINT

Use the settings in this section to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

FILTERING AND SORTING

Filtering

The eigenvalues can be excluded if there is a filter expression that they do not satisfy. In the table below, in the **Filter expression (store if true or >0)** column, add expressions for the filtering Those expressions can be functions of the

eigenvalue `lambda` or eigenfrequency `freq` and can be logical expressions such as `lambda>10`. If desired, add some descriptive text in the **Description** column for the expressions.

The **Store solutions** list is always available: Choose **All converged solutions** (the default) or **First Nth** for the first *N*th solutions. Then specify that number in the **Maximum number of stored solutions** field (default: 1000).

Sorting

The eigenvalues can be sorted in **Ascending** (the default) or **Descending** order depending on the **Ordering** setting. When the **Sorting method** is **Predefined**, you can choose to **Sort primarily** based on the **Real part**, **Imaginary part**, **Real part magnitude**, **Imaginary part magnitude**, or **Absolute value**. The same settings are available for the **Sort secondly** option, which is used to resolve conflicts. The defaults for eigenvalues are **Real part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. For eigenfrequencies, the defaults are **Imaginary part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. Also, the **Sort based on transformed eigenvalues** checkbox is selected by default to take and eigenvalue transformation into account when sorting.

Alternatively, **Manual** can be chosen for the **Sorting method** and then an arbitrary number of (ordered) custom sorting priority expressions can be defined in the table that appears. In the **Sorting priority expression** column, add expressions for the sorting, in order of priority. Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq`. For example, you can specify an expression such as `abs(freq-1)` to sort according to the distance from a given shift (1 in this case). If desired, add some descriptive text in the **Description** column for the expressions.

The **Conjugate-pair consecutive sort** checkbox is selected by default to make sure that complex-conjugate eigenpairs appear one after the other, regardless of the sorting rules.

STUDY EXTENSIONS

This section contains some optional extensions of the study, such as auxiliary sweeps (see Common Study Step Settings). Adding an auxiliary parametric sweep adds an Eigenvalue Parametric attribute node to the Eigenvalue Solver.

ARPACK Settings

If you have selected **ARPACK** as the **Eigenvalue solver** and selected the **Auxiliary sweep** checkbox, these additional settings are available:

With the ARPACK eigenvalue solver, you can supply a starting vector for the eigenvalue computation. Doing so can accelerate convergence if a series of closely related problems are to be solved. More precisely, the convergence and the computation time can be reduced if an approximation of the solution is given. In this case, the starting vector should be a linear combination of the given approximation of the eigenvectors, and the shift should be located close to the given approximation of the eigenvalues. The following settings are related to ARPACK:

From the **ARPACK starting vector** list, choose **Default**, giving a random starting vector, or **From previous eigenvectors**. If you chose **From previous eigenvectors**, a **From previous eigenvectors** list appears, where you can choose **Summation of all eigenvectors** (the default) or **Eigenvector with eigenvalue closest to the shift** as the new starting vector. These options can always be used without compromising the convergence. Use **Summation of all eigenvectors** when more than one eigenpair is requested. Use **Eigenvector with eigenvalue closest to the shift** when only one eigenpair is requested.

From the **ARPACK shift** list, choose **As specified** (the default) or **Based on eigenvalues for last parameter**. If you chose **Based on eigenvalues for last parameter**, also choose an option from the **From previous eigenvalues** list that appears: Choose **Average of converged eigenvalues** (the default) or **Eigenvalue closest to the previous shift**. In the case where the eigenvalue shift value has not been parameterized, these options could be useful, but use them only if the eigenvalues are expected to have a small variation between two consecutive parameters. If this is not the case, ARPACK may converge to unwanted eigenpairs. Use **Average of converged eigenvalues** when the wanted eigenvalues are “around” the shift. More precisely, when the shift is an “internal point” of the convex hull of the wanted

eigenvalues. Use **Eigenvalue closest to previous shift** if the shift is an "external point" of the convex hull of the wanted eigenvalues. For example, if the eigenvalues are known to have positive real part and the shift is set to zero.

The shift corresponds to the value of the **Search for eigenvalues around** field in the **Study Settings** section. The eigenpairs, computed with respect to the previous parameter, are ordered from the closest to the shift to the one farthest from the shift.

Distribute Parametric Solver

If you are running an auxiliary sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric solver** checkbox. To enable this option, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

Stationary Then Eigenfrequency

Selecting a **Stationary Then Eigenfrequency** ( ) study gives a solver configuration with a Stationary Solver followed by an Eigenvalue Solver, effectively setting up a coupling between the two solvers in a single study step. When used together with gradient-based optimization, the coupling is set up without a Solution Store feature. This useful whenever the Helmholtz feature is enabled in a Density Model feature or one of the Free Shape features is used in the shape optimization interface. The study step is not supported with sensitivity, and the behavior is different outside the context of optimization in the sense that different solutions are created for the two solvers.

	The **Physics and Variables Selection**, **Values of Dependent Variables**, **Mesh Selection**, **Adaptation and Error Estimates**, and **Geometric Entity Selection for Adaptation** sections and the **Include geometric nonlinearity** checkbox are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

	The study step is demonstrated in the Optimization Module Application Library model *Maximizing the Eigenfrequency of a Shell*, Application Library path **Optimization_Module/Shape_Optimization/shell_eigenfrequency_shape_optimization**.

STUDY SETTINGS

See the Study Settings for the Eigenfrequency study step.

VALUES OF LINEARIZATION POINT

See the Values of Linearization Point for the Eigenfrequency study step.

STUDY EXTENSIONS

See the Study Extensions for the Eigenfrequency study step.

Frequency Domain

The **Frequency Domain** ( ) study and study step are used to compute the response of a linear or linearized model subjected to harmonic excitation for one or several frequencies.

For example, in solid mechanics, it is used to compute the frequency response of a mechanical structure with respect to particular load distributions and frequencies. In acoustics and electromagnetics, it is used to compute the transmission and reflection versus frequency. A Frequency Domain study step accounts for the effects of all eigenmodes that are properly resolved by the mesh and how they couple with the applied loads or excitations. The output of a Frequency Domain study step is typically displayed as a transfer function, for example, magnitude or phase of deformation, sound pressure, impedance, or scattering parameters versus frequency.

It is also possible to add an auxiliary sweep to this study step, which creates a multiparameter sweep (Parametric solver) over both the frequency and the given parameters, and optionally with continuation in the frequency or in one of the given parameters. It corresponds to a stationary parametric solver that is preset to linearize the equations (Stationary Solver with a Parametric attribute).

Alternatively, select the **Use asymptotic waveform evaluation** checkbox to use an AWE Solver instead of the Parametric solver.

	The **Include geometric nonlinearity** checkbox and the **Results While Solving**, **Mesh Selection**, **Adaptation and Error Estimates**, **Geometric Entity Selection for Adaptation**, and **Auxiliary Sweep** sections are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

	For a problem that requires a linearization point (for example, when the electromechanical forces coupling is used), use the **Frequency Domain, Prestressed** or the **Small-Signal Analysis, Frequency Domain** studies instead. These studies include the **Stationary** step that computes the stationary (or bias) solution followed by the **Frequency Domain Perturbation** step that computes a perturbed solution around the linearization point from the preceding step.

STUDY SETTINGS

Select a **Frequency/parameter list method**. This option only appears if there are active least-squares objective functions defined in the model. The default is **Manual**, which means that the frequency list defined in the **Frequencies** field is used. The other possibility is **From least-squares objective**, which means that the frequency list defined by least-squares objectives is used.

Specify the frequencies to use for the frequency sweep. Select the unit to use from the **Frequency unit** list (default: Hz). Type the frequencies in the **Frequencies** field using space-separated numbers or the `range` function.

Use the **Load parameter values** field to select a file with parameter values. You can browse your file system for files by clicking the **Browse** button ( ). You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy File Location** ( ), and (if you have copied a file location) **Paste File Location** ( ). After selecting a file, click the **Read File** button ( ) to load the parameter values into the **Frequencies** field.

For information about the **Reuse solution from previous step** list, see Reuse Solution from Previous Step List.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field.

STUDY EXTENSIONS

Also see Auxiliary Sweep.

Asymptotic Waveform Evaluation

Select the **Use asymptotic waveform evaluation** checkbox to enable the *asymptotic waveform evaluation (AWE) solver*. The Frequency Domain study generates a solver configuration that is used to solve a stationary parametric problem or an asymptotic waveform evaluation problem. By selecting this checkbox, this study step corresponds to an AWE Solver.

Distribute Parametric Solver

If you are running a parametric sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric solver** checkbox. This requires that your study includes a parametric sweep.

To enable this option, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

Frequency Domain Source Sweep

Use a **Frequency Domain Source Sweep** ( ) study step to solve a frequency domain study that is sweeping among feedings such as ports and lumped ports, extracting automatically a full S-parameter matrix. The settings for this study step are similar to those for the Frequency Domain study step. This study step can for example be used to extract an impedance matrix in the Magnetic and Electric Fields interface.

Frequency Domain Source Sweep with Initialization

The **Frequency Domain Source Sweep with Initialization** ( ) study step is a preset study step for the Magnetic Fields, Currents Only interface, which requires the AC/DC Module. It consists of a Source Initialization, followed by a Frequency Domain Source Sweep study step.

Frequency Domain, RF Adaptive Mesh

The **Frequency Domain, RF Adaptive Mesh** ( ) study and study step are used to perform the mesh adaptation for RF, microwave, and millimeter-wave circuit or antenna models based on the computed norm of electric and magnetic fields of a linear or linearized model subjected to harmonic excitation for one or several frequencies. The adaptation is automatically terminated when the absolute value of S-parameter is converged within the range specified.

	This study requires a license for the RF Module. See also the RF Module documentation for more information about RF frequency-domain studies.

	The **Include geometric nonlinearity** checkbox and the **Results While Solving** and **Mesh Selection** sections are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

STUDY SETTINGS

Specify the frequencies to use for the frequency sweep. Select the unit to use from the **Frequency unit** list (default: GHz). Type the frequencies in the **Frequencies** field using space-separated numbers or the `range` function.

Select **Mesh refinement** — **Physics controlled** (the default) or **User controlled**.

When **Physics controlled** is selected, select a **Type** — **Printed circuit board** or **Domain** (the default)**.** When is **Printed circuit board** selected, edge mesh adaptation is performed on conductive printed traces or slots. For **Domain**, perfect matched layers are excluded in the mesh adaptation.

In the **Maximum number of adaptations** field, enter a suitable number of mesh adaptation steps (default: 10).

In the **Damping factor** field, enter a suitable damping factor (default: 0.1). The damping factor makes the mesh adaptation more robust when there is any sharp resonance. A higher value could turn a sharp peak into a smooth curve of functional and goal-oriented termination expressions.

The **Enforce linear elements** checkbox is selected by default to make sure that elements with linear shape functions are used. They work best for these types of RF adaptive mesh simulations, especially for circuit simulations.

Frequency Domain, Modal

The **Frequency Domain, Modal** ( ) study and study step are used, for example, to compute the response of a linear or linearized structural mechanics model subjected to harmonic excitation for one or several frequencies.

The **Frequency Domain, Modal** study consists of two study steps: an **Eigenfrequency** study step for computing the eigenfrequencies and eigenmodes of the structure followed by a second **Frequency Domain, Modal** study step for computing the modal response. In the mode superposition analysis, the deformation of the structure is represented by a linear combination of the structure's eigenmodes. This means that the frequencies to be studied are limited by the frequencies of the computed eigenmodes. A Frequency, Domain Modal study usually results in a faster computation than a direct solution using the Frequency Domain study.

This is a study type which is built on the linear perturbation machinery. Any load must have the **Harmonic Perturbation** attribute. For contributing loads (that is, loads that can be added without overwriting the same type of node, such as a boundary load in solid mechanics), right-click the node and select **Harmonic Perturbation**.

For loads that do not have an **Harmonic Perturbation** attribute, you can instead use the linper operator.

The following sections describe the settings for the Frequency, Domain Modal study step. See Eigenfrequency for information about the settings for the Eigenfrequency study step.

The Frequency, Domain Modal study step node corresponds to a modal frequency sweep for systems with frequency-based loads. It gives a Modal Solver.

The **Include geometric nonlinearity** checkbox and **Mesh Selection** are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

STUDY SETTINGS

Specify the frequencies to use for the frequency sweep. Select the unit to use from the **Frequency unit** list (default: Hz). Enter the frequencies in the **Frequencies** field using space-separated numbers or the `range` function.

Use the **Load parameter values** field to select a file with parameter values. Click the **Browse** button ( ) to browse the file system. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Edit Location** ( ) (if the location is a database), **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ). After selecting a file, click the **Read File** ( ) button to load the parameter values into the **Frequencies** field.

Use the **Parameter list type** list to control how to interpret the parameter values entered in the **Parameter values** field. Select:

- **Frequency** (the default setting) to use the parameter values without modification.
- **Fraction** to multiply the parameter values by the absolute value of the largest eigenvalue in the reduced model divided by two.
- **Spread** to treat the parameter values as an interval around each eigenvalue in the reduced model. That is, the absolute value of each eigenvalue is multiplied by the parameter values and the resulting parameter value vectors are concatenated into one. In the case when intervals around two or more eigenfrequencies overlap, priority is given to frequencies closest to their corresponding eigenvalue to ensure the resulting intervals are disjoint.

For the last two options above, the **Frequencies** field changes to a **Parameter values** field, and the following settings becomes available:

- From the **Minimum frequency** list, choose **Automatic** (the default) or **Manual**. If you chose **Manual**, also specify a minimum value (in the chosen frequency unit) in the **Value** field.
- From the **Maximum frequency** list, choose **Automatic** (the default) or **Manual**. If you chose **Manual**, also specify a maximum value (in the chosen frequency unit) in the **Value** field.
- If desired, add more frequencies in the **Additional frequencies** field. Use the **Range** button ( ) if you want to add a range of frequencies.

You can add the minimum and maximum frequency if desired (by default there is no limit) to limit the output frequencies to solve for. You can also supply a list of additional frequencies. Those frequencies will be added to the output frequencies to solve for, which makes the spread option effectively an extension of the frequency parameter list type.

These settings are always available:

For information about the **Reuse solution from previous step** list, see Reuse Solution from Previous Step List.

Use a scalar-valued expression for the value in the **Load factor** field (default: 1). The solver uses this expression as a load factor that is multiplied with the residual.

VALUES OF LINEARIZATION POINT

Use the settings in this section to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

With the Structural Mechanics Module, see *Bracket — General Periodic Dynamic Analysis*, Application Library path **Structural_Mechanics_Module/Tutorials/bracket_general_periodic**.

Frequency Domain, AWE Reduced-Order Model

The **Frequency Domain, AWE Reduced-Order Model** ( ) node is not a study in itself; rather, it adds a number of nodes to the Model Builder tree to facilitate a reduced-order model (ROM) creation. These nodes are configured to set up a ROM to perform a frequency-domain sweep using the asymptotic wave evaluation (AWE) technique.

One study with a **Model Reduction** study step, in which the ROM is created. The **Model Reduction** study step contains a **Frequency Domain** subnode. The purpose of that subnode is to provide the model reduction with information about equation forms, participating physics interfaces, mesh selection, and so on.

Under **Global Definitions**, a **Reduced-Order Modeling** node is added. It contains a subnode, which is a **Frequency Domain, AWE Reduced-Order Model** node. This is a placeholder for the ROM to be created.

Frequency Domain, Modal Reduced-Order Model

The **Frequency Domain, Modal Reduced-Order Model** ( ) node is not a study in itself; rather, it adds a number of nodes to the Model Builder tree to facilitate a reduced-order model (ROM) creation. These nodes are configured to set up a ROM to perform a frequency domain analysis using mode superposition.

Two studies are added:

- One study with an **Eigenfrequency** study step for computing the eigenfrequencies and corresponding eigenmodes.
- One study with a **Model Reduction** study step, in which the ROM is created. It references the previous study. In the common case that you have already computed the eigenmodes, you can change the setting of the **Training study** in this node to point to the old eigenfrequency study, and then delete the newly generated one. The **Model Reduction** study step contains a **Frequency Domain** subnode. The purpose of that subnode is to provide the model reduction with information about equation forms, participating physics interfaces, mesh selection, and so on.

Under **Global Definitions**, a **Reduced-Order Modeling** node becomes available. It contains two subnodes:

- A **Global Reduced-Model Inputs** node in which you define the control parameters for the ROM.
- A **Frequency Domain, Modal Reduced-Order Model** node. This is a placeholder for the ROM to be created.

Time Dependent, Modal Reduced-Order Model

The **Time Dependent, Modal Reduced-Order Model** ( ) node is not a study in itself; rather, it adds a number of study nodes to the Model Builder tree to facilitate a reduced-order model (ROM) creation. These nodes are configured to set up a ROM to perform a time dependent analysis using mode superposition.

Two studies are added:

- One study with a **Time Dependent** study step. This study can mainly be considered as a placeholder which is a mandatory input to the model reduction.
- One study with a **Model Reduction** study step, in which the ROM is created. It references the two previous studies. In the common case that you have already computed the eigenmodes, you can change the setting of the **Training study** in this node to point to the old eigenfrequency study, and then delete the newly generated one. The **Model Reduction** study step contains a **Time Dependent** subnode. The purpose of that subnode is to provide the model reduction with information about equation forms, participating physics interfaces, mesh selection, and so on.

Under **Global Definitions**, a **Reduced-Order Modeling** node is added. It contains two subnodes:

- A **Global Reduced-Model Inputs** node in which you define the control parameters for the ROM.
- A **Time Dependent, Modal Reduced-Order Model** node. This is a placeholder for the ROM to be created.

Adaptive Frequency Sweep

The **Adaptive Frequency Sweep** ( ) study and study step are used, for example, to compute the response of a linear or linearized model subjected to harmonic excitation for several frequencies with a fine frequency resolution using a reduced-order model in the frequency domain. The asymptotic waveform evaluation (AWE) model reduction is performed by a moment-matching technique where Padé approximation or a Taylor series expansion is used for the

transfer function in a specified frequency interval. This study step corresponds to an AWE Solver. This study type requires a license for the Acoustics Module, MEMS Module, RF Module, or Wave Optics Module.

The **Results While Solving** section is described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

STUDY SETTINGS

Specify the frequencies to use for the frequency sweep. Select the unit to use from the **Frequency unit** list (default: Hz). Enter the frequencies in the **Frequencies** field using space-separated numbers or use the settings in the **Range** window ( ).

From the **AWE expression type** list, choose **Physics controlled** (the default) to make the physics interface control the AWE expression, or choose **User controlled**. If you chose **User controlled**, use the **Asymptotic waveform evaluation (AWE) expressions** table to specify a list of globally available scalar-valued expressions to be used for error estimation by the AWE algorithm. In the AWE algorithm, the values of the expressions specified in the **Asymptotic waveform evaluation (AWE) Expressions** table in the **Study Settings** section are evaluated at one or more points of a parameter interval using certain expansions. The AWE algorithm is considered to have converged in that interval if the functional values resulting from the different expansions and evaluation points are similar enough.

Use the **Relative tolerance** field to specify to what relative tolerance the functional values must agree at the evaluation points.

MESH SELECTION

In the table in this section, choose the mesh to use in each component for the frequency sweep.

See *Evanescent Mode Cylindrical Cavity Filter*, Application Library path **RF_Module/Filters/cylindrical_cavity_filter_evanescent**.

RF Coil, Application Library path **RF_Module/Passive_Devices/rf_coil**.

Time-to-Frequency FFT

The **Time-to-Frequency FFT** study step ( ), which you can add to a study, where the last study type is typically a time-dependent study, performs a forward FFT from the time domain (input) to the frequency domain (output). As the default solver it adds an FFT solver. The **Settings** window for the **Time-to-Frequency FFT** node includes the following sections:

STUDY SETTINGS

From the **Input study** list, choose the study from which the FFT takes its input data (contains time-domain studies and the name of the Frequency Domain study that correlates to **Current**). You can also choose **Current** to take it from the same study as the one that includes the **Time-to-Frequency FFT** study step. For the remaining settings, see FFT Solver, which takes the settings from this study step by default.

VALUES OF DEPENDENT VARIABLES

The contents of this section is similar to other **Values of Dependent Variables** sections, but it does not include any settings for the initial values of variables solved for.

To enable this option in the context menu, click the **Show More Options** button ( ) and select **Batch** or **Batch and Cluster** (if your license includes cluster computing) in the **Show More Options** dialog.

Use a **Batch** ( ) study to start a COMSOL Multiphysics batch process that solves the current study on your computer. Once the filename and directory are set, right-click the parent **Study** node and choose **Compute** to start a COMSOL Multiphysics batch process that computes the current study.

You cannot create another Batch, Batch Sweep, Cluster Sweep, or Cluster Computing in the same study at the same time.

When the batch process starts, the COMSOL Desktop follows the progress in The External Process Window. When the process finishes (or you click the **Detach Job** button to no longer follow the process), an **External Process** node is added, one for each parameter, under a **Batch Data** node as in Figure 20-5. The External Process node represents the current running process. For more information, see Batch (Job Configurations), Batch Data, and External Process.

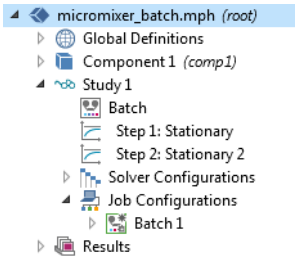

Figure 20-5: An example of the two kinds of Batch nodes available under Study and Job Configurations.

Micromixer — Batch Version: Application Library path: **COMSOL_Multiphysics/Cluster_and_Batch_Tutorials/micromixer_batch**

BATCH SETTINGS

You can specify the batch filename in the **Filename** field on the **Computing** > **Cluster** page in the **Preferences** window if you have selected the **Specify batch filename** checkbox on the same page first. If that checkbox is not selected, the batch filename is taken from the model filename. If you want to use another name, select the checkbox next to the **Filename** field and then specify the filename for the file in which to store the model in the **Filename** field. The directory in which to store the model is the one in the **Batch directory** field, which is also on the **Computing** > **Cluster** page in the **Preferences** window.

Select the **Generate solver sequence in external process** checkbox to delay the generation of the solver sequence (for example, to avoid expensive mesh generation on the desktop before submitting the batch job).

If you are connected to a COMSOL Multiphysics server on another computer, you can control the working directory used by the COMSOL Multiphysics server if you select the **Specify server directory path** checkbox and enter the path to the server **Directory** or **Browse** for the path. Otherwise, a temporary directory on the COMSOL Multiphysics server is used to save files.

STUDY EXTENSIONS

Select the **Use graphics** checkbox when the batch process should run results nodes that create graphical contents such as exporting to file.

Enter the **Number of simultaneous jobs**. The default is 1. This value is the maximum number of batch processes that are allowed to run simultaneously.

Enter the **Number of job restarts**. The default is 0. This value is the maximum number of times the job can be restarted if it fails to complete, so you need to increase it to make the batch process restart the job.

Enter a value for the **Alive time (seconds)**. The default is 300 seconds. This is the longest time the process is allowed to run before it must inform that it is still running. Failure to do so means that the process is considered dead, and a new process is started if the maximum number of job restarts is not reached. The new job is restarted, and data from the previous job run is treated as invalid.

Batch Sweep

To enable this option in the context menu, click the **Show More Options** button ( ) and select **Batch** or **Batch and Cluster** (if your license includes cluster computing) in the **Show More Options** dialog.

Use the **Batch Sweep** ( ) study to find the solution to a sequence of stationary or time-dependent simulations that arise when you vary some parameters of interest. See Batch and Batch Sweep for information about situations where a batch sweep is useful. If you want to make a full multiparameter sweep (solving first for the first value of the first parameter combined with all values of the second parameter, then for the second value of the first parameter combined with all values of the second parameter, and so on), you can add several Parametric Sweep nodes, one for each additional parameter except the outermost parameter. COMSOL Multiphysics then treats the parametric sweeps as a "nested for-loop" and indicates the nested structure using indentations of the **Parametric Sweep** node names. See also Batch Sweeps vs. Cluster Sweeps.

The Batch Sweep is always the outermost sweep. It starts multiple COMSOL Multiphysics batch processes — one for each parameter set in the Batch Sweep node — that solve the current study on your computer given the parameter set.

Once the filename and directory are set, right-click the parent **Study** node and choose **Compute** to start the COMSOL Multiphysics batch processes that compute the current study.

When the batch sweep process starts, the COMSOL Desktop follows the progress in The External Process Window. When the process finishes (or you click the **Detach Job** button to no longer follow the process), an External Process node, one for each parameter, is added under a Batch Data node as in Figure 20-5. The External Process node represents the current running process.

If you click **Detach Job**, the **Batch Sweep** then no longer synchronizes the solutions and accumulated probe table. To reenable the synchronization, use the **Attach Job** button in the **Batch Data** node.

You cannot create another Batch, Batch Sweep, Cluster Sweep, or Cluster Computing in the same study at the same time.

STUDY SETTINGS

The batch sweep is a multiparameter sweep with its parameters solved as a batch job; see Parametric Sweep for more information.

OUTPUT WHILE SOLVING

Use the **Probes** list to select probes to update during the batch sweep. The default is **All**, which selects all probes for plotting and tabulation of probe data. Select **Manual** to open a list with all available probes. Use the **Move Up** ( ),

Move Down (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the probes that you want to see results from while solving. Select **None** to disable probe updating for batch sweep.

Select the **Accumulated probe table** checkbox to activate the accumulation of probe updates for both the variation on the solver level (time, frequency, and so on) and on the batch sweep level. Use the **Output table** to select where to put the data. Select the **Use all probes** checkbox if all the model probes should be accumulated in the table. If not selected, the probes selected from the **Probes** list are used.

No plots are generated automatically from the accumulated probe tables. When a full variation has been accumulated, then the **Format: Filled** is available for the table (see the **Settings** window for **Table**). This format makes it possible to make response surfaces directly from the **Results** view toolbar **Surface Plot** button.

BATCH SETTINGS

You can specify the batch filename in the **Filename** field on the **Computing** > **Cluster** page in the **Preferences** window if you have selected the **Specify batch filename** checkbox on the same page first. If that checkbox is not selected, the batch filename is taken from the model filename. If you want to use another name, select the checkbox next to the **Filename** field and then specify the filename for the file in which to store the model in the **Filename** field. The directory in which to store the model is the one in the **Batch directory** field, which is also on the **Computing** > **Cluster** page in the **Preferences** window.

Select the **Generate solver sequence in external process** checkbox to delay the generation of the solver sequence (for example, to avoid expensive mesh generation on the desktop before submitting the batch job).

From the **Add parameters to filename** list, choose **Parameter name and value** (the default), or choose **Index**, which instead of parameter names and parameter values uses an index scheme `iX`, `iY`, …, where same indices relate to the same parameter value. This option gives much shorter filenames.

Select the **Specify server directory path** checkbox if you have a floating network license and want to perform this computation using an installation at a remote location. Then specify the directory path in the **Directory** field by typing it directly or clicking the **Browse** button ( ) to choose a directory.

Before Sweep

Select the **Clear meshes** checkbox to clear the meshes before running the batch sweep. The default is to clear the meshes. Select the **Clear solutions** checkbox to clear the solutions before running the batch sweep. The default is to clear the solutions. These settings are only important if you run a remote computation on a cluster or cloud and want to minimize the size of the file transferred over the network (only available with a floating network license).

During Sweep

Select the **Synchronize solutions** checkbox to synchronize the solutions computed by the batch processes with the model. This allows additional postprocessing after the sweep has finished. The default is to disable solution synchronization. If desired, and the **Synchronize solutions** checkbox is selected, select the **Clear synchronization data** checkbox to clear synchronization files left by batch jobs. Log files, .status, .recovery, and batch job MPH-files are not removed. To save the model to file before removing all synchronization data, select the **Save model to file after synchronization is completed** checkbox. The filename is the same as the one used for making a backup.

When the **Synchronize solutions** checkbox is selected for some models, the batch sweep stores a large number of files in the directory specified under **Cluster computer settings**. Those files are needed for the synchronization of the solutions.

After Sweep

Select the **Output model to file** checkbox to enable that all batch processes save the models to file. Selecting this checkbox ensures that the MPH-files that are automatically saved contain the solution (for each parameter). In most cases, the solution synchronization and probe synchronization functionality should be used instead because otherwise the data ends up in one file for each process and cannot be postprocessed efficiently.

ADVANCED SETTINGS

Select the **Use graphics** checkbox when the batch process should run results nodes that create graphical contents such as exporting to file. Enter the **Number of simultaneous jobs**. The default is 1. This is the maximum number of batch processes that are allowed to run simultaneously. Enter the **Number of job restarts**. The default is 0. This is the maximum number of times the job can be restarted if it fails to complete. Enter a value for the **Alive time (seconds)**. The default is 300 seconds. This is the longest time the process is allowed to run before it must inform that it is still running. Failure to do so means that the process is considered dead, and a new process is started if the maximum number of job restarts is not reached.

Bidirectionally Coupled Particle Tracing

The **Bidirectionally Coupled Particle Tracing** study ( ) is used to model the interactions of particle trajectories with stationary fields. The study creates a Time-Dependent Solver that solves for all degrees of freedom related to the particles. All other degrees of freedom are computed using a Stationary Solver. The two solvers are repeated using a For-End For loop so that a self-consistent solution is obtained, taking the bidirectional coupling between the moving particles and stationary fields into account.

See the Time Dependent study step and Common Study Step Settings for information about the following sections: **Study Settings**, **Results While Solving**, **Physics and Variables Selection**, **Values of Dependent Variables**, **Mesh Selection**, and **Study Extensions**.

ITERATIONS

Select an option from the **Termination method** list: **Fixed number of iterations** (the default) or **Convergence of global variable**. For **Fixed number of iterations** enter a positive integer for the **Number of iterations** (default 5). Any nodes between this **For** node and the following **End For** node will be repeated a number of times equal to the specified **Number of iterations**.

For **Convergence of global variable** enter the following:

- **Global variable** (default 1)
- **Relative tolerance** (default 0.001)
- **Relative tolerance threshold** (default 1)
- **Maximum number of iterations** (positive integer, default 25)
- **Minimum number of iterations** (positive integer, default 1)

This default solve sequence generated by this study step includes a loop containing the For and End For nodes. The options in this section correspond to the **General** section of the settings window for the **For** node.

USING THE BIDIRECTIONALLY COUPLED PARTICLE TRACING STUDY STEP

In electromagnetics, this study step is used to model particle beams at constant current that are affected significantly by self-fields. In other words, the charge density and current density of the charged particle beam are significantly large enough that they contribute to the electric and magnetic fields in the surrounding domain enough to noticeably perturb the particle trajectories. When tracing particles in a fluid, this study step is used to model the effects of the drag force exerted on the particles and the corresponding body load exerted on the fluid by the particles. This study is available with the Particle Tracing Module.

Bidirectionally Coupled Ray Tracing

The **Bidirectionally Coupled Ray Tracing** study ( ) is used to compute ray trajectories that are affected by external fields. This study solves for all degrees of freedom related to rays using a Time-Dependent Solver. All other degrees of freedom are computed using a Stationary Solver. The two solvers are repeated using a For-End For loop so that a self-consistent solution is obtained, taking the bidirectional coupling between the propagating rays and stationary fields into account.

See the Ray Tracing study step and Common Study Step Settings for information about the following sections: **Study Settings**, **Results While Solving**, **Physics and Variables Selection**, **Values of Dependent Variables**, **Mesh Selection**, and **Study Extensions**. See Bidirectionally Coupled Particle Tracing for information about the **Iterations** section.

USING THE BIDIRECTIONALLY COUPLED RAY TRACING STUDY STEP

The study can be used to model thermal lensing effects, in which heat generated by the attenuation of rays in an absorbing medium changes the shape and refractive index of the domain. The changes to refractive index and shape, in turn, affect the ray trajectories. This study is available with the Ray Optics Module.

Cluster Computing

To enable this option in the context menu, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

Use the **Cluster Computing** ( ) study when you want to submit COMSOL Multiphysics batch jobs to a job scheduler that in turn runs the batch job on a second computer or cluster. For more information, see Cluster Computing (Job Configurations) and its related functionality. Also see Figure 20-5.

Use Cluster Computing to utilize a cluster or cloud to solve a single large model using distributed memory. For maximum performance, the COMSOL cluster implementation can utilize shared-memory multicore processing on each node in combination with the Message Passing Interface (MPI) based distributed memory model. This brings a major performance boost by making the most out of the computational power available.

Cluster Computing is also intended as an interface for setting up distributed COMSOL Multiphysics batch jobs on the computer where the COMSOL Desktop is running. If you are running in distributed mode by starting the COMSOL Desktop with a distributed computing command (for example, `comsol -nn 4 -f hostfile`), the **Cluster Computing** node is not needed.

Once you have specified the settings, click **Compute** to start a COMSOL process that solves the current study.

When the cluster computing process starts, the COMSOL Desktop follows the progress in The External Process Window. When the process finishes (or you click the **Detach Job** button to no longer follow the process), an External Process node is selected that represents the current running process. If you are running COMSOL Multiphysics in distributed mode, the model runs in the current process. In this case it is recommended that you do not create a **Cluster Computing** study step.

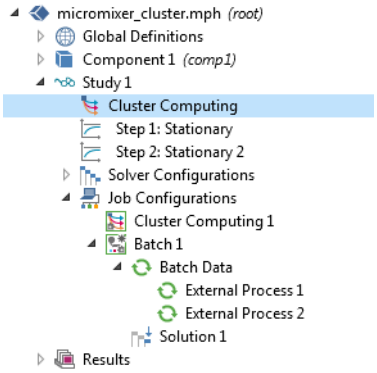

Figure 20-6: An example of the two kinds of Cluster Computing nodes available under Study and Job Configurations.

	Micromixer — Cluster Version: Application Library path: **COMSOL_Multiphysics/Cluster_and_Batch_Tutorials/micromixer_cluster**

	You cannot create another Batch, Batch Sweep, Cluster Sweep, or Cluster Computing in the same study at the same time.

BATCH SETTINGS

	After making these settings, click the **Save as Default** ( ) button in the **Settings** window toolbar to save the current directory settings as the default preference.

You can specify the batch filename in the **Filename** field on the **Computing** > **Cluster** page in the **Preferences** window if you have selected the **Specify batch filename** checkbox on the same page first. If that checkbox is not selected, the batch filename is taken from the model filename. If you want to use another name, select the checkbox next to the **Filename** field and then specify the filename for the file in which to store the model in the **Filename** field. The directory in which to store the model is the one in the **Batch directory** field, which is also on the **Computing** > **Cluster** page in the **Preferences** window.

Select the **Generate solver sequence in external process** checkbox to delay the generation of the solver sequence (for example, to avoid expensive mesh generation on the desktop before submitting the batch job).

Enter the **Number of nodes** (physical nodes) to use for this job (the default is 1 node).

Select the **Use batch license** checkbox to run using batch licenses. Batch licenses can be used to run multiple batch jobs for different models that only depend on a parameter. Usually you should use the **Cluster Sweep** node. This option makes it possible submit a single batch job from the COMSOL Desktop and continue working there while the cluster job is computing on another computer or cluster in the background — this approach works with a license for one concurrent user.

Before Sweep

Under **Before sweep**, select the **Clear meshes** checkbox to clear the meshes before running the batch sweep. Also, select the **Clear solutions** checkbox to clear the solutions before running the batch sweep.

During Sweep

Under **During sweep**, select the **Synchronize solutions** checkbox to synchronize the solutions computed by the batch processes with the model. This allows additional postprocessing after the sweep has finished. The default is to

disable solution synchronization. If desired, and the **Synchronize solutions** checkbox is selected, select the **Clear synchronization data** checkbox to clear synchronization files left by batch jobs. Log files, .status, .recovery, and batch job MPH-files are not removed. To save the model to file before removing all synchronization data, select the **Save model to file after synchronization is completed** checkbox. The filename is the same as the one used for making a backup.

After Sweep

Under **After sweep**, select the **Output model to file** checkbox to enable that all batch processes save the models to file. Selecting this checkbox ensures that the MPH-files that are automatically saved contain the solution (for each parameter). In most cases, the solution synchronization and probe synchronization functionality should be used instead because otherwise the data ends up in one file for each process and cannot be postprocessed efficiently.

Cluster Computing Settings

From the **Settings** list, choose **Preference controlled** (the default) to use settings from the **Cluster computing** part of the **Multicore and Cluster Computing** page in the **Preferences** window. Choose **User controlled** to enter the following cluster computing settings:

Choose the **Scheduler type**: **General** (the default), **Microsoft® HPC Pack**, **OGS/GE**, **SLURM**, **PBS**, **IBM LSF®**, or **Not distributed**.

General

Select **General** (the default) to configure to run on many types of clusters and schedulers, including Linux clusters.

- The entry in the **Host file** field specifies the host file used for the job. If left empty, MPD looks for a file `mpd.hosts` in the Linux home directory.
- Select which bootstrap server MPI should use in the **Bootstrap server** setting.
- Enter details for the Directory Settings for All Cluster Types.

Microsoft HPC Pack

Select **Microsoft® HPC Pack** to use the Microsoft HPC Pack job scheduler to submit the batch job.

Requirements for using the Microsoft HPC Pack is that COMSOL supports the underlying Windows versions and that the underlying Windows version is supported by Microsoft HPC Pack.

When **Microsoft® HPC Pack** is selected:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`, and it should only be changed if you submit your job from a different computer than the head node.
- The entry in the **User** field is the user account that COMSOL Multiphysics uses for submitting the job. You provide the password in a separate command window that opens at execution time with the possibility to save the credentials.
- Enter details for the Directory Settings for All Cluster Types.

OGS/GE

Select **OGS/GE** to use the open grid scheduler/grid engine job scheduler to submit the batch job. When **OGS/GE** is selected:

- Select which bootstrap server should be used by MPI using the **Bootstrap server** setting.
- Specify the name of the scheduler queue in **Queue name**.
- Enter the **Queue name** for the cluster queue.
- Enter details for the Directory Settings for All Cluster Types.

SLURM

Select **SLURM** to use the SLURM job scheduler to submit the batch job. When **SLURM** is selected:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`, and it should only be changed if you submit your job from a different computer than the head node.
- The entry in the **User** field is the user account that the COMSOL Multiphysics software uses for submitting the job.
- Enter the **Queue name** for the cluster queue.
- Enter details for the Directory Settings for All Cluster Types.

PBS

Select **PBS** to use a PBS-based (Portable Batch System) job scheduler to submit the batch job. When **PBS** is selected:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`, and it should only be changed if you submit your job from a different computer than the head node.
- The entry in the **User** field is the user account that the COMSOL Multiphysics software uses for submitting the job.
- Enter the **Queue name** for the cluster queue.
- Enter details for the Directory Settings for All Cluster Types.

IBM LSF®

Select **IBM LSF®** to use an IBM LSF®-based (IBM® Platform Load Sharing Facility) job scheduler to submit the batch job. When **IBM LSF®** is selected:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`, and it should only be changed if you submit your job from a different computer than the head node.
- The entry in the **User** field is the user account that the COMSOL Multiphysics software uses for submitting the job.

Enter details for the Directory Settings for All Cluster Types.

Not Distributed

Select **Not distributed** when you want to run a batch job rather than using distributed computing. Enter details for the Directory Settings for All Cluster Types.

Directory Settings for All Cluster Types

- If you are connected to a COMSOL Multiphysics server on another computer, you can control the working directory used by the COMSOL Multiphysics server if you select the **Specify server directory path** checkbox and enter the path to the server **Directory** or **Browse** for the path to the mounted file system directory where the cluster job result file will be saved. This should be a fully qualified UNC path — for example, `\\head1\shared`. Otherwise, a temporary directory on the COMSOL Multiphysics server is used to save files. The server directory path refers to the location where the COMSOL Multiphysics server reads and writes the corresponding data (assuming a client/server configuration).
- If the batch job has another path to the directory, select the **Specify external COMSOL batch directory path** checkbox and enter the path to the external process (batch) directory in the **Directory** field or click **Browse**. The cluster job uses this path from the compute node to access the input file and write back the result. On Windows

this must be a fully qualified UNC path, for example, `\\head1\shared\clusterprojects`. The external COMSOL batch directory path refers to the location where the batch process reads and writes the data.

- If the COMSOL software is installed in a directory other than where the COMSOL Desktop runs, select the **Specify external COMSOL installation directory path** checkbox and then specify the installation directory (click **Browse** or enter the path to the **Directory**). This can occur if you are submitting jobs to a job scheduler. Typically on Windows this is the UNC path to the COMSOL installation root directory for the compute nodes to access the required COMSOL binaries — for example, `\\head1\shared\COMSOL63`.

See How to Specify Directory Paths for Batch Jobs and Cluster Jobs for some examples of which paths to specify for some common cluster or batch job configurations.

Additional Batch Settings

Enter the **Number of job restarts**. The default is 0. This is the maximum number of times the job can be restarted if it fails to complete.

Enter a value for the **Alive time (seconds)**. The default is 300 seconds. This is the longest time the process is allowed to run before it must inform that it is still running. Failure to do so means that the process is considered dead, and a new process is started unless the maximum number of job restarts is reached.

CLUSTER SETTINGS

If you are running a parametric sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric sweep** checkbox. This requires that your study includes a parametric sweep. In the **Parametric Sweep** node's **Settings** window, you must also select the **Distribute parametric sweep** checkbox in the **Advanced Settings** section.

REMOTE AND CLOUD ACCESS

This settings can be specified here or in the **Preferences** window, on the **Remote Computing** page. From the **Settings** list under **Remote computing settings**, choose **User controlled** to specify the remote computing settings in this section., or choose **Preferences controlled** to use the remote computing settings in the **Preferences** window. The remote computing settings are the same in both places.

Enable the **Run remote** checkbox if you want to run COMSOL Multiphysics on a remote machine using a remote start command such as SSH and using a file transfer program such as SCP to transfer the files to and from the remote computer. This allows you to run on a machine installed on your network without a client/server connection or on a machine installed on a remote cloud. Then specify the settings described below.

COMSOL Multiphysics must be installed on the remote machine and all settings must be specified correctly in the **Specify external COMSOL batch directory path** and **Specify external COMSOL installation directory path** settings according to how COMSOL Multiphysics is installed on the remote machine and the remote machines working directories.

You must also be able to access the remote machine without a password using the access method selected. This can be achieved by using something that does not require a password, for example, SSH or similar.

Remote Invoke Command

Choose the method for starting COMSOL Multiphysics remotely from the **Remote invoke command** list. You can choose **None**, **SSH**, **Write command to file**, **MPI**, or **User** defined.

For the **SSH** method you can choose between using **SSH**, **Putty**, or a **User** defined SSH command. You can select the SSH commands installation directory in the SSH directory if the SSH command is not available on the PATH. The SSH key file directory is set in the **SSH key file** setting. You can set ports you want to forward in **Forward ports** and

the host you want to forward the ports to in **Port host**. This is useful when you have the license manager installed locally, but the machine where COMSOL Multiphysics is running cannot access the license manager; for instance, if the machine is in the cloud. Specify the user name to use on the remote machine with SSH user.

The **Write command to file** method writes all batch command to a file that you specify in the **File with command line** field. This file can then be used to run the command on another computer.

The **MPI** method uses MPI to launch COMSOL batch jobs on the hosts listed in the **Remote hosts** table or file. On Windows, you want to launch `smpd` on the hosts (see Using Microsoft MPI and SMPD on Standalone Computers).

For the **User**-defined **Remote invoke command**, you can enter a command in the **Command** setting. In the **Command** setting, any use of the keyword `{remotehost}` is replaced by the name of the remote host when COMSOL Multiphysics starts.

File Transfer Command

Choose the method for transferring files to the remote computer in **File transfer command**. You can choose **None**, **SCP**, **File list** or **User** defined.

For the **SCP** method, you can choose between using **SCP**, **Putty**, or a **User** defined SCP command. You can select the SCP commands installation directory in **SCP directory** if the SCP command is not available on the PATH. The SCP key file directory is set in the **SCP key file** setting. Specify the user name to use on the remote machine with SCP user.

The **File list** method stores a list of all files that should be transferred to another computer where the batch job runs. In **File with list of files to remote**, it stores a list of all files to transfer to the other computer before running the batch job. In **File with list of files from remote**, it stores a list of all files to transfer from the other computer after the batch jobs have finished. Note that unless you detach, COMSOL Multiphysics will be waiting for the data to be transferred to that remote computer and back and then update its solutions.

For the **User**-defined **File transfer command**, you can enter a command in the **To remote command** for the transfer of files from the local computer to the remote machine and **From remote command** for the transfer of files from the remote machine to the local computer. In the settings, any use of the keyword `{remotehost}` is replaced by the name of the remote host. Any use of the keyword `{localfile}` is replaced by the name of the local file, and any use of the keyword `{remotefile}` is replaced by the name of the remote file.

Remote Hosts

From the **Remote hosts list**, select **Table** if the Remote host list should be read from the **Remote hosts** table or **File** if it should be read from a file.

In the **Remote hosts** table, list the hosts you want to run on. If several hosts are listed, COMSOL Multiphysics allocates a job on the first host that is free. The **Remote hosts file** points to a file on the server side (in a client/server configuration; otherwise, on the current computer) that contains the list of hosts to run on remotely.

Use the **Remote OS** to specify if the remote computer is running the same OS (**Native**) or is running **Linux** or **Windows**.

ADVANCED SETTINGS

Select the **Use graphics** checkbox when the batch process should run results nodes that create graphical contents such as exporting to file.

Enter the **Number of simultaneous jobs**. The default is 1. This is the maximum number of batch processes that are allowed to run simultaneously.

You can also make changes to how some of these settings are displayed throughout COMSOL Multiphysics in The Preferences Window in the **Remote Computing** and **Multicore and Cluster Computing** sections.

Running COMSOL Multiphysics in Client–Server Mode

Cluster Sweep

To enable this option in the context menu, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

Use the **Cluster Sweep** ( ) study to solve several models in parallel where each model has a different set of parameters. For example, find the solution to a sequence of stationary or time-dependent simulations that arise when you vary some parameters of interest. The cluster sweep can include multiple independent parameters directly for a full multiparameter sweep (solve for the first value of the first parameter combined with all values of the second parameter, then the second value of the first parameter combined with all values of the second parameter, and so on, or use a specified combination of parameter values).

You can also add another sweep, such as a **Material Sweep** node, to create nested parametric sweeps. The COMSOL Multiphysics software then treats the sweeps as a "nested for-loop" and indicates the nested structure using indentations of the sweep nodes' names. The Cluster Sweep is always the outermost sweep. It starts multiple COMSOL Multiphysics batch processes, one for each parameter set in the **Cluster Sweep** node, which solve the current study on your cluster given the parameter set by submitting COMSOL Multiphysics batch jobs to a job scheduler that in turn runs the batch job on a second computer or cluster.

For more information, see Cluster Computing (Job Configurations) and its related functionality. If you used a distributed computing command to launch COMSOL Desktop, you do not need to create a **Cluster Sweep** study step. See also Batch Sweeps vs. Cluster Sweeps.

You cannot create another Batch, Batch Sweep, Cluster Sweep, or Cluster Computing in the same study at the same time.

Right-click the **Study** node to add a **Cluster Sweep** study node to run batch jobs on a cluster. Once you have specified the settings, right-click the main **Study** node and select **Compute** in order to start a COMSOL Multiphysics batch process that solves the current study for the given parameter sets.

When the cluster sweep process starts, the COMSOL Desktop follows the progress in The External Process Window. When the process finishes (or you click the **Detach Job** button to no longer follow the process), an External Process node, one for each parameter, is added under a Batch Data node as in Figure 20-5. The External Process node represents the current running process.

Click the **Save as Default** button ( ) in the **Settings** window toolbar to save the current setting as default. If you are running COMSOL Multiphysics in distributed mode, the model runs in the current process.

STUDY SETTINGS

The cluster sweep is a multiparameter sweep with its parameters solved as a distributed batch job; see Parametric Sweep for more information about parameter sweeps.

OUTPUT WHILE SOLVING

This section is not available if the study also contains a Parametric Sweep.

Use the **Probes** list to select probes to update during the batch sweep. The default is **All**, which selects all probes for plotting and tabulation of probe data. Select **Manual** to open a list with all available probes. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the probes that you want to see results from while solving. Select **None** to disable probe updating for batch sweep.

Select the **Accumulated probe table** checkbox to activate the accumulation of probe updates for both the variation on the solver level (time, frequency, and so forth) and on the batch sweep level. Use the **Output table** to select where to put the data. Select the **Use all probes** checkbox if all the model probes should be accumulated in the table. If not checked, the probes selected from the **Probes** list are used.

No plots are generated automatically from the accumulated probe tables. When a full variation has been accumulated, then the **Format: Filled** is available for the table (see the **Settings** window for **Table**). This format makes it possible to make response surfaces directly from the **Results** view toolbar **Surface Plot** button.

BATCH SETTINGS

Except for the information below, see Batch Settings (for the Cluster Computing node) for details.

Before Sweep

Under **Before sweep**, the **Clear meshes** checkbox is selected by default to clear the meshes before running the batch sweep. The **Clear solutions** checkbox is selected by default to clear the solutions before running the batch sweep. Click to clear one or both of the checkboxes as needed.

During Sweep

Under **During sweep**, select the **Synchronize solutions** checkbox to synchronize the solutions computed by the batch processes with the model. This allows additional postprocessing after the sweep has finished. The default is to disable solution synchronization. If desired, and the **Synchronize solutions** checkbox is selected, select the **Clear synchronization data** checkbox to clear synchronization files left by batch jobs. Log files, .status, .recovery, and batch job MPH-files are not removed. To save the model to file before removing all synchronization data, select the **Save model to file after synchronization is completed** checkbox. The filename is the same as the one used for making a backup.

After Sweep

Under **After sweep**, select the **Output model to file** checkbox to enable that all batch processes save the models to file. Selecting this checkbox ensures that the MPH-files that are automatically saved contain the solution (for each parameter). In most cases, the solution synchronization and probe synchronization functionality should be used instead because otherwise the data ends up in one file for each process and cannot be postprocessed efficiently.

Cluster Computing Settings

Under **Cluster computing settings**, from the **Settings** list, choose **Preferences controlled** (the default) to use the settings from the **Preferences** window, or choose **User controlled** to use the settings below. See Cluster Computing (Job Configurations) for more information.

REMOTE AND CLOUD ACCESS

See Remote and Cloud Access described for Cluster Computing.

ADVANCED SETTINGS

See Advanced Settings described for Cluster Computing.

Function Sweep

The **Function Sweep** (f(x)) study step is a special case of Parametric Sweep study step, where the solver sweeps over functions defined under a **Switch** node defined under **Global Definitions** > **Functions** (see Function Switch). After running a function sweep, you can select from the swept functions from a **Switch** list in the **Data** section of plot nodes to, for example, postprocess and visualize the function sweep.

STUDY SETTINGS

Add information to the table for each column: **Switch**, **Cases**, and **Case numbers**. Use the **Move Up** (↑), **Move Down** (↓), **Add** (+), and **Delete** ( ) buttons under the table to organize the data. Use the **Add** (+) button to add a list of existing function **Switch** nodes in the **Switch** column. From the list under **Cases**, select **All** to sweep over all function nodes under the switch. For **User defined**, define a list of functions to switch between as positive integers, representing the first function from the top under the **Switch** node as 1, the second function as 2, and so on.

ADVANCED SETTINGS

See Parametric Sweep for these settings.

Material Sweep

The **Material Sweep** ( ) study step is a special case of Parametric Sweep, where the solver sweeps over materials defined under a **Switch** node defined under **Global Definitions** > **Materials** (see Switch for Materials). After running a material sweep, you can select from the swept materials from a **Switch** list in the **Data** section of plot nodes, for example, to postprocess and visualize the material sweep (solutions for the different materials that the sweep includes).

STUDY SETTINGS

Add information to the table for each column: **Switch**, **Cases**, and **Case numbers**. Use the **Move Up** (↑), **Move Down** (↓), **Add** (+), and **Delete** ( ) buttons under the table to organize the data. Use the **Add** (+) button to add a list of existing material **Switch** nodes in the **Switch** column. From the list under **Cases**, select **All** to sweep over all material nodes under the switch. For **User defined**, define a list of materials to switch between as positive integers, representing the first material from the top under the **Switch** node as 1, the second function as 2, and so on.

ADVANCED SETTINGS

See Parametric Sweep for these settings.

Modal Reduced-Order Model

The **Modal Reduced-Order Model** ( ) study step is used for exporting reduced-order model matrices.

You can add a Modal Reduced-Order Model study step for exporting the reduced-order model matrices after an Eigenfrequency study step for computing the eigenfrequencies and eigenmodes of a linear or linearized model in the frequency domain.

A Modal Reduced-Order Model study step uses the Modal Solver. It uses the transient equation form for the export. The matrices can be accessed through the COMSOL Multiphysics API or in table format from a System Matrix derived value.

The **Modal Reduced-Order Model** is a legacy feature. You are advised to use the Frequency Domain, Modal Reduced-Order Model or Time Dependent, Modal Reduced-Order Model studies to obtain matrices for reduced models.

Multigrid Level

To enable this option in the context menu, click the **Show More Options** button ( ) and select **Multigrid Level** in the **Show More Options** dialog. Then right-click any of the **Study Step** nodes to add a **Multigrid Level** ( ) node, which specifies the geometric multigrid (GMG) level used by the study. Multigrid levels are only used with the GMG solver, and you can set up a manual multigrid mesh hierarchy using **Multigrid Level** nodes when you want to control what the GMG solver is using and if you want to deviate from the automatic multigrid mechanisms. One such case is when the coarser (or finer) meshes generated are not of good enough quality. You can then use user-defined meshes in the multigrid mesh hierarchy. See Multigrid and The Geometric Multigrid Solver with Several Meshes for more information.

PHYSICS SELECTION

Select a **Physics interface**. In the **Discretization** list, you can specify which discretization to use (defined in the main physics interface's **Settings** window or in any added **Discretization** node; see Discretization (Node)). Changing the discretization can affect the discretization order used by this study. You have to add the discretization you want to use in the physics interface.

MESH SELECTION

Select a mesh to use for each geometry in the study. First select the **Geometry** from the list and then select the **Mesh** from the list.

Model Reduction

Use a **Model Reduction** study node ( ) to create a reduced-order model (ROM) based on a time-dependent or frequency-domain simulation (see Reduced-Order Modeling). Reduced-order models are usually thought of as computationally inexpensive mathematical representations that provide the ability to run faster simulations using a small model that captures the dynamic behavior of the original model.

The creation of a reduced-order model can typically be divided into two steps: production of training data and model building. The resulting model can then be used for repeated simulations. When using the Modal method, the training data consists of solution vectors computed by some other study step or study steps. If these study steps are located in a different source study, then the Model Reduction study step assumes that the source study has been computed and that updated solution vectors can be found at the position corresponding to the training study step in an enabled solver configuration. When the training study steps are part of the same study sequence — that is, precede the Model Reduction step — the training data will be automatically recomputed each time the reduced-order model is rebuilt.

To add a **Model Reduction** node, first select **Reduced-Order Modeling** in the **Show More Options** dialog.

There can only be one **Model Reduction** node in a study. When you copy a **Model Reduction** node, it is possible to paste it into another study without a **Model Reduction** node.

The following steps are the main steps needed to set up a model reduction study:

1. Select the model reduction method to apply: **Modal** (the default), **AWE**, or **POD**.
2. For the Modal method only, select the training data. You must specify a study and study step providing eigenmodes. Constraint modes are not always needed but can be specified in the same way.
3. Select the unreduced (source) model (a study and study step reference).
4. Select to create or update an instance of the reduced model under **Global Definitions** > **Reduced-Order Modeling**.
5. For the Modal or POD method only, specify if the reduced model should be capable of reconstruction.
6. For the Modal or POD method only, define reduced-model control inputs under **Model Control Inputs**.
7. Define reduced-model outputs (similar to multiple objective functions). For the AWE method at least one of the outputs must be selected for use as quality indicator during the adaptive generation of the asymptotic waveform expansion.

Click the **Compute** button (=) (or press F8) at the top of the **Settings** window to produce an instance of the reduced-order model under **Global Definitions** > **Reduced-Order Modeling**.

The **Settings** window contains the following sections:

MODEL REDUCTION SETTINGS

In this section, you specify how to run the model reduction.

Model-Reduction Method

From the **Method** list, choose one of the following model-reduction methods:

- The **Modal** method (the default) supports inputs and outputs and makes it possible to export ROM matrices.
- The **AWE** (asymptotic waveform evaluation) method is an alternative reduced-order model that provides a fast frequency sweep (an advanced interpolation) and supports outputs only.
- The **POD** (proper orthogonal decomposition) method is another projection-based method that projects an original full-order problem to a low-dimensional space spanned by POD modes obtained through performing singular value decomposition on training solutions and constraint modes.

Common Settings

From the **Unreduced model study** list, choose a study that contains at least one study step of a type that can be reduced using the selected model-reduction method, or the parent study of the current Model Reduction node. When another study is selected, select an applicable study step from the **Defined by study step** list. When you have chosen **POD**, also specify a specific solution to use from the **Solution selection** list.

Settings for the Modal Method

From the **Training study for eigenmodes** list, choose an existing study whose solution can be used as eigenmodes. If you choose **None**, no eigenmode is selected. The solution from any eigenvalue type of study can be used as eigenmodes.

From the **Study step for eigenmodes** list, choose **Automatic** (the default) to use the last applicable solution in the solver sequence, or select any of the applicable study steps (such as **Eigenvalue**).

Settings for the Modal Method and POD Method

From the **Training study for constraint modes** list, choose an existing study whose solution can be used as constraint modes. If you choose **None** (the default), no constraint mode is selected.

From the **Study step for constraint modes** list, choose **Automatic** (the default) to use the last applicable solution in the solver sequence, or select any of the applicable study steps (such as **Stationary**).

Constraint modes are introduced mainly to handle the constraints that are controlled by inputs in the **Global Reduced-Model Inputs** node in the unreduced problem. There are two different ways to generate the constraint modes. One is via **Auxiliary sweep** settings in the **Study Extensions** section of a **Stationary** study step. First, define the same number of training parameters as the number of inputs that are used by constraints like Dirichlet boundary conditions in the unreduced problem. Training parameters are defined under **Global Definitions** > **Parameters**. Then, for each Dirichlet boundary condition defined by the inputs, define another Dirichlet boundary condition using the training parameter and enable those training boundary conditions in the stationary study. Last, in the auxiliary sweep of the stationary study, set one training parameter to be 1 at a time and set all other training parameters to be zero. The resulting parametric solutions can be used as constraint modes candidates. The other method is via a sensitivity solution. For this method, defining training parameters and training boundary conditions are not needed. Rather, you create a **Sensitivity** interface on top of the stationary study step and then add the control input in the **Parameter name** column in the **Control Variables and Parameters** table in the **Sensitivity** interface. The generated sensitivity solution with respect to each control variable can be used as a candidate for constraint modes.

If the parent study is selected, the unreduced model study step is expected to be a subnode to the Model Reduction node. Right-click the Model Reduction node and add either a **Frequency Domain** or a **Time Dependent** study step from its context menu. Then select it from the **Defined by study step** list.

From the **Reduced-order model** list, choose **New** to create a new reduced-order model, or choose any existing and compatible reduced-order model (available under **Global Definitions** > **Reduced-Order Modeling**).

If the model-reduction method is **Modal** or **POD**, the **Ensure reconstruction capability** checkbox is selected by default to enable reconstruction of the unreduced solution vector also when there are only linear outputs defined. Clear it if you need to save memory; for the ROM to be capable of reconstruction, the modal basis must be stored.

During the online use case, the reduced-order model can then assign reconstructed values to some of the dependent variables not solved for. To do so, go to the **Physics and Variables Selection** section in the destination study that uses a reduced-order model. If the **Modify model configuration for study step** checkbox is not selected, there is a table with **Reconstruction** and **Reduced-order model** columns. There is a row for each physics interface that is not solved whose dependent variables can be reconstructed by at least one reduced-order model. The **Reconstruction** column shows the physics interface name. The list in the **Reduced-order model** column determines which reduced-order model (if any) should be asked to reconstruct the fields for this physics interface. If the **Modify model configuration for study step** checkbox is selected, there is no such table; instead, there is a **Reconstruction** field where you can choose the reduced-order model.

The **Use extra Compile Equations for Results** checkbox is selected by default. This setting controls whether an extra, active **Compile Equations** node will be added last in the default solver sequence. The extra **Compile Equations** step is equivalent to an **Update Solution** call for the unreduced model study step. Most importantly, it includes the newly created reduced-order model feature in the final solution output by the study so that the reduced-order model's outputs can be evaluated directly using this solution. The extra **Compile Equation** node is not necessary when the reduced-order model will only be called from some other study. In particular, when multiple reduced-order models are created in a sweep, it can be removed to save computation time.

For the **POD** method, the value in the **Relative tolerance for truncations** field is used to determine the number of POD modes so that the relative error of approximating a training solution with POD modes is within the specified threshold (default value: 0.01).

MODEL CONTROL INPUTS

In this section, you define the model control inputs when you use the **Modal** method or **POD** method. The **Model Control Inputs** table consists of three columns: **Reduced-model input**, **Use**, and **Training expression**. The **Reduced-model**

input column shows all the variables defined in the **Global Reduced-Model Inputs** node under **Global Definitions**. When the variable is added to the **Global Reduced-Model Inputs** it is automatically added to the **Model Control Inputs** table. The **Use** column controls which of the defined variables that should be used. In the **Training expression** column, enter a training expression around which the model reduction will linearize the model. Note that the training expression value is not passed on to the training study steps: if their solution depends on reduced-order model input variables, they have to be recomputed manually when changing the training value. Also note that it is important to give the training expression (possibly time dependent) whose initial values and initial time derivatives are consistent with the usage of the inputs in constraints (in its online form).

After running the **Model Reduction** study, those control inputs show up in the **Model Control Inputs** table in the generated reduced-order model node.

OUTPUTS

In the **Outputs** section, add outputs for the reduced-order model. You can add output variables by clicking the **Add Expression** (+) and **Replace Expression** ( ) buttons to search through a list of predefined expressions. The **Outputs** table consists of three columns: **Variable**, **Expression**, and **Description**. The **Variable** column defines all output variable names. The **Expression** column provides definitions for the variables. The **Description** column contains descriptions for the variables. After running the **Model Reduction** study, those output variables show up in the **Outputs** section in the generated reduced-order model node.

Settings for the POD Method

This method has some settings common with the **Modal** method. The common settings include the following: **Unreduced model study**, **Defined by study step**, **Training study for constraint modes**, **Study step for constraint modes**, **Reduced-order model**, **Ensure reconstruction capability**, and **Use extra Compile Equations for Results**. See Settings for the Modal Method for a detailed explanation.

From the **Solution selection** list, choose a solution for POD modes training.

The value for **Relative tolerance for truncations** is used to determine the number of POD modes so that the relative error of approximating a training solution with POD modes is within the specified threshold.

For the **Model Control Inputs and Output** section, also see Settings for the Modal Method.

Settings for the AWE Method

This method has some settings in common with the **Modal** method. The common settings include the following: **Unreduced model study**, **Defined by study step**, **Reduced-order model**, and **Use extra Compile Equations for Results**. See Settings for the Modal Method for a detailed explanation.

For the **AWE** method, reconstruction is always enabled. See the information about the **Ensure reconstruction capability** checkbox in Settings for the Modal Method for how reconstruction works.

For the **AWE** method, enter a value for the **Relative tolerance for adaptation** (default: 0.01) see the documentation for the relative tolerance in the AWE Solver.

OUTPUTS

The AWE method uses the output expressions to measure expansion accuracy during the adaptive training process. The expansion is refined until each output expression evaluates to the same value (to the specified tolerance) when computed using the left and right expansions at a number of sampling points in each interval. Clear the **Use for adaptation** column to exclude an output from the adaptation error control. Use the **Scale** column to indicate what

is a typical value of the output. An adaptation error below 0.001 times the scale is by default considered to be acceptable. This absolute tolerance can also be changed in the AWE Solver settings.

Thermal Controller, Reduced-Order Model: Application Library path **COMSOL_Multiphysics/Multiphysics/thermal_controller_rom**.

If you have the Structural Mechanics Module, see *Bracket — Reduced-Order Modeling*: Application Library path **Structural_Mechanics_Module/Tutorials/bracket_rom**.

Parametric Sweep

Use a **Parametric Sweep** ( ) study to find the solution to a sequence of stationary or time-dependent problems that arise when you vary some parameters of interest. The parametric sweep can include multiple independent parameters directly for a full multiparameter sweep (solve for the first value of the first parameter combined with all values of the second parameter, then the second value of the first parameter combined with all values of the second parameter, and so on, or use a specified combination of parameter values). You can also add more than one **Parametric Sweep** node to create nested parametric sweeps. The inner sweep in a nested parametric sweep can also be another type of sweep, such as a sweep over materials by adding a **Material Sweep** node below the **Parametric Sweep** node. The program then treats the parametric sweeps as a "nested for-loop" and indicates the nested structure using indentations of the sweep nodes' names.

See Table Surface for information about how to plot the variation of some quantity as a function of two parameters as a 2D surface plot where you vary two parameters and fix the others.

It is only possible to use one Sensitivity or Optimization study step feature in any study, unless there is an **Optimization** study step, in which case you can combine the **Optimization** study step with one or more **Parametric Sweep** study steps; however, you cannot have an **Optimization** study step over a **Parametric Sweep** study step, if a gradient-based method is used. You can use several **Parametric Sweep** nodes if desired, but they cannot be combined with the other study step types.

The **Settings** window has the following sections:

STUDY SETTINGS

Use the **Sweep type** list to specify the type of sweep to perform. The **Specified combinations** type (the default) solves for a number of given combinations of values, while the **All combinations** type solves for all combinations of values. Using all combinations can lead to a very large number of solutions. The **Parameter switch** type makes it possible to run sweeps over selected parameter groups and associated parameter cases (see Parameters and Parameter Cases). Using the **Parameter switch** sweep type, you can run specified sweeps for all or selected parameter cases for a parameter group, and if you have more than one parameter group, you might want to compute all combinations of these groups. You can do so by setting up a complete parameter list as an outer sweep with all parameter groups and their parameter cases in the parameter switch table (see below). The **Parameter switch** sweep type can also be combined with other parametric sweeps using any sweep type.

For **Specified combinations** and **All combinations**, use the table with **Parameter name**, **Parameter value list**, and (optional) **Parameter unit** to specify parameter names, values, and units for the parametric solver. Use the **Add** button (+) to add a row to the table. Each row has one parameter name, a corresponding parameter value list, and an optional unit. The unit becomes orange if the unit that you specify does not match the unit given for the parameter where it is defined. For the **Specified combinations** sweep type, the list of values must have equal length. When you click in the **Parameter value list** column to define the parameter values, you can click the **Range** button ( ) to

define a range of parameter values. The parameter unit overrides the unit of the global parameter. If no parameter unit is given, parameter values without explicit dimensions are considered dimensionless.

For **Parameter switch**, add parameters to switch by clicking the **Add** button (+) to add a **Parameters** node in the **Switch** column for which to switch its parameters. In the **Cases** column, choose the parameter cases to include. The default is **All** (also when there are no parameter cases); choose **User defined** to specify the parameter cases to include under **Case numbers**. Then, during postprocessing, you can choose from the specified case numbers in lists for the added **Parameters** nodes under the **Dataset** list in the **Data** sections for plots and data evaluations. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons as needed to rearrange the list of **Parameters** nodes for a parameter switch.

The list of parameters in the **Parameter name** column contains parameters from **Parameters** nodes where the **Show in parameter selections** checkbox is selected.

The parameter values for parametric sweeps must be real-valued values. If you want to sweep with complex-valued parameter values, instead introduce real parameters for the real and imaginary parts of a complex-valued parameter and then sweep for those parameters.

If more than one parameter name has been specified, the lists of parameter values are interpreted as follows: Assume that the parameter names are `p1` and `p2`, and that `p1` has the list 1 3 and `p2` has the list 2 4. For the **Specified combinations** sweep type, the solver first uses `p1` equal to `1` and `p2` equal to `2`. Thereafter, it uses `p1` equal to `3` and `p2` equal to `4`. And when the sweep type is **All combinations**, the solver uses the following order for the parameter combinations: 1 2, 1 4, 3 2, and 3 4.

An alternative to specifying parameter names and values directly in the table is to specify them in a text file. Use the **Load from File** button ( ) to browse to such a text file. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window. The program appends the read parameter names, values, and units to the current table. The format of the text file must be such that the parameter names appear in the first column, and the values for each parameter appear in the next columns, comma separated (`1,3,5`) or separated with a space, row-wise enclosed with quotation marks and with spaces separating the values (such as `"1 3 5"`). Finally (separated by a space), the format includes an optional unit using unit syntax such as `[m/s]`. Click the **Save to File** button ( ) to save the contents of the table to a text file (or to a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ *for* Excel®).

The loading and saving of parameter table data using Excel includes the units in the **Parameter unit** column. The unit column is ignored when saving and loading parameter data to *.txt, *.csv, and *.dat files.

You can use the **Keep solutions** list under **Memory settings for jobs** to control how to store the solutions from the individual parametric sweep solutions. Select **All** to store all the parametric sweep solutions in memory, or select **Only last** to store only the last solution from the parametric sweep. If you select **Only last** and the parametric solver is used, all solutions are kept in memory. When only the last solution is stored, you can also select the **Save each solution as model file** checkbox. It stores the separate parametric sweep solutions and their corresponding models in separate MPH-files. Enter a filename in the **Filename** field or click **Browse** to choose a name and location for the model files. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ). You can also use probes to collect some solution values of interest during the sweep rather than storing all solutions, which can save memory and solution time. These settings for keeping solutions are also available in the **Preferences**, under **Computing** > **Study Defaults**.

OUTPUT WHILE SOLVING

Select the **Plot** checkbox to allow plotting of results while solving. Then select what to plot from the **Plot group** list. The software plots the dataset of the selected plot group as soon as the results become available.

Use the **Probes** list to select probes to update during the parametric sweep. The default is **All**, which selects all probes for plotting and tabulation of probe data. Select **Manual** to open a list with all available probes. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the probes that you want to see results from while solving. Select **None** to disable probe updating for parametric sweep. Note that the control of tables and plot windows is done using the probe settings.

If a probe is selected for updates on the **Parametric Sweep** level and also in a solver (for example, a time-dependent solver), this probe is only updated by the solver and not updated at the **Parametric Sweep** level. When the probes themselves (not the probe expression) depend on model parameters, the update of such probes is only correct for parameter sweeps that are done through outer parametric sweeps (not by a parametric solver). Outer parametric sweeps are performed by a **Parametric** node under **Job Configurations**. Currently, COMSOL Multiphysics cannot automatically detect such model parameter dependencies in probes. Select **Off** from the **Use parametric solver** list in the **Study Extensions** section for the **Parametric Sweep** study node in order to get correctly updated probes in this case.

Select the **Accumulated probe table** checkbox to activate the accumulation of probe updates for both the variation on the solver level (time, frequency, and so forth) and on the parametric sweep level. Use the **Output table** to select where to put the data. Select the **Use all probes** checkbox if all the model probes should be accumulated in the table. If not selected, the probes selected from the **Probes** list are used.

No plots are generated automatically from the accumulated probe tables. When a full variation has been accumulated, then the **Format: Filled** is available for the table (see the **Settings** window for **Table**). This format makes it possible to modify the table data and make response surfaces directly from the **Results** view toolbar **Surface Plot** button.

Also, if the **Use parametric solver** setting is **Automatic** and the solver decides to use the parametric solver instead of a parametric sweep, an accumulated probe table is not created.

Settings for Reduced-Order Models

The **Keep reduced-order models** checkbox is selected by default. Then, these additional settings are available:

- From the **Add to tag** list, choose **Parameter name and value** (the default), **Index**, or **Parameter name and nonzero value** (the latter option discards all zero values).
- The **Clear previous** checkbox is selected by default to clear previous versions of the reduced-order models so that you can update all reduced-order models by running the study again.
- The **Keep the generating reduced-order models** checkbox is selected by default. If selected, the generating reduced-order models are saved in addition to the reduced-order model copies.

To make sure that each solution is saved as a Model MPH-file, select **Off** from the **Use parametric solver** list in the **Study Extensions** section (see below). With that setting, the solver uses an outer sweep instead of an inner sweep, and it is then possible to save each solution to file.

ADVANCED SETTINGS

From the **Use parametric solver** list, select one of the following options:

- **Automatic** (the default) to generate a **Parametric** job configuration, unless the problem and parameters are such that the parametric sweep can be realized through a **Stationary Solver** with a **Parametric** solver subnode ( ), which is more efficient.
- **Off** to always generate a **Parametric** job configuration.

From the **Default solver sequence generation** list, select one of the following options:

- **Using global parameters** (the default), to use parameter values from the global parameters.
- **Using first parameter tuple**, to use the first set of parameter values.
- **Using last parameter tuple**, to use the last set of parameter values.
- **Using each parameter tuple**, to use the all sets of parameter values.

From the **Default solver sequence generation** list you can control when a solver sequence should be generated during a parametric sweep (see also the settings for the Solution node under **Job Configurations**):

- Choose **Using global parameters** (the default).
- Choose **Using first parameter tuple**, **Using last parameter tuple**, or **Using each parameter tuple** to instead use the first tuple (set) of parameter values, the last tuple of parameter values, or each tuple of parameter values to control when a solver sequence should be generated.

By default, the solver sequence builds meshes based on the values of the global parameters. These meshes can then influence the generated solver sequence. In some cases, the global parameter values could lead to invalid meshes. Also, the solver sequence is, in the default case, optimized for the global parameter values, which could lead to another choice of solver than the preferred solver. Using one of the other available options in the **Default solver sequence generation** list can avoid such behavior.

Select the **Reuse solution from previous step** checkbox, if you want to reuse the converged values of variables from the previous sweep step as initial condition for the next step during the sweep. If a Parametric Sweep study step wraps an Optimization study step, select this checkbox to reuse variables solved for (both control variables and PDE variables) from the previous converged optimization call. This option is useful for parameters not handled with continuation. See Reuse Solution from Previous Step List for information about reusing solutions.

Distributed Parametric Sweeps

If you are running a parametric sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric sweep** checkbox. To enable this option, click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog. Note that if the **Distribute parametric sweep** checkbox is selected, **Solution** under **Initial values of variables solved for** in the **Values of Dependent Variables** section in the study step node's settings cannot be set to **Current**. Each node is assigned disjoint sets of parameters; hence, the initial solution is undefined for all nodes other than the first.

In order for the **Distribute parametric sweep** checkbox to function, you must start COMSOL with a setup for running COMSOL on clusters or other multicore system using, for example, `comsol -nn 2 -nnhost 2` on Linux® or `mpiexec -n 2 comsolcluster.exe -nnhost 2` on Windows® to start 2 compute nodes. You can also run COMSOL with a distributed parametric sweep from the command line. See Running COMSOL in Parallel on Clusters for more information.

To reduce the size of MPH-files for models using parametric sweeps, you have the option of storing only the last solution in the sweep in the file. If you want to use this setting as the default, open the **Preferences** window and click **Computing** > **Study Defaults**. Then choose **Only last** from the **Keep solutions** list. You then have the further option of saving each solution as a model file. To do this, select the **Save each solution as model file** checkbox and then enter a filename in the **Filename** field, or click **Browse** to choose a name and location for the model files. The default option in the **Keep solutions** list, **All**, stores all solutions in the file.

- Probes
- Stationary for information about the continuation parametric solver versus parametric sweeps.
- Job Configurations
- Using a Job Configuration to Store Parametric Results on File

Sensitivity

To enable this option in the context menu, click the **Show More Options** button ( ) and select **Sensitivity** in the **Show More Options** dialog.

Use the **Sensitivity** ( ) study step to add a sensitivity analysis to the study. Using a Sensitivity study node, you can add sensitivity functions at the study level and use model parameters as global control variables. Compared to The Sensitivity Interface, the Sensitivity study step has these capabilities:

- Model parameters can act as global control variables.
- Sensitivity functions can be added at the study level.
- Sensitivity functions and variables from physics interfaces can be used on the study level.

It is not possible to combine the Sensitivity and Parametric Sweep study steps in a study.

- Theory for the Sensitivity Interface for a general introduction to sensitivity analysis.
- Postprocessing Sensitivities for information about the postprocessing operators `fsens`, `fsensimag`, and `sens`.

Sensitivity Analysis of a Communication Mast Detail: Application Library path **COMSOL_Multiphysics/Structural_Mechanics/mast_diagonal_mounting_sensitivity**.

The **Settings** window has the following sections:

SENSITIVITY METHOD

Choose a method from the **Gradient method** list: one of the analytical methods **Forward** or **Adjoint** (the default). See Choosing a Sensitivity Method for information about the forward and adjoint methods. These methods have similar limitations as the gradient-based optimization methods (MMA, IPOPT, SNOPT, and Levenberg–Marquardt). For example, nonanalytic functions are not correctly treated. Also, when model parameters are used in the geometry or mesh, the sensitivity is not correctly computed.

You choose the study step to use from the **Study step** list, which contains **None** and any supported study steps in the study. Supported types are those for which the default solver is a Stationary Solver, Eigenvalue Solver, or a

Time-Dependent Solver. Note that this includes the Frequency Domain study step, which uses a stationary solver. Click the **Go to Source** button ( ) to move to the **Settings** window for the selected study node. Note that the setting

	Sensitivity evaluation using a Time-Dependent Solver is only available with an Optimization Module license.

is hidden when the study only contains a single compatible study step.

OBJECTIVE FUNCTION

You specify the objective function for the optimization problem in the table's **Expression** column. Only expressions involving the eigenvalue can be entered for eigenvalue problem. Otherwise, you can enter any globally available expression that evaluates to a real number. Optionally, you can add a description in the **Description** column. Click the **Add Expression** ( ) and **Replace Expression** ( ) buttons to search through a list of predefined expressions.

	For a sensitivity objective that is expressed in terms of the solution u of a PDE (or in terms of control variables), Integration is one example of how you can define a scalar objective as required by the sensitivity solver. The evaluation of the objective function is similar to Global Variable Probe, so any variable that can be represented by a global variable probe is suited as an objective.

Multiple Objectives

If you have defined more than one objective function, choose how to evaluate the overall objective: For sensitivity studies, only **Sum of objectives** is available.

Solution

Here you select the evaluation method of the objective function when several solutions are present, like for Time Dependent studies. For sensitivity studies, only **Auto** is available. The solver chooses the evaluation method based on the innermost study. For a Time Dependent study, the optimization solver selects the last solution (final time).

CONTROL VARIABLES AND PARAMETERS

The table under **Control Variables and Parameters** is used to define control variables. In this table you can select all parameters defined in the **Global Definitions** > **Parameters** node's **Settings** window through the **Add** ( ) button.

From a list in the **Parameter name** column, select the parameter to define as a control variable. You can then give it a value and scale as a control variable in the **Value** and **Scale** columns, respectively. If the control value is complex valued, select **Complex** from the list in the **Value type** column (the default is **Real**).

Move control parameter rows up and down using the **Move Up** ( ) and **Move Down** ( ) buttons. To remove a control parameter, select some part of that parameter's row in the table and click the **Delete** button ( ).

You can also save the definitions of the control parameters to a text file by clicking the **Save to File** button ( ) and using the **Save to File** dialog that appears. To load a text file with control variables, click the **Load from File** button ( ) and use the **Load** dialog that appears. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window. Data must be separated by spaces or tabs.

	The tables to activate or deactivate objective functions and control variables in the model are only visible if those functions or variables are present in the model.

If you have the LiveLink™ *for* Excel®, you can also save and load control variables to and from Microsoft Excel Workbook (*.xlsx) files.

Bolt Pretension

The **Bolt Pretension** ( ) study step is a special case of a **Stationary** study step, where the special degrees of freedoms used for modeling prestressed bolts are solved for. In all other study types, these degrees of freedom are inactive. Typically, you include a **Bolt Pretension** study step as the first step in a study in order to simulate the state after the assembly of a bolted joint. You can the add any other types of study steps for computing the effects of the service loads.

Boundary Mode Analysis

The **Boundary Mode Analysis** ( ) study and study step are used to compute the propagation constants or wave numbers as well as propagating mode shapes, for a given frequency at a port.

As a study, the Boundary Mode Analysis combines a Boundary Mode Analysis study step at a port (boundary) (which can represent, for example, a cross section of a waveguide) with a Frequency Domain study step for the full geometry.

This study is available with the Electromagnetic Waves, Frequency Domain and Microwave Heating interfaces, which both require the RF Module, and the Electromagnetic Waves, Frequency Domain; Electromagnetic Waves, Beam Envelopes; and Laser Heating interfaces, which all require the Wave Optics Module. It is also available for the 3D Solid Mechanics interface, if you have a license for the Structural Mechanics Module, and the 3D Pressure Acoustics, Frequency Domain interface, if you have a license for the Acoustics Module.

The Boundary Mode Analysis study step's **Settings** window contains the following sections:

STUDY SETTINGS

If desired, select the **Include geometric nonlinearity** checkbox.

Select a method to **Transform**: **Effective mode index** (the default), **Out-of-plane wave number**, or **None**. For 3D Solid Mechanics and Pressure Acoustics, Frequency Domain, **Effective mode index** is not available, and **Out-of-plane wave number** is the default.

Enter a **Port name** if applicable. The default is 1.

Enter a value or expression for the **Mode analysis frequency**. The default frequency depends on the physics interfaces in the study.

From the **Mode solver** list, choose **ARPACK** (the default), **FEAST**, or **LAPACK (filled matrix)**. See Eigenvalue for more information.

VALUES OF LINEARIZATION POINT

Use the settings in this section to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

FILTERING AND SORTING

Filtering

The eigenvalues can be excluded if there is a filter expression that they do not satisfy. In the table below, in the **Filter expression (store if true or >0)** column, add expressions for the filtering Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq` and can be logical expressions such as `lambda>10`. If desired, add some descriptive text in the **Description** column for the expressions.

The **Store solutions** list is always available: Choose **All converged solutions** (the default) or **First Nth** for the first *N*th solutions. Then specify that number in the **Maximum number of stored solutions** field (default: 1000).

Sorting

The eigenvalues can be sorted in **Ascending** (the default) or **Descending** order depending on the **Ordering** setting. When the **Sorting method** is **Predefined**, you can choose to **Sort primarily** based on the **Real part**, **Imaginary part**, **Real part magnitude**, **Imaginary part magnitude**, or **Absolute value**. The same settings are available for the **Sort secondly** option, which is used to resolve conflicts. The defaults for eigenvalues are **Real part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. For eigenfrequencies, the defaults are **Imaginary part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. Also, the **Sort based on transformed eigenvalues** checkbox is selected by default to take and eigenvalue transformation into account when sorting.

Alternatively, **Manual** can be chosen for the **Sorting method** and then an arbitrary number of (ordered) custom sorting priority expressions can be defined in the table that appears. In the **Sorting priority expression** column, add expressions for the sorting, in order of priority. Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq`. For example, you can specify an expression such as `abs(freq-1)` to sort according to the distance from a given shift (1 in this case). If desired, add some descriptive text in the **Description** column for the expressions.

The **Conjugate-pair consecutive sort** checkbox is selected by default to make sure that complex-conjugate eigenpairs appear one after the other, regardless of the sorting rules.

The Boundary Mode Analysis study step stores the frequency f_{ref} and propagation constant β_{ref} for which it was run. For a TE, TM, or TEM mode, the propagation constant β for an arbitrary frequency f is given by

$$\beta^2 = \beta_{\text{ref}}^2 + k^2\left(1 - (f_{\text{ref}}/f)^2\right).$$

In addition, for TE, TM, and TEM modes, the mode field shape is independent of the frequency. Thus, when making a frequency sweep including only TE, TM, and TEM modes, the Boundary Mode Analysis study steps can be done for just one frequency, with the propagation constants obtained from the expression above for the other frequencies. For waveguides consisting of multiple dielectric materials, like optical fibers, where there are no TE, TM, or, TEM modes, the Boundary Mode Analysis steps must be recomputed for each frequency.

The **Include geometric nonlinearity** checkbox, **Mesh Selection**, and **Study Extensions** are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

- With the RF Module, see *Polarized Circular Ports*, Application Library path **RF_Module/Tutorials/polarized_circular_ports**.
- With the Wave Optics Module, see *Dielectric Slab Waveguide*, Application Library path **Wave_Optics_Module/Verification_Examples/dielectric_slab_waveguide**.

TEM Boundary Mode Analysis

The **TEM Boundary Mode Analysis** ( ) study and study step are used to compute static electric potential or out-of-plane component of magnetic vector potential to define the mode field shapes at all TEM type ports. This is a preprocessing step that must be solved before solving the main study step such Frequency Domain.

As a study, the TEM Boundary Mode Analysis combines a TEM Boundary Mode Analysis study step at ports (boundaries) (which can represent, for example, a cross section of a waveguide) with a Frequency Domain study step for the full geometry.

Coil Geometry Analysis

The **Coil Geometry Analysis** ( ) study is used to compute the current flow of a **Coil** feature in 3D models. This is a preprocessing step that must be solved before solving the main study step (which can be, for example, Stationary or Frequency domain).

The **Coil Geometry Analysis** study and study step are available for 3D models using the Magnetic Fields interface and the **Coil** node (which requires the AC/DC Module). Use it to solve for the current flow in all Coil nodes that:

- have the **Conductor model** parameter set to **Single conductor**, modeling a massive, solid conductor, or
- have the **Conductor model** set to **Homogenized multiturn** and the **Coil type** set to **Numeric**. It gives the current density equivalent to that produced by a bundle of conductive wires in series.

The best results are obtained when the coil has a smoothly varying or constant cross section without sharp bends and bottlenecks. The local current directions are solved for by the specialized **Coil Geometry Analysis** study step.

The **Geometry Analysis** subnode to the **Coil** feature automatically appears to set up the automatic computation of the current flow in the coil. The boundary conditions for the **Geometry Analysis** are specified using the **Input** and **Output** subnodes available with the node. For information about the use of this study and its functionality, see the *AC/DC Module User's Guide*.

The **Mesh Selection** and **Study Extensions** (Adaptive Mesh Refinement (Time-Dependent Adaptation)) described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

With the AC/DC Module, see *Multiturn Coil Above an Asymmetric Conductor Plate*, Application Library path **ACDC_Module/Verifications/multiturn_coil_asymmetric_conductor**.

Time-to-Frequency Losses

The **Time-to-Frequency Losses** ( ) study is used to compute the loss of a **Loss Calculation** subnode. This study is typically added after a Time Dependent study. Note that the **Loss Calculation** subnode needs to be added before the Time Dependent study is computed. The **Time-to-Frequency Losses** study performs a forward FFT from the time domain (input) to the frequency domain that is used to compute the losses (output) based on empirical formulas or the time integral of resistive heating. As the default solver it adds an FFT solver, which takes the input data from T_e–T to T_e, where T_e is the end time and T is the electrical period ($1/f$). The loss is computed by summing the loss contributions from different harmonic frequencies. The **Settings** window for the **Time-to-Frequency Losses** node ( ) has the following sections:

STUDY SETTINGS

From the **Input study** list, choose the study from which the FFT solver takes its input data. You can also choose **Current** to take it from the same study as the one that includes the **Time-to-Frequency Losses** study step. By default, the number of harmonics participating the loss contribution is set to 6.

VALUES OF DEPENDENT VARIABLES

The contents of this section is similar to other **Values of Dependent Variables** sections, but it does not include any settings for the initial values of variables solved for.

Electrochemistry Studies and Study Steps

The AC Impedance, Stationary, AC Impedance, Time Dependent, and Cyclic Voltammetry studies are available with the Battery Design Module, Corrosion Module, Electrochemistry Module, Electrodeposition Module, or Fuel Cell & Electrolyzer Module.

The Time-Dependent with Initialization and Time-Dependent with Initialization, Fixed Geometry studies are available with the Electrodeposition Module or Corrosion Module.

AC IMPEDANCE, INITIAL VALUES

The **AC Impedance, Initial Values** ( ) study is used for electrochemical impedance spectroscopy (EIS) computations in electrochemical cells.

The study consists of a single Frequency-Domain Perturbation study step, which solves for a harmonic linear perturbation. Use this study for electrochemical cells when the steady state solution is known a priori. The outputs are Nyquist and Bode plots for selected electrodes over the specified frequency range.

AC IMPEDANCE, STATIONARY

The **AC Impedance, Stationary** ( ) study is used for electrochemical impedance spectroscopy (EIS) computations in electrochemical cells.

The study consists of two study steps: a Stationary study step followed by a Frequency-Domain Perturbation study step, which solves for a harmonic linear perturbation of the stationary nonlinear solution. The outputs are Nyquist and Bode plots for selected electrodes over the specified frequency range.

	With any of these modules — Battery Design Module, Corrosion Module, Electrochemistry Module, Electrodeposition Module, or Fuel Cell & Electrolyzer Module — see the *Electrochemical Impedance Spectroscopy* example available from the respective Application Libraries.

AC IMPEDANCE, TIME DEPENDENT

The **AC Impedance, Time Dependent** ( ) study is used for electrochemical impedance spectroscopy (EIS) computations in electrochemical cells.

The study consists of two study steps: A Time Dependent study step followed by a Frequency-Domain Perturbation study step, which solves for a harmonic perturbation of the time-dependent solution at the last time step. This study can be used for systems that do not have a steady solution, for example batteries. The outputs are Nyquist and Bode plots for selected electrodes over the specified frequency range.

	Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis

CYCLIC VOLTAMMETRY

The **Cyclic Voltammetry** ( ) study is used for transient computations of voltammetry experiments together with the Electroanalysis interface.

When this study is added, a **Cyclic Voltammetry** study step is added to the Model Builder. The study step sets up a time-dependent solver. The initial and maximum time step solver settings are based on the settings in the Electroanalysis interface, and a Stop Condition is added to the solver to stop the simulation at the end of the voltammetry cycling. The settings are described for the Time Dependent node.

	If the Electroanalysis interface does not contain any Electrode Surface node with active Cyclic Voltammetry settings, no stop conditions are added to the solver. Voltammetry simulations can also be performed using a Time Dependent study step.

	With any of these modules — Battery Design Module, Corrosion Module, Electrochemistry Module, Electrodeposition Module, or Fuel Cell & Electrolyzer Module — see the *Cyclic Voltammetry at a Macroelectrode in 1D* example available from the respective Application Libraries.

STATIONARY WITH INITIALIZATION

The **Stationary with Initialization** study is used for stationary electrochemical problems. The study consists of two study steps: a Current Distribution Initialization study step, which solves for the potential fields only, followed by a second stationary study step, for which the field computed by the first study step is used as initial values.

TIME-DEPENDENT WITH INITIALIZATION

The **Time-Dependent with Initialization** ( ) study can be used to perform transient simulations of electrochemical cells. The study adds a Current Distribution Initialization study step and Time Dependent study step to the study node. The Current Initialization step solves for the electrode and electrolyte potentials as well as all global ODE dependent variables. All other dependent variables in the model, such as concentrations and electrode deformation, are set to the initial values in this step. The Time Dependent step performs a transient simulation for all dependent variables in the model, using the result of the first study step as initial values. See the study steps for settings information.

TIME-DEPENDENT WITH INITIALIZATION, FIXED GEOMETRY

Use the **Time-Dependent with Initialization, Fixed Geometry** ( ) study to exclude geometry deformation effects from a model. The study is similar to the Time-Dependent with Initialization study, with the difference that the second time-dependent study step does not solve for the geometry deformation dependent variables. This study

adds a Current Distribution Initialization study step and Time Dependent, Fixed Geometry study step to the study node. See the study steps for settings information.

CURRENT DISTRIBUTION INITIALIZATION

The **Current Distribution Initialization** ( ) study step is added to the Stationary with Initialization; Time-Dependent with Initialization, Fixed Geometry; and Time-Dependent with Initialization studies. You can use this study step as an initialization step for the electric and electrolyte potentials in a simulation of an electrochemical cell. The Current Distribution Initialization study step is typically followed by a study step that solves for all dependent variables.

The study step solves for a stationary solution of the potential dependent variables of the model only, which implies that for concentration dependent (tertiary) problems, the concentration will be equal to their corresponding initial while solving this study step. The **Current distribution type** setting can be set to either **Primary** (the default) or **Secondary**. If the **Current Distribution type** has been set to **Primary** (which is the default), potential constraints are used, based on the equilibrium potential of the Electrode Reaction or Porous Electrode Reaction nodes in the Electrochemistry interfaces. Note that this means that if you are using user-defined electrode kinetics expressions, you need to also provide equilibrium potential values for the Current Distribution Initialization to work properly when set to **Primary**. The **Primary** step will usually result in a linear problem that converges in one iteration only, regardless of the settings of the **Initial Values** for the potential variables.

For the Primary case, and if multiple Electrode Reactions or Porous Electrode Reactions are used on the same boundary/domain, you can select if the equilibrium potential of the first reaction node or the average should be used for setting up the initialization constraint by using the settings in the Equilibrium Potential Handling (Primary Condition) section in the Electrode Surface or Porous Electrode nodes.

The **Secondary** setting may need to be used for problems where the ohmic drop in the electrolyte is negligible, such as in cathodic protection, mixed potential, or thin wafer deposition with lateral electronic conduction problems. When using a **Secondary** initialization, the **Initial Values** settings of the potential values may be crucial for convergence.

The remaining settings available for this study step are described for the Stationary node.

	With the Electrodeposition Module, see *Electrodeposition on a Resistive Patterned Wafer*, Application Library path **Electrodeposition_Module/Tutorials/resistive_wafer**.

TIME DEPENDENT, FIXED GEOMETRY

The **Time Dependent, Fixed Geometry** ( ) study step is added to the Time-Dependent with Initialization, Fixed Geometry study. Use it to exclude the deformation/ALE (X, Y, Z) variables from the variables that are solved for by the study step. This is a suitable study step if you want to simulate a time-dependent electrodeposition or corrosion problem for cases when the mesh deformation is expected to be small. The settings available for this study step are described for the Time Dependent node.

Fatigue

The **Fatigue** ( ) study is a dedicated study for fatigue evaluation. It processes a load cycle and evaluates a fatigue criterion specified in the Fatigue interface. Before a Fatigue study can be calculated, a load cycle must be simulated. This is done in a Stationary or a Time Dependent study step by simulating structural response to several loading events.

For more information see the *Fatigue Module User's Guide*.

	The following applies if you have the Multibody Dynamics Module and want to evaluate fatigue. If the load cycle is simulated using the Multibody Dynamics interface, use the Stationary study instead of the Fatigue study to perform fatigue analysis. The use of a Stationary study in this case is necessary because of how the geometric nonlinearity is evaluated.

Frequency-Domain Perturbation

The **Frequency-Domain Perturbation** ( ) study step is used for studying small oscillations about a biased solution (small-signal analysis).

This study step is useful for small-signal analysis (AC/DC), prestressed analysis (structural mechanics), and harmonic perturbation (fluid flow) types of analyses.

	This study step is part of some two-step studies (see below).

When this study step is added to the Model Builder as part of a two-step study, the first step is usually a **Stationary** study step that computes the stationary (or bias) solution. The second step is the **Frequency-Domain Perturbation** step, which computes a perturbed solution of the linearized problem around the linearization point (or bias point) computed in the first step.

To add harmonic perturbation, see Harmonic Perturbation — Exclusive and Contributing Nodes. See also linper for information about the `linper` operator for indicating load terms that should be used by stationary solvers setting for harmonic linear perturbation. If your license include the Structural Mechanics Module, then also see *Harmonic Perturbation* in the *Structural Mechanics Module User's Guide*.

STUDY SETTINGS

These settings are the same as those for the Stationary and Frequency Domain nodes.

VALUES OF LINEARIZATION POINT

Use the settings in this section to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

This study step is available for a variety of interfaces and licenses:

- As a study step with the AC Impedance, Stationary and AC Impedance, Time Dependent studies, which require the Battery Design Module or the Electrodeposition Module.
- As a study step with the Frequency Domain, Prestressed study, which requires the Structural Mechanics Module, Geomechanics Module, MEMS Module, or Acoustics Module (depending on which physics interface you use it for).
- As a study step for the Small-Signal Analysis, Frequency Domain study, which requires the AC/DC Module or MEMS Module.

	Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis

	• With the AC/DC Module, see *Small-Signal Analysis of an Inductor*, Application Library path **ACDC_Module/Devices,_Inductive/small_signal_analysis_of_inductor**. • With the Acoustics Module and AC/DC Module, see *Loudspeaker Driver — Frequency-Domain Analysis*: Application Library path **Acoustics_Module/Electroacoustic_Transducers/loudspeaker_driver**. • With the Fuel Cell & Electrolyzer Module, see *Electrochemical Impedance Spectroscopy in a Fuel Cell*, Application Library path **Fuel_Cell_and_Electrolyzer_Module/Fuel_Cells/ac_fuel_cell**. • With the MEMS Module, see *Frequency Response of a Biased Resonator — 2D*, Application Library path **MEMS_Module/Actuators/biased_resonator_2d_freq**. • With the Structural Mechanics Module, see *Bracket — Frequency-Response Analysis*, Application Library path **Structural_Mechanics_Module/Tutorials/bracket_frequency**.

Frequency-Stationary

The **Frequency-Stationary** ( ) study and study step are used to compute the temperature field, at thermal equilibrium, and the electromagnetic field distribution for models created with, for example, the following physics interface and module combinations:

- Induction Heating interface, which requires the AC/DC Module,
- Equilibrium DC Discharge interface, which requires the Plasma Module,
- Microwave Heating interface, which requires the RF Module,
- Acoustic Streaming with Pressure Acoustics, which requires the Acoustics Module,
- Acoustic Streaming with Thermoviscous Acoustics, which requires the Acoustics Module, or
- Laser Heating interface, which requires the Wave Optics Module.

It is a special case of a Stationary study in which the stationary heat transfer equation is solved together with a frequency-domain equation for electromagnetics. In addition to electromagnetic heating, the **Frequency-Stationary** study can also be used to compute other physics field such as force in which time-averaged Lorentz force is computed.

For other interfaces that support the **Frequency** study, like Solid Mechanics, set the equation form to **Stationary** in the main node of the interface when they are solved in a **Frequency-Stationary** study step.

With the RF Module, see *RF Heating*, Application Library path **RF_Module/Microwave_Heating/rf_heating**.

Frequency-Transient

The **Frequency-Transient** ( ) study and study step are used to compute temperature changes over time together with the electromagnetic field distribution in the frequency domain.

The study is available, for example, with the following physics interface and module combinations:

- Induction Heating interface, which requires the AC/DC Module,
- Microwave Heating interface, which requires the RF Module,
- Acoustic Streaming with Pressure Acoustics, which requires the Acoustics Module,
- Acoustic Streaming with Thermoviscous Acoustics, which requires the Acoustics Module, or
- Laser Heating interface, which requires the Wave Optics Module.
- Inductively Coupled Plasma interface, which requires the AC/DC Module and the Plasma Module. For this physics interface, the temperature represents the electron temperature.
- Microwave Plasma interface, which requires the RF Module and the Plasma Module. For this physics interface, the temperature represents the electron temperature.

Physics interfaces that support the **Frequency-Transient** study and study step compute electromagnetic fields in the frequency domain and temperature (electron temperature for Inductively Coupled Plasma and Microwave Plasma) in the time domain. See Time Dependent for all settings. In addition to electromagnetic heating, the **Frequency-Transient** study can also be used to compute other physics field such as force in which time-averaged Lorentz force is computed.

For other interfaces that support the **Frequency** study, like Solid Mechanics, set the equation form to **Transient** in the main node of the interface when they are solved in a **Frequency-Transient** study step.

Only use this study when the power transfer from the fields to any susceptible variables occurs at twice the angular frequency set by the study. In a large number of cases, the thermal time constant of an object of interest is substantially greater than the angular frequency of the electromagnetic radiation. In order to solve the problem in the time domain, tens or hundreds of thousands of RF cycles need to be computed by the solver before the problem evolves to the periodic steady-state solution. By solving for the fields in the frequency domain, the change in the fields over a single RF cycle does not need to be resolved, and the periodic steady state solution is reached much more rapidly. This means that the transient thermal response of an object is computed by this study, but any (small) fluctuations in temperature over any given RF cycle are not.

- With the AC/DC Module, see *Inductive Heating of a Copper Cylinder*, Application Library path **ACDC_Module/Electromagnetic_Heating/inductive_heating**.
- With the Plasma Module (plus AC/DC Module), see *3D ICP Reactor, Argon Chemistry*, Application Library path **Plasma_Module/Inductively_Coupled_Plasmas/argon_3d_icp**.
- With the RF Module, see *RF Heating*, Application Library path **RF_Module/Microwave_Heating/rf_heating**.

Frozen Rotor

The **Frozen Rotor** ( ) study is used to compute the velocity, pressure, turbulence, concentration, temperature, and other fields for flow in rotating machinery and is a special case of a Stationary study. The rotating parts are kept frozen in position, and the rotation is accounted for by the inclusion of centrifugal and Coriolis forces. The study is especially suited for flow in rotating machinery where the topology of the geometry does not change with rotation. It is also used to compute the initial conditions for time-dependent simulations of flow in rotating machinery.

Use the **Frozen Rotor** study with the Rotating Machinery, Laminar Flow and Rotating Machinery, Turbulent Flow interfaces, which require the CFD Module, or the Mixer Module plus the CFD Module. The frozen rotor approach assumes that the flow in the rotating domain, expressed in the rotating coordinate system, is fully developed. See Stationary for all settings. For information about the use of this study and its functionality, see the *CFD Module User's Guide*.

	With the CFD Module: *Turbulent Mixing in a Stirred Tank*, Application Library path **CFD_Module/Single-Phase_Flow/turbulent_mixing**.

Frozen Rotor with Initialization

The **Frozen Rotor with Initialization** study is used for simulations of turbulent fluid flow in rotating machinery. It generally consists of two study steps: a Wall Distance Initialization study step, solving for the distance function to the closest wall, followed by a Frozen Rotor study step solving for velocity, pressure, turbulence, and other fields. Additionally, when the Mixing Plane feature is active for The High Mach Number Flow Interfaces in 3D geometries, a Mixing Plane Initialization study step is added before the Frozen Rotor study step. In the Frozen Rotor study step, the rotating parts are kept frozen in position, and the rotation is accounted for by the inclusion of centrifugal and Coriolis forces.

The study is especially suited for flow in rotating machinery where the topology of the geometry does not change with rotation. It is also used to compute the initial conditions for time-dependent simulations of flow in rotating machinery.

Use the **Frozen Rotor with Initialization** study with the Rotating Machinery, Laminar Flow and Rotating Machinery, Turbulent Flow interfaces, which require the CFD Module, or the Mixer Module plus the CFD Module.

Wall Distance Initialization

The **Wall Distance Initialization** ( ) study step is added to the Stationary with Initialization and the Time Dependent with Initialization studies when using a turbulent model. This first step is dedicated to solving for the reciprocal wall distance. For turbulence models, the distance determined in the initialization step is the distance to the closest wall. For two-phase flow it is the distance to the phase interface. The settings for this study are the same as for the Stationary and Time Dependent studies.

Mixing Plane Initialization

The **Mixing Plane Initialization** ( ) study step is added automatically to the Frozen Rotor with Initialization and the Stationary with Initialization studies when the Mixing Plane feature is active for The High Mach Number Flow Interfaces in 3D geometries. The study step performs initial mixing of flow and turbulence quantities in the mixing plane.

Stationary with Initialization

The **Stationary with Initialization** ( ) study is used for stationary turbulent flow models that require an initialization. It adds a Wall Distance Initialization study step followed by a Stationary study step to the Study node. The **Wall Distance Initialization** study step is dedicated to solving for the reciprocal wall distance (that is, the reciprocal distance to the closest wall). The second step is an ordinary **Stationary** study step, but it excludes the reciprocal wall distance except when the physics is put on a moving frame, in which case the reciprocal wall distance is solved for in the stationary step as well. Additionally, when the Mixing Plane feature is active for The High Mach Number Flow Interfaces in 3D geometries, a Mixing Plane Initialization study step is added before the Stationary study step.

If you have the CFD Module, see an example using the High Mach Number Flow interface:

Transonic Flow in a Sajben Diffuser, Application Library path **CFD_Module/High_Mach_Number_Flow/sajben_diffuser**.

Time Dependent with Initialization

The **Time Dependent with Initialization** ( ) study is used for time-dependent turbulent flow models that require an initialization. It adds a Wall Distance Initialization study step followed by an ordinary Time Dependent study step to the Study node. The **Wall Distance Initialization** study step is dedicated to solving for the reciprocal wall distance, that is, the reciprocal distance to the closest wall.

Stationary Free Surface

The **Stationary Free Surface** ( ) study step is added to the **Frozen Rotor** or **Frozen Rotor with Initialization** study when a Stationary Free Surface postprocessing feature is applied (available with the CFD Module). The **Stationary Free Surface** study step uses the pressure from the **Frozen Rotor** study step to evaluate the surface deformation from a linearized free surface condition including the surface tension force. The settings are the same as for a Stationary study step.

Frozen Rotor with Stationary Free Surface

The **Frozen Rotor with Stationary Free Surface** ( ) study is used for simulations of flow in rotating machinery when a Stationary Free Surface postprocessing feature is applied (available with the CFD Module). It consists of two study steps: a Frozen Rotor study step solving for the velocity, pressure, turbulence, and other fields, followed by a Wall Distance Initialization study step solving for the free surface deformation. In the Frozen Rotor study step, the rotating parts are kept frozen in position, and the rotation is accounted for by the inclusion of centrifugal and Coriolis forces. In the Stationary Free Surface study step, the surface deformation is evaluated from a linearized free surface condition using the pressure from the Frozen Rotor study step.

The study is especially suited for flow in rotating machinery where the topology of the geometry does not change with rotation. It is also used to compute the initial conditions for time-dependent simulations of flow in rotating machinery.

Use the **Frozen Rotor with Stationary Free Surface** study with the Rotating Machinery, Laminar Flow, and Rotating Machinery, Turbulent Flow interfaces, which require the CFD Module, or the Mixer Module plus the CFD Module.

With the CFD Module and Mixer Module: *Free Surface Mixer*, Application Library path **Mixer_Module/Tutorials/free_surface_mixer**.

Frozen Rotor with Initialization and Stationary Free Surface

The **Frozen Rotor with Initialization and Stationary Free Surface** study is used for simulations of turbulent fluid flow in rotating machinery when a Stationary Free Surface postprocessing feature is applied (available with the CFD Module). It consists of three study steps: a Wall Distance Initialization study step, solving for the distance function to the closest wall, followed by a Frozen Rotor study step solving for velocity, pressure, turbulence, and other fields, and a Wall Distance Initialization study step solving for the free surface deformation. In the Frozen Rotor study step, the rotating parts are kept frozen in position, and the rotation is accounted for by the inclusion of centrifugal and Coriolis forces. In the Stationary Free Surface study step, the surface deformation is evaluated from a linearized free surface condition using the pressure from the Frozen Rotor study step.

The study is especially suited for flow in rotating machinery where the topology of the geometry does not change with rotation. It is also used to compute the initial conditions for time-dependent simulations of flow in rotating machinery.

Use the **Frozen Rotor with Initialization and Stationary Free Surface** study with the Rotating Machinery, Laminar Flow, and Rotating Machinery, Turbulent Flow interfaces, which require the CFD Module, or the Mixer Module plus the CFD Module.

Linear Buckling

The **Linear Buckling** ( ) study and study step are used for estimating the critical load at which a structure becomes unstable.

The Linear Buckling study consists of two study steps: a Stationary study step for applying an external load followed by a **Linear Buckling** study step. In the second study step, an eigenvalue solver is used to compute the buckling modes and the associated critical load factors.

A **Linear Buckling** analysis includes the stiffening effects from stresses coming from nonlinear strain terms. The stiffness coming from stresses and material defines an eigenvalue problem in which the eigenvalue is a load factor that, when multiplied with the actual load, gives the critical load in a linear context.

Another way to calculate the critical load is to include large deformation effects and increase the load until the solver fails because the load has reached its critical value.

The Linear Buckling study is available for the Solid Mechanics interfaces using the Structural Mechanics Module or the MEMS Module. It is also available with Shell, Plate, and Truss interfaces when using the Structural Mechanics Module.

STUDY SETTINGS

If desired, select the **Include geometric nonlinearity** checkbox.

Use the **Desired number of buckling modes** field to specify the number of buckling modes you want the eigenvalue solver to return (by first selecting the associated checkbox).

Use the settings under **Values of linearization point** to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

Under **Live loads solution**, you can specify the solution to use for the live loads. In certain studies, only some of the loads should be multiplied by the load factor λ in a linear buckling analysis. Other loads, like self-weight, should be treated as constant loads. These two types of loads are commonly called *live loads* and *dead loads*, respectively.

From the **Settings** list, choose **Same as linearization point** (the default) to use the same settings as for the linearization point above. Choose **User controlled** to use a separate solution for the live loads. See the settings for the linearization point for the user-controlled settings.

STUDY EXTENSIONS

This section contains some optional extensions of the study, such as auxiliary sweeps (see Common Study Step Settings). Adding an auxiliary parametric sweep adds an Eigenvalue Parametric attribute node to the Eigenvalue Solver.

Distribute Parametric Solver

If you are running an auxiliary sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric solver** checkbox. To enable this option, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

For more information about performing a linear buckling analysis, see Linearized Buckling Analysis in the *Structural Mechanics User's Guide*.

The **Include geometric nonlinearity** checkbox should have the same selection in both study steps in a Linear Buckling Study.

The default is to use a geometrically linear analysis. There are some cases when the preload step requires a geometrically nonlinear analysis, and in that case you must use it also in the Linear Buckling study step.

The **Physics and Variables Selection**, **Values of Dependent Variables**, **Mesh Selection**, **Adaptation and Error Estimates**, and **Geometric Entity Selection for Adaptation** sections and the **Include geometric nonlinearity** checkbox are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

With the Structural Mechanics Module: *Bracket — Linear Buckling Analysis*, Application Library path **Structural_Mechanics_Module/Tutorials/bracket_linear_buckling**.

Mapping

The **Mapping** ( ) study is a dedicated study for the Background Fluid Flow Coupling multiphysics feature. The study should only solve for the coupling feature on its own.

For more information see the *Acoustics Module User's Guide*.

Transient Mapping

The **Transient Mapping** ( ) study is a dedicated study for the Aeroacoustic Flow Source Coupling multiphysics feature. The study should only solve for the coupling feature on its own.

For more information see the *Acoustics Module User's Guide*.

Mean Energies

The **Mean Energies** ( ) study and study step are used for entering an array of values for the mean electron energy.

COMSOL Multiphysics computes the electron energy distribution function (EEDF) so that the mean electron energy is equal to the mean energy requested. This study conveniently allows data such as rate coefficients, Townsend coefficients, and electron transport properties to be computed as a function of the mean electron energy.

This study is available with the Boltzmann Equation, Two-Term Approximation interface, which requires the Plasma Module. Except for the section below, see Frequency Domain for all settings information. Also see the *Plasma Module User's Guide*.

STUDY SETTINGS

Specify the **Mean energies** to use for the sweep. Enter the mean energies in the field using space-separated numbers or the `range` function.

Use the **Load parameter values** field to select a file with parameter values. You can browse your file system for files by clicking **Browse**. After selecting a file, click the **Read File** button to load the parameter values into the **Mean energies** field.

For information about the **Reuse solution from previous step** list, see Reuse Solution from Previous Step List.

	With the Plasma Module: *Argon Boltzmann Analysis*, Application Library path **Plasma_Module/Two-term_Boltzmann_Equation/boltzmann_argon**.

Mode Analysis

The **Mode Analysis** ( ) study and study step are used to compute the propagation constants or wave numbers as well as propagating mode shapes for a given frequency.

For example, in electromagnetics, it is used to compute the propagation constants and mode shapes at ports and waveguide cross sections. In acoustics, it is used to compute the propagation constants and mode shapes at inlets, outlets, and cross sections of guiding structures such as ducts.

When you add a Mode Analysis study, it adds a **Mode Analysis** study step under the **Study** node. The Mode Analysis study is available with the Acoustics Module, RF Module, or Wave Optics Module.

STUDY SETTINGS

Select a method to **Transform**: **Effective mode index**, **Effective mode index, 2D axisymmetry**, **Out-of-plane wave number**, **Out-of-plane wave number, 2D axisymmetry**, **Phase velocity**, or **None**. The available transforms and the default transform depend on the physics interfaces in the study.

Enter a value or expression for the **Mode analysis frequency**. The default frequency depends on the physics interfaces in the study.

From the **Mode solver** list, choose **ARPACK** (the default), **FEAST**, or **LAPACK (filled matrix)**. See Eigenvalue for more information.

VALUES OF LINEARIZATION POINT

Use the settings in this section to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

STUDY EXTENSIONS

This section contains some optional extensions of the study, such as auxiliary sweeps (see Common Study Step Settings). Adding an auxiliary parametric sweep adds an Eigenvalue Parametric attribute node to the Eigenvalue Solver.

Distribute Parametric Solver

If you are running an auxiliary sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric solver** checkbox. To enable this option, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

The **Physics and Variables Selection**, **Values of Dependent Variables**, **Mesh Selection**, **Adaptation and Error Estimates**, and **Geometric Entity Selection for Adaptation** sections and the **Include geometric nonlinearity** checkbox are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

- With the Acoustics Module: *Eigenmodes in a Muffler*, Application Library path **Acoustics_Module/Automotive/eigenmodes_in_muffler**.
- With the Wave Optics Module: *Stress–Optical Effects in a Photonic Waveguide*, Application Library path **Wave_Optics_Module/Waveguides/stress_optical**.

Optimization

The **Optimization** ( ) study step specifies an optimization problem and controls the optimization solvers provided by the Optimization Module. For information about the use of this study and its functionality, see the *Optimization Module User's Guide*.

Orbit Calculation

The **Orbit Calculation** ( ) study step is a special case of a **Time Dependent** study step, where only the degrees of freedoms used for modeling the spacecraft orbit are solved for.

The **Orbit Calculation** study step is used with the Orbital Thermal Loads interface to compute and verify the orbit prior to solving for the radiosity and the temperature fields. This study step is not mandatory but serves as a quick verification of the orbital parameters and maneuvers prior to other, more computationally intensive, studies. Except for the **Study Settings** section, see Time Dependent for all settings. This study is available with the Heat Transfer Module.

STUDY SETTINGS

Select a **Time unit** from the list (default SI unit s) to use a time unit that is convenient for the time span of the simulation.

Then, select the **Output times specification**, either in terms of **Orbit Period** (the default) or **Time steps**.

- If **Orbit Period** is selected, output time steps will be selected based on the dimensionless fraction of the orbital period, as specified in the **Output orbit times** field. Use the range operator to define a uniform spacing. For example, `range(0,0.1,3)` will solve for a total of three orbit periods, and output results every one-tenth of the orbit period. The orbit period is determined from the first Orbital Thermal Loads interface that is solved for.
- If **Time steps** is selected, specify the time interval for the output from the simulation in the **Output times** field using the selected time unit.

!	With **User defined** selected as **Orbit type** in the **Orbital Parameters** feature, orbit period is not defined and the **Time steps** option must be used.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field.

Additional output times will be stored immediately before and after every explicit and implicit events, for example: when the spacecraft enters and leaves the eclipse. The solver uses intermediate time stepping by default to force the time-stepping method to take at least one step in each subinterval of the specified times.

Orbital Temperature

The **Orbital Temperature** ( ) study step is a special case of a **Time Dependent** study step, where the external irradiation from a precomputed **Orbit Thermal Loads** study step is reused on multiple orbit periods. The external irradiation from all orbits precomputed are reused periodically. This means that the external irradiation needs to be periodic over the precomputed number of orbit period. If the external irradiation is not periodic, a **Time Dependent** study step should be used instead where the external irradiation is recomputed for each orbit period.
If the precomputed **Orbit Thermal Loads** solution is defined on a time range that is not multiple of the orbit period, the solution is repeated on the greatest entire number of orbit periods that is available in the **Orbit Thermal Loads** solution. For example, if the Orbit Thermal Loads solution has been computed over 3.2 orbit periods, its solution over 3 periods only is repeated.

When the precomputed **Orbit Thermal Loads** solution is defined on a number of orbits not multiple of the orbit period, the solution is repeated on the greatest integer less than or equal to the precomputed solution time.

Except for the **Study Settings** section, see Time Dependent for all settings. This study is available with the Heat Transfer Module.

STUDY SETTINGS

Select a **Time unit** from the list (default SI unit s) to use a time unit that is convenient for the time span of the simulation.

Then, select the **Output times specification**, either in terms of **Orbit Period** (the default) or **Time steps**.

- If **Orbit Period** is selected, output time steps will be selected based on the dimensionless fraction of the orbital period, as specified in the **Output orbit times** field. Use the range operator to define a uniform spacing. For example, `range(0,0.1,3)` will solve for a total of three orbit periods, and output results every one-tenth of the orbit period. The orbit period is determined from the first Orbital Thermal Loads interface that is solved for.
- If **Time steps** is selected, specify the time interval for the output from the simulation in the **Output times** field using the selected time unit.

	With **User defined** selected as **Orbit type** in the **Orbital Parameters** feature, orbit period is not defined and the **Time steps** option must be used.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field.

Use the settings under **Precomputed Orbit Thermal Loads solution** to specify from which Orbit Thermal Loads study step the external irradiation should be extracted.

From the **Settings** list, choose **Reuse solution from previous step** (the default) to use the external irradiation from the previous Orbit Thermal Loads study step in the study sequence, if it exists. If not, the external irradiation will be recomputed. Choose **User defined** to specify the Orbit Thermal Loads solution using the Study list. Select:

- **None** to force the external irradiation computation.
- Any other available Orbit Thermal Loads study. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

Additional output times will be stored immediately before and after every explicit and implicit events, for example: when the spacecraft enters and leaves the eclipse. The solver uses intermediate time stepping by default to force the time-stepping method to take at least one step in each subinterval of the specified times.

Orbit Thermal Loads

The **Orbit Thermal Loads** ( ) study step is a special case of a **Time Dependent** study step, where only the degrees of freedoms used for modeling the spacecraft orbit are solved for. In addition, the external irradiation is stored to be reused in the **Orbital Temperature** study step or for faster postprocessing of the external irradiation.

Except for the **Study Settings** section, see Time Dependent for all settings. This study is available with the Heat Transfer Module.

STUDY SETTINGS

Select a **Time unit** from the list (default SI unit s) to use a time unit that is convenient for the time span of the simulation.

Then, select the **Output times specification**, either in terms of **Orbit Period** (the default) or **Time steps**.

- If **Orbit Period** is selected, output time steps will be selected based on the dimensionless fraction of the orbital period, as specified in the **Output orbit times** field. Use the range operator to define a uniform spacing. For example, `range(0,0.1,3)` will solve for a total of three orbit periods, and output results every one-tenth of the orbit period. The orbit period is determined from the first Orbital Thermal Loads interface that is solved for.
- If **Time steps** is selected, specify the time interval for the output from the simulation in the **Output times** field using the selected time unit.

	With **User defined** selected as **Orbit type** in the **Orbital Parameters** feature, orbit period is not defined and the **Time steps** option must be used.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field.

Additional output times will be stored immediately before and after every explicit and implicit events, for example: when the spacecraft enters and leaves the eclipse. The solver uses intermediate time stepping by default to force the time-stepping method to take at least one step in each subinterval of the specified times.

Curve Fitting

The **Curve Fitting** ( ) study step provides the possibility to perform parameter estimation based on model data and some reference data using various parameter estimation methods. For information about the use of this study and its functionality, see the *Optimization Module User's Guide*.

Shape Optimization

The **Shape Optimization** ( ) study step is a simplified version of the Optimization study step, so that only options relevant for shape optimization are available. For information about the use of this study and its functionality, see the *Optimization Module User's Guide*.

Topology Optimization

The **Topology Optimization** ( ) study step is a simplified version of the Optimization study step, so that only options relevant for topology optimization are available. For information about the use of this study and its functionality, see the *Optimization Module User's Guide*.

Parameter Estimation

The **Parameter Estimation** ( ) study step provides the possibility to perform parameter estimation based on model data and some reference data using various parameter estimation methods. For information about the use of this study and its functionality, see the *Optimization Module User's Guide*.

Prestressed Analyses Studies

The Eigenfrequency, Prestressed ( ) and Frequency Domain, Prestressed ( ) study types (available under **Preset Studies**) perform a stationary analysis of the problem to compute the prestressed state and then perform the

appropriate prestressed analysis. In both cases, the prestressed state can be computed using any stationary problem. You can use the Frequency Domain, Prestressed, Modal study type (available under **More Studies**) to compute the response to harmonic or time-dependent loads fluctuating around a prior static load. The solution is performed using mode superposition.

For exclusive boundary conditions (that is to say, loads which overwrite previously added loads of the same type, such as the potential load in electrostatics) in the frequency-domain studies., you can add **Harmonic Perturbation** as a subnode to the boundary condition node. Its magnitude is added in the subnode itself.

The studies are available for:

- Solid Mechanics, using the Structural Mechanics Module, Geomechanics Module, MEMS Module, or Acoustics Module.
- Electromechanics, using the MEMS Module.
- The **Eigenfrequency, Prestressed** and **Frequency Domain, Prestressed, Modal** are also available for the Shell, Plate, Membrane, and Truss interfaces using the Structural Mechanics Module.

For more information, see Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis.

See also linper for information about the `linper` operator for indicating load terms that should be used by stationary solvers for harmonic linear perturbation. If your license include the Structural Mechanics Module, then also see *Harmonic Perturbation* in the *Structural Mechanics Module User's Guide*.

EIGENFREQUENCY, PRESTRESSED

The **Eigenfrequency Prestressed** ( ) study is used to compute eigenfrequencies and eigenmodes that are influenced by a prior static load.

The study consists of two study steps: a Stationary study step followed by an Eigenfrequency study step. The study computes the eigenfrequencies and the shapes of the eigenmodes when influenced by a prior static load on the structure.

The effects of the preload can be computed with or without taking geometric nonlinearity into account. To perform this study, no additional forces need to be added to the physics interface settings as only the modes and mode frequencies are returned.

- With the MEMS Module: *Normal Modes of a Biased Resonator — 3D*, Application Library path **MEMS_Module/Actuators/biased_resonator_3d_modes**.
- With the Nonlinear Structural Materials Module: *Elasto-Acoustic Effect in Rail Steel*, Application Library path **Nonlinear_Structural_Materials_Module/Hyperelasticity/rail_steel**.
- With the Structural Mechanics Module: *Bracket — Eigenfrequency Analysis*, Application Library path **Structural_Mechanics_Module/Tutorials/bracket_eigenfrequency**.

FREQUENCY DOMAIN, PRESTRESSED

The **Frequency Domain, Prestressed** ( ) study is used to compute the response to harmonic loads fluctuating around a prior static load.

The study consists of two study steps: a Stationary study step followed by a Frequency-Domain Perturbation study step.

The effects of the preload can be computed with or without taking geometric nonlinearity into account. For this study type it is necessary to specify the magnitude of the harmonic load, as this determines the magnitude of the system response. In order to do this, a **Harmonic Perturbation** force must be added to the model. For contributing loads (that is, loads that can be added without overwriting the same type of node, such as a boundary load in solid

mechanics), right-click the node and select **Harmonic Perturbation**. In this case, a load to generate the prestress must be added separately to the model.

FREQUENCY DOMAIN, PRESTRESSED, MODAL

The **Frequency Domain, Prestressed, Modal** ( ) study is used to compute the response to harmonic loads fluctuating around a prior static load. The solution is performed using mode superposition.

The study consists of three study steps: a Stationary study step followed by an Eigenfrequency study step and a Frequency Domain, Modal study step.

The effects of the preload can be computed with or without taking geometric nonlinearity into account. For this study type it is necessary to specify the magnitude of the harmonic load, as this determines the magnitude of the system response. In order to do this, a **Harmonic Perturbation** force must be added to the model. For contributing loads (that is, loads that can be added without overwriting the same type of node, such as a boundary load in solid mechanics), right-click the node and select **Harmonic Perturbation**. In this case, a load to generate the prestress must be added separately to the model.

For loads that do not have an **Harmonic Perturbation** attribute, you can instead use the linper operator.

For different plot settings made available, see Small-Signal Analysis, Prestressed Analysis, and Harmonic Perturbation Plot Settings.

- With the MEMS Module: *Frequency Response of a Biased Resonator — 2D*, Application Library path **MEMS_Module/Actuators/biased_resonator_2d_freq**.
- With the Structural Mechanics Module: *Bracket — Frequency-Response Analysis*, Application Library path **Structural_Mechanics_Module/Tutorials/bracket_frequency**.

Ray Tracing

The **Ray Tracing** ( ) study and study step are used to compute the trajectories of rays. The Ray Tracing study step is a special case of the Time Dependent study step. The time steps taken by the solver can either be specified directly or by specifying a set of path lengths and a characteristic group velocity. Built-in stop conditions can be used to stop the solver when no active rays remain, or when the intensity of active rays is negligibly small. Except for the section below, see Time Dependent for all settings. This study requires the Ray Optics Module or the Acoustics Module.

For example, this study is used with the Geometrical Optics or Ray Acoustics interfaces to compute ray trajectories. By specifying the range of time steps in terms of the maximum path length, it is possible to deduce the optimal study settings from the geometry size and ray properties.

STUDY SETTINGS

Select a **Time step specification**: **Specify time steps** (the default) or **Specify maximum path length**.

- If **Specify time steps** is selected, select a **Time unit** from the list to use a convenient time unit for the time span of the simulation. The default is ms (milliseconds) for models that use the Ray Acoustics interface and ns (nanoseconds) for models that use the Geometrical Optics interface. Then, in the **Times** field, specify the time interval for the output from the simulation using the selected time unit.
- If **Specify maximum path length** is selected, select a **Length unit** from the list (the default is m). Then specify a list of **Lengths** using the selected unit. Enter a **Characteristic group velocity** (SI unit: m/s). For Ray Acoustics simulations the default is `343 m/s`, the approximate speed of sound in air at standard temperature and pressure. For Geometrical Optics simulations the default is `c_const`, the speed of light in a vacuum. The time steps taken by the solver are computed by dividing the list of lengths in the **Lengths** field by the characteristic group velocity.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** check field. The tolerance settings control the internal time steps taken by the solver, so selecting large time steps for the output times does not affect the accuracy in the time stepping.

Select a **Stop condition**: **None** (the default), **No active rays remaining**, **Active rays have intensity below threshold**, or **Active rays exceed maximum number of reflections**. If **No active rays remaining** is selected, the solver terminates immediately when all rays are stuck, frozen, or have disappeared.

If **Active rays have intensity below threshold** is selected, enter a **Threshold ray intensity** (the default is `1[W/m^2]`). The solver terminates immediately when all rays are either stuck, frozen, have disappeared, or have intensity less than the threshold. This setting can only be used if the ray intensity is computed for the Geometrical Optics or Ray Acoustics physics interface (select any option other than **None** from the **Intensity Computation** list in the physics interface **Intensity Computation** section.

If **Active rays exceed maximum number of reflections** is selected, enter a **Number of reflections** (the default is `5`). The solver terminates immediately when all rays are either stuck, frozen, have disappeared, or have been reflected or refracted at least the specified number of times. This setting can only be used if the **Count reflections** checkbox has been selected in the **Additional Variables** section for the Geometrical Optics or Ray Acoustics interface.

Reduced Electric Fields

Use the **Reduced Electric Fields** ( ) study and study step to sweep through a range of reduced electric fields and to compute electron transport properties and electron impact rate coefficients for a given reduced electric field. Specifying a range of values for the reduced electric field allows for these properties to be tabulated. This tabulated data can then potentially be used in a space-dependent plasma simulation. The reduced electric field is defined as the electric field divided by the background gas number density.

This study step is available with the Boltzmann Equation, Two-Term Approximation interface, which requires the Plasma Module. Except for the section below, see Frequency Domain for all settings. Also see the *Plasma Module User's Guide*.

STUDY SETTINGS

Specify the **Reduced electric fields** to use for the sweep. Enter the reduced electric fields in the field using space-separated numbers or the `range` function.

Use the **Load parameter values** field to select a file with parameter values. You can browse your file system for files by clicking **Browse**. After selecting a file, click the **Read File** button to load the parameter values into the **Reduced electric fields** field.

For information about the **Reuse solution from previous step** list, see Reuse Solution from Previous Step List.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field.

With the Plasma Module: *Argon Boltzmann Analysis*, Application Library path **Plasma_Module/Two-term_Boltzmann_Equation/boltzmann_argon**.

Schrödinger–Poisson

Use the **Schrödinger–Poisson** ( ) study and study step to automatically generate the iterations in the solver sequence for the self-consistent solution of the fully coupled Schrödinger–Poisson equation. Also see the *Semiconductor Module User's Guide* for the Schrödinger–Poisson Equation multiphysics interface.

To take advantage of the default settings detailed below, use the **Model Wizard** or the **Add Study** button in the ribbon or toolbar of the COMSOL Desktop. A study step added by right-clicking a Study node does not include any default settings suggested by the physics.

STUDY SETTINGS

From the **Eigenvalue solver** list, choose **ARPACK** (the default), **FEAST**, or **LAPACK (filled matrix)**:

The ARPACK algorithm is based on an algorithmic variant of an Arnoldi process When the matrix A is symmetric it reduces to a variant of the Lanczos process. For its settings, see Study Settings for ARPACK below.

The FEAST algorithm uses an inverse residual iteration algorithm and seeks to accelerate the convergence of the subspace eigenvalue problem. It can be effective for finding clustered eigenvalues by using an ellipse to search within. For its settings, see Study Settings for FEAST.

The LAPACK algorithm is useful for finding all eigenvalues for a filled matrix. This option is only applicable for small eigenvalue problems. For its settings, see Study Settings for LAPACK (Filled Matrix).

For more information about these eigenvalue solvers, see The Eigenvalue Solver Algorithms.

STUDY SETTINGS FOR ARPACK

From the **Eigenvalue search method** list, select a search method:

- **Around shift** (the default), to specify some search criteria manually. See Around Shift Eigenvalue Search Settings below.
- **Rectangle**, to define an eigenvalue search region in a complex plane. See Rectangular Eigenvalue Search Region Settings below and The Eigenvalue Solver Algorithms.

Around Shift Eigenvalue Search Settings

By default, the physics interfaces suggest a suitable number of eigenvalues to search for. To specify the number of eigenvalues, select the checkbox in front of the **Desired number of eigenvalues** field to specify the number of eigenvalues you want the solver to return (default: 6).

In a solid 3D model, the first six eigenvalues are typically zero and correspond to the rigid-body modes of a 3D geometry. You may therefore need to specify a larger number of eigenvalues. The largest number of eigenvalues that the solver can compute is equal to the number of unconstrained degrees of freedom minus two.

From the **Unit** list, choose a suitable unit (default rad/s).

By default, the physics interfaces suggest a suitable value around which to search for eigenvalues. To specify the value to search for eigenvalues around (shift), select the checkbox in front of the **Search for eigenvalues around** field; you can then specify a value or expression around which the eigenvalue solver should look for solutions to the eigenvalue equation (default: 0).

Use the **Search method around shift** list to control how the eigenvalue solver searches for eigenvalues around the specified shift value:

- Select **Closest in absolute value** (the default value) to search for eigenvalues that are closest to the shift value when measuring the distance as an absolute value.
- Select **Larger real part** to search for eigenvalues with a larger real part than the shift value.
- Select **Smaller real part** to search for eigenvalues with a smaller real part than the shift value.
- Select **Larger imaginary part** to search for eigenvalues with a larger imaginary part than the shift value.
- Select **Smaller imaginary part** to search for eigenvalues with a smaller imaginary part than the shift value.

Rectangular Eigenvalue Search Region Settings

Use the **Approximate number of eigenvalues** field to specify the approximate number of eigenvalues you want the solver to return (default: 20). The value of the **Approximate number of eigenvalues** will affect the **Dimension of Krylov space** used by the algorithm; see the **Advanced** section of the Eigenvalue Solver. It means that increasing the value of the **Approximate number of eigenvalues** will increase the memory requirement and the computational time. If the solver indicates that the value of the **Approximate number of eigenvalues** is smaller than the actual number of eigenvalues in the given region, it will perform a search for more eigenvalues, which increases the computational time; see The Eigenvalue Region Algorithm. Within limits it is often more efficient to provide a too large value of **Approximate number of eigenvalues** than a too small.

In the **Maximum number of eigenvalues** field, you can specify a maximum number of eigenvalues to limit the eigenvalue solver's search for additional eigenvalues (default: 200).

Under **Rectangle search region**, you define the size of the search region for eigenvalues as a rectangle in the complex plane by specifying the **Smallest real part**, **Largest real part**, **Smallest imaginary part**, and **Largest imaginary part** in the respective text fields. The search region also works as an interval method if the **Smallest imaginary part** and **Largest imaginary part** are equal; the eigenvalue solver then only considers the real axis and vice versa.

The **Perform consistency check** checkbox is available and selected by default to increase confidence that the solver finds all eigenvalues in the search region. The work required for performing the consistency check constitutes a significant part of the total work of the eigenvalue computation.

Symmetry and Consistency Settings

Eigenvalue computations can be performed with a nonsymmetric solver or, if applicable, a real symmetric solver. From the **Use real symmetric eigenvalue solver** list, choose **Automatic** (the default) or **Off**. For the **Automatic** option there is the option to select the **Real symmetric eigenvalue solver consistency check** checkbox. This consistency check increases the computational time and memory requirements but provides a rigorous check of the applicability of the real symmetric solver.

When using a search for eigenvalues, the nonsymmetric eigenvalue solver is always used, even when the problem to solve is symmetric.

The eigenvalue solver can in some cases return more than the desired number of eigenvalues (up to twice the desired number). These are eigenvalues that the eigenvalue solver finds without additional computational effort.

STUDY SETTINGS FOR FEAST

Using the FEAST eigenvalue solver, you can define an ellipse to explicitly exclude the eigenvalues outside the ellipse. Choosing a suitable search region determines which eigenvalues that will be returned for results analysis.

From the **Eigenvalue search method** list, select a search method:

- **Ellipse** (the default), to define an eigenvalue search contour as an ellipse in a complex plane. See Ellipse Search Region settings below.
- **Half ellipse (Hermitian problem)**, to define an eigenvalue search contour by half of the whole ellipse. See Half Ellipse Search Region below.

Ellipse Search Region

You define the **Ellipse** by specifying the **Unit** (default: rad/s), **Center**, **Real semiaxis**, **Imaginary semiaxis**, and **Rotation angle** in the respective text fields. It is important that the real semiaxis that you specify in the **Real semiaxis** field is large enough to enclose the eigenvalues of interest. In the **Imaginary semiaxis** field, you specify the imaginary

semiaxis in a similar way. In the **Rotation angle** field, specify the rotation angle in degrees from the vertical axis in the range of –180 degrees to 180 degrees.

From the **Number of eigenvalues** list, select the method for evaluating the number of eigenvalues inside the eigenvalue search ellipse:

- **Stochastic estimation** (the default) to use stochastic estimation to evaluate the number of eigenvalues. In this case, **Approximate number of eigenvalues** is an initial guess of the number of eigenvalues (default: 6). After the stochastic estimation finishes, the eigenvalue solver automatically calculates the eigenvalues inside the eigenvalue search contour, using the number of eigenvalues calculated from stochastic estimation.
- **Manual** to specify the number of eigenvalues inside the eigenvalue search contour manually in the **Approximate number of eigenvalues** field (default: 6).

For an eigenvalue problem for which you know how many eigenvalues there are, the solver can compute the eigenvalues directly. For that case, choose **Manual** from the **Number of eigenvalues** list and enter the desired number of eigenvalues in the **Approximate number of eigenvalues** field. If you do not know the number of eigenvalues in the defined region, there are two cases: You can just estimate the number of eigenvalues without computing them, or you can let the software estimate the number of eigenvalues and then compute them automatically afterward. The former is achieved by clicking the **Stochastic Estimation** button ( ) at the top right of the **Study Settings** section. The latter is achieved by choosing **Stochastic estimation** from the **Number of eigenvalues** list, and then click **Compute**. Both cases require doing stochastic estimation, which needs the setting of an **Approximate number of eigenvalues** field as an initial guess in the estimation stage.

The **Stochastic Estimation** works as a **Compute to Selected** step. Because the **Stochastic Estimation** action does not solve the eigenvalue problem, there will not be any valid solution from this action. So, if the **Stochastic Estimation** action is done for a single step or the first step in a multistep study, there will not be any solution that can be used for postprocessing and results analysis. If the action is done for a step after the first step in a multistep study, the main solution of the sequence corresponds to the study step right before the eigenstep for which the estimation is done.

There is an option to select the **Store linear system factorization** checkbox. If selected, linear system factorizations are stored from the first FEAST iteration and reused in later iterations.

If the **Study** > **Batch and Cluster** checkbox is selected in the **Show More Options** dialog, select the **Distribute linear system solution** checkbox to run the FEAST eigenvalue solver in parallel. See Running FEAST in a Parallel MPI Mode for more information.

Half Ellipse Search Region

You define the **Half ellipse (Hermitian problem)** by specifying the **Unit** (default: rad/s), **Smallest real part**, **Largest real part**, and **Imaginary semiaxis** in the respective text fields.

From the **Number of eigenvalues** list, select the method for evaluating the number of eigenvalues inside the eigenvalue search contour:

- **Stochastic estimation** (the default) to use stochastic estimation to evaluate the number of eigenvalues. In this case, **Approximate number of eigenvalues** is an initial guess of the number of eigenvalues (default: 6). After the stochastic estimation finishes, the eigenvalue solver automatically calculates the eigenvalues inside the eigenvalue search contour, using the number of eigenvalues calculated from stochastic estimation.
- **Manual** to specify the number of eigenvalues inside the eigenvalue search contour manually in the **Approximate number of eigenvalues** field (default: 6).

There is an option to select the **Store linear system factorization** checkbox. If selected, linear system factorizations are stored from the first FEAST iteration and reused in later iterations.

If the **Study** > **Batch and Cluster** checkbox is selected in the **Show More Options** dialog, select the **Distribute linear system solution** checkbox to run the FEAST eigenvalue solver in parallel. See Running FEAST in a Parallel MPI Mode for more information.

Symmetry and Consistency Settings

For the **Ellipse** eigenvalue search method, eigenvalue computations can be performed with a nonsymmetric solver or, if applicable, a real symmetric solver. From the **Use real symmetric or Hermitian eigenvalue solver** list, choose **Automatic** (the default) or **Off**. For the **Automatic** option there is the option to select the **Real symmetric eigenvalue solver consistency check** checkbox. This consistency check increases the computational time and memory requirements but provides a rigorous check of the applicability of the real symmetric solver.

STUDY SETTINGS FOR LAPACK (FILLED MATRIX)

To specify a shift to use in the modes computation, select the **Shift used in the modes computation** checkbox and then enter a shift (in rad/s) in the associated text field.

In the **Maximum matrix size** field, enter an upper limit on the matrix size (default: 2000).

From the **Unit** list, choose a suitable unit (default rad/s).

VALUES OF LINEARIZATION POINT

Use the settings in this section to specify a linearization point.

From the **Settings** list, choose **Physics controlled** (the default) to use linearization point settings controlled by the physics interfaces. Choose **User defined** to specify the linearization point using the **Method** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Study** list to specify which solution to use from the available studies. Select:

- **Zero solution** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution. Choose a solution using the **Selection** list (see **Values of Dependent Variables** under Common Study Step Settings).

PHYSICS AND VARIABLES SELECTION

If there are extra domain or boundary conditions used to obtain the initial value for the fully coupled problem, remember to disable them here. For example, see the *Self-Consistent Schrödinger-Poisson Results for a GaAs Nanowire* tutorial model (`schrodinger_poisson_nanowire`), where the Thomas–Fermi solution is used as the initial condition, and the space charge density contribution from the Thomas–Fermi approximation is disabled here.

ITERATIONS

The default option for the **Termination method** list is **Minimization of global variable**, which updates a table displaying the history of a global error variable after each iteration during the solution process. This provides a good indication of the solution process to monitor whether the iteration is converging.

The default expression for the **Global variable** input field uses the built-in global error variable `schrp1.global_err`, which computes the max difference between the electric potential fields from the two most recent iterations, in the unit of V, as discussed in the section Charge Density Computation for the Schrödinger–Poisson Coupling multiphysics node in the *Semiconductor Module User's Guide*. Note that the prefix for the variable, in this case

schrp1, should match the **Name** input field of the Schrödinger–Poisson Coupling multiphysics node. Setting the **Absolute tolerance** to 1e-6 thus means the iteration ends after the max difference is less than 1 uV.

VALUES OF DEPENDENT VARIABLES

Use this section to configure the initial conditions for the study step. See section Values of Dependent Variables for details.

STUDY EXTENSIONS

Use the **Auxiliary sweep** option to solve for a set of parameters. For example, in the Self-Consistent Schrödinger–Poisson Results for a GaAs Nanowire tutorial model (schrodinger_poisson_nanowire), it is used to solve for a set of azimuthal quantum numbers. See Auxiliary Sweep for details.

Semiconductor Equilibrium

Use the **Semiconductor Equilibrium** ( ) study and study step to compute the semiconductor solution assuming the system is under thermal equilibrium. The study consists of a single Semiconductor Equilibrium step. The Semiconductor Equilibrium study step assumes that the charge carriers are in thermal equilibrium, so it only solves Poisson's equation (while still taking into account the space charge density from the charge carriers and the ionized dopants). This provides the most efficient solution for systems known to be in equilibrium, as well as an option to generate the initial condition for solving nonequilibrium models. The settings are similar to those for a Stationary study step. Note that all metal contacts attached to the same **Semiconductor Material Model** feature are biased at a common voltage, as dictated by the equilibrium condition. See Semiconductor Equilibrium Study Settings in the *Semiconductor Module User's Guide* on how to set the common bias voltage. This study is available with the Semiconductor interface in the Semiconductor Module.

Electrostatics Initialization

Use the **Electrostatics Initialization** ( ) study and study step to solve only the electrostatics equations, while neglecting other equations such as charge transport in the Electric Discharge interface. This study is valuable for providing accurate and consistent initial values for subsequent study steps, particularly when there is an electric field present at time zero.

Semiconductor Initialization

Use the **Semiconductor Initialization** ( ) study and study step to adaptively refine the mesh based on the gradient of the impurity doping concentration. The study consists of a single Semiconductor Initialization step. The Semiconductor Initialization study step has adaptive mesh refinement turned on by default and solves an unphysical equation that causes the mesh to be refined in regions where the gradient of the doping is large. The settings are similar to those for a Stationary study step. This study is available with the Semiconductor Module.

Frequency-Stationary, One-Way Electromagnetic Heating

The **Frequency-Stationary, One-Way Electromagnetic Heating** ( ) study is used to sequentially compute the electromagnetic field distribution and then the temperature field at thermal equilibrium for models created with the following physics interface and module combinations:

- Induction Heating interface, which requires the AC/DC Module
- Microwave Heating interface, which requires the RF Module
- Laser Heating interface, which requires the Wave Optics Module

This study first solves a frequency-domain equation for electromagnetics and then use the electromagnetic heat source as a source term when solving a subsequent stationary heat transfer equation. See the documentation in the AC/DC Module, RF Module, or Wave Optics Module for more information.

Frequency-Transient, One-Way Electromagnetic Heating

The **Frequency-Transient, One-Way Electromagnetic Heating** ( ) study is used to sequentially compute the electromagnetic field distribution in the frequency domain and then the temperature changes over time.

The study is available with the following physics interface and module combinations:

- Induction Heating interface, which requires the AC/DC Module
- Microwave Heating interface, which requires the RF Module
- Laser Heating interface, which requires the Wave Optics Module

Use the Frequency-Transient, One-Way Electromagnetic Heating study to compute temperature changes over time together driven by an electromagnetic heat source. It first solves a frequency-domain equation for electromagnetics and then use the electromagnetic heat source as a source term when solving a subsequent time dependent heat transfer equation. See the documentation in the AC/DC Module, RF Module, or Wave Optics Module for more information.

Small-Signal Analysis, Frequency Domain

The **Small-Signal Analysis, Frequency Domain** ( ) study is used for studying small oscillations about a biased solution in electromagnetics.

The study consists of two study steps: a Stationary study step, for computing the biased solution, followed by a Frequency-Domain Perturbation study step, for computing the frequency response about the biased solution. For the second study step, the computation is for a linear perturbation about the biased solution.

For more information, see Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis.

To add harmonic perturbation, see Harmonic Perturbation — Exclusive and Contributing Nodes. See also linper for information about the `linper` operator for indicating load terms that should be used by stationary solvers setting for harmonic linear perturbation.

For information about plotting results from this type of models, see Small-Signal Analysis, Prestressed Analysis, and Harmonic Perturbation Plot Settings.

This study is available with the AC/DC Module, MEMS Module, and Semiconductor Module.

With the AC/DC Module: *Small-Signal Analysis of an Inductor*, Application Library path **ACDC_Module/Devices,_Inductive/small_signal_analysis_of_inductor**.

Stationary and Time Dependent One-Way FSI Studies for Fluid–Multibody Interaction

The Stationary, One Way FSI and Time Dependent, One Way FSI studies are available with the Fluid–Multibody Interaction, Assembly interface, which requires the Multibody Dynamics Module.

STATIONARY, ONE WAY FSI

The **Stationary, One Way FSI** ( ) study is used for stationary fluid-structure interaction computations where the structural deformations are so small that they do not affect the flow. It is available for the Fluid–Multibody Interaction, Assembly multiphysics interface, available with the Multibody Dynamics Module.

The study consists of two study steps: a Stationary, Fluid study step, solving for the fluid velocity and pressure fields, followed by a Stationary, Solid study step, solving for the solid deformation field. The settings available for the two study steps are the same as for a Stationary study step. If an additional physics interface is added, then it is automatically added to both study steps.

TIME DEPENDENT, ONE WAY FSI

The **Time Dependent, One Way FSI** ( ) study is used for time-dependent fluid-structure interaction computations where the structural deformations are so small that they do not affect the flow. It is available for the Fluid–Multibody Interaction, Assembly multiphysics interface, available with the Multibody Dynamics Module.

The study consists of two study steps: a Time Dependent, Fluid study step, solving for the fluid velocity and pressure fields, followed by a Time Dependent, Solid study step, solving for the solid deformation field. The settings available for the two study steps are the same as for a Time Dependent study step. If an additional physics interface is added, then it is automatically added to both study steps.

STATIONARY, FLUID

The **Stationary, Fluid** ( ) study step is added to the Stationary, One Way FSI study, which is available for the Fluid–Multibody Interaction, Assembly interface. The settings available for this node are the same as for the Stationary node.

TIME DEPENDENT, FLUID

The **Time Dependent, Fluid** ( ) study step is added to the Time Dependent, One Way FSI study, which is available for the Fluid–Multibody Interaction, Assembly interface. The settings available for this node are the same as for the Time Dependent node.

STATIONARY, SOLID

The **Stationary, Solid** ( ) study step is added to the Stationary, One Way FSI study, which is available for the Fluid–Multibody Interaction, Assembly interface. The settings available for this node are the same as for the Stationary node.

TIME DEPENDENT, SOLID

The **Time Dependent, Solid** ( ) study step is added to the Time Dependent, One Way FSI study, which is available for the Fluid–Multibody Interaction, Assembly interface. The settings available for this node are the same as for the Time Dependent node.

Stationary, Time Dependent, and Frozen Rotor One-Way Studies for Nonisothermal Flow

The Stationary, One-Way NITF and Time Dependent, One-Way NITF studies are available with the Nonisothermal Flow interfaces and the Conjugate Heat Transfer interfaces, which require the CFD Module or the Heat Transfer Module. The Frozen Rotor, One-Way NITF study is available with the Rotating Machinery, Nonisothermal Flow interfaces, which require the Mixer Module plus the CFD Module.

STATIONARY, ONE-WAY NITF

The **Stationary, One-Way NITF** ( ) study is used for stationary nonisothermal flow computations where the temperature variations are so small that they do not affect the flow.

The study consists of two Stationary study steps, the first solving for the fluid velocity and pressure fields, and the second solving for the temperature field. If an additional physics interface is added, then it is automatically added to both study steps.

TIME DEPENDENT, ONE-WAY NITF

The **Time Dependent, One-Way NITF** ( ) study is used for time-dependent nonisothermal flow computations where the temperature variations are so small that they do not affect the flow.

The study consists of two Time Dependent study steps, the first solving for the fluid velocity and pressure fields, and the second solving for the temperature field. If an additional physics interface is added, then it is automatically added to both study steps.

FROZEN ROTOR, ONE-WAY NITF

The **Frozen Rotor, One-Way NITF** ( ) study is used for frozen rotor nonisothermal flow computations where the temperature variations are so small that they do not affect the flow.

The study consists of two Frozen Rotor study steps, the first solving for the fluid velocity and pressure fields, and the second solving for the temperature field. If an additional physics interface is added, then it is automatically added to both study steps.

Stationary and Time Dependent One-Way Studies for Moisture Flow

The Stationary, One-Way MF and Time Dependent, One-Way MF studies are available with the Moisture Flow interface, which requires the Heat Transfer Module.

STATIONARY, ONE-WAY MF

The **Stationary, One-Way MF** ( ) study is used for stationary moisture flow computations where the moisture variations are so small that they do not affect the flow.

The study consists of two Stationary study steps, the first solving for the fluid velocity and pressure fields, and the second solving for the relative humidity field. If an additional physics interface is added, then it is automatically added to both study steps.

TIME DEPENDENT, ONE-WAY MF

The **Time Dependent, One-Way MF** ( ) study is used for time-dependent moisture flow computations where the moisture variations are so small that they do not affect the flow.

The study consists of two Time Dependent study steps, the first solving for the fluid velocity and pressure fields, and the second solving for the relative humidity field. If an additional physics interface is added, then it is automatically added to both study steps.

Stationary Source Sweep

Use a **Stationary Source Sweep** ( ) study step to solve a stationary study that is sweeping among feedings, extracting lumped matrices (for example, a capacitance matrix in the Electrostatics interface or a resistance matrix in the Electric Currents interface). The settings for this study step are similar to those for the Stationary study step. In addition, the **Settings** window includes the following section.

SOURCE SELECTION

In this section, you can select the **Solve only for specified sources** checkbox to solve and sweep only over the sources that you add in the **Source names** field.

Source Initialization

The **Source Initialization** ( ) is a study step contained in the preset Stationary Source Sweep with Initialization or Frequency Domain Source Sweep with Initialization study for the Magnetic Fields, Currents Only interface, which requires the AC/DC Module. It is usually followed by a Stationary Source Sweep or Frequency Domain Source

Sweep study step. The **Source Initialization** study step is similar to the Coil Geometry Analysis that is used to compute the current flow field.

Stationary Source Sweep with Initialization

The **Stationary Source Sweep with Initialization** ( ) study step is a preset study step for the Magnetic Fields, Currents Only interface, which requires the AC/DC Module. It consists of a Source Initialization, followed by a Stationary Source Sweep study step.

Stationary Plug Flow

The **Stationary Plug Flow** ( ) study and study step are used for plug flow reactor models created with the Reaction Engineering interface. The reactor equations describe the molar flow rate (SI unit: mol/s) as a function of reactor volume (SI unit: m^3) under stationary conditions. The Plug Flow Solver utilizes the mathematical analogy between volume and time in the reactor equations. Therefore, the settings for this study step are similar to those in the Time Dependent study step. This study requires the Chemical Reaction Engineering Module.

	With the Chemical Reaction Engineering Module: *Nonisothermal Plug-Flow Reactor*, Application Library path **Chemical_Reaction_Engineering_Module/Tubular_Reactors/nonisothermal_plug_flow**.

Stationary, Time Dependent, and Frozen Rotor One-Way with Initialization Studies for Nonisothermal Flow

The Stationary, One-Way with Initialization NITF and Time Dependent, One-Way with Initialization NITF studies are available with the Nonisothermal Flow interfaces and the Conjugate Heat Transfer interfaces, which require the CFD Module or the Heat Transfer Module. The Frozen Rotor, One-Way with Initialization NITF study is available with the Rotating Machinery, Nonisothermal Flow interfaces, which require the Mixer Module plus the CFD Module.

STATIONARY, ONE-WAY WITH INITIALIZATION NITF

The **Stationary, One-Way with Initialization NITF** ( ) study is used for stationary nonisothermal flow computations with a turbulent model that requires an initialization. The study assumes that the temperature variations are so small that they do not affect the flow.

The study consists of a Wall Distance Initialization followed by two Stationary study steps. The **Wall Distance Initialization** study step is dedicated to solving for the reciprocal wall distance (that is, the reciprocal distance to the closest wall). The first **Stationary** study step solves for the fluid velocity and pressure fields, and the second solves for the temperature field.

TIME DEPENDENT, ONE-WAY WITH INITIALIZATION NITF

The **Time Dependent, One-Way with Initialization NITF** ( ) study is used for time-dependent nonisothermal flow computations with a turbulent model that requires an initialization. The study assumes that the temperature variations are so small that they do not affect the flow.

The study consists of a Wall Distance Initialization followed by two Time Dependent study steps. The **Wall Distance Initialization** study step is dedicated to solving for the reciprocal wall distance (that is, the reciprocal distance to the closest wall). The first **Time Dependent** study step solves for the fluid velocity and pressure fields, and the second solves for the temperature field.

FROZEN ROTOR, ONE-WAY WITH INITIALIZATION NITF

The **Frozen Rotor, One-Way with Initialization NITF** ( ) study is used for frozen rotor nonisothermal flow computations with a turbulent model that requires an initialization. The study assumes that the temperature variations are so small that they do not affect the flow.

The study consists of a Wall Distance Initialization followed by two Frozen Rotor study steps. The **Wall Distance Initialization** study step is dedicated to solving for the reciprocal wall distance (that is, the reciprocal distance to the closest wall). The first **Frozen Rotor** study step solves for the fluid velocity and pressure fields, and the second solves for the temperature field.

Thermal Perturbation, Eigenfrequency

The **Thermal Perturbation, Eigenfrequency** study is available with various heat transfer interfaces and requires the Heat Transfer Module or the MEMS Module. This study computes the oscillations around an equilibrium steady-state temperature field.

The study consists of two study steps: a **Stationary** study step, for computing the steady-state solution, followed by an **Eigenfrequency** study step, for computing the eigenmodes and eigenfrequencies.

Thermal Perturbation, Frequency Domain

The **Thermal Perturbation, Frequency Domain** study is available with various heat transfer interfaces and requires the Heat Transfer Module or the MEMS Module. This study computes eigenmodes and eigenfrequencies of linearized model around an equilibrium steady-state temperature field.

The study consists of two study steps: a **Stationary** study step, for computing the steady-state solution, followed by a **Frequency-Domain Perturbation** study step, for computing the harmonic oscillations.

Time Dependent with FFT

The **Time Dependent with FFT** study adds two study steps for computing a time-dependent solution using a **Time Dependent** study step and then applying a **Time-to-Frequency FFT** study step.

This study type is available with the Solid Rotor and Beam Rotor interfaces in the Rotordynamics Module.

Time Dependent with Phase Initialization

The **Time Dependent with Phase Initialization** ( ) study is used for time-dependent two-phase flow models that require an initialization of a level set function or phase field function. It adds a Phase Initialization study step followed by a Time Dependent study step to the Study node. The **Phase Initialization** study step is dedicated to solving for the reciprocal distance to the phase interface.

This study requires the CFD Module or Microfluidics Module.

PHASE INITIALIZATION

The **Phase Initialization** ( ) study step is added to the Time Dependent with Phase Initialization study when using two-phase flow or a moving interface. This first step is dedicated to solving for the reciprocal interface distance. In

the case of two-phase flow, the distance determined in the initialization step is the distance to the phase interface. The settings for this study are the same as for the Time Dependent study.

See an example using the Laminar Two-Phase Flow, Level Set interface:

- If you have the CFD Module: *Droplet Breakup in a T-Junction*, Application Library path **CFD_Module/Multiphase_Benchmarks/droplet_breakup**.
- If you have the Microfluidics Module: *Droplet Breakup in a T-Junction*, Application Library path **Microfluidics_Module/Multiphysics_Module/Two-Phase_Flow/droplet_breakup**.

Uncertainty Quantification

The **Uncertainty Quantification** ( ) study specifies an uncertainty quantification study type with its associated settings. For information about the use of this study and its functionality, see the *Uncertainty Quantification Module User's Guide*.

Wavelength Domain

The **Wavelength Domain** ( ) study and study step are used to compute the response of a linear or linearized model subjected to electromagnetic harmonic excitation for one or several wavelengths.

For example, in electromagnetic wave propagation, it is used to compute a structure's transmission and reflection versus wavelength. A Wavelength Domain study accounts for the effects of all eigenmodes that are properly resolved by the mesh and how they couple with the applied excitations. The output of a Wavelength Domain study step is typically displayed as a transfer function (for example, magnitude or phase of scattering parameters versus wavelength).

The Wavelength Domain study step also provides a frequency, defined as

$$f = \frac{c_0}{\lambda},$$

where f is the frequency, c_0 is the speed of light in vacuum, and λ is the vacuum wavelength. This frequency can be used as an input parameter to physics interfaces formulated to be run by Frequency Domain studies.

It is also possible to add an auxiliary sweep to this study step, which creates a multiparameter sweep (Parametric solver) over both the wavelength and the given parameters, and optionally with continuation in the wavelength or in one of the given parameters. It corresponds to a stationary parametric solver that is preset to linearize the equations (Stationary Solver with a Parametric attribute).

Alternatively, select the **Use asymptotic waveform evaluation** checkbox to use an AWE Solver instead of the Parametric solver.

The **Include geometric nonlinearity** checkbox and the **Results While Solving**, **Mesh Selection**, **Adaptation and Error Estimates**, **Geometric Entity Selection for Adaptation**, and **Auxiliary Sweep** sections are described in Common Study Step Settings. There is also detailed information in the Physics and Variables Selection and Values of Dependent Variables sections.

This study and study step require the Wave Optics Module.

STUDY SETTINGS

Specify the vacuum wavelengths to use for the wavelength sweep. Select the unit to use from the **Wavelength unit** list (default: µm). Type the vacuum wavelength in the **Wavelengths** field using space-separated numbers or the `range` function.

Use the **Load parameter values** field to select a file with parameter values. You can browse your file system for files by clicking the **Browse** button ( ). You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ). After selecting a file, click the **Read File** button ( ) to load the parameter values into the **Frequencies** field.

For information about the **Reuse solution from previous step** list, see Reuse Solution from Previous Step List.

From the **Tolerance** list, choose **Physics controlled** (the default) to use the tolerance suggested by the physics. Choose **User controlled** to override the suggested relative tolerance with a value that you enter in the **Relative tolerance** field.

STUDY EXTENSIONS

Also see Auxiliary Sweep.

Asymptotic Waveform Evaluation

Select the **Use asymptotic waveform evaluation** checkbox to enable the *asymptotic waveform evaluation (AWE) solver*. The Frequency Domain study generates a solver configuration that is used to solve a stationary parametric problem or an asymptotic waveform evaluation problem. By selecting this checkbox, this study step corresponds to an AWE Solver.

Distribute Parametric Solver

If you are running a parametric sweep and want to distribute it by sending one parameter value to each compute node, select the **Distribute parametric solver** checkbox. This requires that your study includes a parametric sweep. To enable this option, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog.

With the Wave Optics Module: *Hexagonal Grating*, Application Library path **Wave_Optics_Module/Gratings_and_Metamaterials/hexagonal_grating**.

Computing a Solution

Overview

A solution can be computed in a few ways depending on the sequence implemented for a model.

For the settings in the **Solution** node's Settings window under **Cluster Computing**, see Cluster Computing Settings below.

THE DIFFERENCE BETWEEN COMPUTING A STUDY, SOLVER, OR JOB

There are conceptual differences between computing, or running, a study versus running a solver configuration or a job configuration. When a solver configuration or job configuration is run, no nodes are added or removed; it is computed "as is."

Running a study, on the other hand, can be different. When you compute a Study, it always runs the enabled configurations (see below). What the Study runs can be a Job or a Solver (for example, a Stationary Solver) depending on the study configuration. If a Job is run, it typically also means that a solver is also run (by the job). But before the study runs a job or a solver, it reconstructs the (enabled) configurations from scratch. An exception to this rule is when the enabled configurations are edited (an asterisk indicates this; see Figure 20-7 for an example), in which case the sequences are computed "as is."

ABOUT ENABLED STUDY OR SOLVER SEQUENCES

The particular sequence that is **Enabled** and runs when selecting **Compute** has a green border around its icon ( ). You can disable an enabled sequence by right-clicking the node and selecting **Disable** (which removes the green border). If no sequence is enabled when the study or solver configuration attempts to generate a sequence, a new sequence with default settings is generated. Only one sequence per study can be enabled. For job configurations, the sequence here means a unique path defined from a solver sequence to a job configuration and possibly another job configuration pointing to that job configuration, and so on. Also see Figure 20-6 for other examples of enabled sequences.

COMPUTING A STUDY OR SOLVER

The most straightforward method to compute a solution is to right-click the Study node ( ) and select **Compute** ( ) or press F8. You can also click **Compute** ( ) in the main and **Study** toolbars and in the toolbar at the top of the study steps' and solver nodes' **Settings** windows.

By default, a study creates a Solution dataset and plot groups with results plots suitable for the physics interfaces for which you compute the solution. If you do not want to generate plots automatically, clear the **Generate default plots** checkbox in the **Study Settings** section in the main Study node's **Settings** window. You can also right-click the main **Study** node and select **Show Default Plots** ( ) to add the plot groups and plots that are added by default if the **Generate default plots** checkbox is selected. Right-click the main **Study** node and choose **Reset Default Plots** ( ) to restore the default plots and their settings to the default plots and settings if you have changed or removed the default plots.

If the study contains more than one study step, and you want to compute only a part of the study steps, right-click a study step and select:

- **Compute Selected Step** ( ) (or press F7) to compute just the selected study step.
- **Compute to Selected** ( ) to compute from the first to the selected study step.
- **Compute from Selected** ( ) to compute for all study steps from the selected study step to the last.

If you show the solver sequences under **Solver Configurations**, you can right-click any node in a solver sequence and select:

- **Compute** ( ) (or press F8) to compute the entire solver sequence.
- **Compute to Selected** ( ) (or press F7) to compute the solver sequence from the top down to the selected node.
- **Compute from Selected** ( ) to compute from the **Compile Equations** node ( ) that is associated with the selected node down to the end of the solver sequence.

UPDATING A SOLUTION

To update the solution for a study to use the current values of parameters and user-defined variables, right-click the **Study** node and select **Update Solution** ( ) (or press F5). This is useful in the following situations when you have:

- Added or edited variables or parameters and want to use these during postprocessing without having to solve the model again.
- Changed the element order and want to interpolate the solution onto the new elements for results analysis or other purposes.
- Remeshed or modified a geometry and want to interpolate the solution onto the new geometry for results analysis or other purposes.

In all these cases, the COMSOL software passes or interpolates the solution to the resulting datasets but does not recompute it to reflect any changes in variables, equations, mesh, or geometry.

If you make changes to the model that affect the solution, you must recompute the solution; just updating the solution does not take such changes into account.

COMPUTING A SOLVER CONFIGURATION

When you have added study steps to a study, a Solver Configurations (and maybe a Job Configurations) sequence is generated when the Study is computed. The Solver Configurations branch represents the solvers, dependent variables and degrees of freedom, and other study-related functionality that the study steps require.

A **Solver Configurations** or **Job Configurations** node displays automatically if it has content. Otherwise, if you click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog, it is available as an option from the context menu.

In some cases, the default settings in the study steps are not sufficient to specify the details of how to obtain a solution. In this case you can edit the sequence and run it again. See Editing and Rerunning a Solver Configuration below.

To compute a solution:

- Under **Solver Configurations**, right-click the corresponding **Solution** node and select **Compute**.
- Right-click a Study node and select **Compute** to compute the enabled solver (the node with a green border around its icon), if such a solver configuration exists. If no solver configuration exists, or if all sequences are disabled, a new solver configuration is generated and computed.

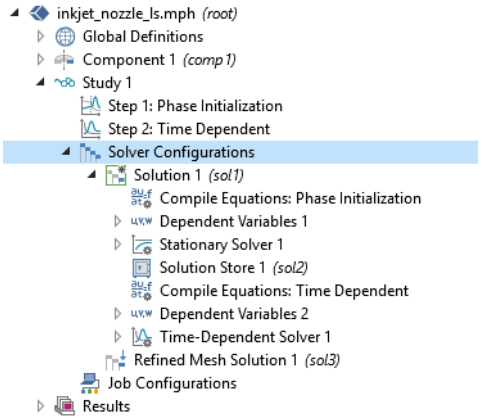

Figure 20-7: A Solver Configurations sequence with more than one solver. This is an example from the CFD Module Application Library.

If you have already generated a solver configuration for the study, or if your solver configuration consists of several solvers, as with the study steps, you can right-click a configuration and choose:

- **Compute to Selected** ( ) (or press F7), to run a particular solver, or
- **Compute from Selected** ( ) to run the selected solver and all solvers below it in the sequence, or
- **Compute** (or press F8), to run the entire solver configuration.

For example, right-click a Dependent Variables node and select **Compute to Selected** to evaluate the initial values for the dependent variables (similar to the **Get Initial Value** and **Get Initial Value for Step** options for the main **Study** nodes and the study steps).

EDITING AND RERUNNING A SOLVER CONFIGURATION

The Solver Configurations branch nodes (or if applicable, the Job Configurations branch) can be edited to adjust solver settings, for example, if you want to change a tolerance or use a different time-stepping method. If you edit any settings in a subnode to a **Solution** node, an asterisk in the upper-right corner (Figure 20-8) indicates that the settings differ from the default settings for the study types in the study.

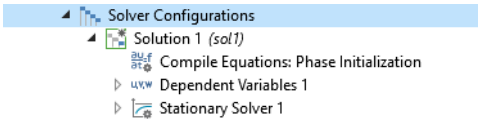

Figure 20-8: A Solution node has an asterisk in the icon to indicate the sequences that have been edited. To compute, highlight the Solution node, press F8, right-click and choose Compute, or click the button in the Settings window.

To see what properties and values that have changed in any node with an asterisk in a solver configuration, the **Changes from Default Values** section at the bottom of each node's Settings window contains a list of all properties that have changed, including descriptions, property names, default values, and current values.

After editing a solver configuration, you run the sequence again. Running a solver configuration is tantamount to computing a solution. Like mesh nodes, solution nodes are not built automatically as they are added. It is possible

to have several solver configurations under a Solver Configurations node (see Figure 20-7), including **Solver - Copy** nodes for copies of a solution (see Create Solution Copy).

CLUSTER COMPUTING SETTINGS

Under **Cluster Computing**, you get information about cluster solution storage. You can also choose a partitioning method from the **Partitioning method for distributed computing** list: **Off** (the default), **Mesh ordering**, **Nested dissection**, or **Weighted nested dissection**. This method affects the partitioning of the mesh data on cluster for the purpose of creating a DOF enumeration optimized for the particular cluster configuration (number of nodes). *Mesh ordering* is doing the partitioning based on existing mesh-element order and will produce a result similar to the existing DOF enumeration without any partitioning of the data. The *nested dissection* will on *n* cluster nodes partition the mesh data into *n* parts, minimizing the overlap between the parts before the DOFs for all the parts are enumerated. The *weighted nested dissection* option takes into account the expected number of DOFs per mesh element to produce parts with comparable total number of DOFs in each part. The benefit of using nested dissection and weighted nested dissection partitioning for cluster configuration-specific DOF enumeration is the performance improvement due to the reduction in the amount of communication between cluster nodes.

CONVERTING A SOLUTION FOR CLUSTER COMPUTING

Right-click a **Solution** node and choose **Domain Decomposition** > **Convert to Domain Decomposition (Schwarz)** and **Domain Decomposition** > **Convert to Domain Decomposition (Schur)** to convert a solver into a similar Domain Decomposition solver with settings adapted for cluster computing. These options for conversion to domain decomposition solvers are also available on the context menus of solver nodes that support direct and iterative solvers (such as **Stationary Solver** and **Time-Dependent Solver** nodes). They are mainly intended for running on larger clusters where the domain decomposition strategy can be faster than the usual solvers. See Domain Decomposition (Schwarz) and Domain Decomposition (Schur) for more information about the domain decomposition solvers.

PROGRESS AND LOG INFORMATION

While a problem is being solved, it is useful to know its progress. The Progress Window monitors the state of the analysis for the solvers during the solution process. In this window, you can Cancel or Stop a Solver Process and also continue the solver process. Alternatively, in The Log Window you can inspect convergence information and other data from the latest and earlier runs.

- Getting Results While Solving and Convergence Plots
- Computing the Initial Values

Getting Results While Solving

The ability to get numerical results and plots of the intermediate solutions while solving can be useful for diagnosing problems and for monitoring the progress of the solution. COMSOL Multiphysics supports the following ways of displaying results while solving:

- Plots in The Graphics Window: You can select any of the plot groups in the model to display while solving. Note that many plots are fast to evaluate whereas others, such as Radiation Patterns and Streamline plots, can be slower to evaluate and can therefore slow down the solution process.
- Probe data in the **Table** window (see The Table Window and Tables Node) and associated line graphics in a separate **Probe Plot** window: You can include any probe defined in the model. See Probes.
- In the **Results While Solving** sections on the study step's **Settings** windows, you can control which plots to display while solving. See Common Study Step Settings.

Computing the Initial Values

In some situations you might want to evaluate and plot values, expressions, or functions that need not be solved for, such as initial values and functions evaluated using the initial values.

To make the initial values available for results evaluation and plotting, right-click the Study node ( ), and select **Get Initial Value** ( ). By default this plots the initial values of the variables solved for as specified by the **Field** subnode ( ) under a Dependent Variables node for the first study step in the solver configuration. For a parametric sweep, it uses the first parameter value.

For each study step you can also right-click and choose **Get Initial Value for Step** ( ) to evaluate the initial value for that step. It is also possible to get the initial value for a particular solution under **Solver Configurations** by right-clicking a **Solution** node and selecting **Solution** > **Get Initial Value** ( ).

Also variables not solved for (such as a solution from a previous time-dependent or parametric analysis) can be made available for results evaluation and visualization. Select **Values of variables not solved for** from the **Keep solution** list under **Output** in the **Dependent Variables** node.

The Progress Window

The **Progress** window ( ) displays the progress of the mesh generator, solver, or postprocessing evaluation during the process, including a progress bar and progress information for each mesh generator, solver, or postprocessing evaluation. You can view the progress from the status bar in the lower-right corner of the COMSOL Desktop.

The solvers call each other in a hierarchical order: the adaptive solver calls the linear, nonlinear, parametric, eigenvalue, or time-dependent solver; the parametric solver calls the nonlinear or linear solver; the time-dependent, eigenvalue, linear, and nonlinear solvers all call both the assembly and the linear system solver. The solver hierarchy is visible in the **Progress** window because each solver adds its own line when it is called.

This window is always available but is empty when no progress information is available. For a log of the progress information, see The Log Window.

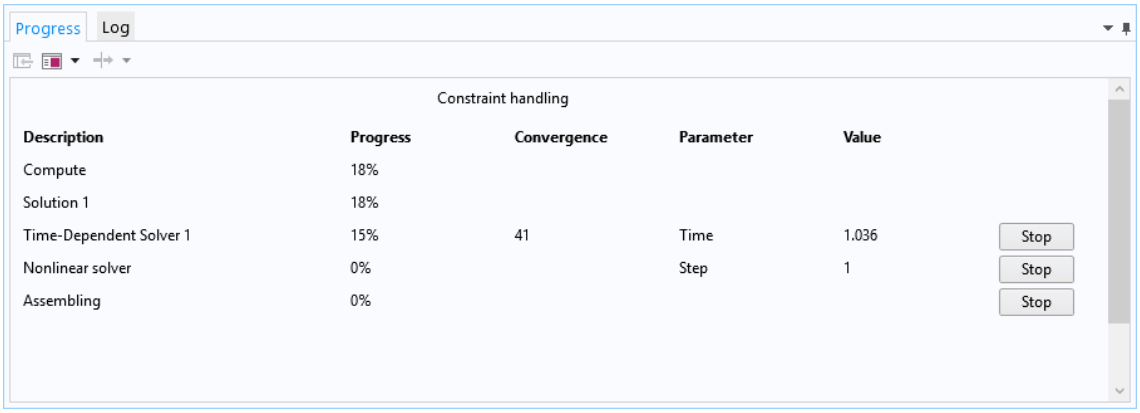

Figure 20-9: An example of the Progress Window solving a model.

The **Progress** window has the following columns:

- The **Description** column shows the solver name.
- The **Progress** column shows an estimate of the solver progress.
- The **Convergence** column shows an estimate of the solver's convergence if available. Also see Convergence Plots for more information.

- The **Parameter** and **Value** columns contain solver-dependent information: the adaptive solver shows the adaptive mesh generation number; the time-dependent solver shows the time; the parametric solver shows the parameter value; and the nonlinear solver and iterative linear system solvers show the iteration number.

If you want to continue an interrupted parametric or time-dependent solution, for example, click **Continue** ( ) in the **Progress** window's toolbar, and then choose the available study that you want to continue. You can also right-click the main **Study** node and choose **Continue**, or click the **Continue** button in the **Study** ribbon, to, for example, continue a stopped or interrupted time-dependent solution or parametric sweep.

The optimization solver can add rows to the **Progress** window, see About the Convergence Plot and Progress Window.

CANCEL OR STOP A SOLVER PROCESS

You can cancel or stop the solver process if the model's solving time or likelihood for convergence is not progressing as expected. Use the horizontal or vertical scrollbars if needed. On the status bar you can follow the progress, cancel the solver process by clicking the **Cancel** button ( ), or click the **Progress** button ( ) to open this window. In the same way, you can also cancel the meshing and the evaluation during postprocessing.

You can use the **Stop** buttons that appear at each solver level to stop the solver's execution. When you click a **Stop** button, the COMSOL software returns a current approximation to the solution if possible. For example, when you click it at the adaptive solver level, the underlying linear, nonlinear, parametric, eigenvalue, or time-dependent solver continues until it is finished, but the adaptive solver stops at its current generation, immediately returning a solution. Similarly, you can click the **Stop** button to return the current iteration for the nonlinear solver or an iterative solver. Also use the **Stop** button during time stepping to return all time steps up to the current one. The parametric solver works similarly: To return the solutions for all parameter values up to the current one, click the **Stop** button.

- Meshing
- Convergence Plots

Convergence Plots

Convergence plots use graphics to show how an error estimate or time step evolves during the solution process for nonlinear, time-dependent, and parametric solvers. By default, convergence plots are generated.

To control which solvers generate convergence plots, click the **Convergence Plot Settings** ( ) button in The Progress Window toolbar to select or clear the convergence plots for each solver. For example, for a nonlinear time-dependent model, the menu that contains the nonlinear solver and Time-Dependent Solver (Generalized-alpha) as options.

By default, all solvers are selected, and the convergence plot for each solver appears in its own **Convergence Plot** window. Click to clear the check mark for a solver to turn off its convergence plot.

Click the **Copy Convergence Data to Model** button ( ) in the toolbar to copy the convergence data to a table in the **Table** window. Clicking this button is also the only way to keep the convergence plots in model files.

NaNs (Not-a-Number entries) that appear in the tabulated convergence data represent breaks between multiple convergence cycles in an interactive solution process.

A special convergence plot is shown when gradient based optimization is performed, see About the Convergence Plot and Progress Window.

CONVERGENCE INFORMATION IN THE PLOTS

The convergence plots show an error estimate against the iteration number for the nonlinear solver and for the iterative linear system solvers (the Conjugate gradients, BiCGStab, GMRES, FGMRES, TFQMR, and multigrid solvers). See Convergence Criteria for Linear Solvers.

For the nonlinear solver, the convergence plots show an error estimate for each nonlinear iteration number. These numbers also appear in The Log Window. The segregated solver shows one plot with one graph for each segregated step.

For the iterative linear system solvers, the error estimate for each linear iteration is a factor times the relative (preconditioned) residual. This number also appears in the Log window as **LinErr**. When these solvers are used together with the nonlinear solver, the graphs for the different linear-system solution steps are merged, and the plots use the accumulated number of iterations. Each linear solver used has a separate plot window.

When using the parametric solver, the graphs for the different parameter steps are merged, and the convergence plots use the accumulated number of iterations. The graphs for the different nonlinear and linear solve steps are concatenated. The plot uses the accumulated number of iterations.

When using a Time-Dependent Solver, the graph in the **Convergence Plot** window shows the reciprocal of the time step size versus the time step. That is, a convergence plot with decreasing values shows that the time-dependent solver takes longer time steps, and vice versa.

The error estimate numbers for the last iteration also appear in the **Convergence** column in The Progress Window.

CHANGING THE DEFAULT SETTINGS

Open the **Preferences** window and click **Results** > **Plots** > **Convergence Plots** to edit the preferences for the plots that you can use to monitor solver convergence.

- The **Generate convergence plots** checkbox is selected by default. Clear that checkbox if you do not want the software to generate convergence plots.
- To control the size of the buffer used for storing the steps in the convergence plot, in the **Convergence plot buffer size (steps per plot)** field (default value: 10,000 steps).

The Log Window

The **Log** window ( ) contains information from previous solver runs, including convergence information, solution time, and memory use. When a solver starts, the log window displays logs from all solver calls. This window is always available. For progress information during a solver or mesher process, see The Progress Window.

A horizontal divider (`===============`) indicates the start of a new solver progress log. To differentiate logs from different models, the log contains a horizontal divider displaying the name of the Model MPH-file each time a model is opened. For example,

```
================ Opened thin_layer_diffusion.mph =================
```

It also contains a similar divide when you save a model to a new file (using **Save As**):

```
================= Saved thin_layer_diffusion.mph =================
```

Arrows indicate the beginning and the end of the compile equation stage and the solver stage.

When the COMSOL Multiphysics software starts to compile the equations for the study, it prints the following information:

- The geometry shape function
- The processor and number of cores and sockets that COMSOL Multiphysics uses.
- The available memory, physical memory, and virtual memory.
- The time required for the equation compilation step.

When a solver starts working, it prints the name of the solvers used and then prints the number of degrees of freedom in the linear systems to be solved to the log. For certain problems, there are additional degrees of freedom involved in the discrete problem formulation that do not affect the size of the matrices assembled by the solver. These are called *internal degrees of freedom* and are displayed separately from the actual degrees of freedom in the log. For example, when solving plasticity problems in structural mechanics, plastic strains are represented by internal degrees of freedom. The log then contains information about if symmetric or nonsymmetric matrices are found and about the scales of the dependent variables. Depending on the solver and the detail level of the solver log (see the **Solver log** settings for the Advanced node), additional information is printed. With a detailed solver log, the log also contains information about the type of null-space function that is used.

When a solver has finished it reports the following information:

- The solution time (in seconds)
- The maximum amount of physical memory used (in MB)
- The maximum amount of virtual memory used (in MB)

If used, the log reports the out-of-core memory used in addition to the core (physical) memory.

For parallel and distributed simulations, the log also contains the memory used per node, and sections that are separated by

```
<<<<< Node X <<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<
```

… some log information here

```
>>>>> Node X >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>
```

contain log information obtained from other nodes than Node 0 (or use the head node if that is used elsewhere). Log information without separators is log information from Node 0 (or the head node). This is the only log information that is updated live. All other log information is obtained after the logging operation is finished.

In addition, the log includes the following information that is specific to the type of solver:

- The Adaptive and Parametric Solver Log
- The Nonlinear Solver Log
- The Iterative Linear System Solver Logs
- The Time-Dependent Solver Log
- The Eigenvalue Solver Log
- The Optimization Solver Log

Also, see Pseudo Time Stepping for information about the CFL ratio in the log.

Scrolling in the Log Window

You can scroll the contents of the **Log** window to display information from earlier runs.

- Click the **Scroll Lock** button ( ) to stop the window from scrolling the log during a solver call, for example.

- Click the **Scroll Lock** button again to resume scrolling.
- Click the **Clear** button ( ) to clear the **Log** window from all information.

Buffer Size of the Log Window

By default, the buffer size of the **Log** window is limited to 30,000 characters.

	To change the size of the buffer, go to the **Preferences** window, choose the **Log and Messages** page under the **User Interface** page, and then enter a maximum buffer size (in characters) in the **Log window size (characters)** field. The default is 30,000 characters. This buffer size also applies to the log stored in the solvers for the last run but not to solver logs stored in a file.

Timestamps in Log Messages

By default, the log messages include timestamps. If you do not want to include timestamps, choose the **Log and Messages** page under the **User Interface** page in the Preferences window and then clear the **Add timestamps to messages** checkbox.

SAVING AND OPENING SOLVER LOGS

The solver log as displayed in the **Log** window is limited to a given number of characters (the buffer size described above). When debugging a larger model, it can be useful to have access to the whole solver log. This is possible by using the ability to store the log in a file. To activate it, go to the **Preferences** window, choose the **Log and Messages** page under the **User Interface** page, and select the **Store in file** checkbox. You can then specify the retention time in the **Retention time for log files (days)** field; the default is 10 days. The solver log is stored in `.comsol/v63/sessions/solverlog_`*`YYYY-MM-DD_HHmmSS_pid`*`.log` or similar in your user directory.

You can also activate the storage in the **Log** window by clicking the **Store in File** button ( ). Click the **Open Log File** button ( ) to open the stored solver log and show its content in a text editor such as Windows Notepad.

THE ADAPTIVE AND PARAMETRIC SOLVER LOG

The adaptive mesh refinement solver prints a section in the log for each adaptive generation containing the current number of elements and a global error indicator value. The Parametric solver similarly outputs one section to the log for each parameter value.

The Stationary Solver, Time-Dependent Solver, and Eigenvalue Solver log their iterations.

THE NONLINEAR SOLVER LOG

The log from the nonlinear solver contains the following information:

- The iteration number (**Iter**).
- A relative error estimate, which is one of the following:
  - The solution error (**SolEst**), if **Solution** is selected from the **Termination criterion** list for the solver.
  - The residual error (**ResEst**), if **Residual** is selected from the **Termination criterion** list for the solver.
  - Both the solution error and the residual error (**SolEst** and **ResEst**), if **Solution or residual** or **Solution and residual** is selected from the **Termination criterion** list for the solver. The convergence is then based on the minimum of the solution error or the residual error multiplied by the residual factor.

    If the solver log detail is set to **Detailed** from the **Solver log** list in the **Advanced** node's **Settings** window, the residual error and the solution error (depending on the selected termination criterion) from each individual field in the model appear in the solver log.
- The damping factor used in each Newton step (**Damping**).
- Fraction of Newton and Cauchy steps for the Double dogleg solver (**Newton, Cauchy**).

- The size of the undamped Newton step (**Stepsize**) in the error estimate norm.
- The numbers of residuals (**#Res**), Jacobians (**#Jac**), and linear-system solutions computed (**#Sol**) so far.

THE DIRECT LINEAR SYSTEM SOLVER LOGS

The direct linear system solvers produce a log that additionally contains a relative error estimate (**LinErr**) and the relative residual (**LinRes**). The relative error is estimated by deferred correction (also called iterative improvement) — that is, by solving $A \cdot dx = r(x)$ for dx and setting $\mathrm{LinErr} = \mathrm{rhoB} \cdot \mathrm{norm}(dx)/\mathrm{norm}(x)$, where rhoB is the *factor in error estimate* value from the direct solver, and $r(x) = Ax - b$. The relative residual is the Euclidean norm of the residual divided by the norm of the linear system's right-hand side; that is, $\mathrm{LinRes} = \mathrm{norm}(r(x))/\mathrm{norm}(b)$.

THE ITERATIVE LINEAR SYSTEM SOLVER LOGS

The iterative linear system solvers produce a log that additionally contains the total number of linear iterations (**LinIt**), a relative error estimate (**LinErr**), and the relative residual (**LinRes**). The relative error estimate is a factor times the relative (preconditioned) residual. The relative residual is the Euclidean norm of the residual divided by the norm, $|b|$, of the linear system's right-hand side.

Convergence Criteria for Linear Solvers

THE TIME-DEPENDENT SOLVER LOG

For the Time-Dependent Solver, the time-stepping algorithm produces a log that contains:

- The time step number (**Step**).
- Time (**Time**; output times are indicated with **out**).
- The step size (**Stepsize**).
- The number of residuals (**Res**), Jacobians (**Jac**), and linear system solutions (**Sol**) computed.

You can see also the order of accuracy of the method (**Order**), the number of error test failures in time stepping (**Tfail**), and the number of failures in the nonlinear iterations (**NLfail**). For iterative linear system solvers, the log also contains the total number of linear iterations, a linear error estimate, and a relative residual (see above). Failures in the nonlinear iterations (**NLfail**), for example, can affect the time stepping so that the solver takes smaller time steps.

If an iterative solver is used, the log includes the total number of iteration (**LinIt**), the relative residual (**LinRes**), and the linear error estimate (**LinEst**).

If you use the Runge–Kutta time-stepping methods with local time stepping, the log includes the local error (**LocError**). It is a weighted root mean square norm of the difference of the fourth-order and fifth-order solutions, or, for RK34, the difference of the third-order and fourth-order solutions. More specifically, it is the relative tolerance times the norm described in Absolute Tolerance Settings for the Time-Dependent Solver.

Also, for the detailed solver log, the time-dependent solver lists any algebraic variables at the start of the solution process.

THE EIGENVALUE SOLVER LOG

The Eigenvalue Solver produces a log that contains the iteration number (**Iter**), an error estimate (**ErrEst**), the number of converged eigenvalues (**Nconv**), and — if you are using an iterative linear solver — the number of linear iterations (**LinIt**).

SNOPT

SNOPT is an iterative procedure that involves *major* and *minor* iterations. A major iteration results in a new solution candidate. For each major iteration, the optimization solver solves a quadratic-programming subproblem using an iterative procedure; these iterations are the minor iterations.

The log produced by the optimization solver SNOPT has the following data:

- The cumulative number of minor iterations (**Itns**).
- The current major iteration number (**Major**).
- The number of minor iterations for the current major iteration (**Minor**). This value should be 1 when the solver is close to the solution.
- The step length taken in the current search direction (**Step**). This value should be 1 when the solver is close to the solution.
- The number of times the multiphysics model has been solved (**nEval**).
- The maximum complementarity gap (**Error**). It is an estimate of the degree of nonoptimality of the reduced costs. For convergence, this value should be smaller than the **Optimality tolerance**.
- The current value of the objective function (**Objective**).

IPOPT

IPOPT is an iterative procedure that involves an interior point line method for finding a local solution to a general nonlinear programming problem.

The log produced by the optimization solver IPOPT has the following data:

- The current iteration count (**Itns**). This includes regular iterations and iterations during the restoration phase.
- The infinity norm of the primal step (**Step**). During the restoration phase, this value includes the values of additional variables, p and n (see Eq. (30) in Ref. 7).
- The number of times the multiphysics model has been solved (**nEval**).
- The total optimality error (**Error**) for the original NLP problem at the current iterate, using scaling factors based on multipliers (see Eq. (6) in Ref. 7). The constraint violation is measured with slacks.
- The current value of the objective function (**Objective**).
- The unscaled constraint violation at the current point (**MaxInfeas**). This is available in the log only when there are active constraints.

MMA

The MMA solver implements another general-purpose optimization algorithm. The method is based on solving a sequence of approximating subproblems, one for each *inner* iteration. The subproblem is constructed from function values and gradients, which are evaluated once per *outer* iteration only. Each outer iteration requires one or more *inner* iterations, depending on whether the last subproblem was found to be conservative or not. Once a feasible point is found, outer iterates stay feasible. If the initial guess is infeasible or the feasible set is empty, nonzero infeasibilities may be reported.

The log produced by the MMA solver contains the following data:

- The cumulative number of outer iterations (**Iter**). One outer iteration per line is reported in the log.
- The number of inner iterations for the current outer iteration (**Inner**). This is the number of attempts needed to find a conservative approximating subproblem, which in some sense measures the nonlinearity of the problem.
- The cumulative number of model evaluations (**nEval**). Each inner iteration requires a model evaluation in order to check the conservativeness of the approximation. Gradients are only computed once for each outer iteration.

- The estimated error (**Error**). The error is defined as the maximum relative change in any control variable since last outer iteration, computed as a percentage of the distance between the control variable's bounds.
- The current value of the objective function (**Objective**).
- The maximum violation of any constraint (**MaxInfeas**). For a feasible solution, this number must be zero. It may be nonzero in the first outer iterations if the initial guess is infeasible.

Levenberg-Marquardt

The optimization solver Levenberg-Marquardt is an iterative procedure used to solve least-squares problems. The log produced by the Levenberg-Marquardt solver contains the following data:

- The number of Levenberg-Marquardt iterations (**Itns**).
- The current Levenberg-Marquardt factor (**lmFact**). A small factor typically indicates fast convergence.
- The number of times the multiphysics model has been solved (**nEval**).
- The maximum absolute value of the gradient (with respect to the control variables) of the objective function (**Gradient**).
- The estimated error based on the gradient, the objective function, and the control variables (**ErrJ**). The solver will terminate, if this value becomes smaller than the **Optimality tolerance**.
- The maximum change of the scaled controls (**Stepsize**). The solver will terminate, if this value becomes smaller than the **Optimality tolerance** times the **Control variable tolerance factor**.
- The sum of squares divided by the initial sum of squares (**ErrF**). The column only appears, when **Terminate also for defect reduction** is enabled. This will also cause the solver to terminate, if the value becomes smaller than the **Optimality tolerance** times the **Defect reduction tolerance factor**.
- The current value of the objective function (**Objective**).

The External Process Window

Use the **External Process** window ( ) to follow external processes (such as distributed batch jobs) that have been started. The window updates when you are attached to the external process. You can do operations that are performed in the External Process nodes under a Parametric or Batch job configuration by selecting an external process from the list and then selecting the operation. When detached, you can reattach by pressing the **Attach Job** button. The window opens automatically when you start a batch process. See Table 20-5 for descriptions of the toolbar buttons available in this window.

To open the **External Process** window:

- Windows users, from the **Home** toolbar select **Windows** > **External Process**.
- Cross platform (macOS and Linux) users, select **Windows** > **External Process**.

TABLE 20-5: EXTERNAL PROCESS TOOLBAR BUTTONS.

ICON	NAME	DESCRIPTION
	Attach Job	If a job has been detached, click to reattach the job to run external processes and follow the status updates.
	Stop All Processes	Sends the stop command to unfinished jobs. Similar to using the Stop button for The Progress Window.
	Cancel All Processes	Sends the cancel command to unfinished jobs. Similar to using the Cancel button for The Progress Window.
	Stop Process	Stops the selected process. Similar to using the Stop button for The Progress Window.
	Cancel Process	Cancels the selected process. Similar to using the Cancel button for The Progress Window.

TABLE 20-5: EXTERNAL PROCESS TOOLBAR BUTTONS.

ICON	NAME	DESCRIPTION
	Rerun Job	Restarts or continues the selected process depending on the status: restarts from the beginning if the job has failed; continues the simulation from a recovery file, in the case that the external process has been interrupted (for example, the scheduler has timed out); or continues the simulation process from the last saved output, in the case that the simulation process has been manually stopped.
	Clear Status	Clears the status of the selected job. Useful when the status indicates that the process is running but the process has failed.
	Log	Shows the current log of the selected process.
	Open File	Opens the output file from the selected process.
	Batch Jobs (generated tables)	Selects the Batch Jobs to view.

- The Time-Explicit Algorithms

About Solver Commands in the *COMSOL Multiphysics Programming Reference Manual*

The settings for the solver operation nodes listed in Table 20-6 are detailed. There is also a list of the References for the Solution Operation Nodes and Solvers.

TABLE 20-6: SOLUTION OPERATION NODES.

ICON	NAME	DESCRIPTION
	AWE Solver	Solve a parametric problem with asymptotic waveform evaluation.
u,v,w	Dependent Variables	Handles the dependent variables solved for (initial values, scaling) and dependent variables not solved for (prescribed values).
	Eigenvalue Solver	Solve linear or linearized eigenvalue problems (also called eigenfrequency problems). Also see The Eigenvalue Solver Algorithms.
	FFT Solver	Use a forward FFT to transform a time-dependent solution to the frequency domain or an inverse NFT/FFT to transform a frequency-domain solution to the time domain.
	Modal Reduction	To solve either parameter stepping (also called frequency response) or time stepping (also called transient response) problems using a reduced model. This approach also produces a reduced-order model or reduced matrices. Also see The Modal Solver Algorithm.
	Modal Solver	To solve either parameter stepping (also called frequency response) or time stepping (also called transient response) problems using a reduced model and a modal approach. Also see The Modal Solver Algorithm.
	Optimization Solver	Solve PDE-constrained optimization problems. Requires the Optimization Module.
	POD Reduction	Model reduction using the POD (proper orthogonal decomposition) method.
	Plug Flow Solver	Solve a plug flow reactor model (requires the Chemical Reaction Engineering Module).
	Stationary Solver	Solve linear and nonlinear stationary problems (also called static or steady-state problems). Also see About the Stationary Solver.

TABLE 20-6: SOLUTION OPERATION NODES.

ICON	NAME	DESCRIPTION
	Time-Dependent Solver	Solve time-dependent problems (also called dynamic or unsteady problems) using the implicit BDF or generalized-α methods or one of the available explicit Runge–Kutta and Adams–Bashforth 3 type of time-stepping methods. Also see About the Time-Dependent Solver.
	Time Discrete Solver	Solve time-dependent problems (dynamic or unsteady problems) that have already been discretized in time using, for example, the prev operator or the bdf operator.
	References for the Solution Operation Nodes and Solvers	Solve time-dependent problems (also called dynamic or unsteady problems) using the family of Runge–Kutta explicit time-stepping schemes or the Adams-Bashforth 3 solver. Also see. The Time-Explicit Algorithms

Selecting a Stationary, Time-Dependent, or Eigenvalue Solver

The chosen study type adds the appropriate solvers for the study; you do not need to select one yourself. If you prefer to make a selection, the first question to ask is whether the problem is stationary or time dependent.

Most real-world phenomena develop in time, but you might know that the system under study approaches a *steady state* described by a stationary solution.

For a stationary problem, select the Stationary Solver. When solving the time-dependent coefficient form problem

$$e_a\frac{\partial^2 u}{\partial t^2}+d_a\frac{\partial u}{\partial t}+\nabla\cdot(-c\nabla u-\alpha u+\gamma)+\beta\cdot\nabla u+au\ =\ f$$

the stationary solver searches for a solution where $\partial u/\partial t = 0$. The Time-Dependent Solver and the stationary solver handle linear as well as nonlinear problems.

In some cases, you might want to study the natural harmonic oscillations of a time-dependent problem. This involves finding the eigensolutions u with the associated eigenvalues λ in a PDE problem of the following form:

$$\nabla\cdot(-c\nabla u-\alpha u)+\beta\cdot\nabla u+au\ =\ \lambda d_a u-\lambda^2 e_a u$$

Such an analysis is particularly interesting in electromagnetics, structural mechanics, acoustics, and wave propagation. To study the eigensolutions and compute the eigenvalues (or eigenfrequencies), select the Eigenvalue Solver.

In addition to these fundamental solvers, COMSOL includes additional solvers for special applications such as an Optimization Solver (which requires the Optimization Module), a Time Discrete Solver, an AWE Solver, and a Plug Flow Solver (which requires the Chemical Reaction Engineering Module). Some of these solvers are connected to special functionality in the add-on modules.

- The Eigenvalue Solver Algorithms
- About the Time-Dependent Solver

THE IMPORTANCE OF A CORRECT JACOBIAN MATRIX

The solvers break down each problem — linear or nonlinear — into one or several linear systems of equations by approximating the given problem with a linearized problem. The coefficient matrix of the discretized linearized problem is called the *Jacobian matrix* (or *stiffness matrix*). In most cases COMSOL Multiphysics computes a correct Jacobian matrix.

The consequences of an incorrect Jacobian matrix depend on the solver in use:

- The linear stationary solver and the eigenvalue solver simply give an incorrect solution.
- The nonlinear stationary solver and the time-dependent solver take longer time to converge to the correct solution, and in some cases the solver even fails to find a solution. However, if the ignored terms have a very weak dependence on the sought solution, the impact on convergence speed is small.

An incorrect Jacobian matrix can occur in the following cases:

- If you supply an incorrect derivative of some of the user-defined functions and then use that function in some PDE coefficient or boundary condition specification with arguments that depend on the solution (for example, with the temperature as the function argument in a heat-transfer simulation).
- If you use a MATLAB M-file function or the External function interface, for which you have specified no derivative, and then call this function in some PDE or boundary condition with arguments that depend on the solution. A correct Jacobian can be computed if the function derivative is defined.
- If you use nonanalytic functions in a complex-valued problem, such as `real`, `imag`, `conj`, `abs`, or `arg`.
- If you use the `nojac` operator.

WORKING WITH COMPLEX-VALUED PROBLEMS

When a problem contains complex numbers, be sure to consider the following two aspects:

- For time-dependent problems, the time-stepping algorithm must know if a problem is complex valued. If your model uses a complex-valued initial solution, the COMSOL software detects this and classifies the problem accordingly. If the problem is complex valued because of a complex-valued PDE coefficient or other material property, go to the **Time-Dependent Solver** node's **Settings** window, and in the **Advanced** section select the **Allow complex numbers** checkbox.
- If you expect to receive complex outputs from real inputs in elementary functions such as `sqrt`, `log`, and `asin`, or when evaluating a nonintegral power of a negative number, add an Advanced subnode. Then in the **Settings** window under **General**, select the **Allow complex-valued output from functions with real input** checkbox. By default, the COMSOL software gives an error message if a real input to a function generates a complex output.

Tracking and Undoing Changes to Solvers and Other Solver Configuration Nodes

For the solver nodes and the associated solver operation nodes and solver attributes node under **Solver Configurations**, any changes from the default solver settings are displayed in a **Changes from Default Settings** section at the bottom of the node's **Settings** window. The table contains the following columns: **Description**, **Property name** (the name used in the API), **Default value**, and **Current value**, so you get an overview of all changes made to the settings for that node. Changes from the default values are also indicated by an asterisk on the node in the model tree. To undo changes to a node, right-click it and choose **Undo Changes** ↶. You can also undo all changes to a solver or solver configuration by right-clicking a **Solution** or **Solver Configurations** node and choose **Reset Solver to Default**.

Scaling of Variables and Equations

If the dependent variables in a model have widely different magnitudes, the solver might have problems with the resulting ill-conditioned matrix. The scaling of the dependent variables also influences the weighted errors computed by the solvers. For instance, in a structural mechanics problem the displacements can be of the order of 0.0001 m while the stresses are 1,000,000 Pa (1 MPa). To remedy this situation, the COMSOL solvers internally rescale the variables so that a well-scaled system results.

The rescaling of the discretized linear system occurs before constraint handling. Assume that the degrees of freedom U_i are expressed terms of rescaled degrees of freedom $\tilde{U}_i$ according to the formula

$$U_i = s_i \tilde{U}_i$$

where s_i are positive scale factors. Using a diagonal matrix S, the relation between U and $\tilde{U}$ is $U = S\tilde{U}$, and you can write the rescaled linear system as

$$\begin{bmatrix} \tilde{K} & \tilde{N}_F \\ \tilde{N} & 0 \end{bmatrix} \begin{bmatrix} \tilde{U} \\ \tilde{\Lambda} \end{bmatrix} = \begin{bmatrix} \tilde{L} \\ \tilde{M} \end{bmatrix}$$

where

$$\Lambda = R\tilde{\Lambda} \qquad \tilde{N}_F = SN_F R \qquad \tilde{K} = SKS \qquad \tilde{N} = RNS$$

and

$$\tilde{L} = SL, \quad \tilde{M} = RM$$

Here, R is a diagonal matrix of positive scale factors chosen such that the rows in the matrix $\tilde{N}$ are of magnitude 1.

About the Stationary Solver

The following background information about the Stationary Solver discusses these topics: Damped Newton Methods, Termination Criterion for the Fully Coupled and Segregated Attribute Nodes, Linear Solvers vs. Nonlinear Solvers, and Pseudo Time Stepping. Also see Selecting a Stationary, Time-Dependent, or Eigenvalue Solver.

Stationary in the *COMSOL Multiphysics Programming Reference Manual*

DAMPED NEWTON METHODS

The nonlinear solver uses an affine invariant form of the damped Newton method as described in Ref. 3. You can write the discrete form of the equations as $f(U) = 0$, where $f(U)$ is the residual vector and U is the solution vector. Starting with the initial guess U_0, the software forms the linearized model using U_0 as the linearization point. It solves the discretized form of the linearized model $f'(U_0)\delta U = -f(U_0)$ for the Newton step δU using the selected linear system solver ($f'(U_0)$ is the Jacobian matrix). It then computes the new iteration $U_1 = U_0 + \lambda\delta U$, where λ ($0 \le \lambda \le 1$) is the damping factor. Next the modified Newton correction estimates the error E for the new iteration U_1 by solving $f'(U_0)E = -f(U_1)$. If the relative error corresponding to E is larger than the relative error in the previous iteration, the algorithm reduces the damping factor λ and recomputes U_1. This algorithm repeats the damping-factor reduction until the relative error is less than in the previous iteration or until the damping factor underflows the minimum damping factor. When it has taken a successful step U_1, the algorithm proceeds with the next Newton iteration.

A value of $\lambda = 1$ results in Newton's method, which converges quadratically if the initial guess U_0 is sufficiently close to a solution. In order to enlarge the domain of attraction, the solver chooses the damping factors judiciously. The success of a nonlinear solver still depends heavily on a carefully selected initial guess, so you should provide the best value for U_0, giving at least an order of magnitude guess for different solution components.

TERMINATION CRITERION FOR THE FULLY COUPLED AND SEGREGATED ATTRIBUTE NODES

You specify the termination criteria in the **Settings** window for a Fully Coupled or Segregated subnode to the Stationary Solver node. Also see The Segregated Solver (Termination Criterion for a Segregated Solver).

Termination Criterion: Solution

For **Termination criterion: Solution**, the nonlinear iterations terminate when the following convergence criterion is satisfied: Let U be the current approximation to the true solution vector, and let E be the estimated error in this vector. The software stops the iterations when the relative tolerance exceeds the relative error computed as the following weighted Euclidean norm:

$$\text{err} = \sqrt{\frac{1}{M}\sum_{j=1}^{M}\frac{1}{N_j}\sum_{i=1}^{N_j}\left(\frac{|E_{i,j}|}{W_{i,j}}\right)^2}$$

Here M is the number of fields; N_j is the number of degrees of freedom in field j. The double subscript denotes degree of freedom index (i) and field (j) component. Let $W_{i,j} = \max(|U_{i,j}|, S_j)$, where S_j is a scale factor that the solver determines from the scaling method. You select the scaling method from the **Method** list in the **Scaling** section of the Dependent Variables node's **Settings** window. The solver then computes the scale factor S_j using the following rules:

- For **Automatic**, S_j is the average of $|U_{i,j}|$ for all DOFs i for fixed j, times a factor equal to 10^{-5} for highly nonlinear problems or 0.1 otherwise.
- For **Manual**, S_j is the value given in the **Scale** field. S_j is multiplied by a factor equal to 10^{-5} for highly nonlinear problems or 0.1 otherwise
- For **Initial value based**, S_j is the average of $|V_{i,j}|$ for all DOFs i with fixed j times a factor equal to 10^{-5} for highly nonlinear problems or 0.1 otherwise. $V = U_0$ is the solution vector corresponding to the initial value. In case all DOFs are zero for that particular field j, the total mean of $|V_{i,j}|$ for all i and j is used instead.
- For **None**, $W_{i,j} = 1$. In this case, err is an estimate for the absolute error.

The (automatically damped Newton) nonlinear solver only checks the convergence criterion if the damping factor for the current iteration is equal to 1. The solver continues as long as the damping factor is not equal to 1 even if the estimated error is smaller than the requested relative tolerance.

Termination Criterion: Residual

For **Termination criterion: Residual**, the nonlinear iterations terminate when the following convergence criterion is satisfied: The software stops the iterations when the relative tolerance exceeds the relative error computed as the weighted Euclidean norm

$$\text{err} = \sqrt{\frac{1}{M}\sum_{j=1}^{M}\frac{1}{N_j\tilde{W}_j^{\,2}}\sum_{i=1}^{N_j}|F_{i,j}|^2}$$

where F is the current residual. In the equation above, the double subscript denotes the degree of freedom index (i) and the field (j) component. The iterations can also terminate if the relative step size is in the range of a hundred machine epsilon, and in addition, a full Newton step is taken. The weights are determined considering both the initial residual f_0 and the residual after the first iteration f_1 as $f = 0.5\,|f_0| + 0.5\,|f_1|$. In the equation above, the

double subscript denotes the degree of freedom index (i) and the field (j) component. The iterations can also terminate if the relative step size is in the range of a hundred machine epsilon and in addition a full Newton step is taken.

You select the scaling method from the **Method** list in the **Residual Scaling** section of the **Dependent Variables** node's **Settings** window. The solver then computes the weights $\tilde{W}_j$ using the following rules:

- For **Automatic**, the weights $\tilde{W}_j$ are determined considering both the initial residual f_0 and the residual after the first iteration f_1 as $f = 0.5|f_0| + 0.5|f_1|$. $\tilde{W}_j$ is the average of $f_{i,j}$ for all DOFs i for a fixed j. In case all $f_{i,j}$ are zero for that particular field j, the total mean of $f_{i,j}$ for all i and j is used instead.

  For time-dependent problems, the first time step calculates the weights $\tilde{W}_j$ based on f as above. Here f is considered as the base residual. In later time steps, the initial residual of the current step f_{0t} and the residual after the first iteration of the current time step f_{1t} will be considered together with the base residual f to determine whether the weights need to be updated for the current time step. The weights $\tilde{W}_t$ are calculated based on $f = 0.5|f| + 0.5|f_{1t}|$ ($i = 0$ or 1). The weights are updated as $\tilde{W} = \tilde{W}_t$ if the ratio $\tilde{W}_{t,j}/\tilde{W}_j$ or $\tilde{W}_j/\tilde{W}_{t,j}$ for a field j exceeds the threshold defined in the **Threshold for updating residual scale** field in the settings for a **Dependent Variables** node or its **Field** subnodes.
- For **Manual**, the weights $\tilde{W}_j$ is the value given in the **Scaling** field.

Additional information about the weights for time-dependent problems:

- With *consistent initialization* active, the base residual f and the weights $\tilde{W}$ will be calculated during the consistent initialization and recalculated after the consistent initialization finishes.
- When the weights $\tilde{W}_j$ for field j need to be updated, then the weights are updated for all fields solved for in the fully coupled solver or in the same segregated step.
- For wave problems, the weights $\tilde{W}$ consist of two parts: the nonvelocity part $\tilde{W}_f$ and the velocity part $\tilde{W}_{\text{vel}}$. The weights $\tilde{W}_f$ are calculated using only the nonvelocity part of the residual f. The weights $\tilde{W}_{\text{vel}}$ for the field j are defined to be proportional to the weights $\tilde{W}_{f,j}$ as $\tilde{W}_{\text{vel},j} = r_j \cdot \tilde{W}_{f,j}$. The proportional ratio r is a fieldwise quantity and is defined as $r = \sum |F_{\text{vel},ij}| / \sum |F_{\text{nonvel},ij}|$, where F is the current residual. The weights $\tilde{W}_{\text{vel}}$ are set to be 1 for the first iteration at the first time step. It is updated when the velocity part of the residual is nonzero for the first time. The velocity weights will be updated again when the nonvelocity weights are updated.

Termination Criterion: Solution or Residual

For **Termination criterion: Solution or residual**, the nonlinear iterations terminate when the relative tolerance exceeds the relative error computed as the minimum of the solution-based error and the error given by the **Residual factor** times the residual-based error above.

Termination Criterion: Solution and Residual

For **Termination criterion: Solution and residual**, the nonlinear iterations terminate the Newton iterations on a solution-based estimated relative error and a residual-based estimated relative error given by the **Residual factor** times the residual-based error above.

LINEAR SOLVERS VS. NONLINEAR SOLVERS

Automatic Nonlinearity Detection

COMSOL Multiphysics automatically detects nonlinearity, so you normally do not need to decide whether to use a linear or a nonlinear solver.

The automatic detection works through analysis of the variables contributing to the residual Jacobian matrix and the constraint Jacobian matrix. If the algorithm finds that both these matrices are complete and do not depend on the solution, the stationary solver (including parametric sweeps) uses a linear solver algorithm. Otherwise, the solver uses a nonlinear solver algorithm. "Complete" here means that the algorithm only found contributing variables for which the correct Jacobian is computed.

Overriding the Automatic Nonlinearity Detection

In some cases you might want to specify explicitly that the stationary solver uses the linear or nonlinear solver algorithm. Such cases include:

- Linear models where the automatic detection of linearity makes COMSOL Multiphysics use the nonlinear solver. This can happen, for example, for models that involve some less common types of coupling variables (directly or indirectly as part of some boundary conditions). The nonlinear solver usually converges directly for linear problems, but if that is not the case, you can switch to the linear solver.

  When using the Fully Coupled solver, you can furthermore

- Use the linear solver to single-step Newton's method for a nonlinear problem.
- Use the linear solver to solve a linearized (nonlinear) problem. See the section about linearity in Stationary Solver for details on how the residual is assembled in this case.

Which Models Are Nonlinear?

How do you determine if a problem is linear or nonlinear? Finding out is not always easy, but for most physics you can apply the following criterion: If any coefficient or material property contains a dependent variable, the model is nonlinear. The same holds true for models based on a PDE in the coefficient form, again with the same criterion.

There are some special cases that arise with some physics interfaces. First, in the Heat Transfer physics interfaces, if you include radiation terms for blackbody radiation, which depend on temperature according to the Stefan–Boltzmann law, the problem is nonlinear. Second, Single-Phase Flow is always nonlinear, unless the convective terms in the momentum equations have been omitted, resulting in the linear Stokes equations.

Whether your problem is linear or nonlinear, the solvers break it down into one or several linear systems of equations. Therefore, the linear solver selection affects the solution time and memory requirements also for nonlinear models.

PSEUDO TIME STEPPING

A pseudo time-stepping method is used in transport problems to stabilize the convergence toward steady state. Here an adaptive feedback controller controls a CFL (Courant–Friedrichs–Lewy) number, which is then used for pseudo time stepping. The CFL number starts from a moderate value (order one) and increases up to several orders of magnitude at convergence.

A simple multiplicative PID controller for CFL control is used

$$\mathrm{CFL}_{n+1} = \left(\frac{e_{n-1}}{e_n}\right)^{k_P}\left(\frac{\mathrm{tol}}{e_n}\right)^{k_I}\left(\frac{e_{n-1}/e_n}{e_{n-2}/e_{n-1}}\right)^{k_D}\mathrm{CFL}_n \tag{20-7}$$

where the controller parameters k_P, k_I, and k_D for the proportional, integral, and derivative parts, respectively, are positive constants. Here e_n is the nonlinear error estimate for step n and tol is a given target error estimate. CFL_n is the built-in solver variable CFLCMP.

- The first factor is nothing but a power of the current convergence rate (based on the last two steps), and is the most important part of this controller. If the error is decreasing, the controller increases the CFL number and if the error is increasing, the controller decreases the CFL number. The strength of this coupling (and the rapidness of this effect) is controlled by the parameter k_P.
- The next factor is used to control the CFL number toward the requested target error estimate. A standard local error estimate control uses only a factor of this sort, but for this type of control, the absolute level of the error is not that important. However, without this factor (k_I=0), the CFL number might drift even though the error

level is fluctuating on the same level. This factor can also be used to select an absolute regime for the error where increasing the CFL number should be more difficult.

- The last factor is a derivative factor; it is affected by the change of the convergence rate.

A hard lower limit $\mathrm{CFL}_n \geq 1$ is used, and to lower the risk of premature termination there is an extra requirement of not accepting convergence until $\mathrm{CFL}_n \geq \mathrm{CFL}_\infty = 10^4$.

After each segregated solver iteration, the log reports the Pseudo time-stepping CFL-ratio defined as $\min(\log(\mathrm{CFL})/\log(\mathrm{CFL}_\infty),1.0)$, where $\mathrm{CFL}_\infty = 10^4$ is the steady-state CFL number. The CFL ratio concerns the overall progress of the segregated solver and not individual groups. Convergence is allowed when this number is one and the usual convergence criteria are met.

Pseudo time stepping is available for stationary problems. In the coupled approach, it functions together with the constant damped Newton solver. See the settings for Fully Coupled and Segregated for related parameters.

About the Parametric Solver

The parametric solver supports two algorithms, continuation and no continuation (*plain sweep*). To use continuation you need to select the **Auxiliary Sweep** checkbox as well as select one of the parameters as the continuation parameter from the list under **Study Extensions** on the **Stationary or Frequency Domain** node's **Settings** window. Continuation can only be used for one parameter; the others are run as a plain sweep outside the continuation sweep. Note that a sweep that is using specified parameter combinations is considered a plain sweep if the secondary (noncontinuation) parameter varies.

When you add a Stationary or Frequency Domain study, a *parametric continuation solver* is used to find the solution to a sequence of stationary PDE problems that arise when you vary some parameter of interest. This can be any parameter that defines an equation, boundary condition, material property, or similar property of the physics but not parameters that, for example, vary the geometry or mesh (for such a parameterization, use a Parametric Sweep). The parametric solver can also prove useful when it is difficult to get convergence in a nonlinear model. You can then introduce a parameter such that the solution is easy if the parameter is small. Then, to obtain the solution for the desired value of the parameter, slowly increase its value. This way, the nonlinear solver gets a good initial guess based on the solution for the previous parameter value.

AUXILIARY SWEEPS VS. PARAMETRIC SWEEPS

A *parametric sweep* is used analyze a set of different parameters, while the *auxiliary sweep* is used to trace a nonlinear solution (in a contact simulation, for example).

About the Time-Dependent Solver

The following background information about the Time-Dependent Solver discusses these topics: The Implicit Time-Dependent Solver Algorithms and BDF vs. Generalized-α and Explicit Methods. Also see Selecting a Stationary, Time-Dependent, or Eigenvalue Solver.

Time in the *COMSOL Multiphysics Programming Reference Manual*.

THE IMPLICIT TIME-DEPENDENT SOLVER ALGORITHMS

The finite element discretization of the time-dependent PDE problem is

$$0 = L(U, \dot{U}, \ddot{U}, t) - N_F(U, t)\Lambda$$
$$0 = M(U, t)$$

which is often referred to as the *method of lines*. Before solving this system, the algorithm eliminates the Lagrange multipliers Λ. If the constraints $0 = M$ are linear and time independent and if the constraint force Jacobian N_F is constant, then the algorithm also eliminates the constraints from the system. Otherwise, it keeps the constraints, leading to a differential-algebraic system.

In COMSOL Multiphysics, the *IDA* and *generalized-α* solvers are available to solve the above ODE or DAE system:

- IDA was created at the Lawrence Livermore National Laboratory (Ref. 4) and is a modernized implementation of the DAE solver DASPK (Ref. 5), which uses variable-order variable-step-size backward differentiation formulas (BDF). Optionally, a nonlinear controller can provide more careful time-step control, which can reduce the thrashing of time steps that increases the number of time steps and degrades performance for highly nonlinear problems in CFD, for example. See Ref. 7 for more information about the nonlinear controller (STAB controller).
- Generalized-α is an implicit, second-order accurate method with a parameter α or ρ_∞ ($0 \le \rho_\infty \le 1$) to control the damping of high frequencies. With $\rho_\infty = 1$, the method has no numerical damping. For linear problems, this corresponds to the midpoint rule. $\rho_\infty = 0$ gives the maximal numerical damping; for linear problems the highest frequency is then annihilated in one step. The method was first developed for second-order equations in structural mechanics (Ref. 10) and later extended to first-order systems (Ref. 11).

For implicit time-stepping schemes, a nonlinear solver is used to update the variables at each time step. The nonlinear solver used is controlled by the active Fully Coupled and Segregated solver subnodes. These subnodes provide much control of the nonlinear solution process: It is possible to choose the nonlinear tolerance, damping factor, how often the Jacobian is updated, and other settings such that the algorithm solves the nonlinear system more efficiently.

For the BDF (IDAS) solver there is another alternative, and that is to use the built-in nonlinear solver IDAS. This solver is used when all **Fully Coupled** and **Segregated** nodes are disabled. The linear solver is in this case controlled by the active linear solver subnode.

The linearization of the above system used in the Newton iteration is

$$E\ddot{V} + D\dot{V} + KV = L - N_F\Lambda$$
$$NV = M$$

where $K = -\partial L/\partial U$ is the stiffness matrix,

$$D = -\partial L/\partial \dot{U}$$

is the damping matrix, and

$$E = -\partial L/\partial \ddot{U}$$

is the mass matrix. When $E = 0$, D is often called the mass matrix.

When using IDA for problems with second-order time derivatives ($E \neq 0$), extra variables are internally introduced so that it is possible to form a first-order time-derivative system (this does not happen when using generalized-α because it can integrate second-order equations). The vector of extra variables, here U_v, comes with the extra equation

$$\dot{U} = U_v$$

where U denotes the vector of original variables. This procedure expands the original ODE or DAE system to double its original size, but the linearized system is reduced to the original size with the matrix $E + \sigma D + \sigma^2 K$,

where σ is a scalar inversely proportional to the time step. By the added equation, the original variable U is therefore always a differential variable (index-0). The error test excludes the variable U_v unless consistent initialization is on, in which case the differential U_v-variables are included in the error test and the error estimation strategy applies to the algebraic U_v-variables.

Absolute Tolerance Settings for the Time-Dependent Solver

For the Time-Dependent Solver under the section **Absolute Tolerance**, the absolute and relative tolerances control the error in each integration step. More specifically, let U be the solution vector corresponding to the solution at a certain time step, and let E be the solver's estimate of the (local) absolute error in U committed during this time step. For the **Unscaled** method, the step is accepted if

$$\left(\frac{1}{M}\sum_j \frac{1}{N_j}\sum_i \left(\frac{|E_i|}{A_{\mathrm{us},i} + R|U_i|}\right)^2\right)^{1/2} < 1$$

where $A_{\mathrm{us},i}$ is the unscaled absolute tolerance for DOF i, R is the relative tolerance, M is the number of fields, and N_j is the number of degrees of freedom in field j. The numbers $A_{\mathrm{us},i}$ are computed from a conversion of the input value A_k for the corresponding dependent variable k. For degrees of freedom for Lagrange shape functions or for ODEs, these values are the same as entered (that is, $A_{\mathrm{us},i} = A_k$), but for vector elements there is a field-to-DOF conversion factor involved.

For the **Scaled** method and when you select **Update scaled absolute tolerance**, the step is accepted if

$$\left(\frac{1}{M}\sum_j \frac{1}{N_j}\sum_i \left(\frac{|E_{Y_i}|}{A_{\mathrm{s},i} + R|Y_i|}\right)^2\right)^{1/2} < 1$$

where E_Y is the solver's estimate of the (local) absolute error in Y, $A_{s,i}$ is the scaled absolute tolerance for DOF i, M is the number of fields, R is the relative tolerance, N_j is the number of degrees of freedom in field j, and Y_i is the scaled solution vector. For dependent variables that are using the scaling method **Automatic**, the numbers $A_{\mathrm{s},i}$ are computed from the input values A_k according to the formula

$$A_{\mathrm{s},i} = A_{k_i}(\beta + \|Y\|_{2,i}) \qquad \beta = \begin{cases} (1 - e^{-\alpha j})\|Y\|_{\infty,k_i} + e^{-\alpha j} & 0 < \|Y\|_{\infty,k_i} < 1 \\ 1 & \text{else} \end{cases}$$

where $\alpha = 1/5$, j is the time-step iteration number $j = 0,1,\ldots$, and $\|Y\|_{2,k_i}$, $\|Y\|_{\infty,k_i}$ are the 2-norm and maximum norm of the dependent variable k_i, respectively. Here A_{k_i} is the converted input value A_k for the field k and DOF i. For dependent variables that are using another scaling method or when the **Update scaled absolute tolerance** checkbox is cleared, then $A_{\mathrm{s},i} = A_{k_i}$.

Note that with the **Tolerance method** set to **Factor**, the absolute tolerance is specified as a factor of the relative tolerance. If you use a specific absolute tolerance instead, that value can reduce the effect of further reductions of the relative tolerance (so that when $R|U_i| \approx A_i$, the effect of further reductions of the relative tolerance diminishes).

If the solution is smaller than the absolute tolerance, there is no accuracy at all.

For DAEs (differential-algebraic equations), you can exclude the algebraic equations from the error estimation so that the error is only based on the differential equations. See Advanced for information about excluding algebraic equations from the error estimate.

BDF VS. GENERALIZED-α AND EXPLICIT METHODS

The BDF solver uses backward differentiation formulas with an order of accuracy varying from one (that is, backward Euler) to five. BDF methods have been used for a long time and are known for their stability. However, they can have severe damping effects, especially the lower-order methods. Backward Euler severely damps any high frequencies. Even if you are expecting a solution with sharp gradients, you might get a very smooth solution due to the damping in the backward Euler method.

The generalized-α (alpha) solver has properties similar to the second-order BDF solver but the underlying technology is different. It contains a parameter, called α in the literature, to control the degree of damping of high frequencies. Compared to BDF (with maximum order two), generalized-α causes much less damping and is thereby more accurate. For the same reason it is also less stable.

The implementation of the generalized-α method in COMSOL Multiphysics detects which variables are first order in time and which variables are second order in time and applies the correct formulas to the variables.

In many cases, generalized-α is an accurate method with good enough stability properties, but the BDF method is more robust and better at handling changes to the time step. The generalized-α method is preferred for simulations when the time step is almost constant and when small or minimal damping is needed, such as pure vibration problems. For that reason, some physics interfaces in COMSOL Multiphysics — for structural mechanics and electromagnetic waves, for example — use generalized-α as the default transient solver. Some complicated problems, however, need the extra robustness provided by the BDF method.

There are also some problem types, like ODE systems, that can benefit from the higher accuracy that higher-order BDF methods provide. For such ODE systems, the explicit methods from the Runge–Kutta family of methods for ODEs — RK34, Cash–Karp 5, and Dormand–Prince 5 — or an Adams–Bashforth method can be the most efficient. For the nodal discontinuous Galerkin method, it is natural and most efficient to use an explicit time-stepping method. Other situations when it can be advantageous is when using only particle tracing or wave problems together with mass lumping.

About the Wave Form PDE Interface

The About Auxiliary Equation-Based Nodes section is tailored toward explicit time stepping. The method is quadrature free as well as matrix free. Only element local matrices are formed. A suitable stable time step can be determined automatically by specifying the variable `wahw.wtc`, which should be an estimate of the maximum wave speed for the equations in the interface. The time-explicit algorithm then translates this speed to a local cell time scale. For a global time marching method like Runge–Kutta or Adams–Bashforth 3, the time step is directly related to the smallest cell time scale. When there is a large difference in cell time scales, a global time marching method is not very efficient. For this reason, there is also a local time-marching method, Adams–Bashforth 3 (local), which divides the cells into groups based on the cell time scale. The groups are then time marched with different time-step sizes, making this a more efficient method.

The Runge–Kutta and Adams–Bashforth methods can handle couplings of the Wave Form PDE interface (or any interface that uses nodal discontinuous Lagrange elements) with any other interface. There are two restrictions:

- The time-dependent PDE problem must be first order in time with a linear dependency with respect to $\dot{U}$ (see About the Time-Dependent Solver for the notation).
- If the finite element discretization leads to a DAE, then its index must be 1 (see the Glossary). The algebraic equations are solved using a **Fully Coupled** solver. The frequency with which these algebraic equations are solved can be controlled with the **Algebraic equations setting**, which makes it possible to reduce the computational time. For example, this setting is useful to reduce the cost of solving a wave problem (discretized using the nodal discontinuous Galerkin method) coupled to an elliptic PDE (see the Glossary).

About the Time Discrete Solver

The Time Discrete Solver is used to solve fluid dynamics problems using a projection method. Also, you can use the time-discrete solver to solve problems that have been discretized in time using the `prev` or `bdf` operator.

In the time-discrete solver you cannot use the `d` operator to get the time derivatives. That is why the `prev` operator is needed so that time derivatives can be written using the backward Euler method. However, the `prev` operator does not make it possible to define variables like this:

a=f(prev(a))

That is, you cannot use the time-discrete solver to solve incremental problems in time because a variable cannot be expressed in terms of itself. Such a formulation leads to a circular variable dependency. If you want to implement a variable that is dependent on itself, that variable must be a dependent variable that you solve for as a continuous ODE or PDE.

The time-discrete solver is not intended for solving general time-dependent structural mechanics problems. What is obtained with the time-discrete solver is a quasi-stationary approach; the inertial terms are not included. Also, it is more correct to compare the results using the time-discrete solver with those using the generalized-α solver with manual time stepping because for both of these solvers, no error checking is done for the local time error.

TimeDiscrete in the *COMSOL Multiphysics Programming Reference Manual*.

The Eigenvalue Solver Algorithms

The Eigenvalue Solver algorithm is described in this section. Also see Selecting a Stationary, Time-Dependent, or Eigenvalue Solver.

Finite element discretization leads to the generalized eigenvalue system

$$(\lambda-\lambda_0)^2 EU-(\lambda-\lambda_0)DU+KU+N_F\Lambda = 0$$
$$NU = 0$$

where the solver evaluates E, D, K, N, and N_F for the solution vector U_0; λ denotes the eigenvalue; and λ_0 is the linearization point. If $E=0$, it is a linear eigenvalue problem; if E is nonzero, it is a quadratic eigenvalue problem. To solve the quadratic eigenvalue problem, COMSOL Multiphysics reformulates it as a linear eigenvalue problem. After constraint handling, it is possible to write the system in the form $Ax=\lambda Bx$.

More general eigenvalue problems sometimes arise when boundary conditions or material properties are nonlinear functions of the eigenvalue. These cases can be handled as a series of quadratic eigenvalue problems. COMSOL Multiphysics treats general dependencies on the eigenvalue by assembling a quadratic approximation around the eigenvalue linearization point λ_0. Normally, iteratively updating the linearization point leads to rapid convergence.

THE ARPACK EIGENVALUE SOLVER ALGORITHM

With the **ARPACK** option, COMSOL Multiphysics uses the ARPACK algorithm. Finding the eigenvalues closest to the *shift* σ is equivalent to computing the largest eigenvalues of the matrix $C=(A-\sigma B)^{-1}B$. To do this, the solver uses the ARPACK FORTRAN routines for large-scale eigenvalue problems (Ref. 13). This code is based on a variant of the Arnoldi algorithm called the *implicitly restarted Arnoldi method* (IRAM). The ARPACK routines must perform several matrix-vector multiplications Cv, which they accomplish by solving the linear system $(A-\sigma B)x=Bv$ using one of the linear system solvers.

The Eigenvalue Region Search Method

The eigenvalue region method uses an algorithm based on ARPACK that makes it possible to find all eigenvalues within a given, sufficiently small region (rectangle) in the complex plane. The algorithm uses ARPACK to find eigenvalues covering a rectangle in the complex plane containing the sought eigenvalues; that is, there are eigenvalues with real or imaginary parts larger and smaller than the given smallest and largest real or imaginary parts. In an optional consistency check, a Schur basis corresponding to the found eigenvalues is used as input to ARPACK for a search for an additional eigenvalue. The initial vector is taken to be orthogonal to the Schur basis. If the new eigenvalue falls outside the rectangle spanned by the eigenvalues previously found, the algorithm uses this information as an indication that all desired eigenvalues are found and the algorithm terminated successfully. The algorithm uses the following inputs:

- Four numbers defining a rectangle in the complex plane: the largest real number, smallest real number, largest imaginary number, and smallest imaginary number. If the largest and smallest real or imaginary numbers are equal, the algorithm considers only an interval on the real or imaginary axis, respectively.
- An approximate number of eigenvalues: the number of eigenvalues in the rectangle and in its proximity.
- The maximum number of eigenvalues.

The shift is taken as the center of the rectangle of sought eigenvalues.

The Eigenvalue Region Algorithm

The eigenvalue region method starts by searching for the given approximate number of eigenvalues. If the converged eigenvalues cover the sought region, it may perform an optional consistency check where it searches for an additional eigenvalue using a Schur basis corresponding to the found eigenvalues covering the sought region and an initial vector guess orthogonal to this basis as input to ARPACK. If the new eigenvalue lies outside the covering rectangle, the algorithm terminates successfully, and the eigenvalues within the sought region are returned. If the new eigenvalue lies inside the covering rectangle, there may be additional eigenvalues within the sought region, and a warning is issued to decrease the region where eigenvalues are sought.

If the converged eigenvalues do not cover the sought region, the number of eigenvalues searched for is doubled. The **Log** window then shows `Searching for more eigenvalues`. If the number of eigenvalues searched for has already been doubled and no additional eigenvalues have been found within the region, a warning is issued. The warning shows, for example, that no (transformed) eigenvalue with a smaller real part is found. It is then advised to decrease the size of the region where you want to search for eigenvalues.

The number of eigenvalues sought for can be reduced by the algorithm if the given approximate number of eigenvalues is found to be larger than the number of eigenvalues inside and close to the sought region. The `LOG` window then shows `Searching for fewer eigenvalues`.

THE FEAST EIGENVALUE SOLVER ALGORITHM

With the **FEAST** option, COMSOL Multiphysics uses the FEAST algorithm. The FEAST eigenvalue solver can be understood as an accelerated subspace iteration combined with the Rayleigh–Ritz procedure (Ref. 20). It calculates the eigenpairs whose eigenvalues lie in a specific region defined in the complex plane.

The accelerator, which is defined as the integral along a complex contour C

$$\rho(B^{-1}A) = \frac{1}{2\pi i}\oint_C dz(zB - A)^{-1}B$$

can also be seen as a filter or a spectral projector that maps all unwanted ones to 0 and all wanted eigenvalues (inside the contour C) to 1 (Ref. 18).

FEAST first projects a random selected initial subspace $X^{(0)}$ onto the subspace spanned by the eigenvectors of interest and then uses the Rayleigh–Ritz procedure in this subspace to extract eigenvalue/eigenvector approximations. Projection onto the subspace of interest is accomplished by

$$Q = \rho(A,B)X^{(0)} = \frac{1}{2\pi i}\oint_C (zB-A)^{-1}B\,dz\,X^{(0)} \tag{20-8}$$

(See also Ref. 19).The integration in Equation 20-8 is approximated by a numerical quadrature with appropriate integration points and weights.

$$Q = \sum_{j=1}^{n_C} \omega_j (z_j B - A)^{-1} B X^{(0)} = \sum_{j}^{n_C} \omega_j Q_j \tag{20-9}$$

Where z_j and ω_j are integration points and weights, respectively, and each Q_j is obtained by solving shifted linear systems $(z_jB - A)\,Q_j = BX^{(0)}$. The resulting subspace Q is then orthogonalized and used in the Rayleigh–Ritz procedure. By repeatedly applying the projection in Equation 20-9, the orthogonalization Q, and the Rayleigh–Ritz procedure, FEAST refines the estimates for the eigenvectors of interest.

THE LAPACK (FILLED MATRIX) EIGENVALUE SOLVER ALGORITHM

With the **LAPACK (filled matrix)** option, COMSOL Multiphysics uses a LAPACK algorithm for finding all eigenvalues and eigenmodes using a filled system matrix for small eigenvalue problems.

THE ARPACK NONLINEAR EIGENVALUE SOLVER ALGORITHM

With the **ARPACK nonlinear** option, COMSOL Multiphysics uses an algorithm that is capable of solving eigenvalue problems which are nonlinear with respect to the eigenvalue. It uses a three-step approach:

1. *Approximation*: approximate the nonlinear functions in λ with a polynomial (Taylor expansion).
2. *Linearization*: from the polynomial eigenvalue problem, build an equivalent linear eigenvalue problem.
3. *Solving*: call ARPACK (see The ARPACK Eigenvalue Solver Algorithm) for the linearization. The call to ARPACK in performed in a way to exploit several problem structures in order to efficiently handle memory and complexity.

The ARPACK nonlinear eigenvalue solver algorithm cannot handle nonlinear eigenvalue problem where the eigenvalue appears in the constraints, and in cases where the nonlinear functions in λ have singularities or discontinuities, it could be difficult to compute eigenvalues close to such points.

Eigenvalue in the *COMSOL Multiphysics Programming Reference Manual.*

The Modal Solver Algorithm

The purpose of the Modal Solver and the Model Reduction study step is to speed up certain simulations by projecting the solution of the original problem onto a space spanned by some basis vectors, so the solution of the underlying system of equations is approximated by a linear combination of the basis vectors. Instead of solving for the original high-dimensional problem, the algorithm solves for the coefficients of the linear combination, which is low-dimensional.

The underlying system can be well represented by some dominant eigenvectors, so making use of the solution to an eigenvalue or eigenfrequency problem to construct a basis becomes a natural choice. Optionally, this basis can be extended with constraint modes. Each constraint mode is a solution to a stationary problem with a

nonhomogeneous boundary condition. These modes make it possible to extend the validity of the reduced model. They also make it possible to use reduced-model inputs in constraints for more general use in a reduced-order model produced by the model reduction.

The Modal solver and Modal Reduction solver use the same algorithm to do reduction. However, the Modal solver cannot handle the case when there is reduced-model inputs. It can only be used to for homogeneous problems or nonhomogeneous problems with constant constraints. The Modal Reduction solver can handle the case when there is reduced-model inputs in constraints.

In the following, the algorithm for the general case, which includes inputs in constraints, is illustrated.

TIME DOMAIN

For time-dependent problems, the starting point of modal reduction is the matrix form of the FEM discretization, which is formulated in COMSOL as

$$\begin{aligned} L(U, \dot{U}, \ddot{U}, \mu, t) &= N_F \tilde{\Lambda} \\ M(U, \mu, t) &= 0 \end{aligned} \tag{20-10}$$

where U is the dependent variable, μ represents control inputs, N_F is the constant constraint force matrix, and $\tilde{\Lambda}$ is the vector of Lagrange multipliers.

Linearizing around a solution U_0, μ_0, and $\tilde{\Lambda}_0$, and introducing

$$\begin{aligned} K &= -\frac{\partial L}{\partial U}\bigg|_{U=U_0,\,\mu=\mu_0} \quad D = -\frac{\partial L}{\partial \dot{U}}\bigg|_{U=U_0,\,\mu=\mu_0} \quad E = -\frac{\partial L}{\partial \ddot{U}}\bigg|_{U=U_0,\,\mu=\mu_0} \\ B &= -\frac{\partial L}{\partial \mu}\bigg|_{U=U_0,\,\mu=\mu_0} \quad B_{\text{dot}} = -\frac{\partial L}{\partial \dot{\mu}}\bigg|_{U=U_0,\,\mu=\mu_0} \quad B_{\text{dotdot}} = -\frac{\partial L}{\partial \ddot{\mu}}\bigg|_{U=U_0,\,\mu=\mu_0} \\ N &= -\frac{\partial M}{\partial U}\bigg|_{U=U_0,\,\mu=\mu_0} \quad N_\mu = -\frac{\partial M}{\partial \mu}\bigg|_{U=U_0,\,\mu=\mu_0} \end{aligned} \tag{20-11}$$

Let $V(t) = U(t) - U_0$, $\upsilon(t) = \mu(t) - \mu_0$, and $\Lambda(t) = \tilde{\Lambda}(t) - \tilde{\Lambda}_0$. The linearized system can then be written as

$$\begin{aligned} E\ddot{V}(t) + D\dot{V}(t) + KV(t) + N_F\Lambda &= l(t)l_0 - B\upsilon(t) - B_{\text{dot}}\dot{\upsilon}(t) - B_{\text{dotdot}}\ddot{\upsilon}(t) \\ NV(t) &= m_0 + N_\mu\upsilon(t) \end{aligned} \tag{20-12}$$

where E is the mass matrix, D is the damping matrix, and K is the stiffness matrix. B, B_{dot}, and B_{dotdot} are the input matrix, the time derivative input matrix, and the second time derivative input matrix, respectively. Either E or D can be identically zero. N is the constraint Jacobian matrix. l_0 is a constant-in-time vector, and $l(t)$ is a scalar load factor. m_0 is a constant constraint vector for the linearized problem.

This linear problem has a solution that is a sum of three parts:

$$V = V_h + V_d + V_c \tag{20-13}$$

where V_h is a solution satisfying homogeneous boundary conditions, V_c is a solution satisfying the nonhomogeneous boundary conditions that are controlled by control inputs, and V_d is a solution satisfying the nonhomogeneous constant boundary conditions that are not controlled by control inputs. The scheme uses basis vectors that can be used to approximate the solutions V_h and V_c. The vector V_d fulfills nonhomogeneous constraints but where $\upsilon = 0$; that is,

$$NV_d = m_0 \tag{20-14}$$

CONSTRUCTION OF EIGENMODES

The modal approach approximates the homogeneous solution V_h by a linear combination of eigenmodes,

$$V_h = \Phi q_h \tag{20-15}$$

where q_h are the reduced DOFs to be determined, and each column of Φ is an eigenmode.

CONSTRUCTION OF CONSTRAINT MODES

Here, *constraint modes* are defined as a special subset of constraint modes as defined in the original version of the Craig–Bampton method (see Ref[7]) from 1968. In this paper, a constraint mode is defined as "the mode shapes of interior freedoms due to successive unit displacement of boundary points, all other boundary points being totally constrained."

In general, "boundary points" refer to all DOFs on constraint boundaries, and each one of these DOFs defines a constraint mode with the Craig–Bampton method. These modes together with "fixed normal modes," which corresponds to the homogeneous eigenvalue problem formulated above for the same constraint formulation, constitute one standard way of connecting substructures, where each substructure is a reduced-order model. The advantage with this construction is that the reduced stiffness matrix is block diagonal, with no connection between the boundary and the interior points. The coupling comes only through the mass and damping matrices. This method is also called static condensation for this reason.

The definition of constraint modes here will be slightly different. Because only global model inputs are supported in constraints, it is only necessary to represent constraints that can be described by these global model inputs. Computing a mode for each boundary DOF would therefore only be an extra cost.

When there are reduced-model inputs in constraints, constraint modes can be introduced to control the constraints set by the inputs. Constraint modes are defined from the equations

$$\begin{aligned} KV + N_F\Lambda &= 0 \\ NV &= N_\mu \upsilon \end{aligned} \tag{20-16}$$

where the input ν for the mode j is defined by

$$\upsilon = \upsilon^{<j>}, \upsilon_i{}^{<j>} = \delta_{ij} \tag{20-17}$$

and δ is the Kronecker delta. Notice that the matrix N is the same for all constraint modes, which means that they fulfill homogeneous constraints for all boundary conditions that do not depend on υ_j.

Let Ψ be the matrix whose columns are formed by the constraint modes, and q_c be the reduced constraint mode DOFs. Define V_c as

$$V_c = \Psi q_c \tag{20-18}$$

By construction, the boundary conditions are fulfilled as long as

$$q_c = \nu(t) \tag{20-19}$$

The COMSOL Multiphysics software supports two ways to compute constraint modes: (a) via the sensitivity solver and (b) via the parametric solver. The order in which these modes are solved for, in method (a) or (b), dictates the order in which they are appended to the matrix Ψ in the Modal Solver or Modal Reduction solver, and thereby control the order of the reduced constraint mode DOFs q_c.

(a) Sensitivity Solver

The constraint solution V in Equation 20-16 is a linear function of the control variables. It is therefore possible to use the forward sensitivity solver, with the reduced-model inputs in the constraints as sensitivity control variables, and directly compute

$$\Psi = \left[\frac{\partial V}{\partial v_1}, \frac{\partial V}{\partial v_2}, \cdots \frac{\partial V}{\partial v_k}\right] \tag{20-20}$$

Each column in Ψ can be a constraint mode, and q_c can be the reduced constraint mode DOFs.

(b) Parametric Solver

Each constraint mode can be constructed directly as a solution to the stationary problem (see Equation 20-16); that is, only one reduced-model input is one ("1"), while the others are zero ("0"), according to Equation 20-17. A simple way to generate such solutions is to introduce a parameter for each constraint and then enable an auxiliary sweep for a Stationary study and these parameters and where all other loads and constraints are zero. By using the specified combinations sweep option, you can solve for the constraint modes by setting the parameters to zero or one according to the condition in Equation 20-17. This construction of constraint modes is similar to the classical Craig–Bampton method (see Ref. 46), but where the boundary DOFs are grouped together. The method here is therefore not as general as the original method, but on the other hand it gives a much smaller reduced system.

COMPUTATION OF REDUCED-SYSTEM INITIAL VALUES AND FURTHER EXPANSION OF BASIS

For some problems, using eigenmodes and constraint modes is not enough to give a good approximation of the unreduced system. It is then possible to also include initial value and initial derivatives to the basis.

To add initial data to the reduced basis, the algorithm

1. First solves for the initialization problem of the unreduced time-dependent study under some training value of the inputs, and for the initial time t_0. This gives an initial value vector V_0 (and the first time-derivative vector).
2. Next, the method removes the constraint mode solution and V_d from the initial values. For the constraint mode solution, the training expressions are used for the model inputs.
3. Next, the remaining vector is projected onto the space spanned by eigenmodes. This gives the initial values for the reduced vector q_h (and $\dot{q}_h$).
4. The remaining vector after this step, is in a vector space that is orthogonal to the space spanned by the used eigenmodes. If this vector is nonvanishing, it makes sense to expand the basis with a normalized version of this vector.

In the following, N_i is used to represent the matrix whose columns consist of the basis from the initial values, and q_i is used to represent the corresponding reduced DOFs.

REDUCTION

Assume that P is the projection matrix whose columns consist of basis vectors. In the case that the basis vectors include eigenmodes, constraint modes, and initial value basis, then

$$P = [\Phi, N_i, \Psi] \text{ and } q = \begin{bmatrix} q_h \\ q_i \\ q_c \end{bmatrix}$$

Substituting $V = P_q$ to the linearized Equation 20-12 and left multiply it by P^H, you will get the following reduced equation (an approximation of the original problem):

$$E_r\ddot{q} + D_r\dot{q} + K_r q = L_r(t) - B_r\upsilon(t) - B_{r\,\mathrm{dot}}\dot{\upsilon}(t) - B_{r\,\mathrm{dotdot}}\ddot{\upsilon}(t) \tag{20-21}$$

where

$$\begin{aligned} E_r &= P^H EP \qquad D_r = P^H DP \qquad K_r = P^H KP \\ B_r &= P^H B \qquad B_{r\mathrm{dot}} = P^H B_{\mathrm{dot}} \; B_{r\mathrm{dotdot}} = P^H B_{\mathrm{dotdot}} \\ L_r &= l(t) l_{0r} - K_{ud} \qquad l_{0r} = P^H l_0 \qquad K_{ud} = P^H K V_d \end{aligned} \tag{20-22}$$

Additional Damping for the Transient Reduced System

The damping matrix D can be present when performing the eigenvalue analysis. It is, however, possible to add additional damping by providing damping ratios per mode (or one ratio for all modes). If λ_i denotes the i:th eigenvalue and ξ_i the associated damping ratio, and D_{ra} represents the additional damping matrix, then

$$D_{ra_{ii}} = 2\xi_i \left|\mathrm{Im}(\lambda_i)\right| \left|\mathrm{Re}(E_r)_{ii}\right| \tag{20-23}$$

For the modal solver, the initial values and initial time derivatives of DOFs are obtained from the initialization process mentioned in Computation of Reduced-System Initial Values and Further Expansion of Basis.

$$q_0 = \begin{bmatrix} q_h(t_0) \\ q_i(t_0) \\ q_c(t_0) \end{bmatrix}, q_{\mathrm{dot0}} = \begin{bmatrix} \dot{q}_h(t_0) \\ \dot{q}_i(t_0) \\ \dot{q}_c(t_0) \end{bmatrix} \tag{20-24}$$

For the modal solver, which supports inputs in constraints, the contribution from the initial value of control inputs needs to be subtracted. The initial condition becomes

$$\begin{aligned} q(t_0) &= U_0 + B_{0r}\mathrm{v}(t_0) \\ \dot{q}(t_0) &= U_{\mathrm{dot0}} + B_{0r\mathrm{dot}}\mathrm{v}(t_0) \end{aligned} \tag{20-25}$$

where U_0 and U_{dot0} are q_0 and q_{dot0} in Equation 20-24.

Reconstruction

After solving the reduced system, the solution to the original problem is reconstructed as

$$U(t) = Pq(t) + V_d + U_0 \tag{20-26}$$

Linearized Output for Modal Reduction Solver

The Model Reduction study makes it possible to define outputs variables. For linearized output, they can be defined as

$$y = Y_0 + C_r q + F\mathrm{v} \tag{20-27}$$

where Y_0 is the output bias vector, C_r is the reduced output matrix, and F is the input feedback matrix.

The Second-Order Time-Dependent Problem and State-Space Form

Defining $x = \begin{bmatrix} q \\ \dfrac{\partial q}{\partial t} \end{bmatrix}$, the second-order system in the reduced form can be rewritten as the first-order system below:

$$\begin{pmatrix} 0 & E_r \\ I & 0 \end{pmatrix} \dot{x} + \begin{pmatrix} K_r & D_r \\ 0 & -I \end{pmatrix} x = \begin{pmatrix} L_r \\ 0 \end{pmatrix} - \begin{pmatrix} B_r \\ 0 \end{pmatrix} \mathrm{v} - \begin{pmatrix} B_{r\mathrm{dot}} \\ 0 \end{pmatrix} \dot{\mathrm{v}} - \begin{pmatrix} B_{r\mathrm{dotdot}} \\ 0 \end{pmatrix} \ddot{\mathrm{v}} \tag{20-28}$$

Rewrite Equation 20-28 in state-space form as

$$Mc \cdot \dot{x} = MA \cdot x + MB \cdot \mathrm{v} + M_L + M_{B\mathrm{dot}} \cdot \dot{\mathrm{v}} + M_{B\mathrm{dotdot}} \cdot \ddot{\mathrm{v}} \tag{20-29}$$

where

$$Mc = \begin{pmatrix} 0 & E_r \\ I & 0 \end{pmatrix}, MA = -\begin{pmatrix} K_r & D_r \\ 0 & -I \end{pmatrix}, MB = -\begin{pmatrix} B_r \\ 0 \end{pmatrix} \tag{20-30}$$

$$M_L = \begin{pmatrix} L_r \\ 0 \end{pmatrix}, M_{B\text{dot}} = -\begin{pmatrix} B_{r\text{dot}} \\ 0 \end{pmatrix}, M_{B\text{dotdot}} = -\begin{pmatrix} B_{r\text{dotdot}} \\ 0 \end{pmatrix} \tag{20-31}$$

Initial Conditions for Solving the State-Space System

For the modal reduction solver, the initial value to solve the state-space system is $x_0 = \begin{bmatrix} U_0 \\ U_{\text{dot}0} \end{bmatrix}$

For the modal reduction solver that supports inputs in constraints, the initial condition is

$$x(t_0) = x_0 + M_{B0}\nu(t_0) \tag{20-32}$$

where

$$M_{B0} = \begin{pmatrix} B_{0r} \\ 0 \end{pmatrix} \tag{20-33}$$

Linearized Output for the Modal Reduction Solver in State-Space Form

The linearized output in state-space form in the case of $Y_0 = 0$ can be written as

$$y = Cq + F\nu \tag{20-34}$$

where $C = \begin{bmatrix} C_r \\ 0 \end{bmatrix}$ is the reduced output matrix.

FREQUENCY DOMAIN

Equation 20-12 is linear and cannot be used to describe this case. The starting point for the reduction of a frequency-domain problem is a FEM residual vector expansion around the angular frequency ω_0, where $\omega_0 = i\lambda_0$, $\lambda_0 = -2\pi i f_0$, and f_0 in the first frequency in the frequency list set in the unreduced frequency domain study. The equation can be written as

$$L(U, \mu, \omega) + N_F(U, \mu, \omega)\Lambda = 0 \tag{20-35}$$

Expand the unreduced residual vector L in Equation 20-35 around ω_0 in a three-term Taylor expansion:

$$L(\omega, U, \mu) \approx L(\omega_0, U, \mu) + (\omega - \omega_0)L'(\omega_0, U, \mu) + \frac{1}{2}(\omega - \omega_0)^2 L''(\omega_0, U, \mu) \tag{20-36}$$

where

$$L'(\omega_0, U, \mu) = \left.\frac{\partial L}{\partial \omega}\right|_{\omega = \omega_0}, L''(\omega_0, U, \mu) = \left.\frac{d^2 L}{d\omega^2}\right|_{\omega = \omega_0} \tag{20-37}$$

Next, considering a linearization point $U = U_0$, $\mu = \mu_0$ for the residual vector $L(\omega, U, \mu)$ in Equation 20-36, and substituting the result to Equation 20-35, you obtain

$$(K - (\omega - \omega_0)D + (\omega - \omega_0)^2 E)V + (B - (\omega - \omega)B_{\text{dot}} + (\omega - \omega_0)^2 B_{\text{dotdot}})\nu + N_F(U, \mu, \omega)\Lambda = L_l(\omega) \tag{20-38}$$

where $V = U - U_0$, $\nu = \mu - \mu_0$ and

$$K = -\left.\frac{\partial L(\omega_0, u, \mu)}{\partial U}\right|_{U = U_0, \mu = \mu_0} \quad D = \left.\frac{\partial L'(\omega_0, u, \mu)}{\partial U}\right|_{U = U_0, \mu = \mu_0} \quad E = -\frac{1}{2}\left.\frac{\partial L''(\omega_0, u, \mu)}{\partial U}\right|_{U = U_0, \mu = \mu_0} \tag{20-39}$$

$$B = -\frac{\partial L(\omega_0, u, \mu)}{\partial \mu}\bigg|_{U=U_0,\,\mu=\mu_0} \quad B_{\text{dot}} = \frac{\partial L'(\omega_0, u, \mu)}{\partial \mu}\bigg|_{U=U_0,\,\mu=\mu_0} \quad B_{\text{dotdot}} = -\frac{1}{2}\frac{\partial L''(\omega_0, u, \mu)}{\partial \mu}\bigg|_{U=U_0,\,\mu=\mu_0} \tag{20-40}$$

Similarly to the time-domain case, for the frequency-domain case, $L_l(\omega)$ is introduced as a load vector for the linearization problem (Equation 20-36). Furthermore, a factorization is supported:

$$L_l(\omega) = l(\omega) l_0(\omega)$$

where $l_0(\omega)$ is a frequency-dependent vector and $l(\omega)$ is a scalar load factor.

In the COMSOL Multiphysics software, the matrices K, D, and E in Equation 20-39 and the matrices B, B_{dot}, and B_{dotdot} are assembled with respect to λ_0, so the matrices differ by a factor of $(-i)^n$, where n can be 0, 1, or 2.

Reduction

This process is similar to the transient case. Suppose the projection matrix is P and $V = P*q$. Substituting to Equation 20-38 and multiplying it by P^H, you get the following reduced equation for the frequency-domain case:

$$(K_r - (\omega-\omega_0)D_r + (\omega-\omega_0)^2 E_r)q + (B_r - (\omega-\omega_0)B_{r\text{dot}} + (\omega-\omega_0)^2 B_{r\text{dotdot}})\nu = L_r \tag{20-41}$$

where

$$L_r = l(\omega) l_{0r}(\omega), l_{0r}(\omega) = P^H l_0(\omega) \tag{20-42}$$

and the definitions of K_r, D_r, E_r, Br, $B_{r\text{dot}}$, and $B_{r\text{dotdot}}$ are the same as in Equation 20-22.

Inhomogeneous Boundary Conditions

For inhomogeneous Dirichlet boundary conditions that are not controlled by inputs, a particular solution is computed by the modal solver. A particular solution V_d is computed from the unreduced equation

$$\begin{aligned} KV_d + N_F\Lambda &= 0 \\ NV_d &= M_0 \end{aligned} \tag{20-43}$$

Where the matrix K is the one defined in Equation 20-39.

The term

$$P^H((\omega-\omega_0)^2 EV_d - (\omega-\omega_0)DV_d) \tag{20-44}$$

is then subtracted from the right side of the reduced Equation 20-41.

Additional Damping for the Frequency-Domain Reduced System

Similar to the transient case, it is possible to add additional damping for frequency-domain reduced system. Using the same notation as in the transient case, the corresponding additional damping is

$$2i\omega\xi_i |\text{Im}(\lambda_i)||\text{Re}(E_r)_{ii}| \tag{20-45}$$

and the term $i\omega D_{ra}$ is added to the left hand side of Equation 20-41.

Reconstruction and linearized output for the Modal Reduction solver in the frequency domain is the same as in the time domain.

EXPORTING THE REDUCED SYSTEM

- Reduced matrices that can be exported from both the Modal solver and the Modal Reduction solver for both time and frequency domain: the projection matrix P; each column of P is a basis vector.

- Reduced matrices that can be exported from the Modal solver for both the time domain and the frequency domain: the stiffness matrix K_r, the damping matrix D_r, the damping ratio matrix D_{ra}, the mass matrix E_r, the input matrix B_r, the time derivative input matrix $B_{r\text{dot}}$, and the second time derivative input matrix $B_{r\text{dotdot}}$. Those matrices are defined in Equation 20-22. The output matrix C_r and the input feedback matrix F defined in Equation 20-27 can also be exported. For the Modal solver, C_r and F are expected to be zero because there are no output variables defined.

  For time-domain problems, the initial value input matrix B_0, the initial value time derivative input matrix $B_{0r\text{dot}}$, and the state-space matrices MA, MB, and Mc defined in Equation 20-30 can also be exported, as well as the output matrix C and the input feedback matrix F. State-space matrices can also be evaluated even for first-order systems with what each matrix represents listed in the following table:

TABLE 20-7: FIRST-ORDER AND SECOND-ORDER DEFINITIONS

NAME	DESCRIPTION	DEFINITION FOR FIRST-ORDER CASE	DEFINITION FOR SECOND-ORDER CASE
Mc	Mass matrix	Dr	[0 Er; Ir 0]
MA	Stiffness matrix	-Kr	[-Kr -Dr; 0 Ir]
MB	Input matrix	-Br	[-Br; 0]
x0	Initial value vector	U0	[U0; Udot0]
C	Output matrix	Cr	[Cr 0]
D	Input feedback matrix	F	F

  Note that D in the table is different from the damping matrix D in the unreduced equation.

- Reduced matrices that can be exported from the Modal Reduction solver for both the time domain and the frequency domain: All matrices mentioned for Modal solver above can be exported. However, they might not be the full size of the reduced matrix. Rather, it is the submatrix of the full-sized reduced matrix defined in Equation 20-22, which corresponds to all unconstrained reduced DOFs according to the current setting in the Constraint Modes section in a reduced-order model node. The counterparts of those submatrices, which correspond to all constrained reduced DOFs, are denoted as, for example, Kr_c, Dr_c, Er_c, MA_c, MB_c, and Mc_c. They can also be exported.
- Reduced vectors can be exported from both the Modal solver and the Modal Reduction solver.
  - For the time domain, the reduced load vector l_{0r} (it is L in the reduced matrices list) and K_{ud} defined in Equation 20-22, the initial value vector U_0, and the initial derivative vector $U_{\text{dot}0}$. For second-order problems, the initial vector x_0 for the state-space system can also be exported.
  - For the frequency domain, the reduced load vector $l_{0r}(\omega)$ (it is L in the reduced matrices list) defined in Equation 20-42 for the last given angular frequency ω, the mass matrix times the particular solution $P^H EV_d$ and the damping matrix times the particular solution $P^H DV_d$ in Equation 20-44. See also the example below.
- Vectors that can be exported from the Modal Reduction solver only: constraint modes to inputs map CI_{map}, unconstrained DOF indices to the mode index map DofToMode, and constrained DOF index to that mode index map.
- Vectors that can be exported from the Modal solver only: All load vectors **AllL**, which export all load vectors (that is, $l_{or}(\omega_0)$, $l_{or}(\omega_1)$,... , $l_{or}(\omega_k)$), where ω_i corresponds to f_i in the **Frequencies** setting in the **Frequency Domain, Modal** study.

For the frequency domain, to linearize around an angular frequency ω_0 is useful, for example, for problems where the underlying problem has a material that depends on frequency. However, it can give some surprising effects compared to the exported matrices from the time domain. For example, consider a simple linear problem:

$$L = L_0 - K_T \cdot U - D_T \cdot \frac{dU}{dt} - E_T \cdot \frac{d^2U}{dt^2}$$

where L_0 is a constant load vector, and K_T, D_T, and E_T are constant time-domain matrices; see Equation 20-11. In the frequency domain, this corresponds to (with a small change of notation):

$$L(\omega, U) = L_0 - K_T \cdot U - i\omega \cdot D_T \cdot U + \omega^2 \cdot E_T \cdot U$$

The definition in Equation 20-39 now gives:

$$K = K_T + i\omega_0 \cdot D_T - \omega_0^2 \cdot E_T$$
$$D = -iD_T + 2\omega_0 \cdot E_T = -i(D_T + 2i\omega_0 \cdot E_T)$$
$$E = -E_T = (-i)^2 E_T$$

As mentioned above, the expansion is internally done in $\lambda = (-i)\omega$, which means that the exported matrices are based on the following:

$$K_T + i\omega_0 \cdot D_T - \omega_0^2 \cdot E_T$$
$$D_T + 2i\omega_0 \cdot E_T$$
$$E_T$$

Notice that for $\omega_0 = 0$ the matrices coincide with the time domain but not otherwise.

The Differences Between the Modal Solver and the Modal Reduction Solver

Note that although the Modal solver and the Modal Reduction solver use the same algorithm to get a reduced system, they are different in several ways:

- The Modal solver solves the reduced system directly and returns the reconstructed solution. The Modal Reduction solver does not solve the reduced system; instead, it creates a reduced-order model, which represents the reduced system and can be solved in the same way as any other physics. The reduced-order model is a **Time Dependent, Modal Reduced-Order Model** for time domain, and **Frequency Domain, Modal Reduced-Order Model** for frequency domain.
- As indicated by the Exporting the Reduced System section above, the reduced matrices can be exported by both solvers. For the Modal solver, it is in the **Output** section of the settings for the **Modal Solver** node. The matrices and vectors are of the full size of the reduced system. For the Modal Reduction solver, you need to go to **Results** > **Derived Values**, create a **System Matrix** node, choose a reduced-order model as the solution, and in the **Output** section, choose the matrix to output. The matrices and vectors are of eliminated size, which reflects the current setting in the **Constraint Modes** section in the settings for the reduced-order model node. An exported matrix like K_r is the submatrix of the full-sized reduced matrix, corresponding to all unconstrained reduced DOFs. You can also output the constrained part of the stiffness matrix Kr_c, which corresponds to the constrained reduced DOFs. If you want to get the full-sized reduced matrices and vectors, then clear all checkboxes in the **Constrained** column in the **Constraint Modes** table.
- The load factor is set by the Modal solver in its solver settings. There is no load factor in the Modal Reduction solver; it is set in the reduced-order model.
- The Model Reduction study supports defining output variables, while studies using the Modal solver do not support it.
- Initial conditions for transient case is different in case the second term in the right side of Equation 20-25 is nonzero.
- The Modal Reduction solver supports inputs in constraints while the Modal solver does not.

If there are inputs in constraints when you run the Modal Reduction solver, the corresponding constraint modes become a constrained DOF in the reduced equation. You can either solve the equation together with the constraints

or solve an eliminated reduced equation in the case that the reduced-order model is stateful (that is, the reduced-order model exposes a set of reduced-order equations and state DOFs to the solver). The eliminated system removes the constraints from the equation.

The eliminated system in the time domain is

$$E_r\ddot{q} + (D_r + D_{ra})\dot{q} + K_r q = l(t)l_{0r} - K_{ud} - B_r\upsilon(t) - B_{\text{dot}}\dot{\upsilon}(t) - B_{\text{dotdot}}\ddot{\upsilon}(t) - E_{rc}\ddot{q}_c - (D_{rc} + D_{rac})\dot{q}_c - K_{rc}q_c \quad (20\text{-}46)$$

and in the frequency domain it is

$$\begin{gathered}(K_r - (\omega - \omega_0)D_r + i\omega D_{ra} + (\omega - \omega_0)^2 E_r)q = \\ l(\omega)l_{0r}(\omega) - (B_r - (\omega - \omega)B_{r\text{dot}} + (\omega - \omega_0)^2 B_{r\text{dotdot}})\nu - (K_{rc} - (\omega - \omega_0)D_{rc} + i\omega D_{rac} + (\omega - \omega_0)^2 E_{rc})q_c\end{gathered} \quad (20\text{-}47)$$

The linearized outputs become

$$y = Y_0 + C_r q + C_{rc} q_c + F\nu \quad (20\text{-}48)$$

Modal in the *COMSOL Multiphysics Programming Reference Manual.*

The Time-Explicit Algorithms

The time-explicit Runge–Kutta and Adams–Bashforth methods are discussed in this section. For the nodal discontinuous Galerkin method, it is natural and most efficient to use an explicit time-stepping method. Other situations when it can be advantageous is when using only particle tracing or wave problems together with mass lumping. These explicit time-stepping methods are included in the Time-Dependent Solver.

TimeExplicit in the *COMSOL Multiphysics Programming Reference Manual.*

RUNGE–KUTTA METHODS

Explicit classical Runge–Kutta methods of order 1–4 are supported. Runge–Kutta 4 is the default choice for the discontinuous Galerkin method.

ADAMS–BASHFORTH METHODS

The third-order Adams–Bashforth multistep method (AB3) for $u_t = R(u)$ is

$$u_{n+1} = u_n + \frac{k}{12}(23R(u_n) - 16R(u_{n-1}) + 5R(u_{n-2}))$$

where u_n is the solution at time t_n, and k is the time step.

The time restriction for the discontinuous Galerkin method for wave problems is directly proportional to the smallest mesh element size.

About Auxiliary Equation-Based Nodes is tailored toward explicit time stepping. The method is quadrature free as well as matrix free. Only element local matrices are formed. A suitable stable time step can be determined automatically by specifying the variable `wahw.wtc`, which should be an estimate of the maximum wave speed for the equations in the interface. The Time Explicit algorithm then translates this speed to a local cell time scale. For a global time marching method like Runge–Kutta or Adams–Bashforth 3, the time step is directly related to the smallest cell time scale. When there is a large difference in cell time scales, a global time marching method is not very efficient. For this reason, there is also a local time-marching method, Adams–Bashforth 3 (local), which divides the cells into groups based on the cell time scale. The groups are then time marched with different time-step sizes, making this a more efficient method.

The Runge–Kutta and Adams–Bashforth methods can handle couplings of the Wave Form PDE interface (or any interface that uses nodal discontinuous Lagrange elements) with any other interface. There are two restrictions:

- The time-dependent PDE problem must be first order in time with a linear dependency with respect to $\dot{U}$ (see About the Time-Dependent Solver for the notation).
- If the finite element discretization leads to a DAE, then its index must be 1 (see the Glossary). The algebraic equations are solved using a **Fully Coupled** solver. The frequency with which these algebraic equations are solved can be controlled with the **Algebraic equations setting**, which makes it possible to reduce the computational time. For example, this setting is useful to reduce the cost of solving a wave problem (discretized using the nodal discontinuous Galerkin method) coupled to an elliptic PDE (see the Glossary).

The AWE Solver Algorithm

Assume that you want to solve an equation of the form

$$A(k)x(k) = y(k)$$

where A is a square matrix, x is an unknown quantity, y is a known quantity, and k is a parameter. In general, the components of the equation depend on k. *Asymptotic waveform evaluation* (AWE) is a basic method based on Padé expansion or Taylor expansion that can be used to speed up the solution of such equations for varying k significantly.

The algorithm used for the AWE solver follows the description in Section 13.4 of Ref. 21. That presentation, in turn, closely follows the original papers (Ref. 22 and Ref. 23). The general form of problems that the AWE solver is intended for is

$$A(k)x(k) = y(k)$$

where the dependence on k can be nonlinear. A truncated Taylor expansion of $x(k)$ around some parameter value k_0 can be written as

$$x(k) = \sum_{n=0}^{Q} m_n (k - k_0)^n \tag{20-49}$$

The unknown coefficient vectors

$$m_n = \frac{x^{(n)}(k_0)}{n!}$$

are commonly denoted *moments* in the literature. By repeated differentiation with respect to k and evaluation at k_0, the moments can be expressed in terms of $A(k_0)$ (and derivatives thereof) and $y(k_0)$ (and derivatives thereof) as

$$m_0 = A^{-1}(k_0)y(k_0)$$

and

$$m_n = A^{-1}(k_0)\left[\frac{y^{(n)}(k_0)}{n!} - \sum_{i=1}^{n}\frac{A^{(i)}(k_0)m_{n-i}}{i!}\right]$$

where $n \geq 1$. Apparently, the linear system has to be solved for several right-hand sides. Furthermore, derivatives of $A(k)$ and $y(k)$ have to be computed. The moments also depend on the choice of k_0, and because expansions likely have to be performed around several points, quite a few solution steps might be needed. Once the moments are available, they can be used to represent each component, $x^l(k)$, of $x(k)$ in terms of a Padé approximation as

$$x^l(k) = \frac{\sum_{i=0}^{L} a_i^l (k^l - k_0^l)^i}{1 + \sum_{j=1}^{L} b_j^l (k^l - k_0^l)^j} \tag{20-50}$$

where L will be equal to 1, 2, or 3. If $L = 3$ and $Q = 6$, the b_j can, via manipulations of Equation 20-49 and Equation 20-50, be seen to be the solution to

$$\begin{bmatrix} m_L^l & m_{L-1}^l & m_{L-2}^l \\ m_{L+1}^l & m_L^l & m_{L-1}^l \\ m_{L+2}^l & m_{L+1}^l & m_L^l \end{bmatrix} \begin{bmatrix} b_1^l \\ b_2^l \\ b_3^l \end{bmatrix} = - \begin{bmatrix} m_{L+1}^l \\ m_{L+2}^l \\ m_{L+3}^l \end{bmatrix}$$

The a_i are then given by

$$a_i^l = \sum_{j=0}^{i} b_j^l m_{i-j}^l$$

Typically, you are interested in the parameter response of some quantity, $\sigma(f)$, in an interval, $[f_1, f_2]$. The following iterative approach achieves reasonable accuracy for the entire interval:

1. Let $f_{\min} = f_1$ and $f_{\max} = f_2$.
2. Compute expansions around $f_{\min}$ and $f_{\max}$. Denote the approximations of $\sigma(f)$ given by those expansions by $\sigma_1(f)$ and $\sigma_2(f)$, respectively.
3. Choose one or several points, f_k, in the interval and compute $\sigma_1(f_k)$ and $\sigma_2(f_k)$.
4. If $|\sigma_1(f_k) - \sigma_2(f_k)| < \varepsilon$ the iterations are done. Otherwise, bisect the original interval and repeat the process for both intervals.

AWE Solver

Use the **AWE Solver** ( ) to perform fast-frequency parameter sweeps using asymptotic waveform evaluation (AWE). If, for a Frequency Domain study, the **Use asymptotic waveform evaluation** checkbox is selected under **Study Extensions**, or for an Adaptive Frequency Sweep study, this solver is used. It is an alternative way to perform

parameter stepping to the one you get by using the Stationary Solver node in conjunction with the Parametric attribute subnode.

- The AWE Solver Algorithm
- AWE in the *COMSOL Multiphysics Programming Reference Manual*.

GENERAL

Use the **Parameter name** field to specify a parameter name. The use of several parameter names is not supported.

Use the **Parameter values** field to enter a vector of parameter values that define the parameter value span for the simulation. Exactly how the vector of parameter values is used by the solver is determined by the option **Parameters to store** in the **Output** section as described below.

Use the **Asymptotic Waveform Evaluation (AWE) Expressions** table to specify a space-separated list of globally available scalar-valued expressions to be used for error estimation by the AWE algorithm.

TOLERANCES

In the AWE algorithm, the values of the expressions specified in the **Asymptotic Waveform Evaluation (AWE) Expressions** table in the **General** section are evaluated at one or more points of a parameter interval using certain expansions. The AWE algorithm is considered to have converged in that interval if the functional values resulting from the different expansions and evaluation points are similar enough. Use the:

- **Relative tolerance** field to specify to what relative tolerance the functional values must agree at the evaluation points.
- **Absolute tolerance** field to specify to what absolute tolerance the functional values must agree at the evaluation points.

EXPANSION SETTINGS

Use the **Evaluation points** field to specify a scalar or vector of values where the expressions defined by the **Asymptotic Waveform Evaluation (AWE) Expressions** table in the **General** section are to be evaluated. The evaluation points must be specified as a number between 0 and 1 because they are interpreted as being relative to the parameter interval under consideration. Entering a scalar value of 0.5 means that the expressions are evaluated at the midpoint of each interval. Use the:

- **Expansion size** list to specify the number of terms to include when performing Taylor expansions of the solution.
- **Expansion type** list to specify which expansion type to use when evaluating the solution at the different evaluation points:
  - Select **Padé** to compute a Padé expansion based on the Taylor expansion. The Padé expansion is then used when evaluating the solution.
  - Select **Taylor** to use the Taylor expansion itself when evaluating the solution.

VALUES OF LINEARIZATION POINT

The problem solved by the AWE solver is assumed to be a linearization about a solution. You can specify such a solution (a linearization point) using the **Prescribed by** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point.

Use the **Solution** list to specify which solution to use if **Prescribed by** has been set to **Solution**. Select:

- **Zero** to use a linearization point that is identically equal to zero.
- Any other available solution to use it as a linearization point. It can be the current solution in the sequence, or a solution from another sequence, or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution.

To store the used linearization point in the output, select the **Store linearization point and deviation in output** checkbox.

RESULTS WHILE SOLVING

See Results While Solving in the Common Study Step Settings section. Also see Getting Results While Solving.

OUTPUT

From the **Output** list, choose **Solution** (the default) or **Reduced-order model**.

If you chose **Solution**, use the **Parameters to store** list to control at what parameter values the solver stores a solution. Select:

- **Steps given** to store solutions at the parameter values entered in the **Parameter values** field in the **General** section.
- **Steps taken by solver** to store solutions at the parameter values where the AWE algorithm has performed an expansion.

If you chose **Reduced-order model**, then from the **Reduced-order model** list choose **New** to create a new reduced-order model, or choose an existing reduced-order model.

ADVANCED

By default the solver allows shorter intervals in the AWE algorithm than the relative tolerance (from the **Relative tolerance** field in the **Tolerances** section) times the length of the interval defined by the values in the **Parameter values** field in the **General section**. But if shorter intervals are detected, these intervals are not bisected and a warning is printed in the log. To modify the shortest allowed interval, select the **Minimal interval** checkbox and enter a limit for the interval length.

The **Accept short intervals** checkbox can be used to control how the solver handles intervals that are found to be too short. If this checkbox is cleared, the solver stops with an error if the interval found is too short. If you select the checkbox, the solver silently accepts short intervals.

Use the **Assembly strategy** list to control how the solver assembles quantities needed to compute a Taylor expansion. Select:

- **All** to assemble all quantities at once. This option is faster than **One**.
- **One** to assemble one quantity at a time. This option requires less memory than **All**.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes

- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

This section, which is initially empty, contains a log from the time stepping. Select the **Keep warnings in stored log** checkbox as needed.

Dependent Variables

The **Dependent Variables** node (u,v,w) handles initial data and scaling for the dependent variables that you solve for as well as how to compute dependent variables not solved for. The methods are applicable to the dependent variables present as Field subnodes ($\bar{w}_{\bar{U}TP}$) under the Dependent Variables node. The Field node name matches the name of the variable.

The **Dependent Variables** node automatically updates the **Field** nodes. So, if the study type for the solver changes or if you use a different study type, then the **Field** nodes change accordingly. Also see Scaling of Variables and Equations for information.

To plot and evaluate the initial values for the dependent variables, right-click the **Dependent Variables** node and choose **Compute to Selected** ( ) or click the button in the toolbar (this is similar to the **Get Initial Value** option for the main Study nodes). Click the **Update Variables** button ( ) in the toolbar to refresh the dependent variable list, which might be useful if you need to manually edit the dependent variable settings (with manual scaling, for example).

The **Settings** window has the following sections:

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step. Select **User defined** to specify all settings locally in the **Dependent Variable** node's **Settings** window. This setting relates to the Field node's setting to **Solve for this field**.

INITIAL VALUES OF VARIABLES SOLVED FOR

This section is only available if you select **User defined** from the **Defined by study step** list.

Use the **Method** list to specify how to compute initial values for the dependent variables that you solve for. Select:

- **Initial expression** (the default) to use the expressions specified on the **Initial Values** nodes for the physics interfaces in the model.
- **Solution** to use initial values as specified by a solution object. Use the **Solution** list to specify what solution object to use (directly or as part of the initial expression). Select:
  - **Zero** to initialize all variables to zero.
  - Any available solution object to use it as initial value.

Solution List Options by Study Type

Depending on the study type for the selected solution object, you can choose different solutions from a list underneath the **Solution** list:

- For a Stationary study, from the **Selection** list, select **Automatic (single solution)** (the default) to use the last (typically the only) solution, select **Automatic (all solutions)** to use all (typically just one) solutions from that study, select **First** to use the first (typically the only) solution, select **Last** to use the last (typically the only) solution, select **From list** to pick solutions from a list, select **Manual** to use a specific solution number that you specify, or select **1** to use the first (typically the only) solution. If you use a parametric continuation of the stationary study or load cases, there can be additional solutions to choose from.
- For a Time Dependent study, from the **Time** list, select **Automatic (single solution)** (the default) to use the solution for the last time, select **Automatic (all solutions)** to use all solutions from that study, select **First** to use the first solution, select **Last** to use the last solution, select **From list** to pick solutions from a list, select **Interpolated** to specify a time in the text field that opens and use the interpolated solution at that time (this option is also available for other study types for robust setup, but if the type is not time dependent when used, an error will appear), select **Manual** to use a specific solution number that you specify, or select one of the output times to use the solution at that time.
- For an Eigenvalue or Eigenfrequency study, from the **Eigenvalue** list, select **Automatic (single solution)** (the default) to use the first eigenvalue or eigenfrequency and its associated eigensolution, select **Automatic (all solutions)** to use all solutions from that study, select **First** to use the first solution, select **Last** to use the last solution, select **From list** to pick solutions from a list, select **Manual** to use a specific solution number that you specify, or select one of the eigenvalues or eigenfrequencies to use the corresponding eigensolution.
- For a Parametric Sweep or Frequency Domain study, from the **Parameter value** list, select **Automatic (single solution)** (the default) to use the last parameter value set or frequency, select **Automatic (all solutions)** to use all solutions from that study, select **First** to use the first solution, select **Last** to use the last solution, select **From list** to pick solutions from a list, select **Manual** to use a specific solution number that you specify, or select one of the parameter value sets or frequencies to use the corresponding solution.

SCALING

Use the **Method** list to specify how to scale the variables solved for. Select:

- **Automatic** to get an automatically determined scaling (the default), which works well for most models. It is initially based on the magnitudes of the elements in the Jacobian and mass matrices. For nonlinear problems these scales are recomputed based on the magnitude of the solution iterate.
- **Initial value based** to get a scaling that is determined from the initial values. Use this if the components of the initial values give a good estimate of the order of magnitude of the solution.
- **Manual** to manually enter a scaling if you know the order of magnitudes of the variables in advance. For instance, suppose that a model solves for a dependent variable u, and that the values of u are on the order of 10^{-4}. To use

this knowledge, type `1e-4` in the **Scale** field. The solvers then internally use a solution vector rescaled to the order of 1 for `u`. If there is more than one dependent variable that the model solves, they are all rescaled with the same factor.

- **None** to skip scaling.

The automatic scaling in COMSOL Multiphysics does not work when using the nonlinear stationary solver and a field or state has an identically zero solution (the solver does not converge). In this case use **Manual** or **None**.

The scaling method also can be specified for each dependent variable in the **Settings** window for the variable's **Field** node. For more information about scaling, see Scaling of Variables and Equations.

RESIDUAL SCALING

From the **Method** list choose **Automatic** (the default) or **Manual**. For time-dependent problems, the Automatic residual scale is updated when a sufficiently large change in the residual is detected during time stepping. You can then enter a value in the **Threshold for updating residual scale** field, so that the residual scale updates automatically when a sufficiently large change in the residual is detected. The default value is 100. For Manual, enter a scale factor in the **Scale** field (default: 1). For the scaling, see Termination Criterion for the Fully Coupled and Segregated Attribute Nodes. A manual tuning of the scale factor may help convergence in some cases where the solution does not converge when using automatic scaling does not work (this could be the case for some contact problems, for example).

VALUES OF VARIABLES NOT SOLVED FOR

This section is only available if you select **User defined** from the **Defined by study step** list.

These settings are only applicable if there are dependent variables in the model that you do not solve for (in the case, for example, when solving a multiphysics model using a sequential approach). Then use the **Method** list to specify how to compute the values of variables not solved for. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes for the physics interfaces in the model.
- **Solution** to use initial values as specified by a solution object. Then use the **Solution** list to specify what solution object to use if **Method** has been set to **Solution**. Select:
  - **Zero** to initialize all variables to zero.
  - Any other available solution object to use it as initial value.

Depending on the solution object to use, you can choose different solutions to use. If a solution has nodes for storing solutions in its sequence, you can choose which solution to use using the **Use** list. The **Current** value is the value that the solution has at the moment the value is read. The other values are the values stored in the respective nodes of the sequence. Choose **Manual** to enter the index for the solution that you want to use. The index can be a global parameter that is swept in a Parametric sweep with solution number inputs to it.

See Solution List Options by Study Type for additional choices based on study type and then available in this section.

You select whether to solve for a variable or not by left-clicking a **Field** subnode ( ) and then select or clear the **Solve for this field** checkbox in the **Settings** window.

INITIAL VALUE CALCULATION CONSTANTS

The settings in this section makes it possible to control values of parameters in models when used as constants in initial values. By default, those values are controlled automatically by the study step, and the settings are not available unless you choose **User defined** from the **Defined by study step** list in the **General** section above. The value is updated as soon as a subsequent solver gets its times, frequencies, or parameter lists updated. The value for each parameter is the first value in each list. You can override this automatic behavior by choosing **Manual** from the **Parameters** list. You can then add parameters as constants to the **Constant name** column and the corresponding initial value as a parameter expression in the **Initial value source** column. The constants defined here must be used in an initial value expression for the dependent variables.

Eigenvalue Solver

Use the **Eigenvalue Solver** ( ) to find the solution to linear or linearized eigenvalue problems (also called eigenfrequency problems). This solver is automatically used when an Eigenvalue or Eigenfrequency study is added to the model.

Also see The Eigenvalue Solver Algorithms. The solver settings are split in the following sections

- General
- Variables
- Values of Linearization Point
- Output
- Advanced
- Constants
- Log

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step. Select **User defined** to specify the properties below (in addition to the relative tolerance and the options for computing and storing left eigenvalues, which are always available).

The settings here are similar to those for the **Eigenvalue** study step, with the following exceptions and options, when applicable:

From the **Eigenvalue transformation** list, select a transformation method for transforming the eigenvalues into another related quantity. The default is **None**, which keeps the original eigenvalues. Depending on the physics in the model, other transformations might also be available.

The number in the **Relative tolerance** field (default $1.0 \cdot 10^{-6}$) controls the relative error in the computed eigenvalues.

From the **Compute and store left eigenvectors** list, choose **Automatic** (the default), **On**, or **Off**. The **Automatic** option typically is the same as **Off**, but, depending on the other settings, if needed, the left eigenvectors will be computed (and eventually stored). The eigenvectors referred to as just "eigenvectors" are right eigenvectors. A left eigenvector is defined as a row vector $\mathbf{X}_\mathrm{L}$ that satisfy $\mathbf{X}_\mathrm{L} A = \lambda_\mathrm{L} \mathbf{X}_\mathrm{L}$. For example, for sensitivity and optimization, when the matrices are nonsymmetric, left eigenvectors will be computed. Also, left eigenvectors can be used for projecting equations in the modal solver.

Select the **Enter transformed values** checkbox to enter the values to search around as the transformed value (an eigenfrequency, for example) instead of the corresponding eigenvalue.

Under **FEAST settings**, the default setting for the **Integration type for estimation** list and the **Number of integration points for estimation** list is **Automatic**. When you choose **Automatic** in the **Integration type for estimation** list, it uses

the Gauss type for real symmetric or Hermitian eigenvalue solvers and the trapezoidal method for other types of solver. Otherwise, choose **Gauss** or **Trapezoidal** to use only one of those methods. When you choose **Automatic** in **Number of integration points for estimation**, it is 6 for real symmetric or Hermitian eigenvalue solvers and 16 for other types of solvers.

Select the **Distribute linear system solution** checkbox to run the FEAST eigenvalue solver in parallel. See Running FEAST in a Parallel MPI Mode for more information.

When you have selected the **A posteriori residual check** checkbox, the solver a posteriori explicitly computes the relative residual of the eigenpair and checks that this quantity is smaller that `100*tol`, where `tol` is the **Relative tolerance**. Notice that, in order to do this computation, the solver needs to store the K, D, and E matrices, and therefore, this option requires more memory. If any residual is larger than the tolerance, a **Warning** node appears with information about which eigenpairs it concerns. That information also appears in the solver log.

If the eigenvalue itself appears nonlinearly, and the solver is not the ARPACK nonlinear solver, the solver reduces the problem to a quadratic approximation around an eigenvalue linearization point. Under **Eigenvalue linearization point**, select the **Transform eigenvalue linearization point** checkbox to transform the linearization point value using the selected eigenvalue transformation. Specify the value of the linearization point in the **Value of eigenvalue linearization point** field (SI unit: rad/s).

If you use the ARPACK nonlinear solver, the solver approximates the nonlinearity in the eigenvalue with a polynomial and, if you have selected the **Quasi-Newton refinement** checkbox, it will activate extra quasi-Newton iterations on the returned solutions given by the ARPACK call. The **Maximum number of iterations** (default: 20) does what the name suggests. The **Tolerance factor** (default: 1) instead makes it possible to refine the solutions more accurately. More precisely, the tolerance for stopping the quasi-Newton refinement process is the product between the values for the **Tolerance factor** and the **Relative tolerance**.

For other settings, see the Eigenvalue or Eigenfrequency study settings. When the eigenvalue search settings are defined by the study step, the settings above that correspond to similar study settings are not available.

VARIABLES

This section is only visible when the study contains a Stationary Then Eigenfrequency study step. It can be used to specify which dependent variables are computed with the Eigenvalue solver. The same dependent variable cannot appear in the equivalent section of the Stationary Solver, control variables excepted.

VALUES OF LINEARIZATION POINT

From the **Linearity** list, choose **Linear** (the default) or **Linear perturbation**.

Both for linear and nonlinear PDE problems, the eigenvalue problem is that of the linearization about a solution. Such a solution is specified with the **Prescribed by** list. Select:

- **Initial expression** (the default) to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as linearization point.

Use the **Solution** list to specify which solution to use if **Prescribed by** is set to **Solution**:

- Select **Zero** (the default) to use a linearization point that is identically equal to zero.
- Select any other available solution to use it as linearization point.

Select the **Store linearization point and deviation in output** checkbox to store the linearization point and the deviation from that linearization instead of the total solution.

OUTPUT

Select an option from the **Scaling of eigenvectors** list to specify the scaling method used to normalize the eigenvectors. Select:

- **RMS** to use root mean square normalization. This RMS scaling of the eigenvector u is such that $\|u\|_2 = \sqrt{\text{u.size()}}$.
- **Maximum** to use maximum norm normalization. The degree of freedom with the largest absolute value will be assigned the value specified in the **Maximum absolute value** field (default: 1), so that $\|u\|_\infty = \text{absmax}$. You can change the maximum absolute value to, for example, keep the eigenmodes small in value. The physics interfaces for structural mechanics set this value to a small number during the solver generation.
- **Mass matrix** to scale the eigenvectors such that the modal masses become unity.

Select **User defined** from the **Defined by study step** list in the General section to specify the settings below for sorting and filtering the eigenmodes. Those settings can be useful to, for example, filter out physically uninteresting solutions or to sort the solutions according to given criteria.

The following parts of this section are available when the **Defined by study step** list is set to **User defined**.

Filtering

The eigenvalues can be excluded if there is a filter expression that they do not satisfy. In the table below, in the **Filter expression (store if true or >0)** column, add expressions for the filtering Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq` and can be logical expressions such as `lambda>10`. If desired, add some descriptive text in the **Description** column for the expressions.

The **Store solutions** list is always available: Choose **All converged solutions** (the default) or **First Nth** for the first *N*th solutions. Then specify that number in the **Maximum number of stored solutions** field (default: 1000).

Sorting

The eigenvalues can be sorted in **Ascending** (the default) or **Descending** order depending on the **Ordering** setting. When the **Sorting method** is **Predefined**, you can choose to **Sort primarily** based on the **Real part**, **Imaginary part**, **Real part magnitude**, **Imaginary part magnitude**, or **Absolute value**. The same settings are available for the **Sort secondly** option, which is used to resolve conflicts. The defaults for eigenvalues are **Real part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. For eigenfrequencies, the defaults are **Imaginary part** for **Sort primarily** and **Imaginary part magnitude** for **Sort secondly**. Also, the **Sort based on transformed eigenvalues** checkbox is selected by default to take and eigenvalue transformation into account when sorting.

Alternatively, **Manual** can be chosen for the **Sorting method** and then an arbitrary number of (ordered) custom sorting priority expressions can be defined in the table that appears. In the **Sorting priority expression** column, add expressions for the sorting, in order of priority. Those expressions can be functions of the eigenvalue `lambda` or eigenfrequency `freq`. For example, you can specify an expression such as `abs(freq-1)` to sort according to the distance from a given shift (1 in this case). If desired, add some descriptive text in the **Description** column for the expressions.

The **Conjugate-pair consecutive sort** checkbox is selected by default to make sure that complex-conjugate eigenpairs appear one after the other, regardless of the sorting rules.

ADVANCED

The eigenvalue solver is an iterative algorithm. Use the **Maximum number of eigenvalue iterations** field to limit the number of iterations (default: 300).

When you use the ARPACK solver, you can use the **Dimension of Krylov space** field to control the algorithm's memory use. The default value of 0 means that the solver sets the dimension automatically to approximately twice the number specified in the **Desired number of eigenvalues** field in the **General** section.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

The **Log** section contains logs of the eigenvalue solver results and properties of the assembled system, including the solver iterations and the total solution time. This log is stored in the Model MPH-file.

	Conical Quantum Dot: Application Library path **COMSOL_Multiphysics/Equation_Based/conical_quantum_dot**

FFT Solver

The **FFT Solver** ( ) performs a discrete Fourier transformation for time-dependent or frequency-dependent input solutions using FFT (fast Fourier transform). You can add the FFT solver to Time Dependent and Frequency Domain studies. The FFT solver supports both forward FFT from the time domain to the frequency domain and inverse NFT (nonuniform Fourier transform) or inverse FFT from the frequency domain to the time domain. The input solution has to be of a Time Dependent type for a forward FFT or of a Parametric type for an inverse NFT (INFT) or inverse FFT (IFFT). The input solution can have real-valued or complex-valued data.

You can visualize the results of an FFT or INFT/IFFT like any other solution, and it can be postprocessed in the same way. The output is typically a complex-valued quantity. Use `abs(u)` to plot the absolute value, or use `real(u)` and `imag(u)` to plot the real and imaginary parts, respectively.

Forward FFT

For the forward FFT (the time-dependent case), a time-dependent solution is transformed from times $\{t_0,\ldots,t_{N-1}\}$ to frequencies $\{f_0, \ldots, f_{N-1}\}$ in the frequency domain.

Inverse NFT/Inverse FFT

For the inverse NFT or inverse FFT (the frequency domain case), a frequency-dependent solution is transformed from frequencies $\{f_0, \ldots, f_{N-1}\}$ to times $\{t_0, \ldots, t_{K-1}\}$ in the time domain. The FFT algorithm is used for the inverse transformation if the input frequency list and the output time list are equidistant and the output time range given matches the input data. Otherwise, the NFT algorithm is used.

If you have the Structural Mechanics Module, see one of these example using the FFT solver:

- *Vibration Analysis of a Deep Beam*: Application Library path **Structural_Mechanics_Module/Verification_Examples/vibrating_deep_beam**
- *Viscoelastic Structural Damper*: Application Library path **Structural_Mechanics_Module/Dynamics_and_Vibration/viscoelastic_damper_frequency**

GENERAL

From the **Defined by study step** list, select a corresponding **Frequency to Time FFT** or **Time-to-Frequency FFT** study step (the default if such a study step created the **FFT Solver** node; the FFT solver settings are then controlled from the study step), or select **User defined** to define the corresponding settings in the FFT solver (see below).

From the **Transformation** list, choose **Forward** for a forward FFT from the time domain to the frequency domain or **Inverse** for an inverse NFT/FFT from the frequency domain to the time domain. If a study step controls the FFT solver, the transformation setting is determined from that study step.

From the **Prescribed by** list, choose **Solution** (the default) to use a solution as the input to the study, or choose **Initial expression** to use an expression for the initial values to couple a field to another field. The mapping then occurs before the FFT.

From the **Solution** list you can select any applicable solution, including solutions from other studies. You can also select **Current**, which uses the current solution. Depending on the type of solution selected, a **Use** list may appear where you can choose **Automatic**, to use the current solution or, if the allowed values are not set correctly, a **Solution Store** node, or a specified stored solution (**Solution Store 1**, for example).

For scaling of the solution, from the **Scaling** list choose **Continuous Fourier transform** (the default) for continuous scaling (scaled by time or frequency step) or **Discrete Fourier transform** for continuous scaling (unscaled). If you chose **Continuous Fourier transform**, also choose an option from the **Continuous scaling** list: **Interval** (the default) or **Discrete Fourier transform compatible**.

Window Function

You can apply a window function for the input data by selecting the **Use window function** checkbox. A window function can be useful to restrict the input data. The following options are available from the **Window function** list:

- Choose **From expression** (the default) to use a real or complex user-defined **Expression**. Every input value is multiplied by this expression. The expression can be parameterized using the following parameters:
  - `t`: the time t_k in the forward FFT case.
  - `freq`: the frequency f_k in the inverse FFT case.
  - `niterFFTin`, which corresponds to the index j in the forward and inverse FFT cases.
  - `nFFTin`: the number of input samples for the forward and inverse FFT cases (that is, $0 \leq$ `niterFFTin` $<$ `nFFTin`).
  - `tperiodFFT`: the period in time for the forward FFT case; that is, `t` in $\{t_0,\ldots, t_{N-1}\}$ with `tperiodFFT` equal to $t_N–t_0$.
  - `freqmaxFFT`: the frequency range for the inverse FFT case; that is, `freq` in $\{f_0, \ldots, f_{N-1}\}$ with `freqmaxFFT` equal to $f_{N-1}–f_0$.
- Choose **Cutoff** to specify a window using a **Cutoff fraction** c in the interval from 0 to 1. The input values are then set to $u(t_j) = 0$ or $\omega(f_j) = 0$ for $j \geq cN$. This window function provides a sharp cutoff, which might be useful in the time domain where you know that your solution has a zero or very small amplitude at the end.
- Choose **Rectangular** to use a rectangular (boxcar) window, which cuts off all input data outside of the start and end values in the **Window start** and **Window end** fields.
- Choose **Gaussian** to use a Gaussian window defined by a **Window center** value and a **Standard deviation**.
- Choose **Hamming** to use a Hamming window defined by a **Window start** value and a **Window end** value.
- Choose **Hanning** to use a Hanning (Hann) window defined by a **Window start** value and a **Window end** value.
- Choose **Blackman** to use a Blackman window defined by a **Window start** value and a **Window end** value.
- Choose **Tukey** to use a Tukey window (tapered cosine window) defined by a **Window start** value and a **Window end** value. In addition, there is a tuning window parameter α, which you define in the **Window parameter** field (default value: 0.5). If the window parameter is set to 0, the Tukey window becomes a rectangular window; if set to 1, it becomes a Hanning (Hann) window.

For general information about window functions, see Ref. 24.

In the case of a forward FFT, for all window types except the one defined from a user-defined expression and the cutoff window, you can also specify a time unit (default: s) in the **Time unit** list provided for the **Start time** and **End time** fields or the **Window center** fields.

In the case of an inverse FFT, for all window types except the one defined from a user-defined expression and the cutoff window, you can also specify a unit (default: Hz) in the **Frequency unit** list.

Additional Setting for the Forward FFT

From the **Time unit** list, choose a time unit (default: s) to use for the times in the transformation. Specify the input time range ($[t_{\text{start}}, t_{\text{end}}]$) for the forward FFT in the **Start time** (t_{start}) and **End time** (t_{end}) fields. The number of interpolated input solutions, N, is derived from the specified maximum output frequency and appears in the solver log. Specify the maximum output frequency $f_{\max}$ using the **Frequency unit** list (default: Hz) and the **Maximum output frequency** field.

If the start time or end time for the FFT exceeds the time range $[t^*_0, t^*_N]$ of the time-dependent input solution, the input solution is padded with zeros for $t_{start} < t^*_0$ and $t_{end} > t^*_N$. Window functions are applied to the original data (that is, the window function is applied first, then the zero padding is added).

The FFT solver adds a warning when zero padding is applied and provides the number of zero solutions added in the log. In addition, there is a warning when the values at the boundaries t_0 and t_N are not zero. In such cases, apply an appropriate window function.

The settings in the **Input data** list are used to specify information about the time-dependent solution. The **Periodic** option (the default) assumes that $u(t_{end}) = u(t_{start})$ and the period of the input solution is $T = t_{end} - t_{start}$. If you select **Not periodic**, the FFT Solver assumes that $u(t_{end} + 0.5/f_{max}) = u(t_{start})$ and the period is $T = (t_{end} + 0.5/f_{max}) - t_{start}$. The FFT Solver can also handle input time-dependent solutions for which the second half of the period equals the first half with opposite sign. For these cases, you can choose **Half-periodic (antisymmetric)** and the period is $T = 2(t_{end} - t_{start})$. For the **Half-periodic (antisymmetric)** case, the condition $u(t_{start}) = u(t_{end}) = -u(T/2)$ must hold.

The number of interpolated input solutions N depends on the **Store output frequencies** option and on the parameter $M = \texttt{floor}(2Tf_{max})$, with T being the period as previously defined. If you choose **No negative frequencies for real input** (the default), the number of input samples $N = M$ when M is odd and $N = M + 1$ when M is even. If you choose **All frequencies**, the number of input samples is $N = M$.

The time-dependent solution is interpolated at $t_0, \ldots, t_{N-1}$, starting at $t_0 = t_{start}$ and spaced by either $\Delta = T/N$ (if **Period input data** is selected) or $\Delta = (t_{end} - t_{start})/(N - 1)$ (if **Periodic input data** is cleared). The FFT solver performs the FFT on the values $\{u(t_0), \ldots, u(t_{N-1})\}$ for the equidistant times $t_0, \ldots, t_{N-1}$. The outputs are $\{\omega(f_0), \ldots, \omega(f_{N-1})\}$, and the frequencies are computed by $f_k = k/T$ for $k = 0, \ldots, N - 1$. The outputs can also be interpreted in terms of positive and negative frequencies using the fact that $\omega(f_k) = \omega(f_{k-N})$.

From the **Store output frequencies** list, choose **No negative frequencies for real input** (the default) or **All frequencies**. If you choose **No negative frequencies for real input**, real data is assumed and only the positive frequencies are stored. This assumption is not a loss of information because $\omega(f_k) = \omega(f_{k+N}) = \overline{\omega}(f_{N-k}) = \overline{\omega}(f_{-k})$ (a warning is given if the input data is not real). If you choose **All frequencies** from the **Output order** list, the output solutions are determined for positive and negative frequencies. Selecting **Symmetric** (the default) results in the following output order:

- $\omega(f_{-n}), \omega(f_{-(n-1)}), \ldots, \omega(f_{-1}), \omega(f_0), \omega(f_1), \ldots, \omega(f_{n-1}), \omega(f_n)$ for $N = 2n+1$.
- $\omega(f_{-n}), \omega(f_{-(n-1)}), \ldots, \omega(f_{-1}), \omega(f_0), \omega(f_1), \ldots, \omega(f_{n-1})$ for $N = 2n$.

If you select **Natural**, the outputs are the same as in the **Symmetric** case but ordered differently:

- $\omega(f_0), \omega(f_1), \ldots, \omega(f_n), \omega(f_{-n}), \omega(f_{-(n-1)}), \ldots, \omega(f_{-1})$ for $N = 2n+1$.
- $\omega(f_0), \omega(f_1), \ldots, \omega(f_{n-1}), \omega(f_{-n}), \omega(f_{-(n-1)}), \ldots, \omega(f_{-1})$ for $N = 2n$.

The forward FFT is computed using the following unscaled formula:

$$\omega(f_k) = \sum_{j=0}^{N-1} u(t_j) e^{\frac{-2\pi i j k}{N}}$$

for $k = 0, \ldots, N - 1$.

Additional Settings for the Inverse NFT/FFT

Solutions in the frequency domain are not interpolated. The input values do not have to be equidistant and they do not have to be sorted with respect to the frequencies. The input data (for nonnegative or nonpositive given frequencies) is by default extended by negative frequencies or positive frequencies with complex-conjugated input

values. You can switch this behavior on and off using the **Extend input samples** list. Choose **Add complex conjugate pairs** (the default) or **Use original data**. The first option allows creation of real output data from complex-valued input data by basically recreating data thrown away by the **Do not store negative frequencies for real input** option for the forward FFT.

From the **Frequencies** list, select **All** (the default) or **Select from interval**:

- For the input selection **All**, the inverse NFT/FFT transforms all available input solutions.
- For the input selection **Select from interval**, you define the interval of frequencies using the **Lower bound** and **Upper bound** fields that appear. Choose the frequency unit from the **Frequency unit** list (default: Hz).

Choose the time unit from the **Time unit** list (default: s). Enter the output time range for the inverse NFT/FFT in the **Times** field. These times correspond to the set of time values selected from the **Times to store** list. The default is **Time steps taken by solver**. If you want to use another set of times (perhaps to reduce the size of the output data), select **From list** and enter the time steps in the **Output times** field. The output data is then interpolated to these output times. Click the **Range** button ( ) to define a range of output time values using the **Range** dialog. The number of output solutions can be different from the number of input solutions.

Use the **Input data** list to specify information about the time-dependent solution. The **Periodic** option (the default) assumes that $u(t_{\text{end}}) = u(t_{\text{start}})$ and the period of the solution is $T = t_{\text{end}} - t_{\text{start}}$. If you select **Not periodic**, the FFT solver assumes that $u(t_{\text{end}} + 0.5/f_{\max}) = u(t_{\text{start}})$ and the period is $T = (t_{\text{end}} + 0.5/f_{\max}) - t_{\text{start}}$. The FFT Solver can also handle time-dependent input solutions for which the second half of the period is antisymmetric with respect to the mean value ($\bar{u}$). For these cases, you can choose **Half-periodic (antisymmetric)** and the period is $T = 2(t_{\text{end}} - t_{\text{start}})$. Only the first half of the period is required as input, and the FFT solver assumes the following relation for the second half of the period: $u(t + T/2) = 2\bar{u} - u(t)$.

The *inverse FFT* is computed for input data $\omega(f_0)$, …, $\omega(f_{N-1})$ using the following formula:

$$u(t_k) = \phi_k \sum_{j=0}^{N-1} \omega(f_j) \mathrm{e}^{\frac{2\pi i j k}{N}}$$

for $k = 0, \ldots, N-1$. The correction factor ϕ_k is defined as

$$\phi_k = \phi_k(f_0) = \mathrm{e}^{\frac{2\pi i k f_0}{F}},$$

where $F = f_N - f_0$, and you can interpret it as a shift of the input values for $f_0 \neq 0$ by means of the following formula:

$$\sum_{j=0}^{N-1} \omega(f_{j+L}) \mathrm{e}^{\frac{2\pi i j k}{N}} = \mathrm{e}^{\frac{-2\pi i k L}{N}} \sum_{j=0}^{N-1} \omega(f_j) \mathrm{e}^{\frac{2\pi i j k}{N}}$$

with $\omega(f_{j+N}) = \omega(f_j)$ for $j = 0, \ldots, N-1$.

Performing an unscaled transformation (**Scaling** list set to **Discrete Fourier Transform**) means that a forward FFT times an inverse FFT results in the original input data multiplied by a factor of N. The original input is obtained if **Scaling** is set to **Continuous Fourier Transform**.

The FFT solver sorts the input data before applying the inverse FFT. For equidistant input frequencies and equidistant output, the fast transformation algorithm (FFT) is applied, if the number of input samples is equal to the number of output time values and if the given output time step (derived from the **Output times** list) correlates to the input frequency range.

The *inverse NFT* is computed using the following formula if **Use original data** is selected from the **Extend input samples** list:

$$u(t_k) = \sum_{j=0}^{N-1} \omega(f_j) e^{2\pi i f_j (t_k - t_0)}$$

for $k = 0, \ldots, K-1$ (K is given by the number of output times; that is, $t_0, \ldots, t_{K-1}$. If you have selected **Add complex conjugate pairs** from the **Extend input samples** list, then the formula

$$u(t_k) = \omega(f_0) + \frac{1}{2} \cdot \sum_{j=1}^{M} (\omega(f_j) e^{2\pi i f_j (t_k - t_0)} + \overline{\omega(f_j)} e^{-2\pi i f_j (t_k - t_0)})$$

for $k = 0, \ldots, K-1$ is used. The input frequencies $f_1, \ldots, f_M$ have to be all positive or all negative, and either $f_0 = 0$ is given as input frequency or $\omega(f_0) = 0$ is used.

Select the **Add stationary solution** checkbox to extend the input data for frequency 0 by a stationary solution that is either taken as the data for frequency 0 or added to the data for frequency 0. Select the method to retrieve the solution from the **Method** list: **Solution** (the default) to use the solution itself, or **Initial expression** to use the expression for the initial value. Choose any available and applicable solution from the **Solution** list, or choose **Zero** for no solution. Depending on the selected solution, additional settings appear for specifying which of the solutions to use and which parameter values, eigenfrequencies, or times to use. Use the **Time** list to select an input solution at a specific time or to interpolate.

ADVANCED

You can specify phase functions for input and output data. This functionality can be used for modifying the input and output data. Select the **Use phase function** checkbox to specify phase functions. The following options are available from the **Phase function for input** and **Phase function for output** lists: **None** (the default, which provides no phase function) and **From expression**:

Select **From expression** to type an expression for the phase function in the **Expression** field. The expression e_{in} for the input data or e_{out} for the output data can be real-valued or complex-valued. In the forward case, each input value $u(t_k)$ is then multiplied by $\texttt{exp}(ie_{\text{in}})$, and similarly, each output value $\omega(f_k)$ is multiplied by $\texttt{exp}(ie_{\text{out}})$. In the inverse case, each input value $\omega(f_k)$ is multiplied by $\texttt{exp}(ie_{\text{in}})$, and similarly, each output value $u(t_k)$ is multiplied by $\texttt{exp}(ie_{\text{out}})$.

- For **Phase function for input**, the expression e_{in} can be parameterized using the following parameters:
  - `t`: the time t_k in the forward FFT case.
  - `freq`: the frequency f_k in the inverse FFT case.
  - `niterFFTin`, which corresponds to the index j for the input data in the forward and inverse FFT cases.
  - `nFFTin`: the number of input samples for the forward and inverse FFT cases.
  - `tperiodFFT`: the period in time for the forward FFT case; that is, `t` in $\{t_0, \ldots, t_{N-1}\}$ with `tperiodFFT` equal to $t_N - t_0$.
  - `freqmaxFFT`: the frequency range for the inverse FFT case; that is, `freq` in $\{f_0, \ldots, f_{N-1}\}$ with `freqmaxFFT` equal to $f_{N-1} - f_0$.

- For **Phase function for output**, the expression e_{out} can be parameterized using the following parameters:
  - `freq`: the frequency in the forward FFT case.
  - `t`: the time in the inverse FFT case.
  - `niterFFTout`, which corresponds to the index j for the output data in the forward and inverse FFT cases.
  - `nFFTout`: the number of output solutions for the forward and inverse FFT cases (that is, $0 \leq$ `niterFFTout` $<$ `nFFTout`).
  - `tperiodFFT`: the period in time for the inverse FFT case; that is, `t` in $\{t_0,\ldots, t_{N-1}\}$ with `tperiodFFT` equal to $t_{N-1} - t_0$.
  - `freqmaxFFT`: the frequency range for the forward FFT case; that is, `freq` in $\{f_0, \ldots, f_{N-1}\}$ with `freqmaxFFT` equal to $f_{N-1} - f_0$.

OUTPUT

Select the **Store intermediate FFT data on disk** checkbox to store intermediate data on disk. The FFT solver then typically becomes slower (due to load and store operations) but uses less memory.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

Select the **Keep warnings in stored log** checkbox if you want the warnings to remain in the log for troubleshooting or other use.

Modal Reduction

Use the **Modal Reduction** ( ) solver to produce a reduced-order model. The modal reduction solver uses precomputed eigenvalues and eigenvectors. This solver is automatically used when a Model Reduction has its **Method** set to **Modal**.

Also see The Modal Solver Algorithm for more information.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step, or select **User defined** to specify all settings locally.

Use the **Study type** list to select the basic study type. Select:

- **Frequency domain** to perform parameter stepping using a reduced model. Then continue defining the settings For Frequency Domain, Modal Studies.
- **Time dependent** to perform time stepping using a reduced model. Then continue defining the settings For Time Dependent, Modal Studies.

For Frequency Domain, Modal Studies

For a Frequency Domain, Modal study, use the **Frequencies** field to enter a vector of frequencies that define the frequency-domain simulation. Only the first frequency is used. Click the **Range** button ( ) to define a range of frequencies using the **Range** dialog. You can also specify a unit in the **Frequency unit** list (default: Hz).

Use the **Linearity** list to specify the type of linear behavior. Select:

- **Linear** to use a linear solver with the same linearization point for both residual and Jacobian computation, which corresponds to one step in Newton's method.
- **Linear perturbation** (the default setting) to use a linear solver that computes the Jacobian in the same way as the **Linear** option but uses a zero solution when computing the residual. It is useful for small-signal analysis and similar applications where the variations around a linearization point are of interest.

For Time Dependent, Modal Studies

For a Time Dependent, Modal study, select a **Time unit** from the list. Then use the **Output times** field to enter a vector of times that define the time span for the simulation. Click the **Range** button ( ) to define time values. For a time-dependent study type, the following additional settings are available:

Tolerance

Use the **Relative tolerance** field to enter a positive number (default value: 0.01). The relative tolerance is copied to the **Reduced-Order Modeling** node when a new node is created, where it can be further modified for use in the online phase for a stateless interface. When the interface is stateful this tolerance is not used. The absolute tolerance settings below work in the same way as for the time-dependent solver, but internally the full length absolute tolerance vector is transferred to the modes by the same transformation (projection) as is used to transform the problem to reduced form (the eigenmodes).

Extending the Basis

From the **Extend basis with initial data** list choose **Automatic**, **On**, or **Off**. If it is **On**, it means that initial data will be considered in the base extension. You can use **On** for rare cases where the automatic method does not add the initial values to the basis but it makes sense to do so. If it is **Off**, then initial data will no be considered. The default is

Automatic, which means that the initial data will be considered in the base extension only if it is large enough to make a difference.

EIGENPAIRS

Use the **Solution** list to specify a solver configuration to be used when constructing the reduced model.

The **Use** list is available for solution sequences with additional stored solutions. When available, select an option to specify a solution containing the modes to be used in the reduced model.

Use the **Eigenpairs** list to specify which of the eigenpairs present in the solution to include when constructing the reduced model. The default setting is **All**, and the solver then uses all available eigenpairs. Select **Manual** to enter a space-separated list of **Eigenpair numbers** in the field.

CONSTRAINT MODES

Use the **Solution** list to specify which solution to be used when constructing the reduced model.

Use the **Constraint modes** list to specify which of the constraint modes present in the solution to include when constructing the reduced model. The default setting is **All**, and the solver then uses all available constraint modes. Select **Manual** to enter a space-separated list of constraint modes numbers in the **Constraint modes numbers** field.

When there is sensitivity solution to be chosen as constraint modes, a **Use sensitivity solution** checkbox is available. When selected, it means that the constraint modes are from the sensitivity analysis. To get a meaningful sensitivity solution, you need to make sure that the inputs in the **Global Reduced-Model Inputs** node are used in some boundaries in a **Stationary** study step. The sensitivity parameter should be set to zero in the **Sensitivity** node. When cleared, it means that the constraint modes are from an auxiliary sweep. To get meaningful parametric solutions, you need to define some training parameters and apply them at the boundaries of the **Stationary** study step. In the **Auxiliary sweep** settings in the **Study Extensions** section of the **Stationary** node, set one parameter to be 1 at a time and set all other parameters to be zero.

VALUES OF LINEARIZATION POINT

A frequency-domain problem solved by the **Modal Solver** is assumed to be a linearization about a solution. You can specify such a solution (a linearization point) with the **Prescribed by** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point. Then, when **Solution** is selected from the **Prescribed by** list, specify which solution to use. Select:
  - **Zero** to use a linearization point that is identically equal to zero.
  - Any other available solution to use it as linearization point.

OUTPUT

From the **Reduced-order model** list, choose **New** to create a new reduced-order model, or choose any existing reduced-order model.

From the **Interface** list, if you chose **New** from the **Reduced-order model** list, choose **Stateless** (the default) or **Stateful**. In the former case, the reduced-order model acts as a black box that uses an internal solver and does not expose its state. In the latter case, the reduced-order model exposes a set of reduced-order equations and state DOFs to the solver used for the calling model, and you can choose whether to solve for the reduced-order model in the same way as for a physics interface.

The **Ensure reconstruction capability** checkbox is selected by default to enable reconstruction of the unreduced solution vector. Clear it if you need to save memory; for the ROM to be capable of reconstruction, the modal basis must be stored.

ADVANCED

For Time Dependent, Modal Studies

Select the **Allow complex numbers** checkbox to be able to solve problems that are not automatically determined to be complex-valued in a correct way.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

Select the **Keep warnings in stored log** checkbox if you want the warnings to remain in the log for troubleshooting or other use.

Modal Solver

Use the **Modal Solver** ( ) solver to perform either parameter stepping (also called frequency response) or time stepping (also called transient response) using a reduced model. The model reduction uses precomputed eigenvalues and eigenvectors. This solver is automatically used when a Time Dependent, Modal or Frequency Domain, Modal study is added to the model.

Also see The Modal Solver Algorithm for more information.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step, or select **User defined** to specify all settings locally.

Use the **Study type** list to select the basic study type. Select:

- **Frequency domain** to perform parameter stepping using a reduced model. Then continue defining the settings For Frequency Domain, Modal Studies.
- **Time dependent** to perform time stepping using a reduced model. Then continue defining the settings For Time Dependent, Modal Studies.

Use a scalar-valued expression for the value in the **Load factor** field (default: 1). The solver uses this expression as a load factor that is multiplied with the residual.

For Frequency Domain, Modal Studies

For a Frequency Domain, Modal study, select a **Frequency unit** from the list.

Use the **Parameter values** field to enter a vector of parameter values that define the parameter value span for the frequency-domain simulation. Click the **Range** button ( ) to define a range of parameter values using the **Range** dialog.

Exactly how the vector of parameter values is used by the solver is determined by the option **Parameter list type**.

An alternative to specifying parameter values or frequencies directly in the **Frequencies** (for the **Frequency** parameter type) or **Parameters values** (for the **Fraction** and **Spread** parameter types) field is to specify them in a text file. You can use the **Load parameter values** field and the **Browse** button ( ) to specify such a text file. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ). Click the **Read File** button ( ) to read the specified file. The read values appear in the **Parameters values** field.

	Reading parameter values from a file overwrites any values already present in that field. The format of the text files must be such that the parameter values appear one per row.

Use the **Parameter list type** list to control how to interpret the parameter values entered in the **Parameter values** field. Select:

- **Frequency** (the default setting) to use the parameter values without modification.
- **Fraction** to multiply the parameter values by the absolute value of the largest eigenvalue in the reduced model divided by two.
- **Spread** to treat the parameter values as an interval around each eigenvalue in the reduced model. That is, the absolute value of each eigenvalue is multiplied by the parameter values and the resulting parameter value vectors are concatenated into one.

If you chose **Fraction** or **Spread**, also specify values for **Minimum frequency**, **Maximum frequency**, and also, if desired, **Additional frequencies**. For the minimum and maximum frequency, the default is **Automatic** to determine them automatically. Select **Manual** to specify a minimum or maximum frequency in the **Value** field.

Use the **Linearity** list to specify the type of linear behavior. Select:

- **Linear** to use a linear solver with the same linearization point for both residual and Jacobian computation, which corresponds to one step in Newton's method.
- **Linear perturbation** (the default setting) to use a linear solver that computes the Jacobian in the same way as the **Linear** option but uses a zero solution when computing the residual. It is useful for small-signal analysis and similar applications where the variations around a linearization point are of interest.

For Time Dependent, Modal Studies

For a Time Dependent, Modal study, select a **Time unit** from the list. Then use the **Output times** field to enter a vector of times that define the time span for the simulation. Click the **Range** button ( ) to define time values. Output from a simulation includes the times given in this field and the corresponding solutions. In addition, for a time-dependent study type, the following settings are available:

Relative Tolerance

Use the **Relative tolerance** field to enter a positive number (default value: 0.01). The relative tolerance is used by the solver in each time step to control the relative error. The absolute tolerance settings below work in the same way as for the time-dependent solver, but internally the full length absolute tolerance vector is transferred to the modes by the same transformation (projection) as is used to transform the problem to reduced form (the eigenmodes).

Maximum Time Step

For the maximum time step, select an option from the **Maximum step constraint** list. By default, the solver chooses a maximum time step automatically. Select **Constant** as the maximum step constraint for manual specification of a fixed maximum time step in the **Maximum step** field. A constant maximum step constraint is a positive scalar value, which can be an expression that evaluates to a numerical value before entering the solver. The expression can include global parameters. Select **Expression** as the maximum step constraint for more general expressions of the allowed maximum time step. These expressions are evaluated while solving and can, for instance, depend on the time parameter itself.

The solver uses the absolute value of the expression for the maximum step constraint.

Extending the Basis

From the **Extend basis with initial data** list choose **Automatic**, **On**, or **Off**. If it is **On**, it means that initial data will be considered in the base extension. You can use **On** for rare cases where the automatic method does not add the initial values to the basis but it makes sense to do so. If it is **Off**, then initial data will no be considered. The default is **Automatic**, which means that the initial data will be considered in the base extension only if it is large enough to make a difference.

EIGENPAIRS

Use the **Solution** list to specify a solver configuration to be used when constructing the reduced model.

The **Use** list is available for solution sequences with additional stored solutions. When available, select an option to specify a solution containing the modes to be used in the reduced model.

Use the **Eigenpairs** list to specify which of the eigenpairs present in the solution to include when constructing the reduced model. The default setting is **All**, and the solver then uses all available eigenpairs. Select **Manual** to enter a space-separated list of **Eigenpair numbers** in the field.

Use the **Damping ratios** field to enter either a scalar value or a space-separated list with values. The total number of entered values must be one or equal to the number of eigenpairs in the reduced model. If one number is entered, that value becomes the damping ratio for all eigenpairs. If the field is empty (the default), no damping is applied by the solver.

CONSTRAINT MODES

Use the **Solution** list to specify which solution to be used when constructing the reduced model.

Use the **Constraint modes** list to specify which of the constraint modes present in the solution to include when constructing the reduced model. The default setting is **All**, and the solver then uses all available constraint modes. Select **Manual** to enter a space-separated list of constraint modes numbers in the **Constraint modes numbers** field.

VALUES OF LINEARIZATION POINT

A frequency-domain problem solved by the **Modal Solver** is assumed to be a linearization about a solution. You can specify such a solution (a linearization point) with the **Prescribed by** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point. Then, when **Solution** is selected from the **Prescribed by** list, specify which solution to use. Select:
  - **Zero** to use a linearization point that is identically equal to zero.
  - Any other available solution to use it as linearization point.

Select the **Store linearization point and deviation in output** checkbox to store the used linearization point in the output.

OUTPUT

The output from the solver can either be the solution, the reduced matrices, or both.

If **Solution** is selected, the reduced problem is solved, and the reconstruction is used to store the full solution in the output object. If you have chosen **Time dependent** for the modal solver, you can select the **Store time derivatives** checkbox to also store the time derivatives in the returned solution object.

If **Reduced matrices** is selected, click to select the checkboxes corresponding to matrices and vectors that should be stored in the output. The following matrices and vectors can be exported for all modal solvers: **Stiffness matrix**, **Damping matrix**, **Damping ratio matrix**, **Mass matrix**, **Constraint modes to inputs map**, **Projection matrix**, **Load vector**, **Input matrix**, **Output matrix**, **Output bias**, and **Input feedback matrix**. For Time Dependent, Modal studies the following can also be exported: **Time derivative input matrix**, **Second time derivative input matrix**, **Initial value vector**, **Initial derivative vector**, **Initial value input matrix**, **Initial value time derivative input matrix**, **Stiffness matrix times ud**, and state-space matrices (**Mc**, **MA**, **MB**, **Null**, **D**, **C**, **ud**, and **x0**). For Frequency Domain, Modal studies the following can also be exported: **Mass matrix times particular solution**, **Damping matrix times particular solution**, and **All load vectors**.

ADVANCED

For Time Dependent, Modal Studies

Select the **Allow complex numbers** checkbox to be able to solve problems that are not automatically determined to be complex-valued in a correct way.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

Select the **Keep warnings in stored log** checkbox if you want the warnings to remain in the log for troubleshooting or other use.

Optimization Solver

The **Optimization Solver** ( ) provides the settings for solving PDE-constrained optimization problems. This solver requires the Optimization Module. See the *Optimization Module User's Guide* for details. Also see The Log Window (The Optimization Solver Log).

	Optimization in the *COMSOL Multiphysics Programming Reference Manual.*

POD Reduction

Use the **POD Reduction** ( ) node to perform a model order reduction using a proper orthogonal decomposition algorithm.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step, or select **User defined** to specify all settings locally.

Use the **Study type** list to select the basic study type. Select:

- **Frequency domain** to perform a frequency-domain simulation using a reduced model. Then continue defining the settings For Frequency Domain.
- **Time dependent** to perform time stepping using a reduced model. Then continue defining the settings For Time Dependent.

For Frequency Domain

From the **Frequency unit** list, choose a unit (default: Hz).

Specify the frequencies to use in the **Frequencies** field. Click the **Range** button ( ) to define frequency values, if desired.

Use the **Linearity** list to specify the type of linear behavior. Select:

- **Linear** (the default setting) to use a linear solver with the same linearization point for both residual and Jacobian computation, which corresponds to one step in Newton's method.
- **Linear perturbation** to use a linear solver that computes the Jacobian in the same way as the **Linear** option but uses a zero solution when computing the residual. It is useful for small-signal analysis and similar applications where the variations around a linearization point are of interest.

The values in the **Relative tolerance for truncations** field is used to determine the number of POD modes so that the relative error of approximating training solution with POD modes is within the specified threshold (default: 0.01).

For Time Dependent

From the **Time unit** list, choose a unit (default: s).

Then use the **Output times** field to enter a vector of times that define the time span for the simulation. Click the **Range** button ( ) to define time values, if desired. Output from a simulation includes the times given in this field and the corresponding solutions. In addition, for a time-dependent study type, the following settings are available:

Use the **Relative tolerance** field to enter a positive number (default value: 0.01). The relative tolerance is used by the solver in each time step to control the relative error. The absolute tolerance settings below work in the same way as for the time-dependent solver, but internally the full length absolute tolerance vector is transferred to the modes by the same transformation (projection) as is used to transform the problem to reduced form (the eigenmodes).

From the **Extend basis with initial data** list choose **Automatic**, **On**, or **Off**. If it is **On**, it means that initial data will be considered in the base extension. You can use **On** for rare cases where the automatic method does not add the initial values to the basis but it makes sense to do so. If it is **Off**, then initial data will no be considered. The default is **Automatic**, which means that the initial data will be considered in the base extension only if it is large enough to make a difference.

The values in the **Relative tolerance for truncations** field is used to determine the number of POD modes so that the relative error of approximating a training solution with POD modes is within the specified threshold (default: 0.01).

TRAINING SOLUTION

From the **Solution** list, choose a solution for POD modes training, which is synchronized from the **Solution selection** setting in the **Model Reduction** study step.

Use the **Variables grouping method** list to specify how to group variables for POD modes construction. Select:

- **One group** (the default) to handle all dependent variables together.
- **One group per variable** to treat each dependent variable as a group.
- **Manual** to customize the grouping of dependent variables. A group can be added or removed by clicking buttons under the table. If you would just to modify the list of dependent variables in a group, click in the **Dependent variables** column and edit the content through the **Variables** list below.

Once the grouping of dependent variables is determined, a reduced-order basis is constructed by concatenating POD modes computed for each group.

CONSTRAINT MODES

Use the **Solution** list to specify which solution to be used when constructing the reduced model.

Use the **Constraint modes** list to specify which of the constraint modes present in the solution to include when constructing the reduced model. The default setting is **All**, and the solver then uses all available constraint modes. Select **Manual** to enter a space-separated list of constraint modes numbers in the **Constraint modes numbers** field.

OUTPUT

From the **Reduced-order model** list, choose **New** to create a new reduced-order model, or choose any existing reduced-order model.

From the **Interface** list, if you chose **New** from the **Reduced-order model** list, choose **Stateless** (the default) or **Stateful**. In the former case, the reduced-order model acts as a black box that uses an internal solver and does not expose its state. In the latter case, the reduced-order model exposes a set of reduced-order equations and state DOFs to the solver used for the calling model, and you can choose whether to solve for the reduced-order model in the same way as for a physics interface.

The **Ensure reconstruction capability** checkbox is selected by default to enable reconstruction of the unreduced solution vector. Clear it if you need to save memory; for the ROM to be capable of reconstruction, the modal basis must be stored.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

Select the **Keep warnings in stored log** checkbox if you want the warnings to remain in the log for troubleshooting or other use.

Plug Flow Solver

The **Plug Flow Solver** ( ) is the default solver for Stationary Plug Flow study steps, and it is a version of the Time-Dependent Solver, except it steps in *volume* instead of time. This is indicated in the output section where volume settings are available. It is specially designed to solve plug flow reactor models set up in the Reaction Engineering interface, which requires the Chemical Reaction Engineering Module.

Stationary Solver

Use the **Stationary Solver** ( ) to find the solution to linear and nonlinear stationary problems (also called static or steady-state problems). This solver is automatically used when a Stationary or Frequency Domain study is added to the model.

Also see About the Stationary Solver for information about Damped Newton Methods, Linear Solvers vs. Nonlinear Solvers, and Pseudo Time Stepping.

When used under an **Optimization Solver** node, some of the settings below are instead available in the settings for the **Optimization Solver** node.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step.

The number in the **Relative tolerance** field (default: 0.001) is used for tolerance-based termination of iterative solver processes and for error checking (if enabled) for direct linear system solvers. To specify it here, you need to select **User defined** from the **Defined by study step** list.

The termination tolerance used for iterative processes is also influenced by values specified in the **Tolerance factor** fields present in active Fully Coupled, Segregated, and Segregated Step subnodes. See Termination Criterion for the Fully Coupled and Segregated Attribute Nodes for details.

Use the **Linearity** list to specify whether to use a nonlinear or linear solver. Select:

- **Automatic** to perform an analysis that automatically detects if the problem can be solved with a linear solver approach. If this option is selected, no other settings are required.
- **Linear** to use a linear solver. When the Fully Coupled solver is used with Automatic or Constant damping (the damping is equal to 1), this option uses the same linearization point for both residual and Jacobian computation and corresponds to one step in Newton's method. If the damping is not equal to 1 and the Termination technique allows for more than one iteration, then an iterative approach will be used; the residual will be reassembled for the updated solution, but the Jacobian will be kept fixed. Notice that if this approach converges, it will converge to the solution to the problem at hand, which can be nonlinear. When a Segregated solver is used, and the Termination criteria allows for more than one iteration, then an iterative approach will be used that is very similar to the Fully Coupled solver, where the residuals for the individual segregated steps are reassembled with the updated solution while the Jacobians are kept constant from its initial assemble using the Linearization point.
- **Linear perturbation** to use a linear solver. This option computes the Jacobian in the same way as the **Linear** option but include only special weak contribution terms when assembling the residual. Only terms encapsulated by the `linper` operator are included. This option is useful for small-signal analysis and similar applications where the variations around a linearization point are of interest.
- **Nonlinear** to use a nonlinear solver. If this option is selected, no other settings are required.

Values of Linearization Point

If **Linear** or **Linear perturbation** is selected, COMSOL assumes that the problem to be solved is a linearization about a solution. Specify such a solution (a linearization point) using the **Prescribed by** list. Select:

- **Initial expression** to use the expressions specified on the **Initial Values** nodes under a specific physics interface as a linearization point.
- **Solution** to use a solution as a linearization point. Use the **Solution** list to specify which solution to use if **Prescribed by** has been set to **Solution**. Select:
  - **Zero** to use a linearization point that is identically equal to zero.
  - Any other solution to use it as linearization point. It can be the current solution in the sequence or a solution from another sequence or a solution that was stored with the Solution Store node. You select a stored solution by changing **Use** to the name of the stored solution.

Select the **Store linearization point and deviation in output** checkbox to store the used linearization point. Also see Linear Solvers vs. Nonlinear Solvers.

VARIABLES

This section is only visible when the study contains a Stationary Then Eigenfrequency study step. It can be used to specify which dependent variables are computed with the Stationary solver. The same dependent variable cannot appear in the equivalent section of the Eigenvalue Solver, control variables excepted.

OUTPUT

Select the **Reaction forces** checkbox to compute and store reaction forces in the output.

The computation of boundary flux variables involves solving a system of equations to obtain a continuous field from nodal flux values. If the **Use lumping when computing fluxes** checkbox is selected, this system of equations is lumped. The benefits of using this option is that it can avoid certain spurious oscillations in the computed flux field and that it is slightly faster. Lumping is not suitable in 3D for shape functions of order higher than 1.

RESULTS WHILE SOLVING

This section is not available in the following cases:

- When you add a Stationary Solver as a subnode to an Optimization node.
- In nested parametric sweeps, it is only available for the innermost sweep.
- When you use one of the following sweep study types: Function Sweep, Material Sweep, Batch Sweep, and Cluster Sweep.

To enable these settings, select **User defined** from the **Defined by study step** list under **General**. Select the **Plot** checkbox to allow plotting of results while solving in the **Graphics** window. Then select what to plot from the **Plot group** list and, for time dependent simulations, at which time steps to update the plot: the output times or the time steps taken by the solver. The software plots the dataset of the selected plot group as soon as the results become available. You can also control which probes to tabulate and plot the values from. The default is to tabulate and plot the values from all probes in the **Table** window and a **Probe Plot** window.

Use the **Probes** list to select any probes to evaluate. The default is **All**, which selects all probes for plotting and tabulation of probe data. Select **Manual** to open a list with all available probes. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the probes that you want to see results from while solving. Select **None** to not include any probe.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

This section, which is initially empty, contains a log from the time stepping. It is not available when the stationary solver is a subnode to another solver. This log is stored in the Model MPH-file. Select the **Keep warnings in stored log** to keep warning messages in this log so that the information in those warnings is also available when reopening the model.

- *Deformation of a Feeder Clamp*: Application Library path **COMSOL_Multiphysics/Structural_Mechanics/feeder_clamp**

The Log Window

Time-Dependent Solver

Use the **Time-Dependent Solver** ( ) to find the solution to time-dependent problems (also called dynamic or unsteady problems) using the implicit time-stepping methods BDF or generalized-α or an explicit method from a family of Runge–Kutta methods as well as an Adams–Bashforth method for solving ordinary differential equations (ODEs). This solver is automatically used when a Time Dependent study is added to the model.

Also see About the Time-Dependent Solver for information about The Implicit Time-Dependent Solver Algorithms and BDF vs. Generalized-α and Explicit Methods.

When used under an **Optimization Solver** node, some of the settings below are instead available in the settings for the **Optimization Solver** node.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step (the default). If you select **User defined** (to override the settings defined in the corresponding study node), you can specify the **Time unit**, **Output times**, and **Relative tolerance** settings.

Use the **Time unit** list to choose a time unit that is suitable for the time span of the simulation. The default time unit is inherited from the corresponding setting in the study step.

Use the **Output times** field to enter a vector of times that define the time span for the simulation using the **Range** button ( ) if needed (default: `range(0,0.1,1)`).

From the **Times to store** list, choose one of the following options:

- Choose **Output times by interpolation** (the default) to store the output times using interpolation from the solver's time steps.

- Choose **Steps taken by solver closest to output times** to use the time steps from the solver that are closest to a given output time among all the steps that have passed this output time.
- Choose **Steps taken by solver** to store the actual time steps from the solver. Specify to store every *N*th step in the **Store every Nth step** field (default value: 1; that is, all time steps are stored).

Use the **Relative tolerance** field to enter a positive scalar number (default: 0.01). The solver uses this number to control the relative error in each time step. The tolerance may need to be set to a smaller (tighter) value if the simulation results seem unexpected or inconsistent.

ABSOLUTE TOLERANCE

See Absolute Tolerance Settings for the Time-Dependent Solver for details about this section.

Specify an absolute tolerance that is used by the solver to control the absolute error. The tolerance specified here is applied to all variables unless modified per variable by selecting a method other than the global method for a variable.

Select a **Global method** to select how the specified absolute tolerance is to be interpreted for the variables that use the global method (by default, all variables use the global method). Select:

- **Scaled** to let the absolute tolerance be applied to scaled variables.
- **Unscaled** to let the absolute tolerance be applied to unscaled variables.

Select a **Tolerance method** to specify how to enter and compute the absolute tolerance. Select:

- **Factor** to specify a factor (default: 0.1) in the **Tolerance factor** field that makes the absolute tolerance proportional to the relative tolerance. With this method, the absolute error does not become dominating when you reduce the relative tolerance so that it is much smaller than the absolute tolerance.
- **Manual** to specify a value for the absolute tolerance. In the **Absolute tolerance** field, enter a positive number that is applied to either scaled or unscaled variables.

Select a **Derivative tolerance method** to specify how to enter and compute the absolute tolerance for the time derivative. It can be useful in some cases where control of the absolute tolerances for the time derivatives must be more elaborate in order to reflect the character of the model solved. Select:

- **Automatic** to use an automatic derivative tolerance. The automatic method sets the time derivative factor (see below) to one over the time span.
- **Factor** to specify a factor (default: 1 Hz) in the **Time derivative factor** field. The time derivative factor acts between the tolerance on the variables and their time derivatives.

Select the **Update scaled absolute tolerance** checkbox as needed. See Absolute Tolerance Settings for the Time-Dependent Solver for details.

To specify the absolute tolerance individually for a variable, select from the **Variables** list and modify the corresponding tolerance using the **Method** list. Select:

- **Scaled** to apply the specified tolerance to scaled variables.
- **Unscaled** to apply the specified tolerance to unscaled variables.
- **Use global** (the default) to apply the tolerance specified for the global tolerance.

If **Scaled** or **Unscaled** is selected as the **Method**, you can specify the absolute tolerance for the selected variable:

Select a **Tolerance method** to specify how to enter and compute the absolute tolerance. Select:

- **Factor** to specify a factor (default: 0.1) in the **Tolerance factor** field that makes the absolute tolerance proportional to the relative tolerance. With this method, the absolute error does not become dominating when you reduce the relative tolerance so that it is much smaller than the absolute tolerance.
- **Manual** to specify values for the absolute tolerances. In the **Tolerance** field, enter a positive number that is applied to either scaled or unscaled variables. If a problem of wave-equation type is being solved, then by default, the solver chooses a tolerance for the variable. To manually enter a tolerance for a variable's time derivatives, use the **Tolerance for time derivatives** field.

Select a **Derivative tolerance method** to specify how to enter and compute the absolute tolerance for the time derivative. Select:

- **Automatic** to use an automatic derivative tolerance. The automatic method sets the time derivative factor to one over the time span.
- **Factor** to specify a factor (default: 1 Hz) in the **Time derivative factor** field. The time derivative factor acts between the tolerance on the variable and its time derivative.

TIME STEPPING (GENERAL SETTINGS)

From the **Solver type** list, choose **Implicit** (the default) to use an implicit time-stepping method or choose **Explicit** to use an explicit time-stepping method. See BDF vs. Generalized-α and Explicit Methods for more information about these methods.

Settings For Implicit Time Stepping

Select an implicit time-stepping **Method**:

- **BDF** to use a backward differentiation formula.
- **Generalized alpha** to use the generalized-α method.
- **Initialization only** to compute consistent initial values only and then stop. If this option is selected, no other settings are required.

See Time Stepping (BDF and Generalized Alpha) below for information about additional settings for those time-stepping methods.

Settings For Explicit Time Stepping

Select an explicit time-stepping **Method**:

- **Runge–Kutta** to use one of the following Runge–Kutta methods from the **Runge–Kutta method** list: **RK34**, **Cash–Karp 5**, or **Dormand–Prince 5**. See Time Stepping (Runge–Kutta Methods) below for more information about these settings for these Runge–Kutta methods.
- **Classical Runge–Kutta** to use classical explicit Runge–Kutta (ERK) methods. Explicit classical Runge–Kutta methods of order 1–4 are supported. Runge–Kutta 4 is the default choice for the discontinuous Galerkin method. See Time Stepping (Classical Runge–Kutta) below for more information about these settings for this method.
- **Adams–Bashforth 3** to use a 3-step explicit Adams–Bashforth method. The third-order Adams–Bashforth multistep method (AB3) for $u_t = R(u)$ is

$$u_{n+1} = u_n + \frac{k}{12}(23R(u_n) - 16R(u_{n-1}) + 5R(u_{n-2}))$$

where u_n is the solution at time t_n, and k is the time step. The time restriction for the discontinuous Galerkin method for wave problems is directly proportional to the smallest mesh element size. See Time Stepping (Adams–Bashforth 3) below for more information about these settings for this method.

- **Adams–Bashforth 3 (local)** to use an Adams–Bashforth method using a local time-marching scheme with the Wave Form PDE interface. See Time Stepping (Adams–Bashforth 3, Local) below for more information about these settings for this method.

For all settings for **Steps taken by solver** except **Strict** for the implicit solvers and for all explicit solvers, the **Interpolate solution at end time** checkbox is selected by default. The solver can then step past the last time in the **Output times** list, leading to the end time being interpolated. If you clear this checkbox, the solver will not step past the last time in the **Output times** list, so that the time stepping includes the last time and takes no steps past that time.

For the explicit solve methods, except **Runge–Kutta**, use the **Mass matrix solver** list to select the linear solver to be used within the time-stepping scheme to invert the mass matrix. Available linear solvers appear in the model tree. The default is to use the **Direct** linear solver. For cheap but approximate inversion of the mass matrix, use the **Lumped** option. From the **Algebraic equations** list, choose **Solve every** N**th step** and then enter a positive integer in the N field (default: 1), or choose **Solve periodically** and then enter the period (SI unit: s) in the **Period** Δt field (default: 0) for solving algebraic equations. For Classical Runge–Kutta, you can also choose **Solve at every stage**. For more information, see About the Wave Form PDE Interface. By default, the full problem is solved, which correspond to **Solve at every stage** for Classical Runge–Kutta and **Solve every** N**th step** with $N = 1$ for Adams–Bashforth 3.

Select the **Check validity of coupled system** checkbox to examine whether the coupled system can be solved properly with a time-explicit method. However, this procedure will increase the peak memory usage. If you already know that a coupled system can be solved explicitly, it is reasonable to skip the validity check, especially when the number of DOFs is large.

TIME STEPPING (BDF AND GENERALIZED ALPHA)

The following settings are available when **BDF** or **Generalized alpha** is selected above.

If a Fully Coupled or Segregated attribute node is attached to a **Time** node, the settings for the nonlinear systems solved by the time-stepping methods come from that node.

The **Generalized alpha** time-stepping method requires a **Fully Coupled** or **Segregated** attribute node.

The **BDF** time-stepping method can be used without a **Fully Coupled** or **Segregated** attribute node. In such a situation, the **BDF** method uses an internal automatic nonlinear solver.

Steps Taken by Solver

To modify how the time-stepping methods select the time steps, choose an option from the **Steps taken by solver** list. Select:

- **Free** to let the time-stepping method choose time steps freely. The times specified in the **Times** field in the **General** section are not considered when a time step is chosen.
- **Intermediate** to force the time-stepping method to take at least one step in each subinterval of the times specified in the **Times** field in the **General** section.

- **Strict** to force the time-stepping method to take steps that end at the times specified in the **Times** field in the **General** section. The solver takes additional steps in between these times if necessary.
- **Manual** to override the automatic choice of time step with a manual choice. Manual time stepping can be useful in cases where the automatic time-step selection does not work; for example, in contact problems, rotating machinery, or fluid-structure interaction.

Manual is available for **BDF** and **Generalized alpha** and overrides the local error estimation made in each time step.

Further options that apply to one or several combinations (as indicated at each bullet) of selections made in the **Method** and **Steps taken by solver** lists are:

If **Free**, **Intermediate**, or **Strict** is selected for the **Steps taken by solver**:

- **Initial step**. By default, the solver chooses an initial step automatically. Select the **Initial step** checkbox for manual specification of an initial step. By default, for generalized-α, the first step is 0.1% of the end time, which can affect your solution so that you do not get the same time-step history up to a certain earlier time when the end time is changed. By default, for BDF, the first step is less than 0.1% of the end time but also fulfills $DT \cdot yp_{\text{norm}} <= 1/2$, where DT is the initial time step and yp_{norm} is the weighted norm of the time derivative vector. Thus, also for this method the end time can affect your solution so that you do not get the same time-step history up to a certain earlier time.This should, however, not change the result appreciably if you use tight enough tolerances for that the automatic time step control. Also, the results of the consistent initialization can be strongly dependent on the initial time step taken, if the initial conditions and the boundary conditions do not match, for example. If needed, you can change the values for the **Initial step** or the **Fraction of initial step for Backward Euler** (see below).
- **Maximum step constraint**. By default, the solver chooses a maximum time step automatically. Select **Constant** as the maximum step constraint for manual specification of a fixed maximum time step. A constant maximum step constraint is a positive scalar value, which can be an expression that evaluates to a numerical value before entering the solver. The expression can include global parameters. Select **Expression** as the maximum step constraint for more general expressions of the allowed maximum time step. These expressions are evaluated while solving and can, for instance, depend on the time parameter itself.

The solver uses the absolute value of the expression for the maximum step constraint.

Additionally, if **BDF** is selected as the time stepping **Method**:

- **Maximum BDF order** (available if **Free**, **Intermediate**, or **Strict** is selected for the **Steps taken by solver**). This setting controls the maximum allowed degree of the interpolating polynomial of the BDF method.
- **Minimum BDF order** (available if **Free**, **Intermediate**, or **Strict** is selected for the **Steps taken by solver**). This setting can be used to prevent the solver from decreasing the order of the BDF method below 2.
- **BDF order** (available if **Manual** is selected for the **Steps taken by solver**). The order of the BDF can be 1–5 (default order: 2).
- **Initial step fraction** (available if **Manual** is selected for the **Steps taken by solver**). During the startup of the BDF method, a shorter time step will be used to compensate for the lower order that is used for the first handful of steps. The initial step is a fraction of the first step, and the solver then exponentially increases the step length until the requested step length is reached. This settings and the initial step growth rate below control that startup phase. The default values depend on the selected BDF order.

- **Initial step growth rate** (available if **Manual** is selected for the **Steps taken by solver**).
- **Time step** (available if **Manual** is selected for the **Steps taken by solver**). Enter a manual time step specification as a scalar, a vector of times, or an expression containing global variables or parameters in the **Time step** field using the base unit for time. The relative and absolute tolerances are still used to terminate the algebraic equations at each time step. Also, the requested time step will be reduced if the algebraic solver does not converge.
- **Event tolerance**. This setting can be used to set the event tolerance (default value: 0.01), which is used for root finding of event conditions when using implicit events; see Explicit Event.

This does not apply to the startup phase of the simulation.

- **Nonlinear controller**. Select this checkbox to use a nonlinear controller for more efficient time-step control in the BDF method, especially for highly nonlinear problems such as multiphase flow and turbulence in fluid dynamics. When nonlinear failures occur, the nonlinear controller becomes active and uses a more careful time step control. The nonlinear controller acknowledges that the step size for Newton stability might be smaller than the step size for BDF accuracy.

If **Generalized alpha** is selected as the time stepping **Method**:

- **Time step increase delay** (available if **Free**, **Intermediate**, or **Strict** is selected for the **Steps taken by solver**). Select this checkbox and enter a positive integer in the field to make the solver more restrictive when increasing the time step. This integer is the number of time steps taken by the solver before the increase of the time step is actually performed, from the first step where the error estimator signals that the current step is too small. This setting is useful when there is a natural variation in the solution, like periodicity or quasi-periodicity, which make the time steps vary up and down in size. The generalized-α method does not work well when the time step changes often, so in those situations it is better to damp the changes by a more conservative strategy using this setting. Entering 0 results in the same behavior as clearing the checkbox.
- **Time step** (available if **Manual** is selected for the **Steps taken by solver**). Enter a manual time step specification as a scalar, a vector of times, or an expression containing global variables or parameters in the **Time step** field.
- **Amplification for high frequency**. Enter a number between 0 and 1 to control how much damping of high frequencies the solver provides. A value close to 0 results in efficient damping, while a number close to 1 results in little damping.
- **Predictor**. Select **Linear** to use linear extrapolation of the present solution to construct the initial guess for the nonlinear system of equations to be solved at the next time step. Select **Constant** to use the current solution as initial guess.

Also, the following settings are available for the BDF and generalized-α methods:

Algebraic Variable Settings

Use the **Singular mass matrix** list to control whether the solver automatically determines if a system includes a differential-algebraic equation or not. Select:

- **Maybe** to make the solver look for zero-filled rows or columns in the mass matrix as a means of detecting a differential-algebraic equation.
- **Yes**, if the model includes a differential-algebraic equation where the mass matrix has no zero-filled rows or columns.

Use the **Consistent initialization** list to control how the solver performs consistent initialization of differential-algebraic systems. The consistent initialization procedure tries to reconcile inconsistent initial values. In doing that, it takes a small time step (by default, 0.1% of the initial step size). If, for example, you have boundary

conditions and initial conditions that do not match, the results of the consistent initialization is strongly dependent on the initial time step taken. Select:

- **Backward Euler** (the default) to perform consistent initialization using a small artificial step with the backward Euler method. When this is selected, enter a value in the **Fraction of initial step for Backward Euler** field. This value is a dimensionless quantity that determines the size of the time step for the backward Euler method (in terms of the initial step). Adjusting this value can improve the accuracy of the initialization step but can also affect the startup of some models. The default value is 0.001 (that is, the small backward Euler step size is 0.1% of the initial step size). Also, the **Safety factor for Backward Euler** is used in the algebraic equation termination during consistent initialization using the **Backward Euler** method. A larger value gives a stricter condition. The default value of 20 corresponds to the normal behavior for any new time step.
- **Off** to indicate that the initial values already are consistent, which means that the solver does not modify them.
- **On** to use a consistent initialization routine that is preferable to **Backward Euler** for index-1 differential-algebraic equations. This method detect the algebraic and differential variables from the sparsity structure of the damping and mass matrices D and E (see Ref. 6).

Use the **Error estimation** list to control how to treat algebraic degrees of freedom of a differential-algebraic system when estimating the time discretization error. Select:

- **Include algebraic** (the default) to include the algebraic degrees of freedom in the error norm.
- **Exclude algebraic** to exclude the algebraic degrees of freedom from the error norm.

  Excluding algebraic degrees of freedom (which stem from stationary equations in the model) means that the algebraic variables are not included in the error test for the time step. The algebraic variables are still solved for as part of the general system of equations. Excluding the algebraic variables from the error test might have the effect that the constraints (including hidden constraints, which are implicitly part of the equations) are not accurately fulfilled. In general, excluding algebraic degrees of freedom is not recommended when solving DAE systems of index 1, whereas it can be generally encouraged for DAE systems of index 2 (see Ref. 7).

If **Backward Euler** is selected from the **Consistent initialization** list, select the **Rescale after initialization** checkbox if you want to perform a rescaling of the variables. In fluid flow simulations, for example, the scaling for velocity can be problematic because the velocity is often zero at the start but then changes dramatically after a consistent initialization. Rescaling of the velocity and pressure can provide a smoother start and avoid using very small time steps.

TIME STEPPING (RUNGE–KUTTA METHODS)

The following settings are available when **Runge-Kutta** is selected as the time-stepping method:

Steps Taken by Solver

To modify how the Runge–Kutta time-stepping methods select the time steps, choose an option from the **Steps taken by solver** list. Select:

- **Free** to let the time-stepping method choose time steps freely. The times specified in the **Times** field in the **General** section are not considered when a time step is chosen.
- **Intermediate** to force the time-stepping method to take at least one step in each subinterval of the times specified in the **Times** field in the **General** section.
- **Strict** to force the time-stepping method to take steps that end at the times specified in the **Times** field in the **General** section. The solver takes additional steps in between these times if necessary.
- **Manual** to override the automatic choice of time step with a manual choice.

For all settings for **Steps taken by solver** except **Strict**, the **Interpolate solution at end time** checkbox is selected by default. The solver can then step past the last time in the **Output times** list, leading to the end time being

interpolated. If you clear this checkbox, the solver will not step past the last time in the **Output times** list, so that the time stepping includes the last time and takes no steps past that time.

Further options that apply to one or several combinations (as indicated at each bullet) of selections made in the **Runge–Kutta method** and **Steps taken by solver** lists are:

If **Free**, **Intermediate**, or **Strict** is selected for the **Steps taken by solver**:

- **Initial step**. By default the solver chooses an initial step automatically. Select the **Initial step** checkbox for manual specification of an initial step in the associated text field. This settings is not available for the Cash–Karp 5 method; instead you specify a value of the time step in the **Time step** field.

  The following settings for **Free**, **Intermediate**, and **Strict** are only available for the Dormand–Prince 5 time-stepping method:

- **PI step controller**. This setting affects the behavior of the PI (proportional-integral) controller that adds damping on step size changes to avoid choosing too large steps, which would then be rejected. The default value is **Quick**, which corresponds to a PI controller that responds quickly to changes. The **Smooth** option sets the controller to react more slowly, giving smoother choices of time steps. You can also turn off the PI controller by selecting **Disabled**. This setting affects the parameters α and β in the relation $h_{n+1} = Sh_n(\mathrm{err}_n)^{-\alpha}(\mathrm{err}_{n-1})^{\beta}$. Here S is the safety factor described above, and err_i is the estimated error in step i.
- **Maximum step constraint**. By default, the solver chooses a maximum time step automatically. Select **Constant** as the maximum step constraint for manual specification of a fixed maximum time step. A constant maximum step constraint is a positive scalar value, which can be an expression that evaluates to a numerical value before entering the solver. The expression can include global parameters. Select **Expression** as the maximum step constraint for more general expressions of the allowed maximum time step. These expressions are evaluated while solving and can, for instance, depend on the time parameter itself.
- **Minimum step size growth ratio** and **Maximum step size growth ratio**. These growth ratio limits restrict how fast the step size may change, enforcing that the values of the ratio $h_{\mathrm{new}}/h_{\mathrm{old}}$ is within the minimum step size growth ratio (default: 0.2) and the maximum step size growth ratio (default: 10).
- **Step size safety factor**. The solver multiplies this factor (default: 0.9) to the estimated largest allowed step size to avoid taking too large step sizes when the estimate overshoots.

If **Manual** is selected for the **Steps taken by solver**:

- **Time step**. Enter a manual time step specification as a scalar, a vector of times, or an expression containing global variables or parameters in the **Time step** field.

For all options in the **Steps taken by solver** list, you can also activate or turn off detection of numerical stiffness using the **Stiffness detection** checkbox (selected by default). If active, the stiffness detection uses a mechanism to detect if the problem that you solve becomes numerically stiff (which means that an explicit time stepping is required to take very small time steps). If the problem is considered to be stiff, an error appears and the solver stops. You can then switch to another solver that is better suited for stiff problems, such as an implicit BDF method.

TIME STEPPING (CLASSICAL RUNGE–KUTTA)

For classical Runge–Kutta, select the order of the time-stepping scheme from the **Order** list (1–4; default 4).

TIME STEPPING (ADAMS–BASHFORTH 3)

This option is intended for the Wave Form PDE interface. See About the Wave Form PDE Interface.

From the **Time steps taken by solver** list, choose **Manual** and then enter a time step in the **Time step** field, or choose time stepping **From expressions**, where the latter is useful for the Wave Form PDE. When you use **From expression**, a list of **Cell time scale expressions** appear, where you can add such expressions to define the time stepping. For explicit methods, the largest stable time step can automatically be computed from an expression. Some physics interfaces (Wave Form PDE, for example) define such an expression in terms of an estimated maximum wave speed (defined by the interface) and the element size (`wahw.wtc`). Here the element order is also taken into account. The expression should in general represent a local cell time scale. For wave problems, the expression should be proportional to the time it takes for the fastest wave to pass one mesh element. Each expression given is evaluated on all mesh elements. The smallest value (time scale), over all elements and all expressions, dictates the time step used. If you select **User defined** from the **Defined by study step** list, you can use the **Add** button (+) and the **Delete** button ( ) to add or delete rows in the list.

TIME STEPPING (ADAMS–BASHFORTH 3, LOCAL)

For the **Adams-Bashforth 3 (local)** method, select **Off** in the **Update time levels** list to use the initial local time levels for the complete simulation. Select **Manual** and then enter a positive number for the **Number of time steps between updates** at which new local time levels will be computed according to the time-stepping expressions in the **From expressions** list above. Select **Factor** and give a positive value for **Relative time step change** in order to recompute the time levels when the relative time-step change for any time level has changed more than the given value.

RESULTS WHILE SOLVING

This section mirrors what is defined for the Time Dependent node's **Results While Solving** section. That is, changes made to the **Time Dependent** node are reflected here.

OUTPUT

Use the **Times to store** list to control at what times the solver stores a solution. Select:

- **Specified values** to store solutions at the values entered in the **Times** field in the **General** section.
- **Steps taken by solver** to store solutions at the time steps taken by the solver.

The selection made in the list **Steps taken by solver** in the **Time Stepping** section influences the output in this situation.

- Select the **Store reaction forces** checkbox to compute and store reaction forces in the output. This option is not supported when using any of the Runge–Kutta time-stepping methods.
- The computation of boundary flux variables involves solving a system of equations to obtain a continuous field from nodal flux values. If the **Use lumping when computing fluxes** checkbox is selected, this system of equations is lumped. The benefits of using this option is that it can avoid certain spurious oscillations in the computed flux field and it is also slightly faster. Lumping is not suitable in 3D for shape functions of order higher than 1. Lumping is not supported when using any of the Runge–Kutta time-stepping methods.

- Select the **Store time derivatives** checkbox to store time derivatives of the variables solved for in the output. Storing the time derivatives gives more accurate results when evaluating quantities that involve these time derivatives.
- Select the **Store solution before and after events** checkbox to store two additional solutions every time an implicit or explicit event is triggered. See The Events Interface. This stores the solutions before and after the reinitialization.

ADVANCED

Select the **Allow complex numbers** checkbox to be able to solve problems that are not automatically determined to be complex-valued in a correct way.

Select the **Use output solution for the time operators** checkbox to provide access to the output solutions stored at the time of access through the `at`, `timeint`, and similar operators. This access has some limitations. It can, for example, not access times after the last saved solution but still before the current solution time. The `at` operator. r does not give an error when used before the start time. The `timeint` operator and other integration operators with start and stop arguments give undefined values when evaluated outside their range during postprocessing. Used while solving, these operators will give errors when used out of range. Used while solving, there are often ways to avoid this error, by either saving the solution more often or by restricting the time steps taken by the solver. However, to use a moving average, for example,

$$Q_I = \int_{t-T}^{t} Q(s)\,ds$$

while solving (Q depends on the variables solved for), it is not possible to use the `timeint` operator. The reason is that the upper limit of this integral will always be evaluated for the current time t, and it will always be out of bounds for the output solution object (since it cannot be stored until it has been solved for). You can make it possible to use a time operator for this problem by introducing a new equation

$$d(Q_I)/dt = Q(t) - Q(t-T)$$

which can be implemented by using the `at` operator for the second term on the right side. See Built-In Operators for more information about the `at`, `timeint`, and other operators.

To allow variables not solved for to be reused in a periodic manner, select the **Periodic values of variables not solved for** checkbox. The specify the periodicity using the **Start time** and **Interval length** fields (default unit: s). Together, they define the interval for which the input solution is periodic. When reusing variables for time instants that fall outside the specified time window, a periodic map is applied, allowing these variables to be used for times longer than one period.

LEAST-SQUARES DATA

The section only appears if you are solving a time-dependent least-squares optimization problem.

Least-squares times are read from least-squares objectives (either a file or a table), and the solver sequence is set up accordingly. If there is a least-squares objective with a time column, the time values are displayed under **Times from least-squares objectives**. If **Use times from least-squares objectives** is on (which is the default), the least-squares times are read and merged with the user-defined time list at runtime. The merged data governs the setup of the time-dependent solver.

General parameter values list here refers to the list of times in the **General** section above. If **Exclude times outside General parameter value lists** is on (which is the default), start and end simulation times that you have provided are respected, when merging with time values from least-squares objectives. Time values from objectives outside the user-defined time range are ignored. Otherwise (that is, **Exclude times outside General parameter value lists** is off), all time values from least-squares objectives are used and merged with the user-defined time list.

If **Use times from least-squares objectives** is off, no time values from least-squares objectives are used.

You can change the default values of **Use times from least-squares objectives** and **Exclude times outside General parameter value lists** only if **Defined by study step** is set to **User defined**.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

This section, which is initially empty, contains a log from the time stepping. This log is stored in the MPH-file. Select the **Keep warnings in stored log** to keep warning messages in this log so that the information in those warnings is available also when reopening the model.

	The Log Window (The Time-Dependent Solver Log)

	The Black–Scholes Equation: Application Library path **COMSOL_Multiphysics/Equation_Based/black_scholes_put**

Time Discrete Solver

Use the **Time Discrete Solver** ( ) to find the solution to time-dependent problems (dynamic or unsteady problems) that have already been discretized in time using, for example, the `prev` operator or the `bdf` operator. This solver is automatically used when a Time Discrete study is added to the model.

See About the Time Discrete Solver for background information.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step. If you select **User defined** (to override the settings defined in the corresponding study node), you can specify the **Time unit**, **Output times**, and **Relative tolerance** settings.

Use the **Time unit** list to choose a time unit that is suitable for the time span of the simulation. The default time unit is inherited from the corresponding setting in the study step.

Use the **Output times** field to enter a vector of times that define the simulation's time span.

The time step is specified in the **Time step** field. Valid entries are a scalar, a vector of times, or an expression containing global expression variables.

Discretizing time derivatives using the `prev` operator or the `bdf` operator requires the solution at previous discrete times. How many previous time steps should be stored is specified in the **Number of time discrete levels** field. If you, for example, use the first-order `bdf` operator (`bdf(u,1)`), the solution at one previous time step is required. Using the second-order `bdf` operator (`bdf(u,2)`) requires the solution at two previous time steps. The default value is 2.

From the **Times to store** list, choose one of the following options:

- Choose **Output times by interpolation** (the default) to store the output times using interpolation from the solver's time steps.
- Choose **Steps taken by solver closest to output times** to use the time steps from the solver that are closest to a given output time among all the steps that have passed this output time.
- Choose **Steps taken by solver** to store the actual time steps from the solver. Specify to store every *N*th step in the **Store every Nth step** field (default value: 1; that is, all time steps are stored).

Use the **Relative tolerance** field to enter a positive number. This number controls how accurately the nonlinear system of equations is solved in each time step. In general, the desired relative error in the solution should be entered here.

ABSOLUTE TOLERANCE

Here you can specify an absolute tolerance that the nonlinear solver uses to control the absolute error. The tolerance specified here is applied to all variables unless modified per variable by selecting a method other than the global method for a variable.

Use the **Global method** list to select how the specified absolute tolerance is to be interpreted for the variables that use the global method (by default, all variables use the global method). Select:

- **Scaled** to let the absolute tolerance be applied to scaled variables.
- **Unscaled** to let the absolute tolerance be applied to unscaled variables.

Select a **Tolerance method** to specify how to enter and compute the absolute tolerance. Select:

- **Factor** to specify a factor (default: 0.1) in the **Tolerance factor** field that makes the absolute tolerance proportional to the relative tolerance. With this method, the absolute error does not become dominating when you reduce the relative tolerance so that it is much smaller than the absolute tolerance.
- **Manual** to specify a value for the absolute tolerance. In the **Absolute tolerance** field, enter a positive number that is applied to either scaled or unscaled variables.

To specify the absolute tolerance individually for a variable, select the variable from the **Variables** list and modify the corresponding tolerance with the **Method** list. Select:

- **Scaled** to apply the specified tolerance to scaled variables.
- **Unscaled** to apply the specified tolerance to unscaled variables.
- **Use global** (the default) to apply the tolerance specified for the global tolerance.

If you select **Scaled** or **Unscaled**, additional fields appear. Use the **Tolerance** field to modify the absolute tolerance for the selected variable.

RESULTS WHILE SOLVING

See Results While Solving in Common Study Step Settings for these settings.

OUTPUT

Use the **Times to store** list to control at what times the solver stores a solution. Select:

- **Specified times** to store solutions at the times entered in the **Times** field in the **General** section.
- **Steps taken by solver** to store solutions at the time steps taken by the solver.

When **Specified times** is selected, the solution to output is computed through interpolation. Therefore, the solution at previous time steps is not computed, which means that expressions with the `prev` and `bdf` operators cannot be used in analysis. Such expressions can only be used in analysis when you have selected **Steps taken by solver**.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes

- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

This section, which is initially empty, contains a log from the time stepping. Select the **Keep warnings in stored log** checkbox as needed.

Solution Attribute Nodes

The first few sections provide some background information about the linear system solvers and preconditioners and the algorithms used:

- About the Advanced Attribute Settings
- Choosing the Right Linear System Solver
- About Incomplete LU
- The Adaptive Solver Algorithms and Error Estimation
- The Domain Decomposition Solvers
- The Fully Coupled Attribute and the Double Dogleg Method
- The Iterative Solvers
- The Multigrid Solvers
- The Parametric Solver Algorithm
- The SCGS Solver
- The Segregated Solver
- The Sensitivity Analysis Algorithm
- About the SOR, SOR Gauge, SOR Line, and SOR Vector Iterative Solver Algorithms
- The Vanka Algorithm

About Solver Commands in the *COMSOL Multiphysics Programming Reference Manual.*

Then the settings for the solver attribute nodes — such as preconditioners, adaptive mesh refinement, and sensitivity analysis listed in Table 20-8 — are detailed. There is also a list of the References for the Linear System Solvers and the Preconditioners.

TABLE 20-8: SOLUTION ATTRIBUTE NODES.

ICON	NAME	DESCRIPTION
	Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation)	Handles adaptive mesh refinement together with a Stationary or Eigenvalue solver. Also see The Adaptive Solver Algorithms and Error Estimation.
	Adaptive Mesh Refinement (Time-Dependent Adaptation)	Handles adaptive mesh refinement together with a Stationary, Eigenvalue, or Time-Dependent solver. The adaptive mesh refinement creates multiple meshes for segments of a time-dependent simulation. Also see The Adaptive Solver Algorithms and Error Estimation.
	Advanced	Advanced general solver parameters.
	AMG Coarse Solver	Administrate coarse grid solvers when using an Auxiliary-Space AMG solver.
	AMG Postsmoother	Handles settings for the AMG postsmoother (when using Auxiliary-Space AMG).
	AMG Presmoother	Handles settings for the AMG presmoother (when using Auxiliary-Space AMG).

TABLE 20-8: SOLUTION ATTRIBUTE NODES.

ICON	NAME	DESCRIPTION
	Automatic Remeshing	Adds automatic remeshing parameters. The remeshing occurs when the mesh quality falls below a specified value. Add it to a Time-Dependent solver.
	Auxiliary-Space AMG	Handles parameters for linear system solvers/preconditioners that use the auxiliary-space AMG solver. Add it to Iterative, Krylov Preconditioner, or Coarse Solver attributes.
	Auxiliary-Space Maxwell (AMS)	Handles parameters for linear system solvers/preconditioners that use the auxiliary-space Maxwell solver (AMS). Add it to Iterative, Krylov Preconditioner, or Coarse Solver attributes.
	Block Navier–Stokes	Adds an efficient preconditioner for the incompressible Navier–Stokes equations in the transient regime.
	Coarse Solver	Administrate coarse grid solvers when using a Multigrid or Domain Decomposition (Schwarz) solver.
p(x)	Control Field	Handles settings for field variables that are acting as control variables. Control variables have a special status when using the Sensitivity or Optimization solver. Used together with the Dependent Variables operation node.
p	Control State	Handles settings for state variables that are acting as control variables. Control (state) variables have a special status when using the Sensitivity or the Optimization solver. Used together with the Dependent Variables operation node.
	Direct	Handles settings for a direct linear solver.
D	Direct Preconditioner	Handles settings for a direct linear solver used as a preconditioner.
	Domain Decomposition (Schur)	Used to set up an additive or multiplicative Schur domain decomposition solver. Add it to an Iterative solver or a Coarse Solver attribute. Also see The Domain Decomposition Solvers.
	Domain Decomposition (Schwarz)	Used to set up an additive, multiplicative, hybrid, or symmetric Schwarz overlapping domain decomposition solver. Add it to an Iterative solver or a Coarse Solver attribute. Also see The Domain Decomposition Solvers.
	Domain Solver	Administrate domain solvers when using a Domain Decomposition (Schwarz) or Domain Decomposition (Schur) solver.
$P_1=$ $2\,1_3$	Eigenvalue Parametric	Used for an eigenvalue parametric study. This attribute can be used together with the Eigenvalue Solver.
E≈	Error Estimation	Display information about the functional for goal-oriented error estimation.
	Domain Solver	Handles settings for the domain solver (when using Domain Decomposition).
U,T,p	Field	Handles settings for field variables, including settings for storing the field in the output or not. Each field variable needs a separate Field node. This attribute is used with the Dependent Variables operation node.
	Fully Coupled	Uses a damped version of Newton's method or a double dogleg method that handles parameters for a fully coupled solution approach. It can be used with the Stationary or Time-Dependent solvers. Also see The Fully Coupled Attribute and the Double Dogleg Method.
	Hardware Acceleration	Use hardware acceleration using a supported GPU for time-dependent simulations using the discontinuous Galerkin (dG) method.
	Hierarchical LU	Handles hierarchical LU factorization for the BEM solver.
LU	Incomplete LU	Handles parameters for linear system solvers/preconditioners that use incomplete LU factorization. Add it to Iterative, Krylov Preconditioner, or Coarse Solver attributes.

TABLE 20-8: SOLUTION ATTRIBUTE NODES.

ICON	NAME	DESCRIPTION
	Iterative	Handles settings for an iterative linear solver or preconditioner. Also see The Iterative Solvers.
	Jacobi	Handles settings for the Jacobi (or diagonal scaling) method. Add it to Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attributes.
	Krylov Preconditioner	Handles settings for the Krylov-type linear solver or preconditioner. Add it to Iterative, Presmoother, Postsmoother, Coarse Solver, Schur Solver, or Schur Source Solver attributes.
	Localized Schur	Handles settings for the localized Schur solver. Add it to Domain Decomposition > Schur Solver nodes and to their Krylov Preconditioner subnodes.
	Lower Limit	Parameters for imposing restrictions on degrees of freedom. Add it to a Segregated attribute.
	Lumped Step	Available with a Segregated attribute node. This step is intended for speeding up the computation of any L_2-projections, stemming from the identity operator, appearing as a single-physics interface within a multiphysics problem.
	Multigrid	Handles settings for a multigrid linear solver or preconditioner. Add it to Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attributes. Also see The Multigrid Solvers.
	Parametric	Handles settings for parameter stepping. This attribute can be used together with the Stationary Solver. Also see The Parametric Solver Algorithm.
	Postsmoother	Handles settings for the postsmoother (when using Multigrid).
	Presmoother	Handles settings for the presmoother (when using Multigrid).
	Pressure Solver	Administrate solvers for the pressure when using Block Navier–Stokes.
	Previous Solution	An optional attribute node of the Parametric attribute node. It handles field variables that have to be accessed at a previous parameter value or time.
	SCGS	Handles the SCGS (symmetrically coupled Gauss-Seidel) solver, which is useful as a preconditioner for solving the Navier–Stokes equations and similar fluid flow problems. Also see The SCGS Solver.
	Schur Solver	Handles settings for the Schur solver when using Domain Decomposition (Schur).
	Schur Source Solver	Handles settings for the Schur solver when using Domain Decomposition (Schur), when an absorbing boundary condition is used.
	Segregated	Handles parameters for a segregated solution approach. This attribute makes it possible to split the solution process into substeps. Each substep uses a damped version of Newton's method. Add it to Stationary and Time Dependent solvers. Also see The Segregated Solver.
	Segregated Step	Handles settings for one substep of a segregated iteration. This attribute uses a damped version of Newton's method and can be used together with a Segregated attribute node.
	Sensitivity	Sensitivity parameters. Also see The Sensitivity Analysis Algorithm.
	SOR	Handles settings for the SOR (successive over-relaxation) iterative method. Add it to Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attributes. Also see The SOR Method.
	SOR Gauge	Handles settings for an SOR Gauge-type linear solver or preconditioner. Also see The SSOR Gauge, SOR Gauge, and SORU Gauge Algorithms.
	SOR Line	Handles settings for an SOR Line linear solver or preconditioner. Also see The SOR Line Algorithm.

TABLE 20-8: SOLUTION ATTRIBUTE NODES.

ICON	NAME	DESCRIPTION
	SOR Vector	Handles settings for an SOR Vector-type linear solver or preconditioner. Also see The SOR Vector Algorithm.
	SCGS	Handles settings for the SAI (sparse approximate inverse) preconditioner, pre- and postsmoother, or coarse solver. Add it to Iterative, Iterative > Krylov Preconditioner, Multigrid > Presmoother and Postsmoother, and Domain Decomposition > Coarse Solver and Domain Solver nodes.
	Sparse Localized Schur	Handles settings for the sparse localized Schur solver. Add it to Domain Decomposition > Schur Solver nodes (it is the default Schur solver).
	State	Handles settings for state variables. A state is composed of a set of ODE variables. Used together with the Dependent Variables operation node.
	Stationary Acceleration	Accelerates the solution process for nonlinear problems with a time-periodic stationary solution.
	Stop Condition	An attribute that stops parameter stepping or time stepping when a specified condition is fulfilled.
	Time Parametric	Handles settings for parameter stepping. This attribute can be used together with the Time-Dependent Solver.
	Vanka	Handles settings for a Vanka linear solver or preconditioner. Also see The Vanka Algorithm.
	Velocity Solver	Administrate solvers for the velocity when using Block Navier–Stokes.

About the Advanced Attribute Settings

	Advanced in the *COMSOL Multiphysics Programming Reference Manual*

WHICH PROBLEMS ARE SYMMETRIC?

When using an Advanced attribute node, you have an option to choose the matrix symmetry. But how do you know which problems are symmetric? When the discretization of a PDE problem results in a symmetric Jacobian (stiffness) matrix (and a symmetric mass matrix for time-dependent or eigenvalue problems), you can often apply faster and less memory-consuming algorithms to solve the resulting linear systems. PDEs with symmetric discretization typically occur in models involving acoustics, diffusion, electromagnetics, heat transfer by conduction, and structural mechanics. In contrast, problems in fluid mechanics, convection-diffusion, and convection-conduction typically involve nonsymmetric Jacobian matrices.

If the model involves complex numbers, you can distinguish between *symmetric* and Hermitian matrices. A *Hermitian matrix* A satisfies

$$\bar{A}^T = A$$

where T denotes the transpose and the bar denotes the complex conjugate.

COMSOL Multiphysics detects symmetry for symmetric and Hermitian matrices. To take advantage of the computational savings for models with symmetric matrices is to use a solver that utilizes the symmetry. The following linear system solvers and preconditioners do not take advantage of symmetric matrices:

- The Vanka preconditioner

- The incomplete LU preconditioner
- The algebraic multigrid solver/preconditioner

Selecting **Symmetric** for a problem that does not result in symmetric matrices leads to an incorrect solution.

ELIMINATION CONSTRAINT HANDLING

The constraint handling is, for simplicity, demonstrated for a stationary problem. The handling is similar for parametric, eigenvalue, and time-dependent problems. Consider the linear (scaled) algebraic system

$$\begin{bmatrix} K & N_F \\ N & 0 \end{bmatrix} \begin{bmatrix} U \\ \Lambda \end{bmatrix} = \begin{bmatrix} L \\ M \end{bmatrix}$$

The Lagrange multiplier vector Λ is typically undetermined, and COMSOL Multiphysics does not solve for it. Similarly, the constraint $NU = M$ often contains the same equation several times. To handle this problem, the COMSOL software turns to a constraint-handling method that uses elimination. The solver computes a solution U_d to the constraint $NU = M$ as well as a matrix Null, whose columns form a basis for the null space of N. For unidirectional constraints ($N_F \neq N^T$) a matrix Nullf is also computed, whose columns form a basis for the null space of $N_F{}^T$. Then it obtains the solution as $U = \mathrm{Null}\, U_n + U_d$. Here U_n is the solution of $K_c\, U_n = L_c$, where

$$\begin{cases} K_c = \mathrm{Nullf}^T K\, \mathrm{Null} \\ L_c = \mathrm{Nullf}^T (L - KU_d) \end{cases}$$

Here K_c is the eliminated stiffness matrix.

For eigenvalue and time-dependent problems, the corresponding eliminated D and E matrices are

$$D_c = \mathrm{Nullf}^T D\, \mathrm{Null}, \qquad E_c = \mathrm{Nullf}^T E\, \mathrm{Null}$$

Choosing the Right Linear System Solver

The following pertains to the Direct attribute node. All linear system solvers above work on general sparse linear systems of the form $Ax = b$ and use LU factorization on the matrix A to compute the solution x. In doing so, they use a preordering algorithm that permutes the columns of A to minimize the number of nonzeros in the L and U factors. Popular preordering algorithms include Minimum degree, Nested dissection, and Multisection. All solvers run distributed when running COMSOL Multiphysics in distributed mode (on clusters, for example). All linear system solvers benefit from shared memory parallelism (multicore processors, for example). MUMPS and PARDISO have an option for reusing the preordering, which speeds up the computation but leads to a higher memory peak.

This section reviews Linear System Solver Selection Guidelines, Which Models Are Positive Definite?, and Elliptic and Parabolic Models.

Linear in the *COMSOL Multiphysics Programming Reference Manual*.

The MUMPS Solver

The MUMPS solver works on general systems of the form $Ax = b$ and uses several preordering algorithms to permute the columns and thereby minimize the fill-in. MUMPS is multithreaded on platforms that support multithreading and also supports solving on distributed memory architectures through the use of MPI. The code is written in Fortran 90. For further details about MUMPS, see Ref. 1.

The PARDISO Solver

The PARDISO solver works on general systems of the form $Ax = b$. In order to improve sequential and parallel sparse numerical factorization performance, the solver algorithms are based on a Level-3 BLAS update, and they exploit pipelining parallelism with a combination of left-looking and right-looking supernode techniques. PARDISO is multithreaded on platforms that support multithreading. On distributed memory architectures, if you clear the **Parallel Direct Sparse Solver for Clusters** checkbox or if you run PARDISO in the out-of-core mode, the solver settings are changed to corresponding MUMPS settings. The code is written in C and Fortran. COMSOL Multiphysics uses the PARDISO version developed by Olaf Schenk and collaborators (Ref. 2), which is included with Intel® MKL (Intel Math Kernel Libraries).

The SPOOLES Solver

The SPOOLES solver works on general systems of the form $Ax = b$ using the multifrontal method and direct LU factorization of the sparse matrix A. When the matrix A is symmetric or Hermitian, the solver uses an LDLT version of the algorithm, which saves half the memory. SPOOLES uses several preordering algorithms to permute the columns and thereby minimize fill-in. SPOOLES is multithreaded on platforms that support multithreading and also supports solving on distributed memory architectures through the use of MPI. The code is written in C. COMSOL uses SPOOLES version 2.2 developed by Cleve Ashcraft and collaborators (Ref. 3).

The Dense Matrix Solver

The dense matrix solver works on general systems of the form $Ax = b$. The dense matrix solver uses LAPACK (Ref. 4) for multithreaded solves and ScaLAPACK (Ref. 5) for distributed memory architectures. This solver is mainly useful for cases where the system matrices are densely populated, such as boundary element (BEM) models.

LINEAR SYSTEM SOLVER SELECTION GUIDELINES

The physics interface in the model selects a default linear system solver that usually is appropriate for the problem type, at least for single-physics interface models. If the default solver does not perform well, use the following guidelines to choose a linear system solver.

1. Try the PARDISO direct solver.
2. Try the MUMPS direct solver.
3. If the solver still runs out of memory or is too slow, use one of the iterative solvers GMRES, FGMRES, BiCGStab, or TFQMR. Select a preconditioner according to the guidelines in the section about the iterative solver.
4. If the system is positive definite and real symmetric or Hermitian, try the conjugate gradients iterative solver, which is more memory-efficient and sometimes faster than GMRES, FGMRES, BiCGStab, and TFQMR. Select a symmetric preconditioner. Alternatively, try the SPOOLES direct solver. It often uses less memory but is less numerically stable. SPOOLES is also slower.

WHICH MODELS ARE POSITIVE DEFINITE?

A model with a real symmetric or Hermitian system matrix is often also *positive definite*, which means that a number of efficient linear system solvers are applicable. Further, the simple preconditioners SSOR, SOR, SORU, Jacobi (diagonal scaling), and the multigrid solvers benefit from a positive definite matrix. A real symmetric or Hermitian matrix is positive definite if all its eigenvalues are positive.

For stationary problems, the system matrix is the Jacobian (stiffness) matrix A. This means that stationary models in diffusion, electromagnetics, heat transfer by conduction, and structural mechanics usually have a positive definite system matrix.

For time-dependent problems, the system matrix is of the form $A + \sigma B + \sigma^2 C$, where B is the damping matrix, C is the mass matrix, and $\sigma > 0$ is inversely proportional to the time step (if $C = 0$, then B is often called the mass matrix). Because these matrices are often positive definite, time-dependent models in diffusion, electromagnetics, structural mechanics, and heat transfer by conduction usually have a positive definite system matrix.

For eigenvalue problems, the system matrix is of the form $A - \sigma B + \sigma^2 C$, where σ is the *shift* — that is, the number around which the software searches for eigenvalues (specified in the **Search for eigenvalues around** field; the default is 0). Because A, B, and C are usually positive definite, eigenvalue problems in acoustics, diffusion, electromagnetics, heat transfer by conduction, and structural mechanics usually have a positive definite system matrix if $\sigma \leq 0$.

ELLIPTIC AND PARABOLIC MODELS

The classes of elliptic and parabolic models include the positive definite models. For such models, the efficient multigrid preconditioners often perform well. A simplified definition of these classes reads as follows. A system of stationary or eigenvalue second-order PDEs is *elliptic* if the second-order terms in the PDE give rise to a positive definite Jacobian matrix. A system of time-dependent PDEs has a time derivative term of the form $d_a \dot{u}$, where the mass coefficient d_a is often a positive definite matrix and the e_a coefficient is 0. Such a system is *parabolic* if the second-order terms in the PDE give rise to a positive definite Jacobian matrix.

Stationary or eigenvalue models in acoustics, convection-diffusion, electromagnetics, heat transfer, and structural mechanics are usually elliptic. Likewise, time-dependent models in convection-diffusion, electromagnetics, and heat transfer are often parabolic. The Navier–Stokes equations, wave-type equations, or formulations involving weak constraints are neither elliptic nor parabolic.

About Incomplete LU

The Incomplete LU preconditioner performs an incomplete LU factorization of the system matrix A. That is, it drops small elements during the column-oriented Gaussian elimination (see Ref. 23 and Ref. 24). Thus it saves memory, and the resulting factors L and U are approximate. The resulting preconditioner is an approximation to A. The preconditioner supports threshold drop, fill-ratio drop, and threshold pivoting. It can optionally respect the nonzero pattern in the original matrix. The preconditioner accepts matrices in symmetric and Hermitian format but expands these to full storage before factorization.

SELECTING A DROP RULE

The Incomplete LU preconditioner uses the *threshold drop rule* (the default) or the *fill-ratio drop rule*. The preconditioner drops (neglects) an element during the elimination phase if its absolute value is smaller than the Euclidean norm of the entire column times a *drop tolerance*. In contrast, the fill-ratio drop rule limits the number of nonzeros in the incomplete factors L and U, and it keeps the largest absolute values. The number of values it keeps depends on the number of nonzeros in the corresponding column of the original matrix times a fill-ratio factor. There are two exceptions to these drop rules:

- The preconditioner never drops diagonal elements.
- The preconditioner optionally drops nonzeros in positions where the original matrix is nonzero. To make the preconditioner drop them, clear the **Respect pattern** checkbox in the settings for the Incomplete LU preconditioner.

The primary problem with setting up a preconditioner is the tradeoff between resources (computer time and memory) and the preconditioner's quality. The computational cost of setting up a preconditioner with the

Incomplete LU preconditioner is at least proportional to the number of nonzeros in the produced factors L and U. An advantage of using the fill-ratio drop rule is that you can estimate and limit the cost beforehand; the main disadvantage is that the quality of the preconditioner is typically not as good as using the threshold drop rule with a drop tolerance resulting in the same number of nonzeros. However, with the threshold drop rule there is no good way of estimating resource requirements beforehand. Furthermore, there is no general formula for these drop rules that gives a drop tolerance or fill ratio that guarantees fast convergence for a certain iterative method. Therefore, it is often necessary to rely on experiments and experience for this difficult and, from a performance point of view, important choice.

The Adaptive Solver Algorithms and Error Estimation

The adaptive solver algorithms and The L_2 Norm Error Estimate, The Functional Error Estimate, and Error Indicator for the Time-Dependent Solver are discussed in this section.

Adaption in the *COMSOL Multiphysics Programming Reference Manual.*

THE ADAPTIVE SOLVER ALGORITHM — STATIONARY AND EIGENVALUE ADAPTATION

The adaptive solver performs the following iterative algorithm (Ref. 15):

1. Solve the problem on the existing mesh using the stationary or eigenvalue solver.
2. Evaluate the residual of the PDE on all mesh elements.
3. Estimate the error in the solution on all mesh elements. The computed error estimate is really an *error indicator* because the estimate involves an unknown constant (C below).
4. Terminate execution if it has made the requested number of refinements or if it has exceeded the maximum number of elements.
5. Refine a subset of the elements based on the sizes of the local error indicators and make other mesh changes as needed (see Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation) and especially the **General modification** method).
6. Repeat these steps.

THE ADAPTIVE SOLVER ALGORITHM — TIME-DEPENDENT ADAPTATION

An adapted solution at $t = t_n$ is mapped to the coarse base mesh. A new adapted mesh for the time interval $[t_n, t_{n+1}]$ is constructed by first computing a coarse solution on the base mesh in $[t_n, t_s]$, where t_s is the largest sample time and $t_{n+1} = 2t_n - t_{n-1}$. The error indicator is evaluated using the coarse solution at the given sample points.

In the case of an automatic time interval, a measure of the amount of refinement is computed and compared to a given requested value. If the computed value is too small or too large, the interval length is increased or decreased, respectively, which results in a new t_{n+1}. If the interval length needs to be changed, the error indicator is sampled again using a new coarse solution. The comparison is done only once.

The new adapted mesh is obtained by using the error indicator sampled at given points in $[t_n, t_{n+1}]$, selecting a set of elements based on the element pick function, and then finally refining these elements. The solution at t_n to the PDE problem on the previous adapted mesh for $[t_{n-1}, t_n]$ is then mapped to the new mesh for $[t_n, t_{n+1}]$ and time integration continues until the next mesh adaptation takes place at t_{n+1}.

The simple measure used for determining the amount of refinement is

$$\rho = \frac{1}{2^p N} \sum_{i=1,\,\gamma(i)\neq 0}^{N} 2^{\gamma(i)}$$

Here γ is an N-vector of integers containing the number of times the element at that position should be refined, $p = \max_i \gamma(i)$, and N is the number of elements of the coarse base mesh.

Now, the next interval length is decreased by a given factor if ρ is larger than 120% of the requested reference value. If ρ is smaller than 80% of the reference value it is instead increased. Otherwise, the interval length is kept the same.

ERROR ESTIMATES

The L_2 Norm Error Estimate

The L_2 norm error estimate relies on an assumption of a strong stability estimate for the PDE problem (satisfied, for example, for Poisson's equation over a domain with a smooth boundary). From such an assumption, it is possible to show that there is a constant C, such that the L_2 norm of the error, e_l, in the lth equation satisfies

$$\|e_l\| \leq C \left\| h^{q_l} \rho_l \right\|$$

where ρ_l is the residual in the lth equation and q_l is the stability estimate derivative order. h is the local mesh element size. The adaptive solver algorithm uses the following L_2-norm error indicator:

$$\left(\int_\Omega \sum_l s_l^{-2} h^{2q_l} |\rho_l|^2 dA \right)^{\frac{1}{2}}$$

with the default value $q_l = 2$. This formula also introduces the scaling factors s_l for the residual with the default value $s_l = 1$. The local error indicator for a mesh element is

$$\sum_l s_l^{-2} h^{2q_l} \tau_l{}^2 A$$

where A is the area (volume, length) of the mesh element, and τ_l is the absolute value of the lth equation residual (one number per mesh element).

The Functional Error Estimate

The functional-based estimate relies on adjoint solution error estimation. Instead of approximating the error of the solution, the adaptive solver uses the approximation of the error of a certain error functional (Ref. 16). Under rather general assumptions, it is possible to show that the error e (of a functional) can be estimated as

$$|e| \leq \sum_l \|e_l^*\| \|\rho_l\|$$

where e_l^* and ρ_l are the error in the dual or adjoint solution to, and the residual for, the lth equation, respectively. The adaptive solver algorithm uses the following error indicator for a mesh element:

$$\sum_l w_l \tau_l A$$

where A is the area (volume, length) of the mesh element, and τ_l is the absolute value of the lth equation residual (one number per mesh element). Here w_l is an estimate of the adjoint solution error for the lth equation. This error

is estimated using the following methods. For all three methods, the sensitivity solver is used to find the discrete adjoint solution.

- If a field is represented using Lagrange shape functions and **Adjoint solution error estimate** is **PPR for Lagrange**, then the PPR technique is used to estimate the error in the adjoint solution.
- If a field is not represented using Lagrange shape functions or if **Adjoint solution error estimate** is **Interpolation error**, then an interpolation error estimate is used.
- On geometric entities of dimension lower than the space dimension, a gradient-based error estimate is always used.

For details, see Error Estimation — Theory and Variables.

ERROR INDICATOR FOR THE TIME-DEPENDENT SOLVER

A possible error indicator is the L_2 norm of the gradient of the dependent variables (for example, `sqrt(comp1.Tx^2+comp1.Ty^2)` for the temperature in a 2D heat transfer model). The gradient of the dependent variable is the default value for the error indicator in most physics interfaces.

A solution on the coarse base mesh is computed in the next time interval, and the error indicator is evaluated at the points specified in the **Sample points** field. In this way a new adapted mesh appropriate for the next time interval can be generated. The sample points must be specified as a number between 0 and 1 because they are interpreted as being relative to the time interval under consideration. Entering a scalar value of 0.5 means that the error indicator is evaluated at the midpoint of the interval. The default value is `range(0.0,0.1,1.0)`, which gives 11 sample points from 0 to 1.

The Domain Decomposition Solvers

The Domain Decomposition (Schwarz) and Domain Decomposition (Schur) solvers or preconditioners are memory-efficient iterative algorithms for large problems where other methods are infeasible. The basic idea of an iterative (spatial) domain decomposition is as follows.

Consider an elliptic PDE over a domain D and a partition $\{D_i\}$ such that

$$D = \bigcup_i D_i$$

Instead of solving the PDE on the entire D at once, the algorithm solves a number of subdomain problems for each subdomain D_i. If the subdomain D_i is adjacent to a boundary, its boundary conditions are used. On the interfaces between subdomains, certain natural transmission conditions arise. It is known (Ref. 29) that the solution to the set of subdomain problems is equivalent to the original problem formulated over D. The solution can be found by iteratively solving each subdomain problem with all other domains fixed until the convergence criteria is met. This principle is used in domain decomposition methods.

Three different kinds of boundary conditions are typically applied on the interfaces between subdomains: Dirichlet, zero flux, and absorbing boundary conditions. These correspond to enforcing the solution as follows:

- Dirichlet: the value of the unknown.
- Zero flux: the derivative of the unknown in the direction normal to the boundary.
- Absorbing: a combination of Zero flux, Dirichlet (zero-order term), and the Laplacian of the unknown (second-order term).

For wave problems, absorbing boundary conditions on subdomains interfaces usually result in the best convergence of the Domain Decomposition algorithm.

THE OVERLAPPING SCHWARZ METHOD

One class of methods is the *overlapping Schwarz method*, where the partition $\{D_i\}$ grows such that each subdomain overlaps its neighboring domains. The size of the overlap is an important parameter that partly determines the convergence rate of the method. An optional coarse grid problem can also be solved that improves the convergence rate of the method. The coarse grid problem, which is solved on the entire D, gives an estimate of the solution on the fine grid on D. The convergence rate of the method depends on the ratio between the size of the coarse grid mesh elements and the physical size of the overlap on the fine grid.

Two practical properties of this method are:

- Control of maximum memory consumption independent of problem formulation: Only a small part of the problem needs to be discretized and solved for at once.
- Coarse-grained concurrency: Disjoint problems can be solved concurrently on different cluster nodes.

The domain decomposition method can be used to control the memory consumption. This is achieved in two ways. The total amount of data needed to solve the subdomain problems is usually less than the data needed to solve the entire problem on the domain D. It is also possible to run the domain decomposition solver in a mode where the data used by each subdomain problem is computed on the fly. This results in a significant memory reduction and allows the solution of larger problems without the need to store the data in virtual memory at the price of reduced performance compared to keeping all data in physical memory. This method is useful when the problem would use virtual memory otherwise.

There is a choice between four overlapping Schwarz methods: the additive, multiplicative, hybrid, and symmetric Schwarz methods. The *additive method* solves all subdomain problems and the coarse grid problem at once before updating the solutions. The *hybrid method* updates the solution when the coarse grid problem is solved and then solves the remaining problems, updates the solution, and solves the coarse grid problem a second time. These methods can solve all the subdomain problems in parallel when running in distributed mode. The *multiplicative method* solves each subdomain problem in sequence. The *symmetric method* also solves the subdomain problems in sequence but in a symmetric way. In these cases, not all problems can be solved in parallel when running in distributed mode, but using coloring techniques it is still possible to achieve parallel speedup. In general, the multiplicative and symmetric methods converge faster than the additive and hybrid methods, while the additive and hybrid methods can result in better speedup.

THE SCHUR COMPLEMENT METHOD

Another class of methods is the *Schur complement methods* where the partitions of D are nonoverlapping and separated by a boundary domain S. If the solution to the boundary domain S is known, the solution for all domains are trivially computed by inverting the local system matrices of each domain. The solution to the boundary domain is computed by inverting the Schur complement matrix. Because the Schur complement matrix in general is dense, an approximate method is used to compute the inverse. One such method is to use a Schwarz method as a preconditioner for the solution of the Schur complement system. The local systems that corresponds to the subdomain problems in the overlapping Schwarz method can either be inverted in full by using the Localized Schur solver or approximately inverted by using the Sparse Localized Schur solver that filters small entries in the local matrix. See also Ref. 30 and Ref. 31.

You can choose from an *additive Schur ordering* or a *multiplicative Schur ordering*. These ordering options determine which corresponding Schwarz algorithm (see The Overlapping Schwarz Method above) to use for solving the Schur complement system.

A variation of the Schur method is obtained by imposing absorbing boundary conditions on the interior boundaries between subdomains. The boundary problem consists of finding artificial boundary sources to impose on each nonoverlapping domain. If the boundary sources are known, the solution is computed by solving each subdomain problem separately (see Ref. 32). The advantage of this approach over the standard Schur method is that the boundary problem is not dense and can be solved with a Krylov solver without explicitly assembling the boundary

matrix, resulting in a significantly lower memory use. On the other hand, the iterative solution of the boundary problem may be computationally expensive, as it requires inverting the local system matrices of all domains at each iteration.

SCHWARZ VS. SCHUR METHODS

The Schur complements method is typically more stable than the Schwarz overlapping method but also requires more computational work for each iteration. The recommendation is therefore to try the Schwarz overlapping method and then the Schur complements method. The Schwarz overlapping method is also more memory lean than the Schur complements method.

THE COMPLEX SHIFTED LAPLACE CONTRIBUTION

The convergence of the Domain Decomposition (Schwarz) method can be improved by adding a complex shifted Laplace (CSL) contribution — that is, a purely complex term that has the effect of damping oscillations in the solution. CSL is typically applied to wave problems at high frequency. Its effect is limited to the preconditioner and the convergence rate, and it can be applied independently both on the fine and on the coarse grid levels. CSL does not change the original system matrix and the final solution. The CSL contribution is a function of the wave number of the problem and is generally multiplied by a relaxation factor $O(1)$. The choice of the relaxation factor is a tradeoff between no damping (0) and large damping but deterioration of the preconditioner performance (large values).

The Fully Coupled Attribute and the Double Dogleg Method

For the Fully Coupled attribute, you can define one of the settings for the double dogleg method. Also see Termination Criterion for the Fully Coupled and Segregated Attribute Nodes.

FullyCoupled and Segregated in the *COMSOL Multiphysics Programming Reference Manual.*

THE DOUBLE DOGLEG METHOD

The double dogleg method (Ref. 33) is available for stationary problems. It is a Newton trust region method and can as such adjust the direction as well as the step length when solving the nonlinear equation $F(u) = 0$, $F: R^n \to R^n$.

In order to apply the double dogleg method, consider the minimization of the quadratic model

$$m_k(u_k + s) = \frac{1}{2}\|F_k + F'_k s\|^2 = \frac{1}{2}F_k^T F_k + (F'_k{}^T F_k)^T s + \frac{1}{2}s^T F'_k{}^T F'_k s$$

subject to $\|s\| \le \delta_k$. Here, F'_k is the Jacobian of F at the current point u_k, $F_k = F(u_k)$, and the size of the double dogleg step s is required to be bounded by the current trust region radius δ_k. Both the Cauchy point — that is, the minimizer of m in the steepest descent direction — and the Newton point are utilized by the double dogleg method. In each iteration, the algorithm dynamically adjusts the size of the trust region depending on the predicted decrease of m compared to the actual one. If the Newton step size, initially optionally reduced with the **Initial damping factor**, is smaller than the trust region radius, the Newton step is taken. Otherwise, the step size will be equal to the trust region radius. The direction of the step will in this case be in the steepest descent direction if the size of the Cauchy step is larger than the trust region radius; otherwise, the direction will be a convex combination of the Cauchy step and the Newton step. For further details, see Ref. 33. For difficult problems, you can choose to start the computation by a damped Newton step. Enter the damping factor between 0 and 1 in the **Initial damping factor** field. The algorithm terminates if the norm of the scaled residual is less than the given tolerance, $\|SF_k\| \le \text{tol}$. You can choose the type of scaling in the **Residual scaling** list. See the Fully Coupled **Method and Termination** settings.

The Iterative Solvers

The following section provides more detailed information about the Iterative solver types: GMRES, FGMRES, Conjugate Gradients, BiCGStab, and TFQMR.

It also discusses the Convergence Criteria for Linear Solvers and Selecting a Preconditioner for an Iterative Linear System Solver.

Linear in the *COMSOL Multiphysics Programming Reference Manual.*

ITERATIVE SOLVER TYPES

The following information also applies to the Krylov Preconditioner attribute.

These solvers can roughly be ordered according to their memory usage and computational time per iteration (with least memory and time first): Conjugate gradients, BiCGStab, TFQMR, GMRES, and then FGMRES. The solvers that require less memory and computational time per iteration typically are less robust and not applicable to all problem types.

GMRES Iterative Solver

This linear system solver uses the restarted GMRES (generalized minimum residual) method (see Ref. 9 and Ref. 10). This is an iterative method for general linear systems of the form $Ax = b$. For fast convergence it is important to use an appropriate *preconditioner*. By default, the GCRO-DR method for Krylov subspace recycling is active (see Ref. 11). This method can be useful while solving sequences of linear systems arising from, for example, nonlinear problems.

FGMRES Iterative Solver

This solver uses the restarted FGMRES (flexible generalized minimum residual) method (Ref. 19). The solver is a variant of the GMRES solver that can handle a wider class of preconditioners in a robust way. You can, for example, use any iterative solver as preconditioner for FGMRES. The downside with the method is that it uses twice as much memory as GMRES for the same number of iterations before restart. FGMRES uses right preconditioning and therefore has the same convergence criterion as right-preconditioned GMRES. If FGMRES is used together with a constant preconditioner such as the Incomplete LU preconditioner, then the FGMRES solver is identical to the right preconditioned GMRES solver.

Conjugate Gradients Iterative Solver

This solver uses the conjugate gradients iterative method (Ref. 9, Ref. 20, and Ref. 21). It is an iterative method for linear systems of the form $Ax = b$ where the matrix A is positive definite and (Hermitian) symmetric. Sometimes the solver also works when the matrix is not positive definite, especially if it is close to positive definite. This solver uses less memory and is often faster than the GMRES solver, but it applies to a restricted set of models.

For fast convergence it is important to use an appropriate *preconditioner*, which should be positive definite and (Hermitian) symmetric.

BiCGStab Iterative Solver

This solver uses the *biconjugate gradient stabilized* iterative method (Ref. 9 and Ref. 22) for solving general linear systems of the form $Ax = b$. The required memory and the computational time for one iteration with BiCGStab is constant; that is, the time and memory requirements do not increase with the number of iterations as they do for GMRES. BiCGStab uses approximately the same amount of memory as GMRES uses for two iterations. Therefore, BiCGStab typically uses less memory than GMRES.

The convergence behavior of BiCGStab is often more irregular than that of GMRES. Intermediate residuals can even be orders of magnitude larger than the initial residual, which can affect the numerical accuracy as well as the rate of convergence. If the algorithm detects poor accuracy in the residual or the risk of stagnation, it restarts the iterations with the current solution as the initial guess.

In contrast to GMRES and conjugate gradients, BiCGStab uses two matrix-vector multiplications each iteration. This also requires two preconditioning steps in each iteration. Also, when using the left-preconditioned BiCGStab, an additional preconditioning step is required each iteration. That is, left-preconditioned BiCGStab requires a total of three preconditioning steps in each iteration.

TFQMR Iterative Solver

This solver uses the *transpose-free quasi-minimal residual* iterative method (Ref. 35 and Ref. 36) for solving general linear systems of the form $Ax = b$. The required memory and the computational time for one iteration with TFQMR is constant; that is, the time and memory requirements do not increase with the number of iterations as they do for GMRES. TFQMR uses approximately the same amount of memory as GMRES uses for two iterations. Therefore, TFQMR typically uses less memory than GMRES.

TFQMR is more stable than BiCGStab because it performs a minimization. It is therefore often a better alternative than BiCGStab. The convergence behavior of TFQMR is often more regular than BiCGStab but slower than GMRES. Sometimes the underlying algorithm can break down. When the algorithm detects this, it restarts the iterations with the current solution as the initial guess.

In contrast to GMRES and conjugate gradients, TFQMR uses two matrix-vector multiplications each iteration. This also requires two preconditioning steps in each iteration.

CONVERGENCE CRITERIA FOR LINEAR SOLVERS

When you use an iterative solver, COMSOL Multiphysics estimates the error of the solution while solving. Once the error estimate is small enough, as determined by the convergence criterion

$$\rho\left|M^{-1}(b - Ax)\right| < \text{tol} \cdot \left|M^{-1}b\right| \tag{20-51}$$

the software terminates the computations and returns a solution. When you use a direct solver, COMSOL Multiphysics can optionally make a check to determine if the above convergence criterion is fulfilled after the solution step. If the error criterion is not met, the solution process is stopped and an error message is given.

The definitions of M for the various solvers are:

- For MUMPS, PARDISO, and SPOOLES, $M = LU$, where L and U are the LU factors computed by the solver.
- When using left preconditioning with the iterative solvers GMRES, conjugate gradients, BiCGStab, and TFQMR, M is the preconditioner matrix.
- For the remaining iterative solvers, M is the identity matrix.

The convergence criterion in Equation 20-51 states that the iterations terminate when the relative (preconditioned) residual times the factor ρ is less than a tolerance tol. For solvers where M is equal to the identity matrix, the iterations can sometimes terminate too early with an incorrect solution if the system matrix A is ill-conditioned. For solvers where M is not equal to the identity matrix, the iterations can sometimes terminate too early if M is a poor preconditioner. If the iterations terminate too early due to an ill-conditioned system matrix or a poor preconditioner, increase the factor ρ to a number of the order of the condition number for the matrix $M^{-1}A$. If ρ is greater than the condition number for the matrix $M^{-1}A$, the convergence criterion implies that the relative error is less than tol: $|x - A^{-1}b| < \text{tol} \cdot |A^{-1}b|$.

SELECTING A PRECONDITIONER FOR AN ITERATIVE LINEAR SYSTEM SOLVER

When using an Iterative linear system solver, you must select a preconditioner. The choice of preconditioner affects the number of iterations and the solver's eventual convergence. Preconditioning can consume more time and

memory than the actual iterative solver itself. To choose a preconditioner, right-click the **Iterative** node and choose one of the following preconditioners from the context menu:

TABLE 20-9: SELECTING A PRECONDITIONER.

PRECONDITIONER	USAGE
GENERAL FRAMEWORK	
Multigrid — Geometric multigrid	For elliptic or parabolic systems.
Multigrid — Algebraic multigrid and smoothed aggregation AMG	For scalar problems or loosely coupled multiphysics problems of the elliptic or parabolic type.
Domain Decomposition (Schwarz)	For large problems in a distributed-memory system or as an alternative to a direct solver.
Krylov Preconditioner	For Helmholtz problems where the mesh does not fulfill the Nyquist criteria. It can be used on the coarse multigrid level or as a smoother.
FULL OR APPROXIMATE FACTORIZATION OR APPROXIMATE INVERSE	
Incomplete LU	For nonsymmetric systems (the default preconditioner).
SCGS	For BEM methods and as a general preconditioner or smoother. It has a costly setup phase but typically shows a good parallel scalability.
Direct Preconditioner	For small fields (an ODE, for example), where a direct solver is efficient.
POINTWISE GENERAL PURPOSE	
SOR	For elliptic problems without zeros on the diagonal. It is typically better than Jacobi and still rather inexpensive.
Jacobi (diagonal scaling)	For large positive definite models.
BLOCK GAUSS-SEIDEL GENERAL PURPOSE	
SCGS	For fluid flow problems with linear elements.
SOR Line	For the same problem class as for SOR but adopted to stretched/anisotropic meshes (for example, boundary layer meshes). More expensive than SOR.
Vanka	For large indefinite problems with zeros on the diagonal of the system matrix.
VECTOR ELEMENT METHODS	
Auxiliary-Space AMG	For complex-valued RF problems and other simulations using vector elements.
Auxiliary-Space Maxwell (AMS)	For curl-curl problems stemming from stationary or time-dependent Maxwell's equations.
SOR Gauge	For ungauged vector element formulations of Magnetostatics.
SOR Vector	For large electromagnetics models using vector elements.
METHOD FOR FLUID FLOW SIMULATIONS	
Block Navier–Stokes	For fluid flow models using the incompressible Navier–Stokes equations in the transient regime,

Each preconditioner has its own settings; to adjust them, select the preconditioner node to open its **Settings** window. If you want to solve a model without a preconditioner, disable all preconditioner nodes. Normally, only one preconditioner can be active, and if you have more than one preconditioner node, an active preconditioner node becomes disabled if you enable another preconditioner. You can use multiple preconditioners in a hybrid preconditioner approach; see Hybrid Preconditioners. It is also possible to run the iterative solver without a preconditioner by not adding any preconditioner or disabling all of them.

The Incomplete LU preconditioner, which is the default preconditioner, works in a more general context than the others, but it might be impractical because of its time and memory requirements; when they work, the multigrid preconditioners are always preferable. The SOR and Jacobi diagonal-scaling preconditioners use less time and memory but only ensure convergence of the iterative solver for positive definite problems. Problems with zeros on

the diagonal are efficiently preconditioned with the Vanka preconditioner. To precondition electromagnetic problems that use vector elements for a PDE containing the curl-curl operator, use the SOR Vector preconditioner.

For details about the individual preconditioners, follow the links in the table above.

Preconditioner Selection Guidelines

The physics interface selects a default preconditioner that is usually appropriate for the problem type, at least for single-physics interface models. If the default does not perform well, select another one using the following guidelines:

- If the system is elliptic or parabolic (see Elliptic and Parabolic Models) use the geometric multigrid preconditioner.
- If you solve a fluid flow problem with linear elements only, try the SCGS preconditioner. This is the default setting for most fluid flow physics interfaces.
- If you solve fluid flow problems in the transient regime, try the block Navier–Stokes preconditioner.
- If you solve an indefinite problem with zeros on the diagonal of the system matrix, such as the Navier–Stokes equations, try the Vanka preconditioner or the geometric multigrid preconditioner with Vanka or Incomplete LU as the smoother. With appropriate stabilization, it is possible in many cases to use SOR or SOR Line as a GMG pre- and postsmoother instead of Vanka, which increases performance. This is the default setting in some fluid flow interfaces.
- If the system is positive definite but so large that the other preconditioners run out of memory, try the SOR Vector as smoother.
- If you solve an electromagnetics problem using vector elements for a PDE containing the curl-curl operator, try the geometric multigrid preconditioner with the SOR vector presmoother and the SOR vector postsmoother, or try the SOR vector preconditioner. Alternatively, if the problem is real valued stationary or time dependent, you can try the geometric multigrid (GMG) preconditioner with the SOR presmoother and the SOR postsmoother, and AMS as the coarse solver. AMS is designed for the lowest-order vector elements. For higher-order discretizations, use GMG with the option **Lower element order first** and sufficiently number of levels such that AMS could be used efficiently as a coarse solver.
- Try the Incomplete LU preconditioner, which works for all linear systems. However, it requires the tuning of the drop tolerance (or fill ratio); it can run out of memory, and in many cases it is not the most efficient preconditioner.
- If the system is elliptic or parabolic and the system is a real-valued PDE for a single solution component (that is, a scalar problem) you can alternatively try the algebraic multigrid preconditioner.
- As an alternative to the multigrid solver and the use of a direct solver, the Domain Decomposition (Schwarz) solver can be a memory efficient alternative and is a scalable solver well suited for use in a distributed memory system. The Domain Decomposition (Schur) is a typically more stable but less memory efficient alternative to the Domain Decomposition (Schwarz) solver.
- When you are solving a problem on a parallel computer (shared or distributed memory), you can try the SAI preconditioner or smoother due to its scalability properties.
- For small models, or as part of a hybrid preconditioner for a multiphysics model that contains a small field (such as an ODE), you can use the Direct preconditioner.

The Incomplete LU preconditioner and sometimes the multigrid preconditioners require some tuning to get fast convergence without running out of memory (see the sections about these preconditioners).

About the Relaxation Factor

The *relaxation factor* ω to some extent controls the stability and convergence properties of a numerical solver by shifting its eigenvalue spectrum. The optimal value for the relaxation factor can improve convergence significantly — for example, for SOR when used as a solver. However, the optimal choice is typically a subtle task with arbitrary

complexity. For preconditioners and smoothers, a sophisticated choice of the relaxation factor is less important. A value $\omega < 1$ (under-relaxation) diminishes the impact of the smoother or preconditioner by limiting the possible modification in the variable update. There is a tradeoff between stability (a small value of ω) and quick advancement in the iterative process (ω close to 1). Some smoothers for multigrid require $\omega < 1$, but the typical default value is 1. Over-relaxation — that is, $1 < \omega < 2$ — might have some benefits in special situations.

HYBRID PRECONDITIONERS

For all preconditioners, you can combine the effect of multiple preconditioners, either as a preconditioner or as smoothers, coarse solvers, or domain solvers. Such hybrid preconditioners can be useful in several cases. For instance, if you need to solve a combined multiphysics problem, you can apply the appropriate smoother to each physics interface and use the combined effect in a multigrid solver, or if the physics interface requires different types of multigrid hierarchies, you can use one multigrid hierarchy for each physics interface as a preconditioner.

You activate hybrid preconditioners in the **Hybridization** section, which is available in all preconditioner node's **Settings** windows.

Hybridization

Select the type of preconditioner from the **Use as** list: Select **Single preconditioner** (the default) to use the preconditioner as a single preconditioner for the solver. Select **Multi preconditioner** to make it possible to create a sequence of preconditioners. The hybrid preconditioner sequence is defined by all enabled preconditioner steps for the solver. For each preconditioner you can select the variables to apply the preconditioner to from the **Preconditioner variables** list. For models where some dependent variables represent vector fields, you can also select individual components from the **Preconditioner components** list. Select **All** (the default), or select **Manual** to choose from all solution components in the **Preconditioner selection** list. The selection in the **Preconditioner selection** list overrides the selection in the **Preconditioner variables** list.

The Multigrid Solvers

The different Multigrid solvers types — geometric multigrid (GMG) and algebraic multigrid (AMG) solvers— are discussed in this section as well as the multigrid algorithm.

THE GEOMETRIC MULTIGRID SOLVER/PRECONDITIONER

The geometric multigrid solver uses a hierarchy of *multigrid levels* where each level corresponds to a mesh and a choice of shape functions. It can then accelerate the convergence of the iterative solver by solving the finite element problem on a series of meshes rather than a single one. The geometric multigrid algorithm starts with an initial physics-controlled mesh or user-defined mesh and then builds a series of coarser meshes. Each additional mesh is approximately twice as coarse as the previous one. The total number of meshes depends on the size of the model: geometric multigrid meshes are automatically built by the solver until the coarsest mesh leads to a low enough number of degrees of freedom to be solved with a direct solver. In addition to coarsening the mesh, it is possible to construct a new "coarser" level by lowering the order of the shape functions. The number of degrees of freedom decreases when you go to a coarser multigrid level. The meshes for the different levels can be constructed manually or automatically. The automatic options use a coarsening algorithm to the fine mesh, which leads to meshes that are not aligned to each other. There is also an option to generate the finer meshes from the coarsest mesh by successive mesh refinements, which leads to aligned (nested) meshes. The manual option can be useful when you have a quadrilateral, hexahedral, or prism mesh, or when you for some other reason want to control details in the meshes.

The geometric multigrid (GMG) solver or preconditioner is a fast and memory-efficient iterative method for elliptic and parabolic models. It performs one or several cycles of the geometric multigrid method. The classical multigrid algorithm uses one or several auxiliary meshes that are coarser than the original (fine) mesh. The idea is to perform just a fraction of the computations on the fine mesh. Instead, it performs computations on the coarser meshes when

possible, which leads to fewer operations. The size of the extra memory used for the coarser meshes and associated matrices is comparable to the size of the original data. This leads to an iterative algorithm that is both fast and memory efficient. See Ref. 25 for more information.

The Geometric Multigrid Solver with Several Meshes

If you want to use the geometric multigrid solver with several meshes, the meshing sequences must be added before setting up the solver settings. It can, for example, be useful when the multigrid solver fails. Then, rather than letting the mesher automatically build coarser meshes from the initial mesh, you can manually build the meshes that failed using user-defined meshing sequences and select these meshes within the **Multigrid** node's solver settings. The number of meshes is determined by the value in the **Number of multigrid levels** field. If the solver returns a **Problem setting up multigrid** message, then to visualize the multigrid meshes and see how many of them failed, select the **Keep generated multigrid levels** checkbox in the settings for the **Multigrid** node. After recomputing, the multigrid level are added as Multigrid Level subnodes under a **Stationary** study step node, for example (if you have selected the **Multigrid Level** checkbox in the **Show More Options** dialog). The corresponding coarser meshes will appear in the **Model Builder** as additional **Mesh** nodes. Possibly, the coarsest mesh fails because it is too coarse to discretize the geometry.

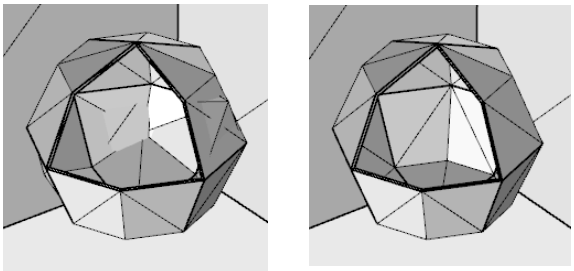

Figure 20-10: Mesh failure example. Left: the surfaces on each side of the thin layer intersect each other, leading to meshing errors. The mesh consist of tetrahedral elements. Right: the intersection of these surfaces does not occur when using a swept (structured) mesh for the thin layer rather than the default tetrahedral elements.

To correct a failing coarse mesh, try one of the following steps:

- Build the meshing sequence for the failing mesh manually using a finer mesh or a swept mesh.
- Add a new coarse mesh and change the settings in corresponding **Multigrid Level** node to point to the new mesh.
- Delete the coarsest mesh and the corresponding **Multigrid Level** node to reduce the number of multigrid levels.

Another approach is to build all multigrid levels manually. To do so, build the meshes using user-defined meshing sequences. See The Mesh Node for more information about adding meshes. Each subsequent mesh should be approximately twice as coarse as the previous one. Set the initial mesh as **Mesh 1** in a **Stationary** study step, for example and set the additional meshes as **Multigrid Level** subnodes to the study step node, assigning the coarser meshes to each multigrid level. Also, in the solver settings for the **Multigrid** node, select **Manual** from the **Hierarchy generation method** list.

THE ALGEBRAIC MULTIGRID SOLVERS/PRECONDITIONERS

The algebraic multigrid (AMG) solvers or preconditioners perform one or several cycles of the algebraic multigrid method. This is similar to the geometric multigrid algorithm, the difference being that it constructs the multigrid levels directly from the finest-level system matrix A_0. That is, it constructs the prolongations P_i from A_0 without using auxiliary meshes. It constructs the coarse level matrices A_i from A_0 with the Galerkin projection method. The advantage is that you need not bother about the coarse multigrid levels. The AMG solver includes a parallel coarsening method, which can reduce the memory consumption and computation time per iteration.

THE MULTIGRID ALGORITHM

To describe the multigrid algorithm, assume that you have $N+1$ multigrid levels numbered from 0 to N, where 0 is the finest level (the level for which you seek the solution). To solve the linear system $A_0x = b$ (corresponding to level 0), the algorithm must reform the system matrices $A_1, \ldots, A_N$ for the coarse multigrid levels. It must also compute the *prolongation matrices* P_i that map a solution x vector on level i to the corresponding solution vector P_ix on the next finer level $i-1$.

The prolongation matrices are constructed using plain interpolation from one multigrid level to the other. The system matrices for the coarse levels can be constructed in two ways:

- By assembling A_i on the mesh of level i (the default method).
- By projection from the finer level: $A_i = P_i^T A_{i-1} P_i$. This is also called the Galerkin method. It typically leads to more nonzero elements in the system matrix A_i, but the convergence can be faster than in the default method.

The following algorithm describes one multigrid cycle:

1. The input to the algorithm is some initial guess x_0 to the solution of the system $A_0x = b$.
2. Starting with x_0, apply a few iterations of a *presmoother* to the linear system $A_0x = b$, yielding a more accurate iterate x_{0s}. Typically the presmoother is some simple iterative algorithm such as SOR, but you can also choose any iterative solver.
3. Compute the residual $r_0 = b - A_0x_{0s}$. The presmoother "smooths" the residual so the oscillations in r have such a long wavelength that they are well resolved on the next coarser level (1). Therefore, project the residual onto level 1 by applying the transpose of the prolongation: $r_1 = P_1^T r_0$.
4. If $N = 1$ use the *coarse solver* to solve the system $A_1x_1 = r_1$. The coarse solver is typically a direct solver such as MUMPS. The number of degrees of freedom on level 1 is less than for level 0, which means that solving $A_1x_1 = r_1$ is less expensive. If instead $N > 1$, solve the system $A_1x_1 = r_1$ (approximately) by recursively applying one cycle of the multigrid algorithm for levels $1, 2, \ldots, N$. In both cases the obtained solution x_1 is called the *coarse grid correction*.
5. Map the coarse grid correction to level 0 using the prolongation matrix: $x_{0c} = x_{0s} + P_1x_1$.
6. Starting with x_{0c}, apply a few iterations of a *postsmoother* to the linear system $A_0x = b$, yielding a more accurate iterate x_{0mg}. The default postsmoother is SORU (the version of SOR using the upper triangle of the matrix). The iterate x_{0mg} is the output of the multigrid cycle.

The cycle just described is called the V-cycle. The recursive call in step 4 (when $N > 1$) is also a V-cycle. For the W-cycle and the F-cycle, steps 1–6 above are the same but with the twist that the recursive call in step 4 is substituted with two multigrid calls for the coarser levels. For the W-cycle these two calls are recursive calls (W-cycle calls). For the F-cycle the first call is a W-cycle and the second a V-cycle.

For only two multigrid levels ($N = 1$) these cycles are the same because the algorithm uses the coarse solver in step 4. Also the amount of work on the finest level is the same for the different cycles. Normally the V-cycle is sufficient, but the W-cycle and the F-cycle can be useful for more difficult problems.

When using multigrid as a preconditioner, the action of this preconditioner is obtained by applying a fixed number of multigrid cycles. When using multigrid as a solver, the multigrid cycle repeats until it reaches convergence.

When using multigrid as a preconditioner for the conjugate gradients method for a symmetric matrix A, the preconditioning matrix M should also be symmetric. This requirement is fulfilled if the matrices M associated with the presmoother and the postsmoother are transposes of each other. For instance, this is the case if the presmoother is SOR and the postsmoother is SORU, and if the same number of smoothing steps is used. This combination with two smoothing steps is the default.

Notes on the Efficiency of Smoothers

COMSOL Multiphysics performs smoothing on all but the coarsest multigrid level. A smoother should be computationally cheap and effective at reducing the part of the error that has a high spatial frequency on the mesh to which it is applied. Therefore, applying a smoother on several meshes with a hierarchy of mesh sizes results in a more efficient solver than if the smoother were applied only on the finest mesh.

The efficiency of the multigrid method with simple iterations as a smoother (such as the Jacobi and SOR iteration) hinges on the ellipticity of the underlying mathematical problem. For Helmholtz problems originating from an equation

$$-\nabla\cdot\left(\frac{1}{a}\nabla u\right)-\omega^2 u = f$$

or

$$\nabla\times\left(\frac{1}{a}\nabla\times\mathbf{E}\right)-\omega^2\mathbf{E} = \mathbf{F}$$

the obtained linear problem is indefinite for large frequencies ω. For these problems, a simple iteration amplifies smooth eigenmodes if the mesh is too coarse and makes these methods unsuitable as smoothers. To determine when to use a simple iteration, apply the *Nyquist criterion*:

$$h_{\max} < \frac{\lambda}{2} = \frac{\pi}{\omega\sqrt{a}}$$

which says that the mesh must have at least two mesh elements per wavelength. Thus, when using the geometric multigrid solver for these types of problems, ensure that this criterion is fulfilled on the coarsest mesh if simple iterations are used as a smoother. In situations where the criterion is not fulfilled on coarse meshes, GMRES can be a suitable smoother (Ref. 28). However, this setting makes smoothers on all levels more expensive and might not always pay off compared to choosing a coarse grid that satisfies the Nyquist criterion. Note also that a smoother based on a Krylov preconditioner like GMRES requires the (outer) iterative solver to be set to FGMRES.

THE COMPLEX SHIFTED LAPLACE OPERATOR

The convergence of the Multigrid method can be improved by adding a complex shifted Laplace (CSL) contribution — that is, a purely complex term that has the effect of damping oscillations in the solution. CSL is typically applied to wave problems at high frequency. Its effect is limited to the preconditioner and the convergence rate, and it can be applied independently both on the fine and on the multigrid levels. CSL does not change the original system matrix and the final solution. The CSL contribution is a function of the wave number of the problem and is generally multiplied by a relaxation factor $O(1)$. The choice of the relaxation factor is a tradeoff between no damping (0) and large damping but deterioration of the preconditioner performance (large values).

The Parametric Solver Algorithm

The Parametric solver performs a loop around the usual stationary solver in which it estimates the initial guess using the solution for the previous parameter value. If the nonlinear solver does not converge and you are solving for a single parameter, it tries a smaller parameter step; COMSOL Multiphysics determines the size of this step from the convergence speed of the Newton iteration using step-size selection criteria based on work in Ref. 14.

The SCGS Solver

The SCGS iterative solver (smoother) works in a similar way to the blocked update of the Vanka solver, but it builds blocks based on the DOFs in each mesh element instead of blocks based on DOF connectivity to a Vanka variable.

The advantage is that the blocks are smaller, allowing for storing their factorization once during the initialization phase (like SOR Line does) instead of factorizing on every update (like Vanka does by default).

Compared to other multigrid smoothers, SCGS provides better performance and is more robust, but it also requires somewhat more memory. SCGS only works for linear elements, and it is the default smoother for fluid flow models with P1 + P1 elements (linear elements for the velocity field and the pressure).

The solver includes three main methods:

- *Mesh elements*: Each mesh element corresponds to one SCGS block.
- *Mesh element lines*: Anisotropic mesh elements are grouped together in SCGS blocks along the direction of anisotropy, which gives better results for boundary layer meshes. Nonanisotropic mesh elements correspond to one SCGS block.
- *Mesh element lines and vertices*: Anisotropic mesh elements are grouped together in SCGS blocks, like above. The DOFs corresponding to nonanisotropic mesh elements are solved using vertex-based SCGS blocks, which consume less memory than element blocks. A separate relaxation factor can be set for the vertex pass.

The solver additionally has an option to use a Vanka hybrid step where Vanka blocks are first built and then SCGS blocks are built excluding the Vanka variable DOFs. This step makes it possible to run iterative solvers when using, for example, the Laminar Inflow boundary condition, independent of whether the mesh is anisotropic or not.

The Segregated Solver

Segregated in the *COMSOL Multiphysics Programming Reference Manual*

TERMINATION CRITERION FOR A SEGREGATED SOLVER

For the **Solution** termination criterion: When termination of the Segregated solver is based on the estimated error, it terminates if, for all the groups j, the error estimate is smaller than the corresponding tolerance,

$$\mathrm{err}_{j,k} < \mathrm{tol}_j$$

where the error estimate in segregated iteration k is

$$\mathrm{err}_{j,k} = \max(\mathrm{e}^N_{j,k}, \mathrm{e}^S_{j,k})$$

The number tol_j is the relative tolerance for the corresponding group. For each degree of freedom (DOF), the field variable solved for is $1 \le p \le M$ and $1 \le i \le N_{j,p}$ is the index of that DOF. The largest damped Newton error is then estimated by:

$$\mathrm{e}^N_{j,k} = \max_l(1-\alpha_{l,j})\left[\frac{1}{M}\sum_{p=1}^{M}\frac{1}{N_{j,p}}\sum_{i=1}^{N_{j,p}}\left(\frac{|\Delta U_i^{l,j,k,p}|}{W_i^{j,p}}\right)^2\right]^{1/2}$$

Here l is taken for all iterations in all substeps solving for the group j, $\alpha_{l,j}$ is the damping factor, $\Delta U^{l,j,k,p}$ is the Newton increment vector, and $N_{j,p}$ is the number of DOFs in the field p. The weight factor $W_i^{j,p}$ is described below. Moreover,

$$\mathrm{e}^S_{j,k} = \left[\frac{1}{M}\sum_{p=1}^{M}\frac{1}{N_{j,p}}\sum_{i=1}^{N_{j,p}}\left(\frac{|(U^{j,k,p}-U^{j,k-1,p})_i|}{W_i^{j,p}}\right)^2\right]^{1/2}$$

is the relative increment over one complete iteration k. In this expression, $U^{j,k,p}$ is the segregated solution vector for the group j, and

$$W_i^{j,p} = \max(\left|U_i^{j,p}\right|, S_i)$$

where S_i is a scale factor that the solver determines from the settings in the **Scaling** section of the **Settings** window for the Dependent Variables node, where the following choices are available in the **Method** list:

- For **Automatic**, S_i is the factor 0.1 times the average of $|U_m|$ for all DOFs m having the same name as DOF i.
- For **Manual**, S_i is the value for DOF i given in the **Manual scaling** field.
- For **Initial value based**, S_i is the factor 0.1 times the average of $|U_{0m}|$ for all DOFs m having the same name as DOF i, where U_0 is the solution vector corresponding to the initial value.
- For **None**, $W_i = 1$.

S_i is independent of the field variable p.

For the **Residual** termination criterion, the segregated solver terminates when the following convergence criterion is satisfied: For all the groups j, the error estimate is smaller than the corresponding tolerance, $\text{err}_{j,k} < \text{tol}_j$, where

$$\text{err}_{j,k} = \left[\frac{1}{M}\sum_{p=1}^{M}\frac{1}{N_{j,p}\tilde{W}_{j,p}^2}\sum_{i=1}^{N_{j,p}}\left|(F^{j,k,p})_i\right|^2\right]^{1/2}$$

where F is the current residual, and $\tilde{W}$ are the weights determined by the first and, if applicable, the second residual. The iterations can also terminate if the relative solution-based error is in the range of a hundred machine epsilon.

Pseudo Time Stepping

Pseudo time stepping is available in a stationary segregated approach as well; see Pseudo Time Stepping for a description of the CFL control. For the segregated solver, the error estimate e_n in Equation 20-1 is the arithmetic average of the errors in the different segregated groups.

The Sensitivity Analysis Algorithm

When you enable Sensitivity analysis, the stationary solvers compute — in addition to the basic forward solution — the sensitivity of a functional

$$Q = Q(u_p, p) \tag{20-52}$$

with respect to the sensitivity variables p. The forward solution u_p is a solution to the parameterized discrete forward problem

$$L(u_p, p) = N_F\Lambda_p \qquad M(u_p, p) = 0 \tag{20-53}$$

where Λ_p are the constraint Lagrange multipliers, or (generalized) reaction forces, corresponding to the constraints M. It is assumed that Q does not explicitly depend on Λ_p.

To compute the sensitivity of Q with respect to p, first apply the chain rule:

$$\frac{d}{dp}Q(u(p), u_{\text{flux}}(p), p) = \frac{\partial Q}{\partial p} + \frac{\partial Q}{\partial u}\frac{\partial u}{\partial p} + \frac{\partial Q}{\partial u_{\text{flux}}}\left\{\frac{\partial u_{\text{flux}}}{\partial u}\frac{\partial u}{\partial p} + \frac{\partial u_{\text{flux}}}{\partial p}\right\} \tag{20-54}$$

where u_{flux} are the accurate boundary degrees of freedom. In this expression, the sensitivity of the solution with respect to the sensitivity variables, $\partial u/\partial p$, is still an unknown quantity. Therefore, differentiate the forward problem in Equation 20-53 formally with respect to p:

$$K\frac{\partial u_p}{\partial p} + N_F\frac{\partial \Lambda_p}{\partial p} = \frac{\partial L}{\partial p} - \left(\frac{\partial N_F}{\partial u_p}\frac{\partial u_p}{\partial p} + \frac{\partial N_F}{\partial p}\right)\Lambda_p \qquad N\frac{\partial u_p}{\partial p} = \frac{\partial M}{\partial p} \tag{20-55}$$

Here, $K = -\partial L/\partial u$ and $N = -\partial M/\partial u$ as usual. The first term inside the parentheses above is assumed to be zero, basically only valid when $\partial N_F/\partial u=0$ (linear constraints). Assuming that the constraint force Jacobian N_F is also independent of p, you can write the above relations in matrix form

$$J\begin{pmatrix}\frac{\partial u_p}{\partial p}\\ \frac{\partial \Lambda_p}{\partial p}\end{pmatrix} = \begin{pmatrix}\frac{\partial L}{\partial p}\\ \frac{\partial M}{\partial p}\end{pmatrix} \qquad J = \begin{bmatrix}K & N_F\\ N & 0\end{bmatrix} \tag{20-56}$$

Solve for the sensitivities $\partial u_p/\partial p$ and $\partial \Lambda_p/\partial p$, and plug them back into Equation 20-54:

$$\frac{dQ}{dp} = \frac{\partial Q}{\partial p} + \begin{pmatrix}\frac{\partial Q}{\partial u}\\ 0\end{pmatrix}^T J^{-1}\begin{pmatrix}\frac{\partial L}{\partial p}\\ \frac{\partial M}{\partial p}\end{pmatrix} \tag{20-57}$$

This formula gives dQ/dp explicitly in terms of known quantities, but in practice it is too expensive to invert the matrix J.

The accurate boundary flux degrees of freedom are obtained internally by solving equation for flux degrees of freedom:

$$K_{\text{flux}}u_{\text{flux}} = L_{\text{flux}}$$

where K_{flux} is not dependent on either the parameter p or the solution. The L_{flux}, on the other hand, can be a solution- and parameter-dependent quantity, and therefore the sensitivity solvers assemble these derivatives:

$$\frac{\partial L_{\text{flux}}}{\partial u} \text{ and } \frac{\partial L_{\text{flux}}}{\partial p}$$

If the number of individual sensitivity variables, p_j, is small, Equation 20-56 can be solved for each right-hand side $[\partial L/\partial p_j\ \partial \mathrm{M}/\partial p_j]^T$, and the solution is then inserted into Equation 20-54. This is the *forward method*, which in addition to the sensitivity dQ/dp returns the sensitivity of the solution, $\partial u_p/\partial p$. The matrix J is in fact the same matrix as in the last linearization of the forward problem. The forward method therefore requires one additional back-substitution for each sensitivity variable.

If there are many sensitivity variables and the sensitivity of the solution itself, $\partial u_p/\partial p$, is not required, the *adjoint method* is more efficient. It is based on using auxiliary variables u^* and L^*, known as the *adjoint solution*, to rewrite Equation 20-57:

$$\begin{aligned}\frac{dQ}{dp} &= \frac{\partial Q}{\partial p} + \begin{pmatrix}u^*\\ \Lambda^*\end{pmatrix}^T\begin{pmatrix}\frac{\partial L}{\partial p}\\ \frac{\partial M}{\partial p}\end{pmatrix}\\ J^T\begin{pmatrix}u^*\\ \Lambda^*\end{pmatrix} &= \begin{pmatrix}\frac{\partial Q}{\partial u}\\ 0\end{pmatrix}\end{aligned} \tag{20-58}$$

In this form only one linear system of equations must be solved regardless of the number of sensitivity variables, followed by a simple scalar product for each variable. This is much faster than the forward method if the number of variables is large. The system matrix, which is solved for, is the transpose of the last linearization of the forward problem. This makes no significant difference for the iterative linear solvers. For the direct solvers, if J is symmetric or Hermitian, this makes no difference compared to the forward method, and the direct solvers can reuse the factorization. In the nonsymmetric case, MUMPS and PARDISO can reuse the factorization of J while SPOOLES needs to do a new factorization of J^T.

SEGREGATED SENSITIVITY SOLVER

When using the segregated solver together with sensitivity, a segregated approach will also be taken for the sensitivity problem. This is important from several aspects, but most importantly to not increase the computational requirements.

When using the segregated solver, you need to add the control variables to the right segregated groups. From Equation 20-55, it is clear that for the forward sensitivity problem to be constrained correctly, the control variables need to be added to all the segregated groups where they are part of the constraints. For the adjoint method, the equations are the ones in Equation 20-58 and here the control variables are not involved. The correct constraint handling is taken into account after the segregated solver has converged by using the formula in Equation 20-58 without the explicit need to add them to any group.

Sensitivity in the *COMSOL Multiphysics Programming Reference Manual.*

About the SOR, SOR Gauge, SOR Line, and SOR Vector Iterative Solver Algorithms

The background information for the SOR, SOR Gauge, SOR Line, and SOR Vector attribute nodes are described in this section.

THE SOR METHOD

The SOR (successive over-relaxation) method provides a simple and memory-efficient solver/preconditioner/smoother based on classical iteration methods for solving a linear system $Ax = b$. Given a relaxation factor ω (usually between 0 and 2), a sweep of the SOR method transforms an initial guess x_0 to an improved approximation $x_1 = x_0 + M^{-1}(b - Ax_0)$, where the preconditioning matrix $M = L + D/\omega$, and D is the diagonal part of A, and L is the strictly lower triangular part of A. When $\omega = 1$ (the default), the Gauss-Seidel method is obtained.

In the SORU method, $M = U + D/\omega$, where U is the strictly upper triangular part of A. The SOR and SORU methods use a more accurate approximation of the matrix, which leads to fewer iterations but slightly more work per iteration than in the Jacobi method.

The SSOR (symmetric successive over-relaxation) method is one SOR sweep followed by a SORU sweep. The output x_1 for an input x_0 also comes from the above formula but with

$$M = \frac{\omega}{2-\omega}\left(L + \frac{D}{\omega}\right)D^{-1}\left(U + \frac{D}{\omega}\right)$$

When the system matrix A is symmetric, the SSOR method has the advantage that the preconditioning matrix M is symmetric. Symmetry of the preconditioner matrix is necessary when using the conjugate gradients iterative method. In such cases, the SSOR preconditioner is preferable to the SOR preconditioner.

THE SSOR GAUGE, SOR GAUGE, AND SORU GAUGE ALGORITHMS

The SOR Gauge algorithms are described.

Magnetostatic problems are often formulated in terms of a magnetic vector potential. The solution of problems formulated with such a potential is in general not unique. Infinitely many vector potentials result in the same magnetic field, which typically is the quantity of interest. A finite element discretization of such a problem results in a singular linear system of equations, $Ax = b$. Despite being singular, these systems can be solved using iterative solvers if the right-hand side of the discretized problem is the range of the matrix A. For discretized magnetostatic problems, the range of A consists of all divergence-free vectors. Even if the right side of the mathematical problem is divergence free, the right side of the finite element discretization might not be numerically divergence free. To ensure that b is in the range of A, SOR gauge performs a divergence cleaning of the right side by using the matrices T and T^T similar to the algorithm for the SOR Vector iterative method. To this end, the system $T^T T\psi = -T^T b$ is first solved. Adding $T\psi$ to b then makes the numerical divergence of the right side small.

THE SOR LINE ALGORITHM

In regions where the mesh is sufficiently anisotropic, the algorithm forms *lines* of nodes (SOR Line) that connect nodes that are relatively close to each other (Ref. 42). Thus, in a boundary layer, a line is a curve along the thin direction of the mesh elements. A smoothing iteration does two things:

- Line update: Performs block SOR smoothing where each block consists of degrees of freedom located on a line. Due to the banded structure of each block matrix, this smoothing runs relatively fast.
- SSOR update: Performs a number of SSOR smoothing iterations on the whole mesh.

Like the SOR and Jacobi smoothers/preconditioners, the algorithm gives an error message if it finds zeros on the diagonal of the system matrix.

THE SOR VECTOR ALGORITHM

The SOR Vector algorithm is an implementation of the concepts in Ref. 39 and Ref. 26. The algorithm applies SOR iterations on the main linear equation $Ax = b$ but also makes SOR iterations on a projected linear equation $T^T A T y = T^T b$. Here the projection matrix, T, is the discrete gradient operator, which takes values of a scalar field in the mesh vertices and computes the vector-element representation of its gradient. Loosely speaking, the argument for using this projection is the following: For example, let the linear equation $Ax = b$ represent the discretization of a PDE problem originating from the vector Helmholtz equation

$$\nabla\times(a\nabla\times\mathbf{E}) + c\mathbf{E} = \mathbf{F}$$

for the unknown vector field $\mathbf{E}$, where a and c are scalars, and $\mathbf{F}$ is some right-hand side vector. Standard preconditioners/smoothers cannot smooth the error in the null space of the operator $\nabla \times (a\nabla \times .)$. This null space is the range of the gradient operator. This algorithm adds a correction $\mathbf{E} \rightarrow \mathbf{E} + \nabla\phi$ to the standard SOR smoothed solution (or residual), where it computes ϕ from SOR iterations on a projected auxiliary problem. The projected problem is obtained by taking the divergence (or discretely $-T^T$) of the Helmholtz equation and plugging in the correction. You then obtain

$$-\nabla \cdot (c\nabla\phi) = -\nabla \cdot \mathbf{F}$$

(for clarity, boundary constraints are disregarded), which, if c is definite (strictly positive or strictly negative), is a standard elliptic type of equation for the scalar field ϕ.

When using this algorithm as a smoother for the multigrid solver/preconditioner, it is important — for the correct discrete properties of the projected problem — to generate nested meshes. Also, it performs an element assembly on all mesh levels (controlled by the multigrid **Assemble on all levels** checkbox). You can generate nested meshes through manual mesh refinements or do so automatically by selecting **Refine mesh** from the **Hierarchy generation method** list in the **Multigrid** node.

The projection matrix T is computed in such a way that nonvector shape functions are disregarded, and you can therefore use it in a multiphysics setting. It can also handle contributions from different geometries. Nonvector

shape function variables are not affected by the correction from the projected system, and the effects on them are the same as when you apply the standard SOR algorithm.

The Sparse Approximate Inverse (SAI) Preconditioner

The goal of the *sparse approximate inverse* (Sparse Approximate Inverse (SAI)) preconditioner is to construct a preconditioner matrix M that is an approximate inverse of the system matrix A. The matrix is constructed by solving the minimization problem

$$\min_M \|I - AM\|_F^2 = \min_M \sum_i \|e_i - Am_i\|_2^2 = \sum_i \min_{m_i} \|e_i - Am_i\|_2^2 \tag{20-59}$$

This problem is easily parallelizable because the problems are independent for each column m_i, but because each problem involves solving the equation $Am_i = e_i$, it is costly to construct the matrix M. In general, the resulting matrix M is dense. This problem is circumvented by constructing an approximation to M. The goal of the approximation matrix is that it should be sparse. One way of achieving this goal is to predefine a sparsity pattern for M with an associated index set I. Then the problem is reduced to

$$\min_{p(I_i)_i} \| e_i - Ap(I_i)_i \|_2^2 \tag{20-60}$$

where I_i is the index set for column i. Because A is sparse and p_i is zero for all entries that are not part of the index set I_i, there is a corresponding index set J_i that defines the row to solve for. Therefore, the original problem is reduced to a least-squares problem

$$\min_{p(I_i)_i} \| e(J_i)_i - A(J_i, I_i)p(I_i)_i \|_2^2 \tag{20-61}$$

for each column p_i in P. The index set can be chosen as the one of the system matrix or of a power of the system matrix. Symmetric problems can be treated using the symmetrization $(P+P^T)/2$.

The Vanka Algorithm

The algorithm is a local smoother/preconditioner of Vanka type. It is based on the ideas in Ref. 27, Ref. 41, and Ref. 42. It is possible to describe it as a block SOR method, where the local coupling of the degrees of freedom (DOFs) determines the blocks. The important idea in this algorithm is to use Lagrange multiplier variables to form the blocks. For illustration purposes, consider the Navier–Stokes equations. For these equations the pressure variable plays the role of Lagrange multiplier. The linearized equations on discrete form have the following structure:

$$A\begin{bmatrix} U \\ P \end{bmatrix} = \begin{bmatrix} S & D^T \\ D & 0 \end{bmatrix}\begin{bmatrix} U \\ P \end{bmatrix} = \begin{bmatrix} F \\ G \end{bmatrix}$$

where U and P are the velocity and pressure degrees of freedom, respectively. The algorithm loops over the Lagrange multiplier variable DOFs (here the pressure DOFs P_j) and finds the direct connectivity to this DOF. To do so, the algorithm locates the nonzero entries in the matrix column corresponding to P_j. The row indices of the nonzero entries define the DOFs U_k, and the algorithm forms a local block matrix based on this connectivity:

$$A_j = \begin{bmatrix} S_j & D_j^T \\ D_j & 0 \end{bmatrix}$$

One *Vanka update* loops over all P_j and updates

$$\begin{bmatrix} U_j \\ P_j \end{bmatrix} \leftarrow \begin{bmatrix} U_j \\ P_j \end{bmatrix} + \omega A_j^{-1} \left(\begin{bmatrix} F \\ G \end{bmatrix} - A \begin{bmatrix} U \\ P \end{bmatrix} \right)_j$$

where the $(.)_j$ denotes the restriction of a vector to the rows corresponding to the block j. ω is a relaxation parameter. The algorithm does not form the inverses of the block matrices explicitly. Instead, it computes the Vanka update with a LAPACK direct solver or a GMRES iterative method subroutine call. The GMRES method is the restarted GMRES without preconditioning. The algorithm relies on the fact that it is possible to invert the submatrices A_j. If it is not possible, the algorithm gives an error message. A zero on the diagonal of A or A_j is not necessarily a problem for this updating strategy. In general, the Vanka update does not necessarily update all DOFs. This is the case for problems with weak constraints, where only a small subset of the problem's DOFs are directly coupled to the Lagrange multipliers for the constraints. Another example is the Navier–Stokes equations coupled to other equations, but where the coupling is not directly through the pressure variable (in the k-ε turbulence model, for example). The Vanka algorithm automatically detects DOFs that are not updated by the above Vanka updating procedure and performs, for each Vanka update, a number of SSOR sweeps for these DOFs. This part of the algorithm is the *SSOR update*; it only works for a submatrix that has a nonzero diagonal. Just as the SOR and Jacobi preconditioner algorithms, this algorithm gives an error message if it finds zeros on the diagonal for the DOFs in the SSOR update.

Complex Shifted Laplacian for Large Helmholtz Problems

Large high-frequency free-space Helmholtz equations in, for example, acoustic and RF models can be difficult to solve with the usual iterative solvers such as multigrid and domain decomposition A method to solve such problems is to solve them with a complex wave number as a preconditioner for a Helmholtz equation without damping, thereby modifying the equation for the preconditioner in such a way that the convergence rate is improved. This strategy is called the *complex shifted Laplacian* (CSL) (even though it is not the Laplacian that is shifted), and it uses the following method:

Consider Helmholtz equation where the linear equation comes from the discretization of the equation

$$-(\Delta + k^2)u = f$$

The preconditioner matrix for the CSL preconditioner M_β is given by the discretization of the equation

$$-(\Delta + (k^2 + i\beta))u = 0$$

where you choose a value of β such that you get evanescent wave solutions. Instead of solving the original system of equation, you now solve

$$M_\beta^{-1} A x = M_\beta^{-1} b$$

when using left preconditioning (or the corresponding equation for right preconditioning).

You can activate complex shifted Laplacian for the following iterative solvers: Multigrid (GMG, and on multigrid levels for AMG) and Domain Decomposition (Schwarz). For details, see the documentation for those solvers.

The WENO Limiter

When computing discontinuous solutions to conservation laws, spurious oscillations and instabilities might arise. For controlling oscillations around discontinuities and stabilizing the computations of typically nonlinear conservation laws, a *WENO (weighted essentially nonoscillatory) limiter* (Ref. 43) is implemented for use in the

discontinuous Galerkin method. WENO is available for the Wave Form PDE and Compressible Euler Equations interfaces.

In order to save computational cost, the WENO limiter is applied where deemed needed. To this end a TVB (total variation bounded) troubled cell indicator is used. You can specify the TVB constant. A larger value means that a smaller number of cells will use WENO.

To avoid generating significant oscillations in the numerical solution, the WENO limiter is applied in each inner stage of a Runge–Kutta scheme. The third-order SSP (strong stability preserving) Runge–Kutta is recommended and is the default for the Compressible Euler Equations interface.

Numerical simulation of the compressible Euler equations might for stability require both a limiter for shocks and a positivity limiter of density and pressure. Together with the WENO limiter it is possible to enforce pressure and density positivity for the Compressible Euler Equations interface. The positivity limiter based on Ref. 44 is active by default and can be controlled by the **Positivity-preserving limiter for density and pressure** checkbox.

Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation)

The **Adaptive Mesh Refinement** node ( ) is a solver attribute that handles adaptive mesh refinement together with a Stationary Solver or Eigenvalue Solver. For information about the time-dependent **Adaptive Mesh Refinement** node, see Adaptive Mesh Refinement (Time-Dependent Adaptation) below.

For stationary and eigenvalue solvers, the **Adaptive Mesh Refinement** node cannot be added manually but is instead added by the solvers to indicate that they run an adaptive mesh refinement. The **Adaptive Mesh Refinement** node then only includes an **Output** section with information about the adaptation solutions and meshes.

GENERAL

The **Defined by study step** list shows the study step from which the main settings for adaptive mesh refinement are taken. Depending on the settings in the study step, some settings below are not available because they are specified in the study step's settings. Choose **User defined** to define all adaptive mesh refinement setting here.

Use the **Adaptation in geometry** list to specify that geometry. If you have specified the geometry in the stationary or eigenvalue study step, which appears in the **Defined by study step** list above, this list is not available.

From the **Solution selection** list, select which solution that should be used to evaluate error estimates:

- Select **Use last** (the default for all study types except Eigenvalue) to use the last solution.
- Select **Use first** to use the first solution.
- Select **All** (the default for Eigenvalue studies) to use all solutions from that study.
- Select **Manual** to use a specific solution number that you specify as solution indices in the **Indices** field.

In the **Weights** field (only available when **Solution selection** is **Manual** or **All**), enter weights as a space-separated list of positive (relative) weights so that the error estimate is a weighted sum of the error estimates for the various solutions (eigenmodes). The default value is 1, which means that the weight is put on all solutions (eigenmodes). If the number of weights is larger than 1 but less than the number of solutions, the omitted weights are treated as zero weights.

The **Save solution on every adapted mesh** checkbox is selected per default. Clear this checkbox if you do not want to save solution on every adapted mesh. In that case, the last two solutions are saved (the finest one and the second finest) regardless of the total number of solutions.

Under **Mesh adaption**, the following settings are available.

Use the **Adaptation method** list to control how to adaptively refine mesh elements. Select one of these methods:

- **General modification**, to use the current mesh as a starting point and modify it by refinements, coarsening, topology modification, and point smoothing. Use the **Allow coarsening** checkbox to control if mesh coarsening is used. If the mesh contains anisotropic elements (for example, a boundary layer mesh), it is best to disable mesh coarsening to preserve the anisotropic structure. If you have selected to allow coarsening, specify the **Maximum coarsening factor** (a value of 5 by default) to scale the refined mesh size in the regions where refinement is not needed.
- **Rebuild mesh**, to set up a size expression describing the error and rebuild the meshing sequence using the size expression as input. Note that structured meshes, such as mapped and swept meshes, in general are not appropriately refined. This method is not supported on imported meshes. The size of the refined mesh is the minimum of the size of the original mesh (previous refined mesh) and the size defined by the refinement. Specify the **Maximum coarsening factor** (a value of 3 by default) to scale the refined mesh size in the regions where refinement is not needed.
- **Regular refinement**, to make the solver refine elements in a regular pattern by bisecting all edges of an element that needs refinement.
- **Longest edge refinement**, to make the solver refine only the longest edge of an element by recursively bisecting the longest edge of edge elements that need refinement. This method is less suitable for models with nonsimplex elements. This is the default method.

For all adaptation methods except **Rebuild mesh**, you can specify the maximum number of refinements of the mesh elements (default: 5) in the **Maximum number of refinements** field.

Use the **Element selection** list to specify how the solver should select which elements to refine. Select:

- **Rough global minimum** to minimize the error by refining a fraction of the elements with the largest error in such a way that the total number of elements increases roughly by the factor specified in the accompanying **Element count growth factor** field. The default value is 1.7, which means that number of elements increases by about 70%.
- **Fraction of worst error** to refine elements whose local error indicator is larger than a given fraction of the largest local error indicator. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the fraction contains the elements with more than 50% of the largest local error.
- **Fraction of elements** to refine a given fraction of the elements. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the solver refines about 50% of the elements.

Use the **Maximum number of elements** field to specify the maximum number of elements in the refined mesh. If the number of elements exceeds this number, the solver stops even if it has not reached the number specified in the **Maximum number of adaptations** field. The default value is 10,000,000 (ten million) elements.

With the **Goal-oriented termination** set to **Auto** or **Manual**, you can control the display of convergence from the adaptation when the **Output goal-oriented termination increments** checkbox is selected. It is possible to choose the plot window to display the convergence as well as the table to be used by the plot from the **Plot window** — select **New window** (the default) or **Graphics** — and **Output table** lists, respectively. If you choose **New** from the **Output table** list, two new tables are created, one for the adaptation convergence plot and one for providing verbose information.

Also choose the level of detail for the log from the **Goal-oriented termination log** list: **Minimal**, **Normal** (the default), or **Detailed**. Choose **Detailed** if you want to include the evaluations for all the parameters, frequencies, or eigenvalues in the log.

Use the **Maximum number of adaptations** field to specify the maximum number of adaptive mesh refinement iterations. The default value is 5 in 1D, 2 in 2D, and 1 in 3D. With the **Goal-oriented termination** set to **Auto**, the default value is set to 20 in 1D, 15 in 2D, and 10 in 3D.

OUTPUT

In this section you find information about the adaptation solutions and meshes, with the tags for the **Solution Store** and **Mesh** nodes for each level in the adaptive mesh refinement.

ADVANCED

If desired, select the **Use classic method for vector elements** checkbox to use the adaptive method from versions 6.0 and earlier, in which higher-order names of DOFs for vector elements are ignored in the residual calculation.

GEOMETRIC ENTITY SELECTION FOR ADAPTATION

See Common Study Step Settings.

Adaptive Mesh Refinement (Time-Dependent Adaptation)

The **Adaptive Mesh Refinement** node ( ) is a solver attribute that handles adaptive mesh refinement together with a Time-Dependent Solver or References for the Solution Operation Nodes and Solvers. The adaptive mesh refinement creates multiple meshes for segments of a time-dependent simulation. Also see The Adaptive Solver Algorithms and Error Estimation.

GENERAL

The software performs adaptive mesh refinement in one geometry only. Use the **Adaptation in geometry** list to specify that geometry. If you have specified the geometry in the time-dependent study step, which appears in the **Defined by study step** list above, this list is not available. Choose **User defined** from the **Defined by study step** list to enable the **Adaptation in geometry** list.

The following properties appear under **Time-interval control**:

- The **Time-interval length** can be controlled manually or automatically. Select **Manual** (default) or **Automatic**. If **Time-interval length** is **Automatic**, the algorithm strives to assume the given value for the fraction of maximum refinement (default value: 0.2) by controlling the size of the time interval. If this setting is defined by the study step, the **Time-interval length** list is not available. A value of zero means no refinement of the base mesh and a value of one means refinement everywhere using the maximum element refinements. The shortening and lengthening of the interval is determined by the interval reduction and growth factors described below.
- The value in the **Interval growth factor** (only available when **Time-interval length** is **Automatic**) field (default value: 2.0) determines how the solver increases the time interval length. A value of 2.0 makes the interval length twice as large as the previous interval length when increased.
- The value in the **Interval reduction factor** field (default value: 0.5) determines how the solver reduces the time interval length. A value of 0.5 makes the interval length half of the previous interval length when reduced.
- By default, the solver determines the **Interval length** (unit: s) automatically (only available when **Time-interval length** is **Manual**) using an interval length that gives a total of 10 intervals. The length of the time interval is the simulation time before a refinement of the mesh takes place. Select the checkbox to specify a user-defined time interval length in the field (default value: 0.1 s).

If the number of intervals (that is, the simulation time divided by the interval length) exceeds 100, the interval length specified here may not be respected. You can enforce such a large number of intervals by prescribing a minimal interval length in the **Minimal interval length** field (see below).

- By default, the solver determines the **Initial interval length** (unit: s) automatically (only available when **Time-interval length** is **Automatic**). The length of the initial time interval is the simulation time before the first

refinement of the mesh takes place. Select the checkbox to specify a user-defined time interval length in the field (default value: 0.1 s).

- By default, the solver also determines the **Minimal interval length** (unit: s) automatically. The minimal length of the time interval is the shortest possible simulation time without performing a mesh refinement. Click to select the checkbox to specify a user-defined minimal interval length in the field (default value: 0.01 s). The interval length is reduced according to the **Interval reduction factor** if the solver fails to converge with the current interval length, in which case the minimal interval length setting can be useful.

The following properties are available under **Mesh element control**:

Use the **Adaptation method** list to control how to adaptively refine mesh elements. Select one of these methods:

- **Longest edge refinement**, to make the solver refine only the longest edge of an element by recursively bisecting the longest edge of edge elements that need refinement. This method is less suitable for models with nonsimplex elements. This is the default method.
- **Regular refinement**, to make the solver refine elements in a regular pattern by bisecting all edges of an element that needs refinement.
- **General modification**, to use the current mesh as a starting point and modify it by refinements, coarsening, topology modification, and point smoothing. Use the **Allow coarsening** checkbox (selected by default) to control if mesh coarsening is used. If the mesh contains anisotropic elements (for example, a boundary layer mesh), it is best to disable mesh coarsening to preserve the anisotropic structure. If mesh coarsening is allowed, enter a **Maximum coarsening factor** (default: 5) if needed.
- **Rebuild mesh**, to set up a size expression describing the error and rebuild the meshing sequence using the size expression as input. Note that structured meshes, such as mapped and swept meshes, in general are not appropriately refined. This method is not supported on imported meshes. The size of the refined mesh is the minimum of the size of the original mesh (previous refined mesh) and the size defined by the refinement. Specify the **Maximum coarsening factor** (a value of 3 by default) to scale the refined mesh size in the regions where refinement is not needed.

If the adaptation method has been specified in the study step, the **Adaptation method** list is not available.

For the **Longest edge refinement** and **Regular refinement** adaptive mesh refinement methods, you can specify the maximum number of refinements of the mesh elements (default: 2) in the **Maximum number of refinements** field. The **Maximum number of refinements** field is only available if the **Element selection** list (see below) is set to **Rough global minimum**. If the **Time-interval length** is set to **Automatic**, you can also specify a value between 0 and 1 in the **Fraction of maximum refinement** field (default value: 0.2) for these adaptation methods. The value in the **Fraction of maximum refinement** field acts as a reference value for a measure of the amount of refinement that the automatic time interval control tries to achieve. In general, a smaller value will lead to shorter adaptation time intervals. See The Adaptive Solver Algorithm — Stationary and Eigenvalue Adaptation for more details on the measure of the amount of refinement. Based on initial data, the **Fraction of maximum refinement** value can be increased. If the value is increased this information will be printed in the log. Also, for these adaptation methods, select or clear the **Convert to simplex mesh** checkbox (the default is to not use this conversion).

Use the **Element selection** list to specify how the solver should select which elements to refine. Select:

- **Rough global minimum** to minimize the L_2 norm of the error by refining a fraction of the elements with the largest error in such a way that the total number of elements increases roughly by the factor specified in the accompanying **Element count growth factor** field. The default value is 1.7, which means that the number of elements increases by roughly 70%.

- **Fraction of worst error** to refine elements whose local error indicator is larger than a given fraction of the largest local error indicator. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the fraction contains the elements with more than 50% of the largest local error.
- **Fraction of elements** to refine a given fraction of the elements. Use the accompanying **Element fraction** field to specify the fraction. The default value is 0.5, which means that the solver refines about 50% of the elements with the largest local error indicator.

Select the **Store solution when new meshes are created** checkbox if you want to save the solution for all new adaptively refined meshes. If cleared, the adaptive mesh refinement solver will only store solutions and meshes for adaptation time intervals that contain requested output times. This option is useful if you have many time adaptation intervals but are only interested in a few output times.

ERROR ESTIMATION

Use the **Error estimate** list to control how the error estimate is computed.

For time-dependent adaptive mesh refinement you need to specify a user-defined error estimate. From **Error indicator** list, choose **Error indicator**, which is the default and the only option for time-dependent adaptation. You can add error expressions to the **Error expression** table below using the **Add** (+) button. The error expression can be any expression, including field variables and their derivatives, defined in the domain. This method will adapt the mesh where the error expression becomes large; the adaptation is typically not optimal. Select the **Active** checkbox for the error expressions that should be part of the error indicator. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons as needed to rearrange and remove error expressions.

You can also specify a range of sample points as an array of real numbers between 0 and 1 for the error estimation in the **Sample points** field. This array controls where to check the error in the next subinterval. For background information to help with this section, see The Adaptive Solver Algorithms and Error Estimation.

RESTART

After each mesh adaptation, the time integration is restarted and you can control the following time-stepping properties:

By default, the solver chooses an initial step automatically. Select the **Initial step** checkbox for manual specification of an initial step.

Use the **Consistent initialization** list to control how the solver performs consistent initialization of differential-algebraic systems by selecting **Off** (the default), **On**, or **Backward Euler**.

OUTPUT

This section contains information about the solution and mesh that contain the results from the adaptive mesh refinement.

GEOMETRIC ENTITY SELECTION FOR ADAPTATION

See Common Study Step Settings.

- The Adaptive Solver Algorithms and Error Estimation
- Adaptive Mesh Refinement (Utility Node)
- The Log Window

Implementing a Point Source: Application Library path **COMSOL_Multiphysics/Equation_Based/point_source**.

Advanced

The **Advanced** node ( ) is an attribute node that handles advanced settings for solver nodes, such as a Stationary Solver, Eigenvalue Solver, and Time-Dependent Solver. Also see About the Advanced Attribute Settings.

GENERAL

Matrix Symmetry

Use the **Matrix symmetry** list to control how the solver handles matrix symmetry of linear system matrices. Select:

- **Automatic** to perform automatic symmetry detection. Both symmetric and Hermitian matrices can be detected.
- **Nonsymmetric** to override the automatic symmetry detection and force the solver to assume that matrices are nonsymmetric.
- **Symmetric** to override the automatic symmetry detection and force the solver to assume that matrices are symmetric.

Selecting **Symmetric** for a problem that does not result in symmetric matrices leads to an incorrect solution. See Which Problems are Symmetric? for information.

- **Hermitian** to override the automatic symmetry detection and force the solver to assume that matrices are Hermitian.

Matrix Format

Jacobian matrices requested by the solvers during solution can be stored in a *sparse* or a *filled* format, which you choose as **Sparse** or **Filled**, respectively, from the **Matrix format** list. In addition, you can choose a matrix-free format, which you choose as **Free**. The matrix-free representation allows evaluation of matrix-vector products without assembling the matrix. This can reduce the memory usage significantly for solver algorithms that only use the matrix to multiply a vector, specifically:

- The Iterative solver without preconditioner
- The Krylov Preconditioner without preconditioner

A warning is issued when the matrix-free format is used with other solvers. COMSOL Multiphysics then assembles the matrix when needed but does not store it between repeated requests from the solver algorithm. This may reduce peak memory usage at the cost of multiple assembly calls.

The default setting is **Automatic**. This setting chooses a sparse, filled, or matrix-free representation based on the equations being assembled and the solver used.

Row Equilibration

Even if variables are well scaled, equations can have very different scales. The **Row equilibration** checkbox is selected to balance the equations using row equilibration. Even when this checkbox is selected, row equilibration is not used in the following situations in order to preserve matrix symmetry:

- Automatic matrix symmetry detection is used and the system matrices are symmetric.
- **Symmetric** or **Hermitian** is selected in the **Matrix symmetry** list.
- The conjugate gradients or geometric multigrid solver is used.
- The eigenvalue solver is used.

Null-Space Function

Use the **Null-space function** list to select a method for the computation of matrices needed for constraint handling (see Elimination Constraint Handling). Select:

- **Automatic** to let the software automatically determine the most appropriate method, which uses an explicit handling of nodal constraints and the Hybrid method for the remaining constraints.
- **Orthonormal** to compute the needed matrices using singular value decomposition.
- **Sparse** to handle constraint matrices with nonlocal couplings using a sparse algorithm.
- **Explicit — Orthonormal** to handle constraints by explicitly eliminating the DOFs on the destination side of the explicit constraints. The remaining constraints are handled using the Orthonormal method.
- **Explicit — Sparse** to handle constraints by explicitly eliminating the DOFs on the destination side of the explicit constraints. The remaining constraints are handled using the Sparse method.
- **Hybrid** to sort constraints into mutually independent constraint blocks first. The blocks that exceed the *Orthonormal Block Limit* are handled with a sparse algorithm while the remaining blocks are handled by SVD.

Explicit constraints are obtained when the Nodal constraint method is used for boundary conditions like Periodicity and Continuity on boundary pairs.

Orthonormal Block Limit

For the Automatic and Hybrid null-space function methods, you can specify an **Orthonormal block limit**, which is used in the automatic choice between Orthonormal and Sparse handling for constraint blocks. If an estimate of the complexity (the number of operations) needed to SVD factorize a constraint block exceeds this limit, the Sparse method is used. Else the Orthonormal method is used. The limit is 10^7 per default. To SVD factorize a block with this complexity is usually fast, so you might want to increase this limit for increased constraint handling stability. To change the value of the orthonormal block limit, use the slider or enter a value in the text field. A small value is more efficient while a large value is more robust.

Store Last Residual

You can store the last residual while solving and also in the solver output, if you want to access it using the `residual` operator during postprocessing. Storing the residual in the output increases the memory requirements for the simulations. From the **Store last residual** list, choose one of the following options:

- **Off** (the default), to not store any data for the latest assembled residual.
- **While solving**, to make the last residual available while solving.
- **While solving and in output**, to make the last residual available while solving and also in the solver's output so that you can access it during postprocessing.

Solver Log

The solver log contains information about the progress and convergence of the solvers (see The Log Window). From the **Solver log** list, choose one of the following formats:

- **Minimal**, which reports a minimal amount of information (for example, warnings and nonstandard feedback). The normal output (once per "step" and so forth) is turned off.
- **Normal** (the default), which reports information about the main solver (the time-dependent solver, for example).
- **Detailed**, which reports information about the main solver and also information about the solver on the level below (a nonlinear stationary solver, for example).

For the time-dependent solvers, you can also specify an interval for the log sampling (in seconds) in the **Log sampling (wall-clock)** field when the **Solver log** list is set to **Normal**. The default is 0.005 s, which means that the log is updated at most every 0.005 s. Increasing the sampling interval can reduce the overhead associated with the log when solving problems with many small time steps. Set the value to 0 to make the log contain every time step regardless of their size.

Recovery File Saving

From the **Recovery saving** list, choose **From preferences** (the default), **On every iteration**, or **Saving ratio**. If you chose **Saving ratio**, also enter a ratio in the **Recovery saving ratio** field (default: 0.1; that is, saving every 10:th iteration). The recovery saving ratio is a number between 0 and 1.

From the **Force save of recovery file** list, choose **From preferences** (the default) or **Manual**. If you chose Manual you can specify a time interval (in seconds) for how often to force a save of the recover file in the **Save every** field (default: 1800 s; that is, once every half hour). This time interval is the longest time that is allowed to pass before the recovery file is saved while computing.

Other Settings

When the **Automatic rescaling of linear equations** checkbox is selected, then under certain circumstances the scaling of the equations for the linear solvers can be changed to scales that are taken from the current solution. These circumstances are the following:

- A stationary main solver
- Constant damping
- Automatic scaling for a field, and the scale for this field is changed significantly (about a 100 times).

When this happens, COMSOL Multiphysics adds a printout of the new scales to the solver log.

ASSEMBLY SETTINGS

This section contains some settings related to the assembly process when computing a solution.

By default, the solver chooses the number of mesh elements that are processed together during the assembly process (the block size). Select the **Assembly block size** checkbox for manual specification of a block size.

If **Use distributed solution for assembly** is set **On**, the assembly will rely on a local subset of data from the distributed solution vector when running in a distributed mode. This is suitable for models with only local contributions in assembly because it reduces the communication overhead. Evaluation of nonlocal terms (such as a *spatial at* operator or extrusion coupling operators) during assembly with this option activated can result in an error message requesting disabling of this option. The default setting, **Automatic**, sets this functionality to on or off depending on the type of model.

Select the **Reuse sparsity pattern** checkbox to store the sparsity patterns of the assembled matrices and try to reuse them for successive assembly processes within the same solution process. In many cases, the sparsity pattern of the system matrices does not change from one nonlinear iteration or time step to the others. Reusing the sparsity pattern from the previous iteration or step can then improve the solution performance at the cost of a usually small amount of memory. This functionality is enabled by default when using physics interfaces that can benefit from it. When active, the functionality can also detect whether the stored pattern cannot be used in the current assembly process (that is, when a "pattern mismatch" occurs) and reassemble it. If such a mismatch occurs, a message is added to the solver log. Pattern mismatches have no consequence on the solution process except for a small impact on the assembly performance during the current step or iteration due to the reassembling. Pattern mismatches can occur, for example, when solving a model with identity pairs and sliding meshes. If you know an expression for which the sparsity pattern needs to be recomputed when it is changed, you can switch from using the default **Automatic** method to using **Keep while expression is constant** instead, from the **Method** list. The expression that you enter in the **Expression** field for the **Keep while expression is constant** option is expected to be possible to evaluate globally and is not allowed to be solution dependent. For instance, in some time-dependent problem with many nonlinear iterations at each time step, `t` could be such an expression. Using the **Keep while expression is constant method**, the pattern will be recomputed when the expression has changed value more than 10^{-12}.

When the **Optimize data locality on cluster** checkbox is selected (the default), the mesh element assignment for processing on different cluster nodes is optimized to reduce data communication.

Select the **Use thread scheduling for matrix assembly** checkbox to assign the same blocks of elements to the same core each time a matrix is assembled. This type of assembling can have advantages for data management.

Select the **Use static distribution of assembly blocks** checkbox to force the assembly blocks to have a deterministic distribution between threads. This leads to numerically more stable results. For certain types of models, the load balancing can be worse, so use this option mainly when you run simulations where computing multiple times results in a nondeterministic behavior.

Select the **Allow complex-valued output from functions with real input** checkbox to control whether the solver treats such complex-valued output as an error or not.

The **Stop when undefined mathematical operation is detected** checkbox controls how the solver handles undefined mathematical operations such as division by zero. It is selected by default.

Select the **Check for undefined numerical values after each operation** checkbox to make COMSOL Multiphysics check intermediate results for undefined numerical values (Inf or NaN) when numerical overflow occurs, for example. Selecting this option gives more accurate error messages when such undefined numerical values occur.

The **Optimize element data initialization** checkbox is selected by default to make some elements (components of the discretization of the problem) try to optimize parallelization of their initialization. Currently, this is only implemented for contact problems and reduced-order modeling. The optimization can be turned off by clearing the **Optimize element data initialization** checkbox.

If desired, modify the drop tolerance in the **Drop tolerance for local matrix contributions** field (default value: $1 \cdot 10^{-12}$). For semiconductor simulations, the default solver settings will use 0 as a value for the drop tolerance for local matrix contributions, which is a drop tolerance that is better suited for such simulations.

Select the **Manual control of reassembly** checkbox to be able to override the solver mechanism that automatically detects which quantities need to be reassembled. This can be useful to improve efficiency in situations when the automatic mechanism is too sensitive and reassembles quantities that do not need to be reassembled.

Constant Load

If the **Manual control of reassembly** checkbox is selected, the **Constant load** is **On** by default.

The load (residual vector) is constant if the PDE and the Neumann boundary conditions are linear with time-independent coefficients and right-hand sides. For the discretized model, this means that the residual vector L depends linearly on U:

$$L = L_0 - KU - D\dot{U} - E\ddot{U}$$

and that L_0, K, D, and the mass matrix E are constant.

If you choose to turn **Off** the **Constant load**, it instructs the solver to perform a reassembly process for the computation of the residual vector (when **Off**) or not. However, even if it is off, you might still want to treat some of the matrices as constant. Manual control of reassembly of these quantities can be controlled with the available checkboxes, which makes the assembly only occur once for the corresponding matrix.

- Select the **Constant stiffness** checkbox to treat the stiffness matrix K as constant.
- Select the **Constant damping or mass** checkbox if you want to treat the coefficients of the first-order time-derivative terms or the second-order time-derivative terms as constant. In the discretized model, this means that the damping (sometimes called mass) matrix D or the mass matrix E is treated as constant.
- Select the **Constant mass** checkbox to treat the mass matrix E as constant.

Constant Constraint

If the **Manual control of reassembly** checkbox is selected, you can control reassembly of the constraint residual. By default the **Constant constraint** is **On**. The constraint is constant if the Dirichlet boundary conditions (constraints)

are linear and time independent. For the discretized model, this means that the constraint residual M depends linearly on U ($M = M_0 - NU$) and that M_0 and N are constant. It is also assumed that the constraint Jacobian N is correct.

If you choose to turn **Off** the **Constant constraint**, it instructs the solver to perform a reassembly process for the computation of the constraint residual vector (when **Off**) or not. However, even if it is off, the constraint Jacobian might still be constant. To control the reassembly of this quantity, select the **Constant constraint Jacobian** checkbox if the Dirichlet boundary conditions are linear with time-independent coefficients (not right-hand side). For the discretized model this means that N is constant.

AMG Coarse Solver

The **AMG Coarse Solver** node ( ) is an auxiliary attribute subnode used by the Auxiliary-Space AMG attribute nodes This node does not have any settings. Instead, its purpose is to administrate coarse grid solvers for an auxiliary-space AMG solver. To add a solver, right-click the **AMG Coarse Solver** node.

AMG Postsmoother

The **AMG Postsmoother** node ( ) is an auxiliary attribute node used by the Auxiliary-Space AMG attribute node. This attribute does not have any settings. Instead, its purpose is to administrate postsmoothers for an auxiliary-space AMG solver. To add a postsmoother, right-click the **AMG Postsmoother** node.

AMG Presmoother

The **AMG Presmoother** node ( ) is an auxiliary attribute node used by the Auxiliary-Space AMG attribute node. This attribute does not have any settings. Instead, its purpose is to administrate presmoothers for an auxiliary-space AMG solver. To add a presmoother, right-click the **AMG Presmoother** node.

Automatic Remeshing

The **Automatic Remeshing** node ( ) is an attribute that adds automatic remeshing. The remeshing occurs when the mesh quality falls below a specified value. It is added if you have selected the **Automatic remeshing** checkbox for an auxiliary sweep in the **Study Extension** section in the settings for a Stationary study step, for example. It can also be used together with The Moving Mesh Interface to assure a satisfactory mesh quality throughout the simulation. Right-click a Time-Dependent Solver operation node to add it.

	AutoRemesh in the *COMSOL Multiphysics Programming Reference Manual.*

GENERAL

The software only performs automatic remeshing in one geometry. Use the **Remesh in geometry** list to specify that geometry if the model contains more than one geometry.

CONDITIONS FOR REMESHING

From the **Condition type** list, choose between different types of conditions for when remeshing should occur. Select:

- **Mesh quality** (the default). The solver remeshes when the mesh quality becomes less than a given limit. Edit the **Mesh quality expression** as needed, or click the **Replace Expression** button ( ) to choose another expression. Edit the limit in the **Stop when mesh quality is below** field (default value: 0.2).

- **Distortion**. The solver remeshes when the distortion that the mesh has undergone becomes larger than a given limit. Edit the **Distortion expression** or click the **Replace Expression** button ( ) and choose another expression for the distortion if desired. Edit the limit in the **Stop when distortion exceeds** field (default: 2) if desired. The condition for stopping is (for a model component called `comp1`)

  ```
  sqrt(comp1.material.I1isoMax) > 2
  ```

  The variable `comp1.material.I1isoMax` is the (nonnegative) first invariant of the isochoric Green–Lagrange strain, E_{iso}, defined as

  $$I_1(E_{\text{iso}}) = \text{tr}\frac{1}{2}\left(\frac{F^T F}{J^{2/n}} - I\right) = \frac{\text{tr}F^T F}{2J^{2/n}} - \frac{n}{2}$$

  where F is the deformation gradient, J its determinant, and n is the space dimension. When the distortion is small, the following approximation is applicable:

  $$I_1(E_{\text{iso}}) \approx 2I_2(E_{\text{dev}}) \approx 2I_2(\varepsilon_{\text{dev}}) = \sum_{i<j}\frac{1}{n}(\varepsilon_i - \varepsilon_j)^2 + 2\varepsilon_{ij}^2$$

- **General**. The solver remeshes when a logical condition becomes true. Edit the condition in the **Stop when condition is true** field or click the **Replace Expression** button ( ) and choose another expression.
- **Specified times**. The solver remeshes at the specified times that you enter in the **Remeshing times** field. Use the **Range** button ( ) if desired to specify a range of times.
- **Specified time step**. The solver remeshes after a specific time step, which you enter in the **Remeshing time step** field. If desired, click the **Replace Expression** button ( ) to choose an expression to use. The time step can be a constant, a parameter, a variable, or a function in the model.

The **Remesh at** setting determines which previous solution is used for the remeshing:

- When **Last output from solver before stop** is selected, the remeshing is done on the last solution that would have been stored by the solver if remeshing would not have occurred. This setting discards any solver progress done since the last output.
- When **Last step taken by solver before stop** is selected (the default), the remeshing is done using the solution from the last solver step before the condition for remeshing became fulfilled. Only the very last solver step, at which the condition was triggered, is discarded. Typically, this setting is preferred because then the progress of the automatic remeshing does not depend on the solver's list of output times.

REMESH

After each remeshing, the time integration is restarted and you can control the following time-stepping properties.

By default, the solver chooses an initial step automatically. Select the **Initial step** checkbox to enter a different value (SI unit: s).

To control how the solver performs **Consistent initialization** of differential-algebraic systems, select **Off** (the default), **On**, or **Backward Euler** from the list.

Select the **Store solution when new meshes are created** checkbox if you want to save the solution for all new meshes. If cleared, the automatic remeshing solver will only store solutions and deformed configurations for time intervals that contain requested output times. This option is useful if you have many remeshing times but are only interested in a few output times.

OUTPUT

This section contains information about which solution and meshes contain the results from the automatic remeshing node.

Auxiliary-Space AMG

The **Auxiliary-Space AMG** node ( ) is an attribute that handles parameters for linear system solvers and preconditioners that use the auxiliary-space AMG solver. Right-click an Iterative, Krylov Preconditioner, or Coarse Solver node to add an **Auxiliary-Space AMG** node.

The auxiliary-space AMG iterative solver is suitable for solving complex-valued RF problems and other electromagnetics simulations that use vector elements (Nédélec elements); see Ref. 45. Compared to the Auxiliary-Space Maxwell (AMS) solver, it has the following advantages:

- Complex arithmetic is supported.
- More intermediate smoothers are available, which makes it possible to, for example, use Auxiliary-Space AMG when a gauge feature is used or in general to use it combined with Vanka smoothers.

The Auxiliary-Space AMG is an implementation of AMS, except for the matrix S that, which in AMS is the Gauss–Seidel smoother; in Auxiliary-Space AMG it is more general and can be any available smoother in the COMSOL Multiphysics software (including Gauss–Seidel).

The **Settings** window contains the following sections:

GENERAL

Use the **Termination technique** list to control how the iterations of the auxiliary-space AMG solver are terminated. Select:

- **Use tolerance** to terminate the iterations when the estimated relative error is smaller than a specified tolerance. Then enter the **Maximum number of iterations** to limit the number of iterations. When the maximum number of iterations have been performed, the auxiliary-space AMG solver is terminated even if the tolerance is not fulfilled.
- **Fixed number of iterations** to specify the number of iterations of the auxiliary-space AMG solver in the **Number of iterations** field. The default is 2.
- **Iterations or tolerance** to terminate the auxiliary-space AMG solver iterations when the estimated tolerance is smaller than a specified tolerance or after a specified number of iterations, whichever comes first. Then enter the **Number of iterations** to specify a fixed number of iterations to perform and a tolerance to use in the **Relative tolerance** field (default: 0.1).

In the **Variables** field, add the applicable dependent variables that use vector elements and that you want to include in the auxiliary-space AMG solver. Use the **Delete** ( ) and **Add** (+) buttons to configure the list of variables.

From the **Cycle type** list, select one of the available auxiliary-space AMG cycle types 1–4 (the default is cycle type 1, a multiplicative solver that should work well in most cases; see Ref. 7 for details). These cycle types are various combinations of smoothing and applications of algebraic multigrid on decomposed problems, based on the subspace correction method with respect to three terms:

$$x \rightarrow x + S(b - Ax) \quad (1)$$

$$x \rightarrow x + G(A_G^{-1})G^T(b - Ax) \quad (2)$$

$$x \rightarrow x + \Pi(A_\Pi^{-1})\Pi^T(b - Ax) \quad (3)$$

Where *cycle type 1* corresponds to the sequence (1), (2), (3), (2), and (1); *cycle type 2* corresponds to the sequence (1), (2), (1), (3), (1), (2), and (1); *cycle type 3* corresponds to the sequence (1), (3), (2), (3), and (1); and *cycle type 4* corresponds to the sequence (1), (3), (1), (2), (1), (3), and (1). In the method above, G is a discrete gradient matrix, Π is a matrix representation of the interpolation operator from vector linear to edge finite elements, S is an intermediate smoother (or smoothing in the original edge space), and A is the (reduced) stiffness matrix usually denoted by K, and it is the matrix that is solved (that is, the method solves $Ax = b$). Auxiliary-space AMG consists in a subspace correction method with respect to the three correction terms G, Π, and S. The order in which these

corrections are applied is defined by the **Cycle type** (see above). The linear systems with the matrices G and Π are then solved with the algebraic multigrid or the smoothed aggregation AMG methods.

From the **Magnetostatics** list, select **Automatic** (the default), **Yes**, or **No**. The automatic case determines magnetostatics by comparing the maximum row sum of absolute values for the projected matrix T^TAT and A. Here T is the discrete gradient matrix; see documentation for SOR Vector. Magnetostatics is deduced if the projected matrix is negligible compared to A. If magnetostatics is deduced or chosen, auxiliary-space AMG skips the subspace corrections associated with the projected matrix T^TAT.

From the **Divergence cleaning** list, select **Automatic** (the default), **Yes**, or **No**. The automatic case is the same as for the determination of magnetostatics. In the magnetostatic case, auxiliary-space AMG should skip corrections associated with T^TAT and use divergence cleaning of the right-hand side. You can also manually specify the magnetostatics and divergence cleaning settings. This can be useful if divergence cleaning has already been made or if you suspect that the automatic detection fails.

ALGEBRAIC MULTIGRID

The action of A_G^{-1} and A_Π^{-1} are performed by calling the algebraic multigrid (AMG) solvers. The settings for the AMG solvers appear in this **Algebraic Multigrid** section. The settings for the presmoother, postsmoother, and coarse solver for the AMG solver are collected in the AMG Presmoother, AMG Postsmoother, and AMG Coarse Solver subnodes.

From the **Solver project problem** list, choose an AMG solver: **Algebraic multigrid** (the default) or **Smoothed aggregation AMG**. The smoothed aggregation AMG (SAAMG) solver works by clustering nodes of degrees of freedoms into aggregates based on a connection criterion. Each aggregate then becomes a new node on the next multigrid level, and the algorithm proceeds until a certain number of levels has been reached or until the number of degrees of freedoms is sufficiently small.

For either choice, enter the:

- In the **Number of iterations** field, enter the desired number of iterations (default: 1).
- Select a **Multigrid cycle**: **V-cycle** (the default), **W-cycle**, or **F-cycle**. For **Multigrid cycle**, the settings are the same as for the geometric multigrid (GMG) and algebraic multigrid (AMG) solvers.
- Enter the **Number of multigrid levels** to generate (the default is 1 for **Geometric multigrid** and 5 for **Algebraic multigrid**).
- Enter a **Maximum number of DOFs at coarsest level**. The default is 5000. Coarse levels are added until the number of DOFs at the coarsest level is less than the max DOFs at coarsest level or until it has reached the number of multigrid levels.
- Enter a **Minimum number of DOFs per thread on multigrid levels** (default: 5000) to control the size of the computation threads on a multicore computer.

The following settings control the algebraic multigrid algorithm:

Choose a **Coarsening method**: **Parallel modified independent set** (the default) or **Classical**. The **Parallel modified independent set** method makes the algebraic multigrid solver more efficient in distributed computing using the method described in Ref. 13. The **Classical** method corresponds to the implementation of AMG in COMSOL versions before version 6.0 (that is, Ruge–Steuben coarsening). See below for the settings for each coarsening method.

If you chose **Classical**, enter a value or use the slider to set the **Quality of multigrid hierarchy**. Higher quality means faster convergence at the expense of a more time-consuming setup phase. For instance, if the linear solver does not converge or if it uses too many iterations, try a higher value to increase the accuracy in each iteration, meaning fewer iterations. If the algebraic multigrid algorithm runs into memory problems, try a lower value to use less memory. The range goes from 1 to 10, where 10 gives the best quality. The default is 3.

If you chose **Parallel modified independent set**:

- Enter a value for the **Strength of connections** is a positive number, typically between 0.25 and 0.75 (default value: 0.25). This is a strength threshold used to determine the relation of strong influence dependence between the points. There is some indication that you should use a lower number, such as 0.25, for problems with denser matrices, whereas for other problems with sparser matrices you should use larger values, such as 0.75.

  Let A denote the system matrix and θ the strength threshold; a point i then depends strongly on j, or j strongly influences i if $-a_{ij} \geq \theta \max_{k \neq j} -a_{ik}$.
- The **Sparser prolongator** checkbox is selected by default. When interpolating the value of the error in a specific fine point "i", only the coarse points that strongly influencing "i" are used. If you clear the checkbox, all the coarse points that are influencing "i" are used.

  The interpolation formula, referred to as "direct interpolation", is given in equation 7 in Ref. 17. The prolongator is the matrix defining the interpolation operator between the coarse and fine grid. By selecting the **Sparser prolongator** checkbox, you achieve better performance per iteration (less memory and computation time) but the solver may require more iterations to converge.
- Use the **Prolongator truncation factor** (default: 0.1) to control the fill-in of the prolongator. Small elements from the prolongator are removed. More precisely, let P denote the prolongator and M the truncation factor, the element p_{ij} is removed if $\frac{|p_{ij}|}{\max_{0 \leq k \leq m} |P_{ik}|} \leq M$

  The rows of the truncated prolongator are rescaled afterward by following the reasoning in Section 7.2 of Ref. 18. More precisely, the sum of the ith row before and after truncation should not change.

The following settings control the smoothed aggregation algorithm:

- The aggregation algorithm is based on a connection criterion, which you specify as a coefficient in the **Strength of connections** field. A node j is connected to another node i, if $\|A_{ij}\| \geq \varepsilon \|A_{ii}\| \|A_{jj}\|$, where ε is the strength of connection coefficient, and A_{ij} is the submatrix of the stiffness matrix defined by the degrees of freedoms on node i and j, respectively. Loosely speaking, the strength of connection value determines how strongly the aggregation should follow the direction of anisotropy in the problem. The default value is 0.01.
- From the **Null-space vectors** list, choose **Constant** (the default) or **Rigid body modes**. For linear elasticity problems, always select **Rigid body modes** because it enhances the convergence properties significantly.
- Select the **Compact aggregation** checkbox to use an aggregation algorithm that forms, on average, smaller aggregates, which leads to a less rapid coarsening.
- Choose how to control the prolongator smoothing using the **Smoothing** list, which is active when the **Prolongator smoothing** checkbox (selected by default) is selected. The **Auto** option postpones the smoothing for `sdim-1` levels, where `sdim` is the space dimension of the problem. If you choose **Manual**, enter the level to start smoothing at in the **Start smoothing at multigrid level** field.
- The final transfer operator, P, between the fine and coarse problems are smoothed by one application of Jacobi smoothing:

$$P = (I - \omega D^{-1} A_F)\tilde{P}$$

  where ω is the *Jacobi damping factor*, A_F is the *filtered stiffness matrix*, and D is the diagonal of A_F. Specify ω in the **Jacobi damping factor** field. The default value is $2/3$.
- By default, the **Use filtering** checkbox is selected. Filtering means that entries in the stiffness matrix have been dropped if they correspond to degrees of freedoms on a node that has no strong connections. Loosely speaking, filtering highlights anisotropy in the problem and results in a sparser coarse level problem.

INTERMEDIATE SOR SMOOTHER

The action of S is performed by calling the smoothers available in the **Intermediate Smoother** section, where you also find the other settings for these smoothers. See the documentation for the smoothers for more information

about their specific settings. From the **Smoother** list, choose SOR (the default), SOR Vector, SCGS, SOR Line, Vanka, SOR Gauge, or Jacobi.

Specify the **Number of iterations** for the intermediate smoother. The default is 2.

The **Variables** list used in with the Vanka smoother is the same as the **Variables** list that otherwise appears in the **General** section; that list is therefore not visible in this case

LOWER ELEMENT ORDER

If the discretization is nonlinear, before using the auxiliary-space AMG solver, the order is lowered by using geometric multigrid (GMG). The smoothers and their settings, which are used by GMG to lower the order can be set in this section.

Under **Presmoother** and **Postsmoother**, choose a smoother from the **Smoother** list: SOR (the default), SOR Vector, or Vanka. Then from the **Solver** list, choose a compatible solver for the selected smoother. For **SOR** and **Vanka**, choose **SSOR**, **SOR**, or **SORU**; and for **SOR vector**, choose **SSOR vector**, **SOR vector**, or **SORU vector**.

For the remaining settings, see the documentation for the chosen presmoother and postsmoother.

HYBRIDIZATION

Use the settings in the **Hybridization** section to set up a hybrid preconditioner where the direct preconditioner is active for some dependent variables. See Hybrid Preconditioners for more information.

Auxiliary-Space Maxwell (AMS)

The **Auxiliary-Space Maxwell (AMS)** node ( ) is an attribute that handles parameters for linear system solvers/preconditioners that use the auxiliary-space Maxwell solver (AMS). Right-click an Iterative, Krylov Preconditioner, or Coarse Solver node to add an **Auxiliary-Space Maxwell (AMS)** node.

The AMS solver uses the auxiliary-space Maxwell solver preconditioner from the Lawrence Livermore National Laboratory linear solver/preconditioner library *hypre*, a software library of high-performance preconditioners and solvers (Ref. 6). AMS provides edge finite element discretization of variational curl-curl problem stemming from stationary or time-dependent Maxwell's equations. The version of AMS available in COMSOL Multiphysics is designed for the lowest-order edge elements. For higher-order discretizations, use it together with the geometric multigrid (GMG) solver with the option **Lower element order first** and a sufficient number of levels so that AMS can work efficiently as a coarse solver. For details, see Ref. 7.

The **Settings** window contains the following sections:

GENERAL

Enter the **Number of iterations** of the AMS solver. The default is 2.

In the **Variables** field, add the applicable dependent variables that use vector elements (such as magnetic scalar potential) and that you want to include in the AMS solver. Use the **Delete** ( ) and **Add** (+) buttons to configure the list of variables.

From the **Cycle type** list, select one of the available AMS cycle types 1–14 (the default is cycle type 1, a multiplicative solver that should work well in most cases; see Ref. 7 for details). These cycle types are various combinations of smoothing and applications of algebraic multigrid on decomposed problems.

From the **Magnetostatics** list, select **Automatic** (the default), **On**, or **Off**. The automatic case determines magnetostatics by comparing the maximum row sum of absolute values for the projected matrix T^TAT and A. Here T is the discrete gradient matrix; see documentation for SOR Vector. Magnetostatics is deduced if the projected

matrix is negligible compared to A. If magnetostatics is deduced or chosen, AMS skips the subspace corrections associated with the projected matrix T^TAT.

From the **Divergence cleaning** list, select **Automatic** (the default), **On**, or **Off**. The automatic case is the same as for the determination of magnetostatics. In the magnetostatic case, AMS should skip corrections associated with T^TAT and use divergence cleaning of the right-hand side. You can also manually specify the magnetostatics and divergence cleaning settings. This can be useful if divergence cleaning has already been made or if you suspect that the automatic detection fails.

HYBRIDIZATION

Use the settings in the **Hybridization** section to set up a hybrid preconditioner where the direct preconditioner is active for some dependent variables. See Hybrid Preconditioners for more information.

Block Navier–Stokes

Add a **Block Navier-Stokes** node ( ) under an **Iterative** solver node as an efficient preconditioner for the incompressible Navier–Stokes equations in the transient regime. This preconditioner is based on a block factorization of the Jacobian matrix problem coming from the Newton–Krylov approach to solve the time-and-space discretization of the incompressible Navier–Stokes equations. The Pressure Solver and Velocity Solver subnodes are always available for specifying general preconditioners for the pressure block and the velocity block, respectively.

MAIN

In the **Number of iterations** field, enter the desired number of iterations (default: 1). When the convergence rate is poor, using a larger number of iterations can be a more efficient alternative compared to spend more efforts in either the velocity or pressure solver.

From the **Schur complement approximation** list, choose one of the following options:

- **Velocity matrix diagonal** (the default)
- **Lumped velocity matrix**
- **Lumped mass matrix**
- **Absolute row-summed velocity matrix**
- **Absolute row-summed mass matrix**

The Schur complement approximation component H is then computed as $\mathrm{diag}(F)^{-1}$, $\bar{F}^{-1}$, $\sigma^{-1}\bar{D}^{-1}$, $|F|^{-1}$, and $\sigma^{-1}|D|^{-1}$, respectively, where the overline notation is used for row summation (also called lumping) and the vertical bar notation is used for absolute row summation. $F = \sigma D + K$ in the COMSOL Multiphysics formulation with implicit time stepping. In that equation, F is a convection-diffusion-like operator, D is the velocity mass matrix, and K is the "stiffness matrix" from the convection and dissipation (including optional stabilization). σ is a factor that is proportional to the inverse time step.

For practical large-scale computations, use of the exact Schur complement is not feasible. Instead an approximation is used based on $H \approx F^{-1}$, where H is diagonal. The Schur matrix S is then approximated as

$$S \approx \hat{S} = C + \hat{B}HB^T$$

where $\hat{B}$ is the divergence operator matrix, B^T is the gradient operator matrix, and C is an operator that stabilizes the finite element discretization.

For each new assembly of the Jacobian matrix, the building blocks are updated, and the subsequent solver gets their corresponding updates. For certain problems — for example, formulations that do not require stabilization — the

off-diagonal blocks are constant. For such formulations, and also for problems where the stabilization effect is small, a small performance benefit can be obtained by selecting the **Reuse off-diagonal matrix blocks** checkbox.

Enter a value between 0 and 2 in the **Pressure update relaxation factor** field (default: 0.95). See below for more information.

Under **Velocity variables**, click to add velocity variables, typically a velocity field from a fluid flow interface.

Under **Pressure variables**, click to add pressure variables, typically a pressure field from a fluid flow interface.

The **Velocity variables** and **Pressure variables** settings determine how the blocks are defined from the total Jacobian matrix. In cases where there are more variables than what is included in these settings solved for by the parent linear solver, the preconditioner will act like a hybrid preconditioner and only apply its action on the equations (residual) for the velocity and pressure variables. If you want updates for other variables, add another preconditioner and enable hybridization for them. Also, if the Navier–Stokes equations are formulated with other auxiliary equations that are of saddle-point type (for example, ODE variables for fully developed inlet boundary conditions), the corresponding variables should be added to the **Pressure variables**.

Each iteration j of the preconditioner applies the following operations and updates:

$$(\Delta U)'_{j+1} = F^{-1} r_{U,j}$$
$$(\Delta p)'_{j+1} = -\hat{S}^{-1}(r_{p,j} + \hat{B}(\Delta U)'_{j+1})$$
$$(\Delta U)_{j+1} = (\Delta U)_j - (\Delta U)'_{j+1} + HB^T(\Delta p)'_{j+1}$$
$$(\Delta p)_{j+1} = (\Delta p)_j - \omega(\Delta p)'_{j+1}$$

In the equations above, ω is the **Pressure update relaxation factor** and $r_{U,j} = f(\Delta U)_j + B^T(\Delta p)_j - L_U$, $r_{p,j} = \hat{B}(\Delta U)_j - C(\Delta p)_j - L_p$. The **Number of iterations** controls how many of these iterations are performed. When the preconditioner is used with one iteration, an optimal value for the **Pressure update relaxation factor** should be around 0.9. When the preconditioner is used with two iterations a relaxation around 0.4–0.5 is often needed for good performance.

The operations $F^{-1}, \hat{S}^{-1}$ are performed by the **Velocity Solver** and **Pressure Solver** subnodes, respectively. Those solvers can be chosen in the user interface. Algebraic multigrid solvers can be used. One of the benefits of the Block Navier–Stokes preconditioner is that standard SOR or SOR Line smoothers can be used for these multigrid solvers. Geometric multigrid is not supported.

HYBRIDIZATION

Use the settings in the **Hybridization** section to set up a hybrid preconditioner where the direct preconditioner is active for some dependent variables. See Hybrid Preconditioners for more information.

Coarse Solver

The **Coarse Solver** node ( ) is an auxiliary attribute subnode used by the Multigrid and Domain Decomposition (Schwarz) attribute nodes. This node does not have any settings. Instead, its purpose is to administrate coarse grid solvers for a multigrid solver. To add a solver, right-click the **Coarse Solver** node.

Control Field

The **Control Field** node ( ) is an attribute node that handles settings for field variables that are acting as control variables. Control variables have a special status when using the Sensitivity or Optimization solver. Each control field has a separate **Control Field** node. This attribute is used together with the Dependent Variables node.

GENERAL

The **Field components** section displays the variable names for the field components.

Use the **Solve for this field** checkbox to control whether to use this variable when solving a sensitivity or optimization problem. For other parts of the solution process, the control fields are held fixed. This setting is only available if the **Dependent Variables** node's setting **Defined by study step** is set to **User defined**. If the variable is not solved for, its values are determined by the settings in the **Values of Variables Not Solved For** section of the corresponding **Dependent Variables** node.

Use the **Store in output** checkbox to control whether to store the variable in any output solution or not. Clearing this checkbox saves memory by not storing the field if it is not needed for the postprocessing.

A variable can still be solved for despite not being stored in output and vice versa.

Control State

The **Control State** (p) node is an attribute node that handles settings for state variables that are acting as control variables. Control (state) variables have a special status when using the Sensitivity or Optimization solver. Each control state has a separate **Control State** node. This attribute is used together with the Dependent Variables node.

GENERAL

The **State Components** section displays the variable names for the state components.

Use the **Solve for this state** checkbox to control whether to use this variable when solving a Sensitivity or Optimization problem. For other parts of the solution process, the control variables are held fixed. This setting is only available if the **Dependent Variables** node's setting **Defined by study step** is set to **User defined**. If the variable is not solved for its value is determined by the settings in the **Values of Variables Not Solved For** section of the corresponding **Dependent Variables** node.

Use the **Store in output** checkbox to control whether to store the variable in any output solution or not.

A variable can still be solved for despite not being stored in output and vice versa.

Direct

The **Direct** node ( ) is an attribute that handles settings for direct linear system solvers. Use it together with a Stationary Solver, Eigenvalue Solver, and Time-Dependent Solver, for example. The attribute can also be used together with the Coarse Solver attribute when using multigrid linear system solvers.

An alternative to the direct linear system solvers is given by iterative linear system solvers which are handled via the Iterative attribute node. Several attribute nodes for solving linear systems can be attached to an operation node, but only one can be active at any given time.

Also see Choosing the Right Linear System Solver, which describes The MUMPS Solver, The PARDISO Solver, and The SPOOLES Solver.

GENERAL

Select a linear system **Solver**. Select:

- **MUMPS** (multifrontal massively parallel sparse direct solver) (the default).

- **PARDISO** (parallel sparse direct solver). See Ref. 2 for more information about this solver.
- **SPOOLES** (sparse object-oriented linear equations solver). See Ref. 3 for more information about this solver.
- **Dense matrix** to use a dense matrix solver. The dense matrix solver stores the LU factors in a filled matrix format. It is mainly useful for boundary element (BEM) computations.

MUMPS

For **MUMPS** it estimates how much memory the unpivoted system requires. Enter a **Memory allocation factor** to tell MUMPS how much more memory the pivoted system requires. The default is 1.2.

Select a **Preordering algorithm**: **Automatic** (the default automatically selected by the MUMPS solver), **Approximate minimum degree**, **Approximate minimum fill**, **Quasi-dense approximate minimum degree**, **Nested dissection**, or **Distributed nested dissection**.

Select the **Row preordering** checkbox (selected by default) to control whether the solver should use a maximum weight matching strategy or not. Click to clear the checkbox to turn off the weight matching strategy.

Select the **Reuse preordering** checkbox (selected by default) to reuse the reordering of the system, which speeds up the computation but leads to a higher memory peak.

The **Reuse preordering** option has a weak dependence on the system matrix. In extreme cases, this can cause the solvers to fail. If you suspect this is the problem, make sure that the **Check error estimate** setting is not set to **No** in the **Error** section below. Then, if the linear solvers fail and the preordering is old, a new preordering will be done.

The default **Use pivoting** is **On**, which controls whether or not pivoting should be used.

- If the default is kept (**On**), enter a **Pivot threshold** number between 0 and 1. The default is 0.01. This means that in any given column, the algorithm accepts an entry as a pivot element if its absolute value is greater than or equal to the specified pivot threshold times the largest absolute value in the column.
- For **Off**, enter a value for the **Pivoting perturbation**, which controls the minimum size of pivots (the pivot threshold). The default is 10^{-8}.

The perturbation strategy is not as robust as ordinary pivoting. In order to improve the solution, MUMPS uses iterative refinements.

Select the **Block low rank factorization** checkbox to make a low rank approximation of the LU factors, both when computing them and when storing them. The value for the **Block low rank factorization tolerance** controls the quality of the approximation. The block low rank factorization is an approximate but accurate LU-factorization method that can provide a faster factorization and potentially save memory in your models. For the compression, select a type from the **Compression type** list: **Normal** (the default) or **Aggressive**. The aggressive compression can potentially use less memory and be faster, at the expense of a slightly lower accuracy for the approximations of the LU factors.

The MUMPS out-of-core solver stores the LU factors on the hard drive. This storage minimizes the internal memory usage. The cost is longer solution times because it takes longer time to read and write to disk than it takes using physical memory.

You can specify the temporary directory where MUMPS stores the LU factors using the `-tmpdir` switch. See Running COMSOL Multiphysics.

From the **Out-of-core** list, choose **On** to store all matrix factorizations (LU factors) as blocks on disk rather than in the computer's memory. The solver reads some of the blocks into memory and performs the LU-factorization on the part that is currently in memory. The blocks of data are then written back to disc and new blocks are read into memory. The size of the blocks that the solver reads from disc is controlled by the in-core memory setting. Choose **Off** to not store the matrix factorizations on disk. The default setting is **Automatic**, which switches the storage to disk (out-of-core) if the estimated memory (for the LU factors) is exhausting the physically available memory. For the automatic option, you can specify the fraction of the physically available memory that will be used before switching to out-of-core storage in the **Memory fraction for out-of-core** (a value between 0 an 1). The default is 0.99; that is, the switch occurs when 99% of the physically available memory is used.

When the **Out-of-core** list is set to **Automatic** or **On**, you can choose to specify how to compute the in-core memory to control the maximum amount of internal memory allowed for the blocks (stored in RAM and not on disk) using the **In-core memory method** list:

- Choose **Automatic** (the default) to derive the in-core memory from system data and a given formula:

$$M_{\text{incore}} = \max\{M_{\min}, f_{\text{use}} \cdot (M_{\text{tot}} - K_{\text{int}} \cdot M_{\text{use}})\} \tag{20-62}$$

  where you can specify $M_{\min}$ in the **Minimum in-core memory (MB)** field (default 512 MB), f_{use} in the **Used fraction of total memory** field (default: 0.8; that is, 80% of currently available memory), and K_{int} in the **Internal memory usage factor** field (default: 3). M_{tot} is the total physical memory on the computer, and M_{use} is the physical memory used on the computer before the solver starts.
- Choose **Manual** to specify the in-core memory directly in the **In-core memory (MB)** field. The default is 512 MB.

PARDISO

Select a **Preordering algorithm**: **Nested dissection multithreaded** (the default to perform the nested dissection faster when COMSOL Multiphysics runs multithreaded), **Minimum degree**, or **Nested dissection**.

Select a **Scheduling method** to use when factorizing the matrix:

- **Auto** (the default): Selects one of the two algorithms based on the type of matrix.
- **One-level**
- **Two-level**: Choose this when you have many cores as it is usually faster.

Select the **Row preordering** checkbox (selected by default) to control whether the solver should use a maximum weight matching strategy or not. Click to clear the checkbox to turn off the weight matching strategy.

Select the **Reuse preordering** checkbox (selected by default) to reuse the reordering of the system, which speeds up the computation but leads to a higher memory peak.

The **Reuse preordering** option has a weak dependence on the system matrix. In extreme cases, this can cause the solvers to fail. If you suspect this is the problem, make sure that the **Check error estimate** setting is not set to **No** in the **Error** section below. Then, if the linear solvers fail and the preordering is old, a new preordering will be done.

By default, the **Bunch-Kaufman pivoting** checkbox is not selected. Click to select it and control whether to use 2-by-2 Bunch-Kaufman partial pivoting instead of 1-by-1 diagonal pivoting.

By default, the **Multithreaded forward and backward solve** checkbox is selected so that the backward and forward solves run multithreaded. This mainly improves performance when there are many cores and the problem is solved several times, such as in eigenvalue computations and iterative methods. Click to clear this checkbox and not run the solver multithreaded.

The **Pivoting perturbation** field controls the minimum size of pivots (the pivot threshold ε).

To avoid pivoting, PARDISO uses a pivot perturbation strategy that tests the magnitude of the potential pivot against a constant threshold of $\varepsilon = \alpha|PP_{\text{MPS}}D_rAD_cP|_\infty$, where P and P_{MPS} are permutation matrices, D_r and D_c are diagonal scaling matrices, and $|\cdot|_\infty$ is the infinity norm (maximum norm). If the solver encounters a tiny pivot during elimination, it sets it to $\text{sign}(l_{ii})\varepsilon|PP_{\text{MPS}}D_rAD_cP|_\infty$. The perturbation strategy is not as robust as ordinary pivoting. In order to improve the solution, PARDISO uses iterative refinements.

Select the **Parallel Direct Sparse Solver for Clusters** checkbox to use the Parallel Direct Sparse Solver (PARDISO) for Clusters from the Intel® MKL (Intel® Math Kernel Library) when running COMSOL Multiphysics in a distributed mode.

The PARDISO out-of-core solver stores the LU factors on the hard drive. This storage minimizes the internal memory usage. The cost is longer solution times because it takes longer time to read and write to disk than it takes using physical memory.

You can specify the temporary directory where PARDISO stores the LU factors using the `-tmpdir` switch. See Running COMSOL Multiphysics.

From the **Out-of-core** list, choose **On** to store all matrix factorizations (LU factors) as blocks on disk rather than in the computer's memory. The solver reads some of the blocks into memory and performs the LU-factorization on the part that is currently in memory. The blocks of data are then written back to disc and new blocks are read into memory. The size of the blocks that the solver reads from disc is controlled by the in-core memory setting. Choose **Off** to not store the matrix factorizations on disk. The default setting is **Automatic**, which switches the storage to disk (out-of-core) if the estimated memory (for the LU factors) is exhausting the physically available memory. For the automatic option, you can specify the fraction to be stored on disk in the **Memory fraction for out-of-core** (a value between 0 an 1; the default is 0.99). If needed, the out-of-core PARDISO solver automatically increases the in-core memory that is required.

When the **Out-of-core** list is set to **Automatic** or **On**, you can choose to specify how to compute the in-core memory to control the maximum amount of internal memory allowed for the blocks (stored in RAM and not on disk) using the **In-core memory method** list:

- Choose **Automatic** (the default) to derive the in-core memory from system data and a given formula:

$$M_{\text{incore}} = \max\{M_{\text{min}}, f_{\text{use}} \cdot (M_{\text{tot}} - K_{\text{int}} \cdot M_{\text{use}})\} \quad (20\text{-}63)$$

  where you can specify M_{min} in the **Minimum in-core memory (MB)** field (default 512 MB), f_{use} in the **Used fraction of total memory** field (default: 0.8; that is, 80% of currently available memory), and K_{int} in the **Internal memory usage factor** field (default: 3). M_{tot} is the total physical memory on the computer, and M_{use} is the physical memory used on the computer before the solver starts.
- Choose **Manual** to specify the in-core memory directly in the **In-core memory (MB)** field. The default is 512 MB.

SPOOLES

Select a **Preordering algorithm**: **Best of ND and MS** (the best of nested dissection and multisection), **Minimum degree**, **Multisection**, or **Nested dissection**.

Enter a **Pivot threshold** number between 0 and 1. The default is 0.1. This means that in any given column the algorithm accepts an entry as a pivot element if its absolute value is greater than or equal to the specified pivot threshold times the largest absolute value in the column.

ERROR

You can control the accuracy of the solution of the linear system from the **Check error estimate** list:

- The default is **Automatic**, meaning that the main solver is responsible for error management. The solver checks for errors for every linear system that is solved. To avoid false termination, the main solver continues iterating until the error check passes or until the step size is smaller than about $2.2 \cdot 10^{-14}$. With this setting, linear solver errors are either added to the error description if the nonlinear solver does not converge, or added as a warning if the errors persist for the converged solution.
- Choose **Yes** to check for errors for every linear system that is solved. If an error occurs in the main solver, warnings originating from the error checking in the direct solver appear. The error check asserts that the relative error times a constant ρ is sufficiently small. This setting is useful for debugging problems with singular or near singular formulations.
- Choose **No** for no error checking.

Use the **Factor in error estimate** field to manually set the constant ρ. The default is 1. See Convergence Criteria for Linear Solvers for more information.

The **Iterative refinement** checkbox is selected by default (except for the eigenvalue solver) so that iterative refinement is used for direct and iterative linear solvers. For linear problems (or when a nonlinear solver is not used), this means that iterative refinement is performed when the computed solution is not good enough (that is, the error check returned an error). It is possible that the refined solution is better. Iterative refinement can be a remedy for instability when solving linear systems with a solver where convergence is slow and errors might be too large, due to ill-conditioned system matrices, for example. If a nonlinear solver is used, iterative refinement is not used by default. You can often get away with intermediate linear solver steps, but if that is not the case, select the **Use in nonlinear solver** checkbox to use an iterative refinement. The default value in the **Maximum number of refinement** field is 15; you can change it if needed. By default, the **Error ratio bound** is set to 0.5. For both linear and nonlinear solver runs where iterative refinements are used, iterative refinements should be terminated when the error is not decreasing along the iteration. Therefore, the error ratio bound should always be smaller than 1. Because the error is computed in the L_2 norm, the error ratio bound should always be greater than 0. Setting the error ratio bound to 0.5, as suggested by Ref. 9, is a more cautious approach that rarely yields significant underestimations or overestimations of errors, and it always terminates quickly compared to an error ratio bound much closer to 1. When **Check error estimate** is set to **Automatic**, a single warning, *Iterative refinement triggered*, appears in the **Log** window if the iterative refinement is triggered. When **Check error estimate** is set to **Yes**, the same warning and the number of iterative refinements applied in each linear solver call are shown in the **Log** window.

For an example using a Stationary Solver, *The Blasius Boundary Layer*: Application Library path **COMSOL_Multiphysics/Fluid_Dynamics/blasius_boundary_layer**.

For an example using an Eigenvalue Solver, *Isospectral Drums*: Application Library path **COMSOL_Multiphysics/Equation_Based/isospectral_drums**.

Direct Preconditioner

The **Direct Preconditioner** node ( ) is an attribute that you can add as a preconditioner. Using a direct solver as a preconditioner makes it possible to solve one of the physics interfaces in a multiphysics model using a direct solver. With this preconditioner you can use a direct solver for one of the smaller fields (an ODE, for instance) and combine it with another more efficient solver for another larger physics problem (a displacement field in 2D or 3D, for instance).

The settings in the **Direct Preconditioner** node's **Settings** window's **General** section are the same as for the **Direct** solver node (see Direct).

Use the settings in the **Hybridization** section to set up a hybrid preconditioner where the direct preconditioner is active for some dependent variables. See Hybrid Preconditioners for more information.

Domain Decomposition (Schur)

The **Domain Decomposition (Schur)** node ( ) is an attribute node that can be used together with the Iterative and Coarse Solver nodes. Use it to set up a domain-decomposition solver using the Schur complement method. Domain decomposition divides the modeling domain into subdomains where the equations in the subdomains are easier to solve. The total solution is then obtained by iterating between the computed solutions for each subdomain using the currently known solutions from the other subdomains as boundary conditions. The domain decomposition (Schur) solver is a typically more stable but less memory efficient alternative to the domain decomposition (Schwarz) solver.

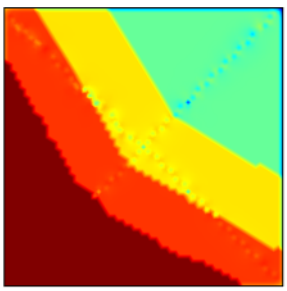
Default Schur Solver, Domain Solver, and Schur Source Solver nodes are also added. The domain can be any of the direct and iterative solvers, and also a geometric multigrid solver. When you use a multigrid solver as the domain solver for domain decomposition, each domain solves an independent linear problem using a multigrid solver. Each linear problem is created from the underlying multigrid solver's mesh case hierarchy. The domain problems can then be solved independently. See also The Domain Decomposition Solvers.

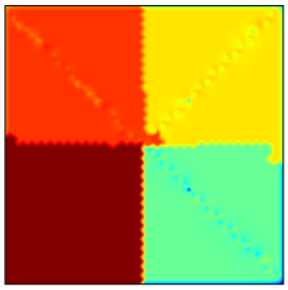
GENERAL

Select a **Schur ordering**: **Multiplicative** (the default) or **Additive**. These ordering options determine which corresponding Schwarz algorithm (see Domain Decomposition (Schwarz)) to use for solving the Schur complement system. Schur ordering is not used if absorbing boundary conditions are selected; see The Domain Decomposition Solvers.

For any **Schur ordering**, enter values or choose an option as needed:

- **Number of iterations**. The default is 1.
- **Minimum number of subdomains**. The default is 4. The subdomain partition is created from an element partition on the solver level.
- **Maximum number of DOFs per subdomain**. The default is 100,000 DOFs. The solver tries to not create subdomains larger than this and increases the number of subdomains to fulfill the target. The lowest value accepted is 1000.
- **Maximum number of nodes per subdomain**. The default is 1. This option is only relevant in cluster computations. Each subdomain is then handled by the selected number of compute nodes.
- **Preordering algorithm**: **Nested dissection** (the default), **Space-filling curve**, or **None**. The **Nested dissection** option creates a subdomain distribution by means of the element and vertex lists taken from the mesh. This option typically gives a low number of colors and gives balanced subdomains (equal number of DOFs, small subdomain interfaces, and a smaller overlap if extended). To avoid slim domains, you can also use a preordering algorithm based on a **Space-filling curve**. The following plots show a 2D subdomain configuration without element preordering (left) and with an element reordering based on a space-filling curve (right):





- Choose an option from the **Recompute and clear subdomain data** list if required: **Automatic** (default), **Off**, or **On**. The **On** option is a computationally expensive option because the subdomain problems are factorized for each iteration and then cleared from memory. If you use the **Automatic** option, the recompute and clear mechanism is activated if there is an out-memory-error during the domain decomposition setup phase. The setup is then repeated with recompute and clear activated. A warning is given in this case.
- If **Multiplicative** is selected as the **Schur ordering**, the **Use subdomain coloring for localized Schur complements** checkbox is selected by default to use a coloring technique that leads to more efficient computations for the multiplicative method because it requires the global residual to be updated after each subdomain. The coloring technique gives each subdomain a color such that subdomains with the same color are disjoint and can be computed in parallel before the residual is updated. Click to clear the checkbox as needed.
- In the **Partition geometries** list, include the geometries (components) in the model that you want to partition using domain decomposition. By default, this list includes all geometries in the model. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to configure the lists of geometries.
- The **Include extra dimensions in partitioning** checkbox is selected by default to include extra dimension in the domain decomposition partitioning in models that include extra dimensions. Clear the checkbox to exclude any extra dimensions from the partitioning.
- Select the **Only visualize the domains** checkbox to visualize the domains in the domain decomposition using a surface plot, for example. The plot then shows the numbering of the domains instead of the physics solution. A **Warning** node appears in the solver configuration under the **Domain Decomposition (Schur)** node to inform you that the solution can only be used to visualize domains in the domain decomposition. You will then have to re-solve the model to postprocess the physics in the model.

EQUATIONS

From the **Domain boundary** list, choose a boundary condition: **Dirichlet boundary condition**, **Zero flux**, or **Absorbing boundary condition**.

Absorbing Boundary Condition

If you have selected the **Absorbing boundary condition**, then select:

- The **Physics** from the list.
- Select a weak contribution method from the **Add weak boundary contribution** list:
  - **Automatic**: The code internally creates an **Absorbing Boundary Conditions Weak Contribution** for the selected physics. Specify a zero-order coefficient as a scalar value in the **Zero-order coefficient** field (default: 0.75). You can add a second-order term by selecting the **Second-order term** checkbox and specifying a **Second-order coefficient** (default: 0.005). These coefficients correspond to α and β, respectively, in the following equation for an absorbing boundary condition:

$$\left(\frac{\partial}{\partial \mathbf{n}} + \alpha k + \beta \Delta_{\partial\Omega_i}\right) u^j = 0$$

    The **Automatic** option is only supported for the Helmholtz equation. Select the **Keep generated weak contribution** checkbox in order to keep the **Absorbing Boundary Conditions Weak Contribution** feature in the Physics node.
  - **Manual**: Specify the complete weak-form expression in the **Weak expression** field. This expression can be applied to any Physics available in the list above. Select the **Keep generated weak contribution** checkbox to keep the **Absorbing Boundary Conditions Weak Contribution** feature in the Physics node.
  - **From physics**: the **Absorbing Boundary Conditions Weak Contribution** is taken from the Physics node. Only use this option if a weak contribution feature was previously added by selecting the **Keep generated weak contribution** checkbox together with the **Automatic** or **Manual** options as described above.
  - **Off**: No absorbing boundary condition is added for the selected Physics.

HYBRIDIZATION

User the settings in the **Hybridization** section to set up a hybrid preconditioner where the direct preconditioner is active for some dependent variables. See Hybrid Preconditioners for more information.

Domain Decomposition (Schwarz)

The **Domain Decomposition (Schwarz)** node ( ) is an attribute node that can be used together with the Iterative and Coarse Solver nodes. Use it to set up an additive, multiplicative, hybrid, or symmetric Schwarz overlapping domain decomposition solver. Domain decomposition divides the modeling domain into subdomains where the equations in the subdomains are easier to solve. The total solution is then obtained by iterating between the computed solutions for each subdomain using the currently known solutions from the other subdomains as boundary conditions. The domain decomposition (Schwarz) solver is efficient for distributed memory systems (cluster computing) and as a more memory-efficient alternative to a direct solver for large problems.

Default Coarse Solver and Domain Solver nodes are also added. The domain solver can be any of the direct and iterative solvers, and also a geometric multigrid solver. When you use a multigrid solver as the domain solver for domain decomposition, each domain solves an independent linear problem using a multigrid solver. Each linear problem is created from the underlying multigrid solver's mesh case hierarchy. The domain problems can then be solved independently.

Also see The Domain Decomposition Solvers.

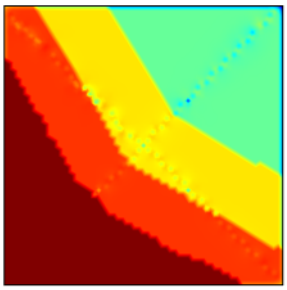
GENERAL

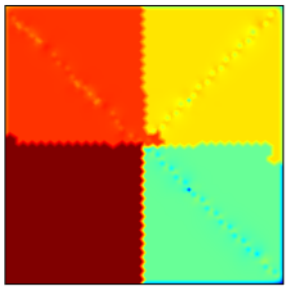
Select a **Solver**: **Multiplicative Schwarz** (the default), **Additive Schwarz**, **Hybrid Schwarz**, or **Symmetric Schwarz**.

For any **Solver**, enter values or choose an option as needed:

- **Number of iterations**. The default is 1.
- **Minimum number of subdomains**. The default is 2. The subdomain partition is created from an element partition on the solver level.
- **Maximum number of DOFs per subdomain**. The default is 100,000 DOFs. The solver tries to not create subdomains larger than this and increases the number of subdomains to fulfill the target. The lowest value accepted is 1000.
- **Maximum number of nodes per subdomain**. The default is 1. This option is only relevant in cluster computations. Each subdomain is then handled by the selected number of compute nodes.
- **Additional overlap**. The default is 1 mesh element. Each subdomain in the initial (nonoverlapping) partition is extended via the connectivity of the stiffness matrix in a recursive algorithm or by the connectivity of the mesh (see **Overlap method**); this setting controls the number of additional mesh elements — added to the necessary single mesh element — in the overlap between adjacent subdomains.
- **Overlap method**: **Automatic** (the default), **Matrix based**, or **Mesh based**. The automatic setting chooses the overlap method based on the matrix format used. The matrix-based overlap method considers the matrix connectivity whereas the mesh-based overlap method considers neighboring mesh elements. Select **Mesh based** if the matrix-based overlap generates too large overlapping subdomains.
- **Overlap correction**: **None** (default), **Restricted Schwarz**, **Harmonic extension**, or **Unity weighting**. These options affect the definition of the restriction operators and have benefits in terms of less communication on cluster and less iteration numbers for Additive Schwarz methods.
- **Preordering algorithm**: **Nested dissection** (the default), **Space-filling curve**, or **None**. The **Nested dissection** option creates a subdomain distribution by means of the element and vertex lists taken from the mesh. This option typically gives a low number of colors and gives balanced subdomains (equal number of DOFs, small subdomain interfaces, and a smaller overlap if extended). To avoid slim domains, you can also use a preordering algorithm

based on a **Space-filling curve**. The following plots show a 2D subdomain configuration without element preordering (left) and with an element reordering based on a space-filling curve (right):





- Choose an option from the **Recompute and clear subdomain data** list if required: **Automatic** (default), **Off**, or **On**. The **On** option is a computationally expensive option because the subdomain problems are factorized for each iteration and then cleared from memory. If you use the **Automatic** option, the recompute and clear mechanism is activated if there is an out-memory-error during the domain decomposition setup phase. The setup is then repeated with recompute and clear activated. A warning is given in this case.
- If **Multiplicative Schwarz** or **Symmetric Schwarz** is selected as the **Solver**, the **Use subdomain coloring** checkbox is selected by default to use a coloring technique that leads to more efficient computations for the multiplicative and symmetric methods because they require the global residual to be updated after each subdomain. The coloring technique gives each subdomain a color such that subdomains with the same color are disjoint and can be computed in parallel before the residual is updated. Click to clear the checkbox as needed.
- Select the **Prefer the free matrix format** checkbox to automatically choose the matrix free format, which can save memory. Then select a boundary condition from the **Domain boundary** list: **Dirichlet boundary condition**, (the default), **Zero flux**, or **Absorbing boundary condition** (see The Domain Decomposition Solvers). The **Absorbing boundary condition**'s settings are described in Absorbing Boundary Condition below. To improve the convergence rate for large Helmholtz-type problems, select the **Shifted Laplace contribution** checkbox. See Shifted Laplace Contribution (CSL) below.
- In the **Partition geometries** list, include the geometries (components) in the model that you want to partition using domain decomposition. By default, this list includes all geometries in the model. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to configure the lists of geometries.
- The **Include extra dimensions in partitioning** checkbox is selected by default to include extra dimension in the domain decomposition partitioning in models that include extra dimensions. Clear the checkbox to exclude any extra dimensions from the partitioning.
- Select the **Only visualize the domains** checkbox to visualize the domains in the domain decomposition using a surface plot, for example. The plot then shows the numbering of the domains instead of the physics solution. A **Warning** node appears in the solver configuration under the **Domain Decomposition (Schwarz)** node to inform you that the solution can only be used to visualize domains in the domain decomposition. You will then have to re-solve the model to postprocess the physics in the model.

COARSE LEVEL

From the **Use coarse level** list, choose one of the following types:

- **Geometric** (the default). This option uses geometric multigrid method (GMG). See Geometric below.
- **Algebraic**: This option uses the algebraic multigrid method (AMG). See Algebraic below.
- **Aggregation**: This option uses the smoothed aggregation AMG method. See Aggregation below.
- **Nicolaides**: This option uses the Nicolaides coarse space as a way of constructing a coarse space for Schwarz domain decomposition. This option has no additional settings because it does not need any additional

information, such as a coarser mesh, except the local system matrices from the local domains. It is useful when computing a coarse grid when **Geometric**, **Algebraic**, and **Aggregation** are not feasible. For instance, if they require too much memory or are too expensive to compute. Using **Nicolaides** improves the convergence rate compared to the **Off** option.

- **Off**: No coarse level is used.

Geometric

Select an option from the **Coarse level generation method** list to specify how to generate the coarse multigrid level:

- **Lower element order first (any)**. The default. Generates first a coarse level by lowering the order (by one) of any of the used shape functions. If there are no shape functions that can be lowered, the mesh is coarsened.
- **Coarsen mesh and lower order**. Combines lowering of the used shape function order and a coarsening of the mesh.
- **Lower element order first (all)**. Generates first a coarse level by lowering the order (by one) of all the used shape functions. If this is not possible, the mesh is coarsened.
- **Coarsen mesh**. Does not change the order.
- **Lower element order and refine (all)**. Generates a coarse level by lowering the order (by one) of all the used shape functions. If this is not possible, the mesh is refined a number of times. The mesh solved for can, with this method, be a finer one than the one selected under the study node.
- **Lower element order and refine (any)**. Generates a coarse level by lowering the order (by one) of any of the used shape functions. If there are no shape functions that can be lowered, the mesh is refined. The mesh solved for can, with this method, be a finer one than the one selected under the Study node.
- **Refine mesh**. Does not change the order.
- **Manual**. Use this setting to select a coarse multigrid level from the existing ones. You then specify the coarse multigrid level to use in the **Use coarse level** list. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to configure the list of multigrid levels. Use the **Assemble on coarse level** checkbox to assemble the discrete differential operators on the coarse multigrid level (selected by default).
- **None**. Use this setting to not generate a coarse level.

For any **Coarse level generation method** (except Manual), additional settings are available:

- In the **Use coarse level in geometries** list, select the geometries to apply the coarse multigrid level to. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to configure the list of geometries.
- The **Assemble on coarse level** checkbox is selected by default to assemble the discrete differential operators. Otherwise, these operators are formed using the restriction and prolongation operators. Click to clear the checkbox as needed.

When **Coarsen mesh and lower order**, **Lower element order first (all)**, **Lower element order first (any)**, or **Coarsen mesh** are selected from the **Coarse level generation method** list:

- Enter a **Mesh coarsening factor** to select the degree of coarsening to apply to the meshes when using mesh coarsening as the multigrid hierarchy generation method. The higher this number, the more aggressive the mesh coarsening is. The default is 2.
- Select the **Keep generated coarse level** checkbox to save the meshes for all levels under the mesh node.

When **Lower element order and refine (all)**, **Lower element order and refine (any)**, or **Refine mesh** are selected from the **Hierarchy generation method** list, select a **Refinement method** to refine the multigrid levels when using mesh refinement as the multigrid hierarchy generation method. The options are:

- **Split longest side**. The default method. Elements are subdivided such that the longest side in each element is always split. This yields not so many new elements, while also preserving mesh quality.
- **Regular refinement**. Elements are subdivided in a regular manner.

Also, for the methods that include a refinement, the solver uses the original mesh as the coarse mesh and the refined mesh as the new solution mesh.

Algebraic

For the Algebraic option the following settings are available:

- Enter the **Number of multigrid levels** (default: 5).
- To enter a **Maximum number of DOFs at coarsest level**, first select the associated checkbox. If the checkbox is cleared (the default), the value is taken from the **Maximum number of DOFs per subdomain** field. The default is 5000. Coarse levels are added until the number of DOFs at the coarsest level is less than the max DOFs at coarsest level or until it has reached the number of multigrid levels.
- Enter a value or use the slider to set the **Quality of coarse grid**. Higher quality means faster convergence at the expense of a more time-consuming setup phase. For instance, if the linear solver does not converge or if it uses too many iterations, try a higher value to increase the accuracy in each iteration, meaning fewer iterations. If the algebraic multigrid algorithm runs into memory problems, try a lower value to use less memory. The range goes from 1 to 10, where 10 gives the best quality. The default is 3.
- The **Lower element order first (any)** checkbox is selected by default. This setting provides the combination of GMG with lower order until order 1 is reached and then uses AMG to generate the coarser levels. The **Assemble on the order-lowered levels** checkbox, which is selected by default, then corresponds to the GMG option top assemble on all level. Using this setting is equivalent to using GMG with AMG as a coarse grid solver.

See The Algebraic Multigrid Solvers/Preconditioners for more information.

Aggregation

The following settings control the smoothed aggregation algorithm:

- Enter the **Number of multigrid levels** (default: 5).
- To enter a **Maximum number of DOFs at coarsest level**, first select the associated checkbox. If the checkbox is cleared (the default), the value is taken from the **Maximum number of DOFs per subdomain** field. The default is 5000. Coarse levels are added until the number of DOFs at the coarsest level is less than the max DOFs at coarsest level or until it has reached the number of multigrid levels.
- The aggregation algorithm is based on a connection criterion, which you specify as a coefficient in the **Strength of connections** field. A node j is connected to another node i, if $\|A_{ij}\| \geq \varepsilon \|A_{ii}\| \|A_{jj}\|$, where ε is the strength of connection coefficient, and A_{ij} is the submatrix of the stiffness matrix defined by the degrees of freedoms on node i and j, respectively. Loosely speaking, the strength of connection value determines how strongly the aggregation should follow the direction of anisotropy in the problem. The default value is 0.01.
- From the **Null-space vectors** list, choose **Constant** (the default) or **Rigid body modes**. For linear elasticity problems, always select **Rigid body modes** because it enhances the convergence properties significantly.
- Select the **Construct prolongators componentwise** checkbox to do the construction on each component, which can be a good choice for not strongly coupled physics. This checkbox is only available when the **Null-space vectors** list is set to **Constant**.
- Select the **Compact aggregation** checkbox to use an aggregation algorithm that forms, on average, smaller aggregates, which leads to a less rapid coarsening.
- Choose how to control the prolongator smoothing using the **Smoothing** list, which is active when the **Prolongator smoothing** checkbox (selected by default) is selected. The **Auto** option postpones the smoothing for `sdim-1` levels, where `sdim` is the space dimension of the problem. If you choose **Manual**, enter the level to start smoothing at in the **Start smoothing at multigrid level** field.
- The final transfer operator, P, between the fine and coarse problems are smoothed by one application of Jacobi smoothing:

$$P = (\dot{I} - \omega D^{-1} A_F)\tilde{P}$$

where ω is the *Jacobi damping factor*, A_F is the *filtered stiffness matrix*, and D is the diagonal of A_F. Specify ω in the **Jacobi damping factor** field. The default value is $2/3$.

- By default, the **Use filtering** checkbox is selected. Filtering means that entries in the stiffness matrix have been dropped if they correspond to degrees of freedoms on a node that has no strong connections. Loosely speaking, filtering highlights anisotropy in the problem and results in a sparser coarse level problem.
- The **Lower element order first (any)** checkbox is selected by default. This setting provides the combination of GMG with lower order until order 1 is reached and then uses SAAMG to generate the coarser levels. The **Assemble on the order-lowered levels** checkbox, which is selected by default, then corresponds to the GMG option top assemble on all level. Using this setting is equivalent to using GMG with SAAMG as a coarse grid solver. In order to solve a coarse grid correction problem, the prolongation matrices are multiplied into a single matrix that maps from the fine level to the coarse level.

Select the **Shifted Laplace contribution on coarse level** checkbox to add the term to the coarse grid level. The options are the same for the fine grid level as described in the **General** section above. The created feature is a **Shifted Laplace Weak Contribution on Multigrid Levels**.

EQUATIONS

From the **Domain boundary** list, choose a boundary condition: **Dirichlet boundary condition**, **Zero flux**, or **Absorbing boundary condition**.

Absorbing Boundary Condition

If you have selected the **Absorbing boundary condition**, then select:

- The **Physics** from the list.
- Select a weak contribution method from the **Add weak boundary contribution** list:
  - **Automatic**: The code internally creates an **Absorbing Boundary Conditions Weak Contribution** node for the selected physics. Specify a zero-order coefficient as a scalar value in the **Zero-order coefficient** field (default: 0.75). You can add a second-order term by selecting the **Second-order term** checkbox and specifying a second-order coefficient (default: 0.005). These coefficients correspond to α and β, respectively, in the following equation for an absorbing boundary condition:

    $$\left(\frac{\partial}{\partial \mathbf{n}} + \alpha k + \beta \Delta_{\partial\Omega_i}\right) u^j = 0$$

    The **Automatic** option is only supported for the Helmholtz equation. Select the **Keep generated weak contribution** checkbox in order to keep the **Absorbing Boundary Conditions Weak Contribution** feature in the Physics node.
  - **Manual**: Specify the complete weak-form expression in the **Weak expression** field. This expression can be applied to any Physics available in the list above. Select the **Keep generated weak contribution** checkbox to keep the **Absorbing Boundary Conditions Weak Contribution** feature in the Physics node.
  - **From physics**: the **Absorbing Boundary Conditions Weak Contribution** is taken from the Physics node. Only use this option if a weak contribution feature was previously added by selecting the **Keep generated weak contribution** checkbox together with the **Automatic** or **Manual** options as described above.
  - **Off**: No absorbing boundary condition is added for the selected Physics.

Shifted Laplace Contribution (CSL)

If you have selected the **Shifted Laplace contribution** checkbox to use CSL, then select:

- The **Physics** from the list.

- Select a weak contribution method from the **Add weak contribution** list:
  - **Automatic**: The code internally creates a **Shifted Laplace Weak Contribution on Main Level** feature for the selected physics. Specify a **Shift coefficient** relaxation factor, which is a scalar value (default: 1). The shift coefficient multiplies the expression for the shifted Laplace contribution. You can think of it as the β coefficient in the Complex Shifted Laplacian for Large Helmholtz Problems section. It might be the case that you need more or less damping than what the original equation provides; you can then choose another value for this factor. The **Automatic** option is only supported for Helmholtz-type equations. In that case, the meaning of the shift coefficient is the factor α in the term $-i\alpha k^r u$, where r is 1. Select the **Keep generated weak contribution** checkbox in order to keep the **Shifted Laplace Weak Contribution on Main Level** feature in the Physics node.
  - **Manual**: Specify the complete weak-form expression in the **Weak expression** field. This expression can be applied to any Physics available in the list above. The added weak term does not modify the solution of the original problem. It is only used on the multigrid levels to help with convergence. Select the **Keep generated weak contribution** checkbox to keep the **Shifted Laplace Weak Contribution on Main Level** feature in the Physics node.
  - **From physics**: the **Shifted Laplace Weak Contribution on Main Level** feature is taken from the Physics node. Only use this option if a weak contribution feature was previously added by selecting the **Keep generated weak contribution** checkbox together with the **Automatic** or **Manual** options as described above.
  - **Off**: No CSL is added for the selected Physics.

Also see the section "Complex Shifted Laplacian for Very Large Frequency Domain Models" in the *Acoustics Module User's Guide* for an example of how to set up the shifted Laplace contribution for a pressure acoustics model.

Shifted Laplace Contribution (CSL) on Coarse Level

If you have selected the **Shifted Laplace contribution on coarse level** checkbox, the settings there are the same as for the shifted Laplace contribution above but used on the coarse level.

Select the **Keep generated weak contribution** checkbox to keep the new feature in the physics.

HYBRIDIZATION

User the settings in the **Hybridization** section to set up a hybrid preconditioner where the direct preconditioner is active for some dependent variables. See Hybrid Preconditioners for more information.

Domain Solver

The **Domain Solver** node ( ) is an auxiliary attribute subnode used by the Domain Decomposition (Schwarz) attribute node. This node does not have any settings. Instead, its purpose is to administrate domain solvers for a domain-decomposition Schwarz solver.

Eigenvalue Parametric

The **Eigenvalue Parametric** node ( ) is an attribute node that handles settings for parameter stepping to add parametric sweeps. For each set of parameter values, an eigenvalue problem is solved.

This attribute can be used together with an Eigenvalue Solver. The functionality is then similar to when Parametric is added as a subnode to a Stationary Solver, but continuation is not supported.

	EigenvalueParam in the *COMSOL Multiphysics Programming Reference Manual.*

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step. Select **User defined** to modify the parameter table and sweep type.

Use the **Sweep type** list to specify the type of sweep to perform. The **Specified combinations** type (the default) solves for a number of given combinations of values, while the **All combinations** type solves for all combinations of values. Using all combinations can lead to a very large number of solutions.

Use the table with **Parameter name**, **Parameter value list**, and (optional) **Parameter unit** to specify parameter names, values, and units for the parametric solver. Use the **Add** button (+) to add a row to the table. Each row has one parameter name, a corresponding parameter value list, and an optional unit. The unit becomes orange if the unit that you specify does not match the unit given for the parameter where it is defined. For the **Specified combinations** sweep type, the lists of values must have equal length. When you click in the **Parameter value list** column to define the parameter values, you can click the **Range** button ( ) to define a range of parameter values. The parameter unit overrides the unit of the global parameter. If no parameter unit is given, parameter values without explicit dimensions are considered dimensionless.

If more than one parameter name has been specified, the lists of parameter values are interpreted as follows: Assume that the parameter names are `p1` and `p2`, and that `p1` has the list `1 3` and `p2` has the list `2 4`. For the **Specified combinations** sweep type, the solver first uses `p1` equal to `1` and `p2` equal to `2`. Thereafter, it uses `p1` equal to `3` and `p2` equal to `4`. And when the sweep type is **All combinations**, the solver uses the following order for the parameter combinations: 1 2, 1 4, 3 2, and 3 4.

An alternative to specifying parameter names and values directly in the table is to specify them in a text file. You can use the **Load from File** button ( ) to browse to such a text file. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window. The read names and values are appended to the current table. The format of the text file must be such that the parameter names appear in the first column and the values for each parameter appear row-wise with a space separating the name and values, and a space separating the values. Click the **Save to File** button ( ) to save the contents of the table to a text file (or to a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ *for* Excel®).

When loading and saving parameter table data using Excel®, the units in the **Parameter unit** column are included. The unit column is ignored when saving and loading parameter data to *.txt, *.csv, and *.dat files.

With the ARPACK eigenvalue solver, you can supply a starting vector for the eigenvalue computation. Doing so can accelerate convergence if a series of closely related problems are to be solved. More precisely, the convergence and the computation time can be reduced if an approximation of the solution is given. In this case, the starting vector should be a linear combination of the given approximation of the eigenvectors, and the shift should be located close to the given approximation of the eigenvalues. The following settings are related to ARPACK (see The ARPACK Eigenvalue Solver Algorithm):

From the **ARPACK starting vector** list, choose **Default**, giving a random starting vector, or **From previous eigenvectors**. If you chose **From previous eigenvectors**, a **From previous eigenvectors** list appears, where you can choose **Summation of all eigenvectors** (the default) or **Eigenvector with eigenvalue closest to the shift** as the new starting vector. These options can always be used without compromising the convergence. Use **Summation of all eigenvectors** when more than one eigenpair is requested. Use **Eigenvector with eigenvalue closest to the shift** when only one eigenpair is requested.

From the **ARPACK shift** list, choose **As specified** (the default) or **Based on eigenvalues for last parameter**. If you chose **Based on eigenvalues for last parameter**, also choose an option from the **From previous eigenvalues** list that appears: Choose **Average of converged eigenvalues** (the default) or **Eigenvalue closest to the previous shift**. In the case where

the eigenvalue shift value has not been parameterized, these options could be useful, but use them only if the eigenvalues are expected to have a small variation between two consecutive parameters. If this is not the case, ARPACK may converge to unwanted eigenpairs. Use **Average of converged eigenvalues** when the wanted eigenvalues are "around" the shift. More precisely, when the shift is an "internal point" of the convex hull of the wanted eigenvalues. Use **Eigenvalue closest to previous shift** if the shift is an "external point" of the convex hull of the wanted eigenvalues. For example, if the eigenvalues are known to have positive real part and the shift is set to zero.

The shift corresponds to the value of the **Search for eigenvalues around** field in the study settings. The eigenpairs, computed with respect to the previous parameter, are ordered from the closest to the shift to the one farthest from the shift.

To determine what the solver does when there is a solver error or the parameter stepping fails, select an option from the **On error** list. Select one of the following options:

- **Stop** (the default) to stop the parametric sweep and only return solutions before the error.
- **Skip parameter step** to skip the parameter when there is an error and then continue.
- **Store empty solution** to continue the parametric sweep and store an empty (NaN) solution for this step.

CLUSTER SETTINGS

Select the **Distribute parameters** checkbox to distribute the parameters on several computational nodes. If the problem is too large to run on a single node, you can enable the **Maximum number of groups** field to use the nodes' memory more efficiently. In this case the same parameter is solved for by several nodes that cooperate as if running a nondistributed sweep. The number of nodes that cooperate is equal to the maximum of the total number of nodes divided by the **Maximum number of groups** setting and 1. So if the total number of nodes is 12 and the **Maximum number of groups** is 3, 3 groups with 4 nodes each cooperate.

LEAST-SQUARES DATA

The section only appears if you are solving an eigenvalue least-squares optimization problem.

Least-squares data are read from least squares objectives (either a file or a table), and the solver sequence is set up accordingly: If there is a least-squares objective containing parameter columns in an eigenvalue study step, an Eigenvalue Parametric solver is set up, and the parameter names and values appear under **Parameters from least-square objectives**.

Parameter values corresponding to the same parameter names are merged between different objectives. If the **Use parameters from least-squares objectives** checkbox is selected (which is the default), user-defined parameter values are merged with corresponding merged data from objectives. For parameters that are defined only in objectives and not user defined (and vice versa), globally defined values are used. If the **Use parameters from least-squares objectives** checkbox is selected, the following settings are available:

- The **Create bounding box from the General parameter value lists** checkbox is selected by default to exclude values outside the bounding box.
- The **Add solution data points from the General Parameter value lists** checkbox is selected by default to control if data points should also be added to the solution process that is given in the **General** section that are not least-squares data. These points do not affect the solution process or the least-squares objectives but can be useful, for example, for postprocessing purposes or for model debugging.

If **Use parameters from least-squares objectives** is off, no least-squares parameters from files are used.

You can change the default values of the **Use parameters from least-squares objectives** and its associated settings only if **Defined by study step** is set to **User defined**.

Error Estimation

The **Error Estimation** node ( ) appears under the solver node when you use goal-oriented error estimation (see Error Estimation — Theory and Variables) and when **Adaptation and error estimates** in the defining study step is not set to **None**.

GENERAL

From the **Defined by study step** list, choose any applicable study step or choose **None**. If you choose **None**, no settings are displayed here, and none of the otherwise available setting values are used.

The **Error estimate** list is set in the parent study step list and affects the settings available here:

- If it is **L2 norm of error squared**, use the **Scaling factor** field to enter a space-separated list of scaling factors, one for each field variable (default: 1). The error estimate for each field variable is divided by this factor. Also, the L_2 norm error estimate is based on a stability estimate for the PDE. Use the **Stability estimate derivative order** field to specify its order (default: 2). For certain problems, which are symmetric and where strong error estimates hold, this method is equivalent to a functional error estimation with the functional being the L2 norm squared of the solution. This method can be used also for problems where these assumptions do not hold, but then the adaptation will not be optimal. See the following for some more in-depth information about these settings.

  The **L2 norm of error squared** method estimates the error for a mesh element as a summation of contributions for the different equations solved for. It sums over

  $$Ah^{2q}\frac{\rho^2}{s^2}$$

  where A is the element area (volume, length), h is the element size, q is the **Stability estimate derivative order**, s is the **Scaling factor**, and ρ is an estimate of the PDE residual. The asymptotic behavior for ρ is that it is proportional to h^p, where p is the **Residual order** (see below). Even if it is possible to estimate the actual value for ρ very generally, assisting the algorithm with this order is important — for example, for the **Element selection** method **Rough global minimum** (in the **Adaptive Mesh Refinement** subnode; see Adaptive Mesh Refinement (Stationary and Eigenvalue Adaptation)), which essentially solves an optimization problem for where to refine so that the total error is reduced as much as possible (constrained by how many elements that can be added). All of the values for the **Stability estimate derivative order**, **Scaling factor**, and **Residual order** (q, s, and p, respectively) can be given as vectors for the different equations. For the **Stability estimate derivative order**, the default is 2, and it is related to the stability estimate that holds for the problem at hand. If it is not of a Poisson type, then it might need adjustment. For the **Scaling factor**, the default is 1. It is mainly important to relatively weigh in the different parts of the equations solved for, which means that you need to give a space-separated array of numbers in general. Notice that when solving a multiphysics problem, the summation over different equations will not have the same unit since the different ρ will have different units. So, a first effort with scaling would be to take this into account. In fact, not even a single-physics case like fluid flow will make this summation unit consistent because the residual for momentum and mass conservation will be added up with the default scaling factors of 1. For the **Residual order**, the default is one order lower than the shape functions used for the equation. Change this only for nonstandard PDEs. Roughly speaking, the expected order is the basis order minus the highest spatial derivative order in the weak formulation. For a second-order PDE formulation with an integration by parts (lowering all second-order derivatives to first order) this will be of order one.
- If it is **Functional** and specify a **Functional type**. Available functional types are **Predefined** and **Manual**. This option adapts the mesh toward improved accuracy in the expression for the functional (for example, some energy, drag, or lift). Select **Manual** to specify a globally available scalar-valued expression in the **Functional** field (for example,

the name of a global variable probe). If you select **Predefined**, you can choose from a predefined list of functional from the **Solution functional** list:

- **Integral** (the default)
- **L2 norm**
- **L1 norm**
- **Approximate max norm**

For a **Stationary** study step `stat`, a global variable is defined for the functional with the name `stat.gfunc` (and similarly for a frequency-domain study step). The functional can be evaluated under **Results** > **Derived Values** by adding a **Global Evaluation** node and, in the **Expressions** section in its Settings window, selecting **Global Definitions** > **Error estimation** > **stat.gfunc - Functional - Stationary**.

The functional must be differentiable (or complex-valued analytic). Also, the expressions in the formulation must be differentiable. If this does not hold, the adjoint solution and its error estimate risk not being accurate, and the adaptation will then not be optimal for the functional used. The **Functional** option estimates the error for a mesh element as a summation of contributions. It sums over $A\,\omega_K\rho$, where ω_K is computed from the adjoint (or dual) solution. ω_K can be computed with different methods (**PPR for Lagrange** or **Interpolation error**). Equation 20-5 is about how ω_K is computed for **PPR for Lagrange**. Notice that this method is not using scaling factors or the stability estimate derivative order because they are not part of the formula (they are built into ω_K). But ρ is part of the formula and the residual order can therefore be important (for example, for the **Rough global minimum** method; see below). For the **Approximate max norm**, high order p-norm. The reason for this is that it is possible to differentiate this functional.

By default, the software automatically determines the order of decrease in equation residuals on basis of the shape function orders in the geometry. To specify a residual order manually, select the **Residual order** checkbox and specify a nonnegative integer in the accompanying field (available when **Error estimate** is **L2 norm of error squared** or **Functional**).

From the **Adjoint solution error estimate** list (only available when **Error estimate** is **Functional**), select an error estimate method for the adjoint solution. Select **PPR for Lagrange** (the default) to use the polynomial preserving recovery technique when possible (that is, for fields represented using Lagrange elements). Select **Interpolation error** to always use an estimate based on the interpolation error. For details, see The Functional Error Estimate.

ADVANCED

From the **Compensate for nojac terms** list, choose **Automatic** (the default), **On**, or **Off**.

- With **Automatic**, the software tries to assemble the complete Jacobian if an incomplete Jacobian has been detected. If the assembly of the complete Jacobian fails or in the case of nonconvergence, a warning is written and the incomplete Jacobian is used in the sensitivity analysis for stationary problems. For time-dependent problems, an error is returned.
- With **On**, the software tries to assemble the complete Jacobian if an incomplete Jacobian has been detected. If the assembly of the complete Jacobian fails or in the case of nonconvergence, an error is returned.
- If you get a warning about an incomplete Jacobian, you can then avoid that warning choosing **Off** from this list. With that setting, the software does not attempt to assemble the complete Jacobian (the incomplete Jacobian is used immediately).

Field

The **Field** node ( ) is an attribute node that handles settings for field variables. Each field variable has a separate **Field** node. This attribute is used together with the Dependent Variables node. The Field node name matches the name of the variable and its variable in the namespace (for example, **Temperature (comp1.T)**).

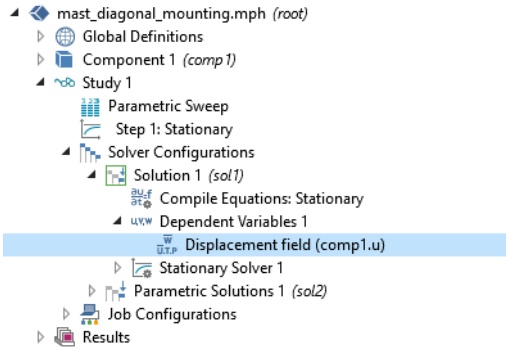


Figure 20-11: An example of a Field node, which takes the name of the variable, in this case Displacement field (Material).

GENERAL

The **Field components** section displays the variable names for the field's components. Also, when extra internal variables are used, these are displayed here as **Internal variables**.

The **Solve for this field** checkbox and, if applicable, the **Reconstruction** list are available if the Dependent Variables **Defined by study step** setting is **User defined**.

The **Solve for this field** checkbox controls whether to solve for the field (variable) or not. If the variable is not solved for, its value is determined by the settings in the **Values of Variables Not Solved For** section of the parent **Dependent Variables** node.

If this field is part of a physics for which a **Model Reduction** node is computing a reduced model that include reduction, you can choose a **Reduced Model** node from the **Reconstruction** list, if you want this field to use another reconstruction than the rest of the study.

If the **Dependent Variables** node is user defined, you can choose what to store in the output using the **Store in output** list:

- Choose **All** (the default) to store all solutions for the field in the output.
- Choose **None** to not store any solution for the field in the output.
- Choose **Selection** to use one or more selection nodes to define what part of the field to store in the output; for example, to only store the field on a boundary of interest, thereby reducing the required memory. Then, under **Selections**, click the **Add** button (+) to open an **Add** dialog that contains all available selections. Select the selections that you want to add and then click **OK**. You can also delete selections from the list using the **Delete** button ( ) and move them using the **Move Up** (↑) and **Move Down** (↓) buttons.

SCALING

Select a **Method** to control the scaling of a variable.

Unless **From parent** is selected, specifying a **Method** for a variable here overrides the **Method** selected in the **Scaling** section of the corresponding **Dependent Variables** operation node.

Select:

- **Automatic** to get an automatically determined scaling.
- **From parent** to use the scaling type selected in the **Method** list in the **Scaling** section of the corresponding **Dependent Variables** operation node.
- **Initial value based** to get a scaling that is determined from the initial values. Use this if the components of the initial values give a good estimate of the order of magnitude of the solution.
- **Manual** to manually enter a scaling, then enter a value in the **Scale** field.
- **None** to get no scaling.

RESIDUAL SCALING

From the **Method** list choose **From parent** (the default), **Automatic**, or **Manual**. For time-dependent problems, the Automatic residual scale is updated when a sufficiently large change in the residual is detected during time stepping. You can then enter a value in the **Threshold for updating residual scale** field, so that the residual scale updates automatically when a sufficiently large change in the residual is detected. The default value is 100. For Manual, enter a scale factor in the **Scale** field (default: 1). For the scaling, see Termination Criterion for the Fully Coupled and Segregated Attribute Nodes. A manual tuning of the scale factor may help convergence in some cases where the solution does not converge when using automatic scaling does not work (this could be the case for some contact problems, for example).

Fully Coupled

The **Fully Coupled** attribute node ( ) uses a damped version of Newton's method or, for stationary problems, a double dogleg method to handle parameters for a fully coupled solution approach. It can be used with the Stationary Solver and the Time-Dependent Solver.

An alternative to the fully coupled approach is given by the segregated solver, which you control with the Segregated node. Although several **Fully Coupled** and **Segregated** attribute subnodes can be attached to an operation node, only one can be active at any given time.

For more information about the settings below, see:

- The Fully Coupled Attribute and the Double Dogleg Method
- Damped Newton Methods
- Termination Criterion for the Fully Coupled and Segregated Attribute Nodes

GENERAL

Select a **Linear solver** for linear systems that appear in the corresponding solver configuration. The available solvers are attribute nodes of the types Direct and Iterative.

METHOD AND TERMINATION

Select a **Nonlinear method** to control which damping factor to use in the damped Newton iterations. Select:

- **Automatic (Newton)** to let the solver automatically determine a damping factor in each iteration of Newton's method. Go to Automatic (Newton) and Automatic Highly Nonlinear (Newton) for settings.
- **Backtracking (Newton)** to let the solver use a globalization method that uses information about the nonlinear residual as well as the system matrix to estimate the damping that minimizes the residual. Go to Backtracking (Newton) for settings.
- **Constant (Newton)** to manually specify a constant damping factor that is used in all iterations of Newton's method. Go to Constant (Newton) for settings.

- **Automatic highly nonlinear (Newton)** if the solver does not converge with **Automatic (Newton)** first. It is similar to **Automatic (Newton)** but this method can make the solver more careful when solving highly nonlinear problems. Go to Automatic (Newton) and Automatic Highly Nonlinear (Newton) for settings.
- For stationary problems, choose **Double dogleg** to use the double dogleg nonlinear solver. Go to Double Dogleg for settings.

Automatic (Newton) and Automatic Highly Nonlinear (Newton)

For **Automatic (Newton)** or **Automatic highly nonlinear (Newton)** enter values or expressions for:

- **Initial damping factor**, to specify a damping factor for the first Newton iteration. The default value is 1 for Automatic (Newton) and $1.0 \cdot 10^{-4}$ for Automatic highly nonlinear (Newton).
- **Minimum damping factor**, to specify the smallest allowed damping factor. The default value is $1.0 \cdot 10^{-4}$ for Automatic (Newton) and $1.0 \cdot 10^{-8}$ for Automatic highly nonlinear (Newton).
- **Restriction for step-size update**, to specify a factor that limits how much the damping factor is allowed to change in a Newton iteration. The damping factor can change up or down by at most this factor. The default is 10.
- **Restriction for step-size increase**, to specify the maximum for the allowed absolute increase in the damping factor for a Newton iteration, as opposed to the **Restriction for step-size update** value, which limits how much the damping factor can change relative to the current damping factor. The default value of 1 means that this setting is not active. A smaller value imposes a restriction (0–1 is the valid range for this value).

The automatic Newton solver can get stuck at the minimum damping factor resulting in no convergence. If you enable the **Use recovery factor**, the Newton solver can try additional steps starting with a damping factor equal to the value of the **Recovery damping factor**. This might help to recover from a state where the solver is stuck at the minimum damping factor.

Select an option from the **Use recovery damping factor** list: **Automatic** (the default), **On**, or **Off**.

The default, **Automatic**, is equivalent to **On** for stationary problems and **Off** for time-dependent problems. For stationary parametric continuation problems, **Automatic** corresponds to **On** when solving for the first parameter value and **Off** when solving for subsequent parameter values.

Choose **Off** if a damping factor smaller than the **Minimum damping factor** is required. The nonlinear solver then terminates. For **On**, the nonlinear solver takes a Newton step using the constant damping factor, which is defined in the **Recovery damping factor** field. The default **Recovery damping factor** is 0.75 when **Automatic** or **On** is selected.

From the **Update automatic scale factors in weights** list, available for stationary and parametric studies, choose **On** (the default), **Off**, or **Use threshold for weights**. **On** is the behavior in versions of the COMSOL Multiphysics software earlier than version 6.2. If you choose **Off**, the automatic scale factors are not taken into account when updating the weights. When the option **Use threshold for weights** is selected as the strategy for **Update automatic scale factors in weights** the following algorithm is used:

1. For the calculation of the weights U, the current, possibly damped, approximation to the solution is used. The weights are computed as $W_{i,j} = \max((|U_{i,j}|), S_j)$, where S_j is the average of $|U_{i,j}|$ for all DOFs i for a fixed j, times a factor equal to 10^{-5} for highly nonlinear problems or 0.1 otherwise.
2. The newly computed weights, $W_{i,j}^{\text{new}}$, are compared to the weights currently used, $W_{i,j}$, using a threshold value W_{thr}. This value is given by the user as the **Weights threshold factor for update** (default value: 100). If any of the weights satisfies $W_{i,j}^{\text{new}}/W_{i,j} > W_{\text{thr}}$ or $W_{i,j}^{\text{new}}/W_{i,j} < 1/W_{\text{thr}}$, the weights are updated to.
3. When the weights are updated the Newton algorithm is restarted, old step-size norms are cleared, and a new damping factor will be used. The new damping factor is controlled by **Damping factor at update**, where the strategies are **Fraction of current** (the default) or **Constant**. For **Fraction of current** there is an option to select a

Fraction of current damping factor (default value: 1). For **Constant** the damping factor will be the **Update damping factor**.

Then continue with the Termination Technique and Termination Criterion settings that follow.

Backtracking (Newton)

This method, inexact Newton backtracking (INB), uses information about the nonlinear residual as well as the system matrix to estimate the damping that minimizes the residual. This way a faster convergence can be achieved as compared with using a constant damping factor. For more information about INB, see Ref. 15. For more information about the choice of parameters, see Ref. 16. When used for a segregated solver, backtracking is applied for each segregated step individually. Two types of backtracking methods are supported: one using a full estimate and a method using constant damping factors whenever the step taken by the solver does not improve the residual, which makes that method computationally effective. Models that use a fully coupled solver and that only need mild damping are examples of models that are well suited for the constant step algorithm. For **Backtracking (Newton)**:

- First select one of the two methods mentioned above from the Backtracking method list: **Full estimate** (the default) or **Constant step**.
- If you chose **Full estimate**, select the **Backtrack at least once** checkbox to let the algorithm always determine and apply a damping at least once per nonlinear iteration. This is done regardless of whether the general criteria for backtracking are fulfilled, so even if the solver is converging nicely. For certain models this can improve the stability of the solvers.
- If you chose **Constant step**, enter a value between 0 and 1 in the **Damping in one step** field (default: 0.5). The **Constant step** method evaluates the residual for every backtracking step it takes. Choosing appropriate values for the **Damping in one step**, **Maximum damping factor**, and **Minimum damping factor** can help to reduce the number of backtracking steps.
- Enter values for the **Maximum damping factor** (default: 1) and the **Minimum damping factor** (default: 0.1) to specify the maximally and minimally allowed damping that is applied during one nonlinear iteration. Especially at the beginning of a solving process it can happen that the convergence is rather slow and that the backtracking algorithm would determine an arbitrarily small damping, effectively trapping the solvers there. In order to prevent this behavior, you can set a minimum damping factor, forcing the solvers to advance. This approach can also be used to accelerate the convergence for problems where generally only mild damping is needed.
- All other settings are identical to those for Constant (Newton) below (except that there is no **Damping factor** setting).

Then continue with the Termination Technique — Backtracking (Newton) and Constant (Newton) and Termination Criterion settings that follow.

Constant (Newton)

For **Constant (Newton)**:

- Enter a value for the **Damping factor** to specify a constant damping factor for Newton's method. The default is 1.
- With a Time-Dependent Solver, select the **Limit on nonlinear convergence rate** checkbox to force the nonlinear solver to terminate as soon as the convergence is estimated to be too slow. The default is 0.9. Enter a limit on the convergence rate in the field as required. The *nonlinear convergence rate* is estimated as $\gamma = (e_n/e_1)(1/(n-1))$, where e_n is the error estimate for iteration n. This can be seen as the average convergence rate after n steps ($n>1$). If $\gamma \backslash \gamma_{\text{limit}}$ (γ_{limit} is the limit on nonlinear convergence rate), then the nonlinear solver will terminate (as if it fails). This means that the current time step will be disqualified, and a new nonlinear solve attempt will be performed with a reduced time step. For problems where the convergence rate can be slow, this option can be used to avoid unnecessary nonlinear iterations (because the solver will in those cases not converge anyways within the allotted iterations specified in the **Maximum number of iterations** field).

- With a Time-Dependent Solver, choose a **Jacobian update**: **Minimal** (the default), **On every iteration**, or **Once per time step**:
  - **Minimal** reuses the Jacobian for several nonlinear systems whenever deemed possible.
  - **On every iteration** computes a new Jacobian for all iterations of Newton's method.
  - **Once per time step** computes a new Jacobian on the first iteration of each time step.
- With a Time-Dependent Solver, by default, a stricter tolerance is used at each Newton iteration step when Jacobian is not updated. This approach typically leads to more robust time stepping. Therefore, more nonlinear iterations might be required in each time step, and more Jacobian updates might be needed. To use the minimal Jacobian update used in earlier versions of the COMSOL Multiphysics software, select the **Use linear heuristics for adaptive tolerance** checkbox.
- With a Stationary Solver or a parametric solver, choose a **Jacobian update**: **Minimal**, **On every iteration** (the default), or **On first iteration**:
  - **Minimal** reuses the Jacobian for several nonlinear systems whenever deemed possible.
  - **On every iteration** computes a new Jacobian for all iterations of Newton's method.
  - **On first iteration** computes a new Jacobian on the first iteration of each parameter step.
- The **Update automatic scale factors in weights** checkbox, available for stationary and parametric studies, is selected by default. When selected it is the behavior in earlier versions of COMSOL Multiphysics; see Termination Criterion for the Fully Coupled and Segregated Attribute Nodes. If the automatic scale factors have changed by two orders of magnitude this will be indicated in the **Log** window. If you clear this checkbox, the automatic scale factors are not taken into account when updating the weights.

Then continue with the Termination Technique — Backtracking (Newton) and Constant (Newton) and Termination Criterion settings that follow.

Double Dogleg

If **Double dogleg** is selected for stationary problems:

- Enter a value for the **Initial damping factor**, to specify a damping factor for the first Newton iteration. The default value is $1.0 \cdot 10^{-4}$.
- Choose a **Residual scaling**: **Field-wise** or **Uniform**. **Field-wise** scales the equations based on the field-wise sizes of the initial residual. If **Uniform** is selected, the algorithm terminates on the relative residual based on the initial residual.
- The double dogleg solver can restart, if the solver iterations are considered as stagnated. The stagnation is defined by a given number of consecutive iterations that all have a Newton damping factor less than 0.1 and a step size smaller than 0.1 times the tolerance. By default, the restart is active with 7 iterations before the restart. To turn off the restart, clear the **Number of iterations before restart** checkbox. The number of iterations before restart must be a positive integer.

Continue with the Termination Technique settings that follow.

Termination Technique

For any **Nonlinear method**, select a **Termination technique** to control how the Newton iterations are terminated. Select:

- **Tolerance** to terminate the Newton iterations when the estimated relative error is smaller than a specified tolerance. Then enter the **Maximum number of iterations** to limit the number of Newton iterations. When the maximum number of iterations have been performed, Newton's method is terminated even if the tolerance is not fulfilled.

- **Iterations or tolerance** to terminate the Newton iterations when the estimated tolerance is smaller than a specified tolerance or after a specified number of iterations, whichever comes first. Then enter the **Number of iterations** to specify a fixed number of iterations to perform.
- If **Tolerance** or **Iterations or tolerance** are set as the **Termination technique**, then enter a **Tolerance factor** to modify the tolerance used for termination of the Newton iterations. The actual tolerance used is this factor times the value specified in the **Relative tolerance** field in the **General** sections of the Stationary Solver and Time-Dependent Solver.

Termination Technique — Backtracking (Newton) and Constant (Newton)

When **Backtracking (Newton)** or **Constant (Newton)** is the nonlinear method, you can also choose **Iterations** to terminate the Newton iterations after a fixed number of iterations. Enter the **Number of iterations** to specify a fixed number of iterations to perform.

Termination Criterion

For all termination techniques except **Iterations**, the **Termination criterion** controls how the Newton iterations are terminated. Select:

- **Solution** to terminate the Newton iterations on a solution-based estimated relative error.
- **Residual** to terminate the Newton iterations on a residual-based estimated relative error.
- **Solution or residual** to terminate the Newton iterations on the minimum of the solution-based and residual-based estimated relative errors. Enter a scalar **Residual factor** multiplying the residual error estimate. The default is 1000.
- **Solution and residual** to terminate the Newton iterations on a solution-based estimated relative error and a residual-based estimated relative error (that is, a more stringent termination criterion). Enter a scalar **Residual factor** multiplying the residual error estimate. The default is 1000.

For time-dependent solvers and when **Residual** or **Solution or residual** is selected as **Termination criterion**, the convergence check is applied before and after solving for the linear system. Doing so avoids unnecessary resources spent on solving the linear system when the solution is already converged. It can also avoid stagnation issues in iterative linear solvers when started with an initial guess too close to the true solution. For segregated steps the termination criterion of the segregated solver can enforce solving the linear system in certain cases, despite residual termination wanting to terminate (see Segregated).

Adaptive Tolerance in the Linear Solver — Backtracking (Newton) and Constant (Newton)

When **Backtracking (Newton)** or **Constant (Newton)** is the nonlinear method, select the **Use adaptive tolerance in linear solver** checkbox to activate such an adaptive tolerance. Based on an estimate of the global convergence, the algorithm then tries to find an optimal tolerance for the linear solver. Doing so can avoid expensive oversolving of the linear system when still far away from global convergence. When selected, also specify these additional settings:

First, choose a convergence estimator from the **Method** list:

- **Full error estimate** (the default): It uses full vectorial information of the linear and nonlinear residuals (needs to compute the linear residual).
- **Partial error estimate**: It uses only the norms of the linear and nonlinear residuals (needs to compute the linear residual).
- **Nonlinear residual**: It uses norms of only the nonlinear residuals (no need of the linear residual).
- **CFL weighting**: It uses CFL suppression (see the **Apply CFL weighting** checkbox below) to the initial tolerance without using an additional algorithm for determining the adaptive tolerance. The resulting tolerance will be interpolated between the initial tolerance and the target tolerance based on the current value of the CFL number. The interpolation is done logarithmically in the CFL number and logarithmically in the tolerance. This option is only available in model using a pseudo time-stepping method. The only additional setting is an initial tolerance

(see below). For other models using a stationary solver, the **Nonlinear error weighting** is available instead (see below).

- **Nonlinear error weighting**: It uses a suppression mechanism based on the nonlinear error estimate (for stationary solvers not using pseudo time stepping only).

Also specify these additional settings:

- In model using a pseudo time-stepping method, the **Apply CFL weighting** checkbox is selected by default. If selected, the algorithm will apply a suppression to the adaptive tolerance based on the progression of the CFL number. Doing so insures that the adaptive tolerance reaches the user-requested tolerance when the model converges, at the cost of a slight increase in the local number of linear iterations (that is, the number of linear iterations needed at a constant value of the CFL number). Given the increased stability, many models will converge faster using this option, thereby reducing the global amount of linear and nonlinear iterations.
- For other models, the **Apply nonlinear error weighting** checkbox is selected by default. If selected, the algorithm will apply a suppression to the adaptive tolerance based on the nonlinear error estimate.
- An initial tolerance in the **Initial tolerance** field (default: 0.1).
- A maximal tolerance in the **Maximal tolerance** field (default: 0.9).
- A threshold for safeguard purposes in the **Threshold for safeguard** field (default: 0.1). This is the value for the tolerance above which the safeguards are applied. The safeguards are there to prevent a too fast decrease of the tolerance. Selecting a too low value can prevent the adaptive tolerance to become smaller fast enough, leading to convergence issues. Selecting a too high value, in turn, can allow for an accidentally small tolerance, leading to resources wasted on unnecessary precision.
- If you chose **Nonlinear residual**, also specify a damping exponent between 1 and 2 and a damping factor between 0 and 1 in the **Damping exponent** (default: 2) field and **Damping factor** (default: 1) field, respectively, to define a nonlinear residual.

The full and partial error estimates usually have a similar behavior whereas the tolerance determined by the nonlinear residual tends to be larger, especially when the damping is different from 1.

Stabilization and Acceleration — Backtracking (Newton) and Constant (Newton)

When **Backtracking (Newton)** or **Constant (Newton)** is the nonlinear method, you can select one of the following methods for stabilization and acceleration of the nonlinear convergence from the **Stabilization and acceleration** list:

- **None** (the default) to not use any stabilization or acceleration method.
- **Pseudo time-stepping** to use a pseudo time-stepping method to stabilize convergence toward steady state for a stationary solver. Pseudo time stepping is not available for time-dependent solvers. See Pseudo Time Stepping for more information. For the pseudo time-stepping method, specify the following controller parameters:
  - **PID Controller**. Choose **Simple** (the default) or **Interpolated**. The simple controller corresponds to the PID controller in versions of the COMSOL Multiphysics software earlier than version 6.2. The interpolated controller blends different types of controllers when the error reaches the **Target error estimate**.
  - **Initial CFL number**. The default is 5.
  - **Target CFL number**. The default is 10,000. The solver does not converge unless the target CFL number is reached.
  - The **Limit to target CFL number** checkbox is selected by default. This setting controls how the CFL number is changed once the **Target CFL number** is reached. If you clear this checkbox, the CFL number can continue to increase until the error tolerance is fulfilled.
  - **PID controller - proportional**. The default is 0.65.
  - **PID controller - integral**. The default is 0.05.
  - **PID controller - derivative**. The default is 0.05.
  - **Target error estimate**. The default is 0.1.
  - Select the **Anderson acceleration** checkbox to activate Anderson acceleration for the pseudo time-stepping method. See below for more information about the settings for Anderson acceleration.
  - Select the **Override Jacobian update** checkbox to override updates of the Jacobian for the segregated steps. The **CFL threshold** value (default: 100), which is the value of the CFL number where overriding of the Jacobian update becomes active. That is, the overriding becomes active for larger CFL numbers than the threshold. From the **Jacobian update** list, choose **On first iteration** (the default) or **Minimal**, which updates the Jacobian at least once and then only when the nonlinear solver fails during parameter stepping. It reuses the Jacobian for several nonlinear systems whenever deemed possible.
  - Select the **Residual smoothing** checkbox to enable that the residual smoothing term is applied to the residual on each iteration in the pseudo time-stepping solver. The value in the **Relaxation factor** field (default: 0.1) controls the magnitude of the residual smoothing term.
- **Anderson acceleration**, which is a nonlinear convergence acceleration method that uses information from previous Newton iterations to accelerate convergence. The Anderson acceleration method is primarily intended for acceleration of nonlinear iterations in transport problems involving, for example, crosswind diffusion stabilization. It is useful is for solving linear or almost linear problems using the segregated solver, where convergence can be improved and the performance increased. You can control the number of iteration increments to store using the **Dimension of iteration space** field (default: 10) and the mixing parameter as a value between 0 and 1 using the **Mixing parameter** field (default: 1.0). The **Iteration delay** field (default 0) contains the number of iterations between pseudo time stepping becomes inactive and Anderson acceleration becomes active. Enter a threshold value in the **Threshold for Anderson step** field (default: 10). This threshold value controls if the Anderson step or the Newton step is used in the nonlinear step. If the norm of the new step is less than the threshold times the norm of the previous step, the Anderson step is used. Otherwise, the Newton step is used. Lowering the value for the **Threshold for Anderson step** can improve robustness at the price of performance.

  When used for pseudo time stepping, you can enter a **CFL threshold** value (default: 100), which is the value of the CFL number where Anderson acceleration becomes active and pseudo time stepping becomes inactive. You can also choose **Use PID controller** (the default) or **Lock target CFL number** from the **Above CFL threshold** list. Select

Lock target CFL number if the solver should set the target CFL number once the threshold is reached, or select **Use PID controller** if the PID controller should still control the CFL number based on the error estimate.

RESULTS WHILE SOLVING

See Results While Solving in the Common Study Step Settings section. Also see Getting Results While Solving.

For an example using a Stationary Solver, see *Tubular Reactor with Nonisothermal Cooling Jacket*: Application Library path **COMSOL_Multiphysics/Chemical_Engineering/tubular_reactor**.

For an example using a Time-Dependent Solver, see *Effective Diffusivity in Porous Materials*: Application Library path **COMSOL_Multiphysics/Diffusion/effective_diffusivity**.

Hardware Acceleration

The **Hardware Acceleration** node ( ) can be added under a **Time-Dependent Solver** node for hardware acceleration using a supported GPU for time-dependent simulations using the discontinuous Galerkin (dG) method.

A CUDA Toolkit must be available The path can be specified in the installer and changed on the **Computing** > **GPU Acceleration** page in the **Preferences** window, where you can also verify your CUDA installation.

DISCONTINUOUS GALERKIN

Select the **Accelerated solver for discontinuous Galerkin** checkbox to use an optimized solver that can be run on either a CPU or a GPU. When enabled, the default is to run calculations on the GPU using single-precision floating-point arithmetic.

The **Compute residual on GPU** checkbox is selected by default. When enabled, calculations on the GPU can be run with either single or double floating-point arithmetic. You can control the precision using the **Use single precision on GPU** checkbox (cleared by default to use double precision). Clear the **Compute residual on GPU** checkbox to run the accelerated solver on the CPU. When disabled, all calculations are performed using double floating-point arithmetic.

Hierarchical LU

The **Hierarchical LU** node ( ) is an attribute node that handles parameters for boundary element method (BEM) solvers that use hierarchical LU factorization. Right-click an Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attribute node to add an **Hierarchical LU** node.

This node can only be used together with the boundary element method. The Hierarchical LU algorithm approximately factorizes a matrix stored in the BEM Far field approximation format. It is useful when other preconditioners for BEM fails to converge because it usually converges quickly. You can control the numerical accuracy of the approximate LU factorization with the **Drop tolerance** and **Elimination tolerance** settings.

GENERAL

In this section you specify the properties of the hierarchical LU preconditioner.

Use the **Drop tolerance** field to tune the maximum allowed sizes of dropped (neglected) elements (default: 0.001). A smaller drop tolerance means that the preconditioner drops fewer elements and so the preconditioner becomes more accurate. This leads to fewer iterations in the iterative solver, but memory requirements and preconditioning time increase. A larger drop tolerance means that the preconditioner drops more elements and so memory use and preconditioning time decrease. In this case, however, the preconditioner becomes less accurate, which leads to more iterations in the iterative solver, or, if the drop tolerance is too high, to no convergence at all. Often it is most efficient to use as high a drop tolerance as possible; that is, choose it so that the iterative solver barely converges.

Use the **Elimination tolerance** field to specify the tolerance (default: 1) for the computation of the eliminated Jacobian (multiplies with **Drop tolerance** value).

Use the **Number of iterations** field to specify how many iterations to perform (default: 2). The relaxation factor ω is similar to the one used by, for example, the **SOR** node. Specify such a factor in the **Relaxation factor** field (default: 1). See also About the Relaxation Factor.

HYBRIDIZATION

Use the settings in the **Hybridization** section to set up a hybrid preconditioner where the direct preconditioner is active for some dependent variables. See Hybrid Preconditioners for more information.

Incomplete LU

The **Incomplete LU** node ( ) is an attribute node that handles parameters for linear system solvers/preconditioners that use incomplete LU factorization. Right-click an Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attribute node to add an **Incomplete LU** node. Also see About Incomplete LU.

GENERAL

In this section you specify the properties of the incomplete LU preconditioner.

Select a **Solver**. Select:

- **ILU** (the default) to use a solver designed specifically for incomplete LU factorization.
- **ILUT (MKL)** to use the ILUT solver (preconditioner) from Intel® MKL (Intel® Math Kernel Library). Unlike ILU0, ILUT preserves some resulting fill-in in the preconditioner matrix (see Ref. 34).
- **ILU0 (MKL)** to use the ILU0 solver (preconditioner) from Intel® MKL. ILU0 preserves the structure of the original matrix in the result (see Ref. 34).
- **SPOOLES** to use the sparse object-oriented linear equations solver SPOOLES.

The ILUT (MKL) and ILUT0 (MKL) preconditioners can perform better than ILU when solving large systems but are not multithreaded.

ILUT (MKL) and ILU0 (MKL) are not applicable to complex-valued problems.

Drop Using

For **Incomplete LU**, select an option from the **Drop using** list to specify a drop rule. See Selecting a Drop Rule. Select:

- **Tolerance** (the default) to let the solver drop (neglect) elements that have small enough absolute values. Tune the sizes of the neglected elements either in the **Drop tolerance** field or using the accompanying slide bar. A larger tolerance neglects more elements.
- **Fill ratio** to let the solver keep a certain fraction of the elements. The elements with largest absolute values are kept. Tune the number of nonzero elements in the incomplete factorization using either the **Fill ratio** field or the accompanying field. A smaller fill ratio neglects more elements.

For **ILUT (MKL)**, you can specify both a drop tolerance and a fill ratio.

Drop Tolerance

For **Incomplete LU**, **ILUT (MKL)**, and **SPOOLES**, use the **Drop tolerance** field or the accompanying slide bar to tune the maximum allowed sizes of dropped (neglected) elements (default: 0.01). A smaller drop tolerance means that the preconditioner drops fewer elements and so the preconditioner becomes more accurate. This leads to fewer iterations in the iterative solver, but memory requirements and preconditioning time increase. A larger drop

tolerance means that the preconditioner drops more elements and so memory use and preconditioning time decrease. In this case, however, the preconditioner becomes less accurate, which leads to more iterations in the iterative solver, or, if the drop tolerance is too high, to no convergence at all. Often it is most efficient to use as high a drop tolerance as possible; that is, choose it so that the iterative solver barely converges.

Respect Pattern

For **Incomplete LU**, by default the solver never drops elements in positions where the original matrix is nonzero. Clear the **Respect pattern** checkbox to allow the solver to also drop such elements.

Pivot Threshold

For both **Incomplete LU** and **SPOOLES**, use the **Pivot threshold** field to enter a number between 0 and 1 that acts as pivot threshold (default: 1). This means that in any given column, the algorithm accepts an entry as a pivot element if its absolute value is greater than or equal to the specified pivot threshold times the largest absolute value in the column. The solver permutes rows for stability. In any given column, if the absolute value of the diagonal element is less than the pivot threshold times the largest absolute value in the column, it permutes rows such that the largest element is on the diagonal. Thus the default value 1 means that it uses partial pivoting.

Number of Iterations and Relaxation Factor

For **Incomplete LU**, **ILUT (MKL)**, and **ILU0 (MKL)** — once the approximate factors L and U have been computed — you can use the incomplete LU factorization as an iterative preconditioner/smoother. Here, $M = (LU)/\omega$, where ω is a relaxation factor, and L and U are the approximate factors. Use the **Number of iterations** field to specify how many iterations to perform (default: 1). The relaxation factor ω is similar to the one used by, for example, the **SOR** node. Specify such a factor in the **Relaxation factor** field (default: 1). See also About the Relaxation Factor.

Preordering Algorithm

For **SPOOLES**, use the **Preordering algorithm** list to select one of the following preorderings:

- **Nested dissection** (NS, the default)
- **Minimum degree**
- **Multisection** (MS)
- **Best of ND and MS** (the best of nested dissection and multisection)

Iterative

The **Iterative** node ( ) is an attribute that handles settings for iterative linear system solvers. You can use it with an Eigenvalue Solver, Stationary Solver, or Time-Dependent Solver, for example.

An alternative to the iterative linear system solvers is given by direct linear system solvers, which are handled via the Direct attribute node. Although several attribute subnodes for solving linear systems can be attached to an operation node, only one can be active at any given time.

The iterative solver iterates until a relative tolerance is fulfilled. You specify this tolerance in the **Relative error** field of the operation node to which this attribute belongs.

Also see The Iterative Solvers, Iterative Solver Types, and Selecting a Preconditioner for an Iterative Linear System Solver for more details about the settings under **General**.

GENERAL

This section contains settings for choosing an iterative linear system solver and for specifying the type of preconditioning and some settings for the error norm and error estimation.

Iterative Linear System Solver Settings

Use the **Solver** list to select an iterative linear system solver. Select:

- **GMRES** to use the restarted GMRES (Generalized Minimum RESidual) iterative method.
- **FGMRES** to use the restarted FGMRES (Flexible Generalized Minimum RESidual) iterative method.
- **BiCGStab** to use the BiCGStab (BiConjugate Gradient Stabilized) iterative method.
- **Conjugate gradients** to use the Conjugate gradients iterative method.
- **TFQMR** to use the TFQMR (transpose-free quasi-minimal residual) iterative method.
- **Use preconditioner** to use the active preconditioner attached to this **Iterative** node as the linear system solver. This solver uses the settings for **Factor in error estimate** and **Maximum number of iterations** from the **Error** section of the corresponding **Iterative** node.

If **GMRES** or **FGMRES** is selected, specify the **Number of iterations before restart** that the solver performs until it restarts (the default is 50). There is no guarantee that a restarted GMRES converges for a small restart value. A larger restart value increases the robustness of the interactive procedure, but it also increases memory use and computational time. For large problems, the computational cost to produce a preconditioner of such quality that the termination criteria are fulfilled for a small number of iterations and for a small restart value is often large. For those problems, it is often advantageous to set up a preconditioner with a somewhat lesser quality and instead increase the restart value or iterate more steps. Doing so typically increases the condition number for the preconditioned system, so an increase in the error-estimate factor might be needed as well.

If any other linear system solver than **FGMRES** is selected, specify whether you are **Preconditioning** the linear system matrix from the **Left** or **Right**. Normally, this setting does not significantly influence the convergence behavior of the selected solver. The default choice is left preconditioning. Normally, for GMRES, the two versions of GMRES have similar convergence behavior (see Ref. 19). If the preconditioner is ill-conditioned, there could, however, be differences in the behavior. For the conjugate gradient method, this choice only affects the convergence criterion and not the algorithm itself.

If you use left preconditioning, a residual tolerance is available in the **Residual tolerance** field (default: 0.01). You can use this setting to obtain extra accuracy. If you for some reason do not want that extra accuracy, set the relative tolerance to one (1).

Settings for Error Norms and Error Estimation

If you use preconditioning, select the **Nonlinear-based error norm** checkbox to allow termination of the linear iterative methods using a criterion other than the standard ones (that is, norm checks of the relative preconditioned residual or the relative residual). The nonlinear-based error norm is foremost used for time-dependent studies (enabled per default), where the (initial) residual can be very small for certain time steps and the requirements become too strict. The nonlinear-based error norm normalizes the preconditioned residual with the scales from the solution instead of the initial residual. This method is more reliable when the scales for (size of) the solution have saturated. This is the reason for having a level, which you can specify as a relative error norm value in the **Use below error level** field (default: 0.1 for stationary solvers and 1 for time-dependent solvers). For Stationary studies it is not common that the initial residual is small, so this functionality is not enabled per default. Also, if **GMRES** is selected and left preconditioning is used, the **Use nonlinear scales** checkbox is available and selected so that the termination of the iterative solver use nonlinear scales. This setting corresponds to the termination behavior in earlier versions.

The stopping criteria for the iterative solvers are based on an error estimate, which checks if the relative residual times a stability constant ρ is less than a tolerance. This tolerance is specified in the **Relative error** field of the operation node to which this attribute belongs. Use the **Factor in error estimate** field to set ρ, which serves as a safety factor to avoid premature termination of the iterations due to, for example, ill-conditioning of the matrix A or poor preconditioning (default: 400). A larger value of ρ increases the number of iterations but decreases the chance that

the iteration is terminated too early. To avoid false termination, the main solver continues iterating until the error check passes or until the step size is smaller than about $2.2 \cdot 10^{-14}$.

For information about the convergence criteria used by the iterative solvers, see Convergence Criteria for Linear Solvers

The GCRO-DR Methods for Krylov Subspace Recycling (GMRES)

If **GMRES** is selected, the **Use GCRO-DR** checkbox is selected by default. GCRO-DR is a method for Krylov subspace recycling. It can be useful while solving sequences of linear systems arising from, for example, nonlinear problems. The idea behind the GCRO-DR method is to retain the subspace determined while solving previous systems and use it to reduce the cost of solving the next system. This method reuses and improves the basis when GMRES is restarting. However, because the GCRO-DR method stores left and right vectors for the Krylov space (similar to FGMRES), the memory requirements are about twice as high for the iteration data stored by the GCRO-DR method compared to GMRES. GCRO-DR is therefore activated only when GMRES reaches its restart length.

When the **GCRO-DR** checkbox is selected, you can specify the following settings:

- You can specify the size of the stored subspace between nonlinear or parametric iterations k (where $k <$ GMRES restart length) can be set using the **Number of approximate eigenvectors** field (default: 25).
- Use the options in the **Reuse subspace** list to control if the subspace is stored or deleted between iterations. If you choose **Off**, the subspace is always deleted. This means that GMRES will be called again in the next nonlinear or parametric iteration. If you choose **On**, the subspace is always stored. By default, the **Automatic** storage is selected, and it means that the subspace is deleted if you get quick convergence, because in that case, GMRES can be expected to converge quickly in the next nonlinear or parametric iteration.
- In the **Minimum number of restarts** field, which is available when **Reuse subspace** is set to **Automatic**, you can specify a minimum value for the number of restarts (default: 5). Using this setting can be useful to control when the subspace should be cleared between solver calls in cases when a subspace exists between solver calls — for instance, in a frequency sweep. The GCRO-DR method might then requires more cycles than usual to converge.
- Select the **Use relative subspace size** checkbox to force the subspace storage whenever GMRES converges in more than k iterations (set in the **Number of approximate eigenvectors** field). In that case, the size of the stored subspace is equal to the fraction of GMRES iterations controlled by the value (larger than 0, maximum 1) in the **Fraction of GMRES iterations** field.

Maximum Number of Iterations

Use the **Maximum number of iterations** field to enter a maximum number of iterations that the iterative solver is allowed to take (default: 10,000 iterations). When this number of iterations has been performed without reaching the specified tolerance, the solver stops with an error message.

ERROR

The error handling mechanism in the linear iterative solvers is intended to contribute to a general robustness of the computation. For example:

- Elimination of a possible premature termination.
- Obtaining extra accuracy for the linear system of equations for the sake of a fewer nonlinear iterations.
- Avoiding warnings and errors related to ill-conditioned preconditioners.

Use the **Factor in error estimate** field to manually set the constant ρ. The default is 400. See Convergence Criteria for Linear Solvers for more information.

You can control the accuracy of the solution of the linear system from the **Check error estimate** list:

- The default is **Automatic**, meaning that the main solver is responsible for error management. The solver checks for errors for every linear system that is solved. To avoid false termination, the main solver continues iterating until the error check passes or until the step size is smaller than about $2.2 \cdot 10^{-14}$. With this setting, linear solver errors are either added to the error description if the nonlinear solver does not converge, or added as a warning if the errors persist for the converged solution. The nonlinear solver continues when it reaches the maximum number of iterations. Use the **Maximum number of intermediate iterations** field to control the efforts spent in each linear solver call (default: 100 iterations).
- Choose **Yes** to check for errors for every linear system that is solved. If an error occurs in the main solver, warnings originating from the error checking in the direct solver appear. The error check asserts that the relative error times a stability constant ρ is sufficiently small. This setting is useful for debugging problems with singular or near singular formulations.
- Choose **No** for no error checking.

For an example using a Stationary Solver, see *Micromixer*: Application Library path **COMSOL_Multiphysics/Fluid_Dynamics/micromixer**.

Jacobi

The **Jacobi** node ( ) is an attribute that handles settings for the Jacobi (or diagonal scaling) method. Right-click the Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attribute nodes to add a **Jacobi** feature.

The Jacobi method provides a simple and memory-efficient solver/preconditioner/smoother based on classical iteration methods for solving a linear system of the form $Ax = b$. Given a relaxation factor ω (usually between 0 and 2), a sweep of the Jacobi (diagonal scaling) method transforms an initial guess x_0 to an improved approximation $x_1 = x_0 + M^{-1}(b - Ax_0)$, where $M = D/\omega$, and D is the diagonal part of A.

GENERAL

Settings When Not Used with Coarse Solver

Enter the **Number of iterations** to perform when this node is used as a preconditioner or smoother. This setting is not considered when the attribute is used as a linear system solver (with the **Use preconditioner** option in the **Solver** list of the **Iterative** attribute node). The solver then iterates until the relative tolerance specified by the corresponding operation node is fulfilled rather than performing a fixed number of iterations.

With the Molecular Flow Module plus the Particle Tracing Module, see *Molecular Flow Through an RF Coupler*: Application Library path **Molecular_Flow_Module/Benchmarks/rf_coupler**.

Settings When Used With a Coarse Solver

If this node is used with a Coarse Solver, select a **Termination technique** to determine how to terminate the solver. Select **Fixed number of iterations** to perform a fixed number of iterations each time the **Coarse Solver** is used, or **Use tolerance** to terminate the **Coarse Solver** when a tolerance is fulfilled.

If **Fixed number of iterations** is selected, enter a value for the **Number of iterations** to perform. The default is 10.

If **Use tolerance** is selected, enter a value for each of the following:

- **Relative tolerance** to specify the termination tolerance. The default is 0.1.
- **Maximum number of iterations** that the solver is allowed to take. When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver is automatically stopped with an error message.

Also enter a **Relaxation factor** to specify a scalar relaxation factor ω. The allowed values of this factor are between 0 and 2. The default is 1. See About the Relaxation Factor for more information.

Krylov Preconditioner

The **Krylov Preconditioner** node ( ) is an attribute node that handles settings for Krylov-type methods. The settings are similar to the Iterative attribute node; the difference is that this node is an auxiliary attribute node, whereas Iterative handles settings for a main iterative solver.

Right-click an Iterative, Presmoother, Postsmoother, Coarse Solver, Schur Solver or Schur Source Solver attribute node to add a **Krylov Preconditioner**.

GENERAL

Select a linear system **Solver**: **GMRES** (the default), **FGMRES**, **BiCGStab**, **TFQMR**, or **Conjugate gradients**. See Iterative Solver Types for descriptions. The **FGMRES** option is not available when the **Krylov Preconditioner** subnode is added under a **Schur Source Solver** node.

- When **GMRES** or **FGMRES** is selected, enter a **Number of iterations before restart** to specify how many iterations the solver should take between each restart. A larger number increases robustness but also memory use and computational time.
- When **GMRES**, **BiCGStab**, **TFQMR**, or **Conjugate gradients** is selected, select an option from the **Preconditioning** list to specify whether to precondition the linear system matrix from the **Left** or from the **Right**. Normally, this setting does not significantly influence the convergence behavior of the selected solver. This setting is not available when the **Krylov Preconditioner** subnode is added under a **Schur Source Solver** node.
- When **GMRES** is selected, the **Use GCRO-DR** checkbox is available for the use of a GCRO-DR method. See The GCRO-DR Methods for Krylov Subspace Recycling (GMRES) for more information.
- For all **Solver** types, select a **Termination technique**:
  - **Fixed number of iterations** to perform a fixed number of iterations each time the solver is used.
  - **Use tolerance** to terminate the solver when a tolerance is fulfilled. Then enter a **Relative tolerance** and the **Maximum number of iterations** the solver is allowed to take. When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver is automatically stopped with an error message.
  - **Iterations or tolerance** to terminate when the estimated tolerance is smaller than a specified tolerance or after a specified number of iterations, whichever comes first. Then enter a **Relative tolerance**.
- For all **Solver** types, enter the **Number of iterations**. The default is 500.

ERROR

Select an option from the **Validate error estimate** list: **Automatic** (the default), **Yes**, or **No**. By choosing the appropriate option from the **Validate error estimate** list, the error estimate for left preconditioned solvers can be validated. **No** implies no error estimate validation, whereas **Automatic** or **Yes** does. By default, the validation is enabled with the **Automatic option**, meaning that it is performed, but preconditioner warnings are only issued if the iterative solver fails with an error. This setting is propagated recursively and applies to all children with left preconditioning.

Localized Schur

The **Localized Schur** node ( ) is an attribute to a Schur Solver and to a Krylov Preconditioner added under a Schur Solver node. It is an alternative to the default Sparse Localized Schur node. The Localized Schur method solves a filled, dense equation system, whereas the Sparse Localized Schur method filters out small matrix elements and can therefore use all solvers.

Use the **Termination technique** list to select how to terminate the solver. Select:

- **Fixed number of iterations** (the default) to perform a fixed number of iterations each time the **Schur Solver** is used.
- **Use tolerance** to terminate the **Schur Solver** when a tolerance is fulfilled.
- **Iterations or tolerance** to terminate when the estimated tolerance is smaller than a specified tolerance or after a specified number of iterations, whichever comes first.

Further options that apply to the selection (as indicated at each bullet) made in the **Termination technique** list are:

- **Number of iterations** (available when **Termination technique** is set to **Fixed number of iterations** or **Iterations or tolerance**). Use this field to specify the fixed number of iterations to perform (default: 2).
- **Relative tolerance** (available when **Termination technique** is set to **Use tolerance** or **Iterations or tolerance**). Use this field to specify the termination tolerance (default: 0.1).
- **Maximum number of iterations** (only available when **Termination technique** is set to **Use tolerance**). Use this field to enter a maximum number of iterations that the solver is allowed to take (default: 10). When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver automatically stops with an error message.

Lower Limit

The **Lower Limit** node ( ) makes it possible to impose restrictions on degrees of freedom (field variables). These restrictions are checked after each substep of a segregated approach. The restriction is performed without any regards to the equations, so use this restriction with care. Enforcing a lower limit on a field variable can be useful to ensure positivity of a volume fraction of particles or the positivity of turbulence model variables, for example. Right-click a Segregated node to add a **Lower Limit** node.

LOWER LIMIT

By default, no variables have active lower limits. To activate lower limits for field variables, use the **Lower limits (field variable)** field to specify the variables and their scalar lower limits as space-separated pairs: *field_variable_1 limit_value_1 field_variable_2 limit_value_2*, and so on. For example, to impose a lower limit of 0.25 for the value of a field **u** in Component 1, enter `comp1.u 0.25`.

Lumped Step

The **Lumped Step** node ( ) is available when using the Segregated attribute node. This step is intended for speeding up and regularizing the computation of any L_2-projection stemming from a FEM formulation; for example, where a dependent variable field u is updated or computed from some source field `uSrc`:

```
test(u)*(u-uSrc)
```

Using the lumped step approximates the Jacobian matrix resulting from finite element discretization when solving the linear system for the unknown field variables. The approximation consists of replacing the Jacobian by a diagonal matrix with row sums. In doing so, take care to ensure that the resulting approximate Jacobian is invertible (nonsingular).

GENERAL

Use the **Variables** list to specify variables to be solved for in this step.

By default, all field or state components are included. Select **Manual** from the **Components** list to specify which fields or states to include.

The variables are the ones that appear under the **Dependent Variables** node, and the components are the components listed by each of these (for instance, `u` is the variable and `u`, `v`, and `w` are the components for a Solid Mechanics model); see also the Field and State nodes.

Jacobian matrices requested by the lumped solver during solution can be stored in a *sparse* or a *filled* format, which you choose as **Sparse** or **Filled**, respectively, from the **Matrix format** list. The default setting is **Automatic**. In this case, the setting from the **Advanced** node is used.

In addition, you can choose a matrix-free format, which you choose as **Free**. Since the Lumped solver does not benefit from matrix-free evaluation of matrix-vector products, a warning will be issued. COMSOL Multiphysics then assembles the matrix when needed but does not store it between repeated requests from the segregated solver. This may reduce peak memory usage at the cost of multiple assembly calls.

Multigrid

The **Multigrid** solver ( ) is used to set up a geometric multigrid (GMG) solver or an algebraic multigrid (AMG) solver. Right-click the Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attribute node to add a **Multigrid** solver.

	Linear in the *COMSOL Multiphysics Programming Reference Manual*

GENERAL

Select a multigrid **Solver**: **Geometric multigrid** (the default), **Algebraic multigrid**, or **Smoothed aggregation AMG**. You can use the smoothed aggregation AMG (SAAMG) solver for linear elasticity problems when geometric multigrid cannot be used or when classical algebraic multigrid performs poorly. That method works by clustering nodes of degrees of freedoms into aggregates based on a connection criterion. Each aggregate then becomes a new node on the next multigrid level, and the algorithm proceeds until a certain number of levels has been reached or until the number of degrees of freedoms is sufficiently small.

For either choice, enter the:

- **Number of iterations**. The default is 2.
- Select a **Multigrid cycle**: **V-cycle** (the default), **W-cycle**, or **F-cycle**. For **Multigrid cycle**, the settings are the same as for the geometric multigrid (GMG) and algebraic multigrid (AMG) solvers.
- Enter the **Number of multigrid levels** to generate (the default is 1 for **Geometric multigrid** and 5 for **Algebraic multigrid**).

Select the **Prefer the free matrix format** checkbox to automatically choose the matrix free format, which can save memory.

Geometric Multigrid

Select an option from the **Hierarchy generation method** list to specify how to generate the multigrid levels:

- **Lower element order first (any)**. The default. Generates first a multigrid level by lowering the order (by one) of any of the used shape functions. If there are no shape functions that can be lowered, the mesh is coarsened.
- **Coarsen mesh and lower order**. Combines lowering of the used shape function order and a coarsening of the mesh.

- **Lower element order first (all)**. Generates a multigrid level by lowering the order (by one) of all the used shape functions. If this is not possible, the mesh is coarsened.
- **Coarsen mesh**. Does not change the order.
- **Lower element order and refine (all)**. Generates a multigrid level by lowering the order (by one) of all the used shape functions. If this is not possible, the mesh is refined a number of times. The mesh solved for can, with this method, be a finer one than the one selected under the study node.
- **Lower element order and refine (any)**. Generates a multigrid level by lowering the order (by one) of any of the used shape functions. If there are no shape functions that can be lowered, the mesh is refined. The mesh solved for can, with this method, be a finer one than the one selected under the Study node.
- **Refine mesh**. Does not change the order.
- **Manual**. Use this setting to select a multigrid level from the existing ones. You then specify the multigrid level to use in the **Use multigrid level** list. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to configure the list of multigrid levels (see Multigrid Level). Use the **Assemble on multigrid levels** list to specify for which multigrid levels to assemble the discrete differential operators. See also The Geometric Multigrid Solver with Several Meshes.

For any **Hierarchy generation method** (except **Manual**), additional settings are available:

- In the **Use hierarchy in geometries** list, select the geometries to apply the multigrid level to. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to configure the list of geometries.
- The **Assemble on all levels** checkbox is selected by default to assemble the discrete differential operators. Otherwise, these operators are formed using the restriction and prolongation operators. Click to clear the checkbox as needed.
- When **Coarsen mesh and lower order**, **Lower element order first (all)**, **Lower element order first (any)**, or **Coarsen mesh** are selected from the **Coarse level generation method** list, select the **Keep generated multigrid levels** checkbox to save the meshes for all levels under the mesh node.

See also The Geometric Multigrid Solver/Preconditioner for more information.

The Coarse Level options are described for the Direct node.

If **None** is selected, no coarse mesh is used in addition to the fine mesh. This can lead to severe reduction in convergence rate but saves memory.

Algebraic Multigrid

For **Algebraic multigrid**, see The Algebraic Multigrid Solvers/Preconditioners for more information. In addition to the settings above, the following settings control the automatic construction of the multigrid hierarchy:

- Enter a **Maximum number of DOFs at coarsest level**. The default is 5000. Coarse levels are added until the number of DOFs at the coarsest level is less than the max DOFs at coarsest level or until it has reached the number of multigrid levels. Also, you can specify the **Maximum number of DOFs per thread on multigrid level** for AMG on a parallel multithreaded system. The default is 5000.
- Choose a **Coarsening method**: **Parallel modified independent set** (the default) or **Classical**. The **Parallel modified independent set** method makes the algebraic multigrid solver more efficient in distributed computing using the method described in Ref. 13. The **Classical** method corresponds to the implementation of AMG in COMSOL versions before version 6.0 (that is, Ruge–Steuben coarsening). See below for the settings for each coarsening method.

If you chose **Classical**:

Enter a value or use the slider to set the **Quality of multigrid hierarchy**. Higher quality means faster convergence at the expense of a more time-consuming setup phase. For instance, if the linear solver does not converge or if it uses too many iterations, try a higher value to increase the accuracy in each iteration, meaning fewer iterations. If the algebraic multigrid algorithm runs into memory problems, try a lower value to use less memory. The range goes from 1 to 10, where 10 gives the best quality. The default is 3.

If you chose **Parallel modified independent set**:

- Enter a value for the **Strength of connections** is a positive number, typically between 0.25 and 0.75 (default value: 0.25). This is a strength threshold used to determine the relation of strong influence dependence between the points. There is some indication that you should use a lower number, such as 0.25, for problems with denser matrices, whereas for other problems with sparser matrices you should use larger values, such as 0.75.

  Let A denote the system matrix and θ the strength threshold; a point i then depends strongly on j, or j strongly influences i if $-a_{ij} \geq \theta \max_{k \neq j} -a_{ik}$.
- The **Sparser prolongator** checkbox is selected by default. When interpolating the value of the error in a specific fine point "i", only the coarse points that strongly influencing "i" are used. If you clear the checkbox, all the coarse points that are influencing "i" are used.

  The interpolation formula, referred to as "direct interpolation", is given in equation 7 in Ref. 17. The prolongator is the matrix defining the interpolation operator between the coarse and fine grid. By selecting the **Sparser prolongator** checkbox, you achieve better performance per iteration (less memory and computation time) but the solver may require more iterations to converge.
- Use the **Prolongator truncation factor** (default: 0.1) to control the fill-in of the prolongator. Small elements from the prolongator are removed. More precisely, let P denote the prolongator and M the truncation factor, the element p_{ij} is removed if $\frac{|p_{ij}|}{\max_{0 \leq k \leq m} |P_{ik}|} \leq M$

  The rows of the truncated prolongator are rescaled afterward by following the reasoning in Section 7.2 of Ref. 18. More precisely, the sum of the ith row before and after truncation should not change.

The **Lower element order first (any)** checkbox is selected by default. This setting provides the combination of GMG with lower order until order 1 is reached and then uses AMG to generate the coarser levels. The **Assemble on the order-lowered levels** checkbox, which is selected by default, then corresponds to the GMG option to assemble on all level. Using this setting is equivalent to using GMG with AMG as a coarse grid solver.

Smoothed Aggregation AMG

For **Smoothed aggregation AMG** (SAAMG), which is a version of AMG that works well alternative for CFD and other problems where GMG works well but is more robust in the sense that only one valid mesh is needed.

The following settings control the aggregation algorithm:

- Enter a **Maximum number of DOFs at coarsest level**. The default is 5000. Coarse levels are added until the number of DOFs at the coarsest level is less than the max DOFs at coarsest level or until it has reached the number of multigrid levels.
- The aggregation algorithm is based on a connection criterion, which you specify as a coefficient in the **Strength of connections** field. A node j is connected to another node i, if $\|A_{ij}\| \geq \varepsilon \|A_{ii}\| \|A_{jj}\|$ where ε is the strength of connection coefficient, and A_{ij} is the submatrix of the stiffness matrix defined by the degrees of freedoms on node i and j, respectively. Loosely speaking, the strength of connection value determines how strongly the aggregation should follow the direction of anisotropy in the problem. The default value is 0.01.
- From the **Null-space vectors** list, choose **Constant** (the default) or **Rigid body modes**. For linear elasticity problems, always select **Rigid body modes** because it enhances the convergence properties significantly.
- Select the **Construct prolongators componentwise** checkbox for CFD applications and other not strongly coupled physics. It is selected by default in predefined solver suggestions for CFD. This setting is only available when the **Null-space vectors** settings is set to **Constant**.

- Select the **Compact aggregation** checkbox to use an aggregation algorithm that forms, on average, smaller aggregates, which leads to a less rapid coarsening.
- By default, the **Reuse prolongators** checkbox is selected to avoid computing the prolongator matrix P when an old prolongator can be reused.
- Choose how to control the prolongator smoothing using the **Smoothing** list, which is active when the **Prolongator smoothing** checkbox (selected by default) is selected. The **Auto** option postpones the smoothing for `sdim-1` levels, where `sdim` is the space dimension of the problem. If you choose **Manual**, enter the level to start smoothing at in the **Start smoothing at multigrid level** field.
- The final transfer operator, P, between the fine and coarse problems are smoothed by one application of Jacobi smoothing:

$$P = (\dot{I} - \omega D^{-1} A_F)\tilde{P}$$

  where ω is the *Jacobi damping factor*, A_F is the *filtered stiffness matrix*, and D is the diagonal of A_F. Specify ω in the **Jacobi damping factor** field. The default value is $2/3$.
- By default, the **Use filtering** checkbox is selected. Filtering means that entries in the stiffness matrix have been dropped if they correspond to degrees of freedoms on a node that has no strong connections. Loosely speaking, filtering highlights anisotropy in the problem and results in a sparser coarse level problem.
- The **Lower element order first (any)** checkbox is selected by default. This setting provides the combination of GMG with lower order until order 1 is reached and then uses SAAMG to generate the coarser levels. The **Assemble on the order-lowered levels** checkbox, which is selected by default, then corresponds to the GMG option to assemble on all level. Using this setting is equivalent to using GMG with SAAMG as a coarse grid solver.

EQUATIONS

Shifted Laplace Contribution (CSL)

If you have selected the **Shifted Laplace contribution** checkbox to use CSL, then select:

- The **Physics** from the list.
- Add a weak contribution method from the **Add weak contribution** list:
  - **Automatic**: The code internally creates a weak contribution for the selected physics. Specify a **Shift coefficient** relaxation factor, which is a scalar value (default: 1). The shift coefficient multiplies the expression for the shifted Laplace contribution. You can think of it as the β coefficient in the Complex Shifted Laplacian for Large Helmholtz Problems section. It might be the case that you need more or less damping than what the original equation provides; you can then choose another value for this factor. The **Automatic** option is only supported for Helmholtz-type equations. In that case, the meaning of the shift coefficient is the factor α in the term $-i\alpha k^r u$, where r is 1.5. Select the **Keep generated weak contribution** checkbox in order to keep the CSL weak contribution feature in the Physics node.
  - **Manual**: Specify the complete weak-form expression in the **Weak expression** field. This expression can be applied to any Physics available in the list above. Select the **Keep generated weak contribution** checkbox to keep the CSL weak contribution feature in the Physics node.
  - **From physics**: the CSL weak contribution is taken from the Physics node. Only use this option if a weak contribution feature was previously added by selecting the **Keep generated weak contribution** checkbox together with the **Automatic** or **Manual** options as described above.
  - **Off**: No CSL is added for the selected Physics.

The CSL can be applied on the fine grid and on the multigrid levels independently Select the **Shifted Laplace contribution on multigrid levels** checkbox to use CSL on the multigrid levels. The CSL group for the fine grid can be used only if the **Prefer the free matrix format** checkbox is active. When CSL is used together with GMG, it is

possible to specify the **Minimum multigrid level** and **Maximum multigrid level** on which CSL is to be applied. By default, the latter is set to the maximum multigrid level.

HYBRIDIZATION

Use the settings in the **Hybridization** section to set up a hybrid preconditioner. See Hybrid Preconditioners for more information.

- The Multigrid Solvers
- Multigrid Level

Parametric

The **Parametric** node ( ) is an attribute node that handles settings for parameter stepping using a parametric solver. This node can be used together with a Stationary Solver node.

There is also an option to run a Stationary study with an **Auxiliary sweep**, with or without a continuation parameter. When a continuation parameter is selected, the continuation algorithm is run, which assumes that the sought solution is continuous in these parameters. If no continuation parameter is given, a plain sweep is performed where a solution is sought for each value of the parameters. In both cases, a **Stationary Solver** node plus a **Parametric** attribute is used. The parametric solver is the algorithm that is run when a Parametric attribute node is active under a Stationary Solver. Similarly the adaptive solver is the algorithm that is run when an Adaptive Mesh Refinement (Time-Dependent Adaptation) node is active under a Stationary Solver.

In order to run a parametric continuation, select the **Auxiliary sweep** checkbox under **Study Extensions** for the Stationary or Frequency Domain study step. Then on the study node's **Settings** window, define the parameters in the table and choose one from the **Run continuation for** list.

- The Adaptive and Parametric Solver Log
- The Parametric Solver Algorithm

GENERAL

Select an option from the **Defined by study step** list to specify if the settings are synchronized with the Stationary or Frequency Domain study step, in which case this section does not require any input. The **Run continuation for** list also displays the same settings made under **Study Extensions**.

The continuation algorithm is used if a parameter is selected. Normally the step size, damping, and predictor settings are automatic. If required, you can edit the settings in the **Continuation** section described next.

To edit the settings, select **User defined** to modify the sweep type, parameter table, reuse solution from previous step setting, and the parameter to run continuation for. These settings are the same as described in Common Study Step Settings under **Study Extensions**.

Exactly how the parameter values are used by the solver is determined by the **Sweep type** and the option **Parameters to store** in the **Output** section as described below. If more than one parameter name is specified, the lists of parameter values are interpreted as follows. Assume that the parameter names are `p1` and `p2`, and that `p1` has the list 1 3 and `p2` has the list 2 4:

- For **Specified combinations**, the solver first uses `p1` equal to `1` and `p2` equal to `2`. Thereafter, it uses `p1` equal to `3` and `p2` equal to `4`.
- For **All combinations**, the solver uses this order for the parameter combinations: 1 2, 1 4, 3 2, and 3 4.

To determine what the solver does when there is a solver error or when the continuation backtracking fails, select an option from the **On error** list. Select one of the following options:

- **Stop** (the default) to stop the parametric sweep and only return solutions before the error.
- **Skip parameter step** to skip the parameter when there is an error and then continue.
- **Store empty solution** to continue the parametric sweep and store an empty (NaN) solution for this step (or for the remaining continuation).

Using **Store empty solution** can be useful if you need to sweep over many different combinations of parameters and it is unknown which ones that will solve. It can also be useful when doing frequency sweeps where frequencies close to resonances fail.

From the **Parameter value run order** list choose **Automatic** (the default) or **As specified**. When using As specified, the specified order of the parameter values is used. When you use the **Automatic** setting, the parametric solver performs an analysis of the cost of changing the values of involved parameters, and the run order of the parameter values is modified when it is found to be more efficient. If the parameter run order is modified, the modified order is indicated in the **Log** window.

CONTINUATION

This section is disabled, if **Least-squares time/parameter method** is set to **From least-squares objective** in the Optimization study step. In this case **Constant** is used as **Predictor**.

By default, the solver selects the parameter steps automatically based on the values entered in the **Parameter values** field in the **General** section.

Click to select the

Tuning of step size checkbox to edit these settings:

- **Initial step size** field to enter a positive number that determines the magnitude of the first parameter step.
- **Minimum step size** field to specify a safeguard against too small parameter steps.
- **Maximum step size** field to specify an upper bound on the parameter step size. Use this if you suspect that the solver tries to take unnecessarily long steps.

Use the **Use initial damping factor for all parameter steps** list to control the initial damping factor for the nonlinear solvers for the parameter steps.

- Select **On** to use the given **Initial damping factor** for the nonlinear solvers for all parameter steps.
- Select **Off** to use the initial damping factor only for the first parameter step.
- Select **Automatic** (default) to use the initial damping factor only for the first parameter step when the **Automatic (Newton)** or **Automatic highly nonlinear (Newton)** nonlinear solver method is used in the Fully Coupled solver node and use the initial damping factor in all steps for other solver combinations.

Use the **Predictor** list to control how the initial value for the next parameter value is determined. Select:

- **Automatic** (the default) to let the parametric solver choose a constant or linear predictor based on the type of stationary solver: a constant predictor for segregated solvers and a linear predictor for fully coupled solvers. If the fully coupled solver does not converge for a parameter step using the linear predictor, and after reducing the parameter step to the minimum step size, it will use a constant predictor. If the fully coupled solver converges, linear prediction is again used for the next step. When the **Automatic** method changes the predictor in this fashion, a line is added to the solver log about this.
- **Constant** to use the solution for the present parameter value as initial guess.
- **Linear** to compute the initial guess by following the tangent to the solution curve at the present parameter value.

This option is overridden, and **Constant** used instead if you are solving for more than one parameter (that is, when you have entered more than one parameter name in the **Parameter name** field).

LOAD CASE

This section displays the settings made under **Study Extensions** for the Stationary study step; it is synchronized with the study settings.

LEAST-SQUARES DATA

The section only appears if you are solving a least-squares optimization problem with defined parameters.

Least-squares data are read from least-squares objectives (either a file or a table), and the solver sequence is set up accordingly: If there is a least-squares objective containing parameter columns or experimental parameters, a Parametric solver is set up, and the parameter names and values appear under **Parameters from least-square objectives**.

Parameter values corresponding to the same parameter names are merged between different objectives. If the **Use parameters from least-squares objectives** checkbox is selected (which is the default), user-defined parameter values are merged with corresponding merged data from objectives. For parameters that are defined only in objectives and not user defined (and vice versa), globally defined values are used. If the **Use parameters from least-squares objectives** checkbox is selected, the following settings are available:

- The **Use all for Continuation** checkbox is selected by default. It will then expand all least-squares data points into a Continuation. If the least-squares data has data for the continuation parameter, it will be merged with the list that you have provided. If the direction of the continuation is not consistent, an error will be given. If you clear the **Use all for Continuation** checkbox, the given list will only be merged with the least-squares data that matches the given tuples. However, continuation will still be done for the least-squares data. This checkbox has no effect when Continuation is not used.

- The **Create bounding box from the General parameter value lists** checkbox is selected by default to exclude values outside the bounding box.
- The **Add solution data points from the General non-continuation Parameter value lists** checkbox is selected by default to control if extra data points should be added to the solution process. These extra data points do not affect the solution process or the least-squares objectives but can be useful, for example, for results evaluation or for model debugging. When selected and when a continuation is not used, it adds all the user-provided points and removes the duplicates. When selected with a continuation, it adds continuation sweeps for all given parameter value lists. When it is cleared, no extra continuation sweeps are added.

If **Use least-squares parameters from objectives** is off, no least-squares parameters from objectives are used.

You can change the default values of the **Use parameters from least-squares objectives** and its associated settings only if **Defined by study step** is set to **User defined**.

OUTPUT

Use the **Parameters to store** list to control at what parameter values the solver stores a solution. Select:

- **Steps given** to store solutions at the parameter values entered in the **Parameter values** field in the **General** section.
- **Steps taken by solver** to store solutions at all parameter values where the solver has computed a solution. This option can generate solutions in-between the values specified by the **Parameter values** field in the **General** section if the solver needs to take shorter steps than specified by the values in that field.

RESULTS WHILE SOLVING

See Results While Solving in the Common Study Step Settings section. Also see Getting Results While Solving.

CLUSTER SETTINGS

Select the **Distribute parameters** checkbox to distribute the parameters on several computational nodes. If the problem is too large to run on a single node, you can enable the **Maximum number of groups** field to use the nodes' memory more efficiently. In this case, the same parameter is solved for by several nodes that cooperate as if running a nondistributed sweep. The number of nodes that cooperate is equal to the maximum of the total number of nodes divided by the **Maximum number of groups** setting and 1. So if the total number of nodes is 12 and the **Maximum number of groups** is 3, then 3 groups with 4 nodes each cooperate.

	Buoyancy Flow of Free Fluids: Application Library path **COMSOL_Multiphysics/Fluid_Dynamics/buoyancy_free**

Postsmoother

The **Postsmoother** node ( ) is an auxiliary attribute node used by the Multigrid attribute node. This attribute does not have any settings. Instead, its purpose is to administrate postsmoothers for a multigrid solver. To add a postsmoother, right-click the **Postsmoother** node.

Presmoother

The **Presmoother** node ( ) is an auxiliary attribute node used by the Multigrid attribute node. This attribute does not have any settings. Instead, its purpose is to administrate presmoothers for a multigrid solver. To add a presmoother, right-click the **Presmoother** node.

Pressure Solver

The **Pressure Solver** node ( ) is an attribute subnode used by the Block Navier–Stokes attribute node. This node does not have any settings. Right-click it to add a general preconditioner for the pressure block. By default, a **Direct** node for direct linear system solvers is the added as the preconditioner.

Previous Solution

The **Previous Solution** node ( ) is an optional attribute node of the Parametric attribute node and the Time-Dependent Solver node. It handles field variables that have to be accessed at a previous parameter value or time. In time-dependent studies, it can be useful for time-dependent contact problems with friction, for example.

Use the **Variables** list to specify which variables to associate with the previous parameter value or time step rather than the present one.

Use the **Linear solver** list to select a solver for the linear systems associated with the quantities specified by **Variables**. The available solvers are of the types Direct, Iterative, and **Lumped**. The **Lumped** option provides the same functionality as the Lumped Step for the **Segregated** attribute node, applied to all variables specified in the **Variables** list in the **Previous Solution** node's settings.

As a subnode for a **Time-Dependent Solver** node, there is a **Damping factor** checkbox (cleared by default) and an associated input field allowing a value between 0 and 1 (default: 1). If selected, the damped $u_{\text{prev}}(t_{n+1})$ is equal to $u_{\text{prev}}(t_n) + \text{damping_factor}(u_{\text{prev}}(t_{n+1}) - u_{\text{prev}}(t_n))$.

SCGS

The **SCGS** node ( ) is an attribute that handles the SCGS (symmetrically coupled Gauss–Seidel) solver, which is useful as a preconditioner for solving the Navier–Stokes equations and similar fluid flow problems. See The SCGS Solver for more information.

The **Settings** window includes the following sections:

MAIN

Settings When Used with Any Attribute Node

From the **Sweep type** list, choose **SSOR** (the default), **SOR**, or **SORU**. This setting decides in which order the blocks are looped through. **SOR** means lexical order (or forward), the order they are stored, while **SORU** means the opposite (backward) order. **SSOR** means **SOR** followed by **SORU**. The sweep type also decides if SOR, SORU, or SSOR is used in the secondary iteration (called *SSOR update* when the algorithms are described).

Settings When Not Used with Coarse Solver

If a Coarse Solver is not used, enter the **Number of iterations** to specify a fixed number of iterations to perform when this attribute node is being used as a preconditioner (default: 2) or smoother (default: 1).

Settings When Used with Coarse Solver

Use the **Termination technique** list to select how to terminate the solver. Select:

- **Fixed number of iterations** (the default) to perform a fixed number of iterations each time the **Coarse Solver** is used.
- **Use tolerance** to terminate the **Coarse Solver** when a tolerance is fulfilled.
- **Iterations or tolerance** to terminate when the estimated tolerance is smaller than a specified tolerance or after a specified number of iterations, whichever comes first.

Further options that apply to the selection (as indicated at each bullet) made in the **Termination technique** list are:

- **Number of iterations** (available when **Termination technique** is set to **Fixed number of iterations** or **Iterations or tolerance**). Use this field to specify the fixed number of iterations to perform (default: 10).
- **Relative tolerance** (available when **Termination technique** is set to **Use tolerance** or **Iterations or tolerance**). Use this field to specify the termination tolerance (default: 0.1).
- **Maximum number of iterations** (only available when **Termination technique** is set to **Use tolerance**). Use this field to enter a maximum number of iterations that the solver is allowed to take (default: 500). When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver automatically stops with an error message.

General Settings

Use the **Relaxation factor** field to specify a scalar relaxation factor ω. The allowed values of this factor are between 0 and 2 (default: 0.8). See About the Relaxation Factor for more information.

Use the **Block solver** list to specify how to solve the Vanka block linear systems by selecting one of these options:

- **Direct, stored factorization** (the default) to store the factorization. If two SCGS smoothers are used as presmoother and postsmoother of a Multigrid solver, with similar enough settings, they share the same stored factorization, which means that they only use half the memory.
- **Direct** to use a direct solver. The direct solver is slower than the default option to store the factorization, but it uses less memory.
- **Iterative, GMRES** to use the iterative method GMRES. When **Iterative, GMRES** has been selected from the **Block solver** list, the following options become available:
  - Use the **Tolerance** field to specify the termination tolerance of GMRES (default: 0.02).
  - Use the **Number of iterations before restart** field to specify how many iterations the solver should take between each restart (default: 100).

If you use the SCGS algorithm as preconditioner, or as a smoother to a multigrid preconditioner when either of GMRES, Conjugate gradients, BiCGStab, or TFQMR is used as the linear system solver, use the **Direct, stored factorization** or the **Direct** option in the **Block solver** list in order to get a stationary preconditioner.

The **Iterative, GMRES** option in the **Block solver** list can be useful if you use the FGMRES method as a linear system solver because it can handle preconditioners that are not stationary. The GMRES option can also be useful if you use the SCGS algorithm as a smoother to a multigrid solver because GMRES can in some cases be faster than the direct solver if set to a high tolerance, although this advantage is less pronounced with SCGS than Vanka due to the smaller block size used by SCGS.

From the **Method** list, select one of the following methods:

- **Mesh element lines and vertices** (the default), where anisotropic mesh elements are grouped together in SCGS blocks. The DOFs corresponding to nonanisotropic mesh elements are solved using vertex-based SCGS blocks, which use less memory than element blocks. A separate **Vertex relaxation factor** is the relaxation factor for the vertices part of the smoother when you choose **Mesh element lines and vertices**.
- **Mesh elements**, where each mesh element corresponds to one SCGS block.
- **Mesh element lines**, where anisotropic mesh elements are grouped together in SCGS blocks along the direction of anisotropy, which gives better results for boundary layer meshes. Nonanisotropic mesh elements correspond to one SCGS block.

Select the **Vanka** checkbox and then use the **Variables** list to specify variables to include in a Vanka block approach. With this option, you can choose the **Use approximate factorization** checkbox to reduce the memory consumption and use an approximate smoother suitable for saddle-point problems such as Stokes flow (Ref. 14). Use the **Use Schur complement approximation for block with size larger than** field (default value: 150) to specify a size so that the solver can continue to use stored LU factorizations as long as the blocks are not above that size.

Select the **Blocked version** checkbox (selected by default) to use a version of the SCGS method that is optimized for parallel computations.

The **Apply filter to lines** checkbox is selected by default. You can then specify the following options:

- The **Aggressive** checkbox is selected by default. By clearing this checkbox you get a slightly more expensive smoother that is more robust. If you are experiencing convergence issues it may help to disable this option.
- The **Filter individual elements** checkbox is selected by default and controls if the filtering is applied to individual elements or if the lines are first created and the algorithm then filter lines that cover eliminated DOFs that have already been used.
- Select the **Apply filter to AMG levels only** checkbox to ensure that the filter is applied to AMG only.
- From the **Apply filter to elements** list, choose **Prioritize unique start elements** (the default) to control if the start element is filtered. You can also choose **Prioritize unique lines** to filter the entire line, which might be less efficient, or choose **None** to use the algorithm used prior to version 6.0.

Select the **Reuse data** checkbox (selected by default) to reuse the data in the blocks that define the SCGS method. SCGS is a mesh-based method, so formally this performance enhancement is possible as soon as the mesh is the same. If you have selected that checkbox, these additional checkboxes are available:

- The **Reuse sparsity pattern** checkbox is selected by default to store the sparsity patterns of the assembled matrices and try to reuse them for successive assembly processes within the same solution process. In many cases, the sparsity pattern of the system matrices does not change from one nonlinear iteration or time step to the others. Reusing the sparsity pattern from the previous iteration or step can then improve the solution performance at the cost of a usually small amount of memory.
- The **Reuse mesh data** checkbox is also selected by default to control if the mesh data should be kept and reused. Clear this checkbox to regenerate the mesh data when needed, which saves memory but is slower.

SECONDARY

Use the **Number of secondary iterations** field to specify the number of SSOR iterations (default: 1) to perform for degrees of freedom not involved in the SCGS blocks.

Use the **Relaxation factor** field to specify a scalar relaxation factor for the iterations specified in the **Number of secondary iterations** field (default: 1). The allowed values of this factor are between 0 and 2 (default: 0.5). See About the Relaxation Factor for more information.

Schur Solver

The **Schur Solver** node ( ) is an auxiliary attribute subnode used by the Domain Decomposition (Schur) attribute node. This node does not have any settings. Instead, its purpose is to administrate domain solvers for a domain-decomposition Schur solver.

Schur Source Solver

The **Schur Source Solver** node ( ) is an auxiliary attribute subnode used by the Domain Decomposition (Schur) attribute node. This node does not have any settings. Instead, its purpose is to administrate solvers for the artificial sources on the internal boundaries for a domain-decomposition Schur solver when an **Absorbing boundary condition** is used.

Segregated

The **Segregated** node ( ) is an attribute that handles parameters for a segregated solution approach. This attribute makes it possible to split the solution process into substeps. Each substep uses a damped version of Newton's method.

The attribute can be used together with the Stationary Solver and Time-Dependent Solver nodes. An alternative to the segregated approach is given by the coupled solver, which is handled with the Fully Coupled attribute node. Although several **Fully Coupled** and **Segregated** attribute nodes can be attached to an operation node, only one can be active at any given time.

To add substeps to a segregated iteration, right-click the **Segregated** node. One segregated iteration consists of executing each active Segregated Step in the order shown in the model tree.

	The convergence properties of a model might depend on the order of the segregated steps. You can move the Segregated Step nodes to change the order in which the solver runs each step.

	Using the segregated solver, you can impose lower limits and upper limits for the field variables by adding **Lower Limit** and **Upper Limit** subnodes. See Lower Limit and Upper Limit.

For more information about the settings below, see:

- The Segregated Solver
- Damped Newton Methods
- Pseudo Time Stepping
- Termination Criterion for the Fully Coupled and Segregated Attribute Nodes

GENERAL

Select a **Termination technique** list to control how the segregated iterations are terminated. Select:

- **Tolerance** (the default) to terminate the segregated iterations when the estimated relative error is smaller than a specified tolerance.
- **Iterations or tolerance** to terminate the segregated iterations when the estimated tolerance is smaller than a specified tolerance or after a specified number of iterations, whichever comes first.
- **Iterations** to terminate the segregated iterations after a fixed number of iterations.

Then, based on the selected **Termination technique**, use the following settings:

- If **Tolerance** is selected, enter a **Maximum number of iterations** to limit the number of segregated iterations (default: 10). When the maximum number of iterations has been performed, the segregated method is terminated even if the tolerance is not fulfilled.
- If **Tolerance** or **Iterations or tolerance** is selected, enter a **Tolerance factor** to modify the tolerance used for termination of the segregated iterations. The actual tolerance used is this factor times the value specified in the **Relative tolerance** field in the **General** sections of the **Stationary Solver** and **Time-Dependent Solver** nodes.

- If **Tolerance** or **Iterations or tolerance** is selected, choose a **Termination criterion** to control how the Newton iterations are terminated. Select:
  - **Solution** to terminate the Newton iterations on a solution-based estimated relative error.
  - **Residual** to terminate the Newton iterations on a residual-based estimated relative error.
  - **Solution or residual** to terminate the Newton iterations on a solution-based estimated relative error and a residual-based estimated relative errors. Enter a scalar **Residual factor** multiplying the residual error estimate. The default is 1000.

    For time-dependent solvers and if **Solution** or **Solution and residual** is selected as **Termination criterion** for the segregated solver, the segregated steps will always solve the linear system at least once, even if the residual termination criterion would allow for early termination (see Fully Coupled). Should all segregated steps allow for termination before solving the linear system, but the segregated solver does not allow convergence yet, solving the linear system will be enforced as well.
- If **Iterations** or **Iterations or tolerance** is selected, enter a **Number of iterations** to specify a fixed number of iterations to perform. The default is 1.

With a Time-Dependent Solver, also select the **Limit on nonlinear convergence rate** checkbox to force the nonlinear solver to terminate as soon as the convergence is estimated to be too slow. Enter a limit on the convergence rate in the accompanying field. The *nonlinear convergence rate* is estimated as $\gamma = (e_n/e_1)(1/(n-1))$, where e_n is the error estimate for iteration n. This can be seen as the average convergence rate after n steps ($n > 1$). If $\gamma \backslash \gamma_{\text{limit}}$ (γ_{limit} is the limit on nonlinear convergence rate), then the nonlinear solver will terminate (as if it fails). This means that the current time step will be disqualified, and a new nonlinear solve attempt will be performed with a reduced time step. For problems where the convergence rate can be slow, this option can be used to avoid unnecessary nonlinear iterations (because the solver will in those cases not converge anyways within the allotted iterations specified in the **Maximum number of iterations** field).

Also, with a Time-Dependent Solver, by default, a stricter tolerance is used at each Newton iteration step when Jacobian is not updated. This approach typically leads to more robust time stepping. Therefore, more nonlinear iterations might be required in each time step, and more Jacobian updates might be needed. To use the minimal Jacobian update used in earlier versions of the COMSOL Multiphysics software, select the **Use linear heuristics for adaptive tolerance** checkbox.

You can select one of the following methods for stabilization and acceleration of the nonlinear convergence from the **Stabilization and acceleration** list:

- **None** (the default) to not use any stabilization or acceleration method.
- **Pseudo time-stepping** to use a pseudo time-stepping method to stabilize convergence toward steady state for a stationary solver. Pseudo time stepping is not available for time-dependent solvers. See Pseudo Time Stepping for more information. For the pseudo time-stepping method, specify the following controller parameters:
  - **PID Controller**. Choose **Simple** (the default) or **Interpolated**. The simple controller corresponds to the PID controller in versions of the COMSOL Multiphysics software earlier than version 6.2. The interpolated controller blends different types of controllers when the error reaches the **Target error estimate**.
  - **Initial CFL number**. The default is 5.
  - **Target CFL number**. The default is 10,000. The solver does not converge unless the target CFL number is reached.
  - The **Limit to target CFL number** checkbox is selected by default. This setting controls how the CFL number is changed once the **Target CFL number** is reached. If you clear this checkbox, the CFL number can continue to increase until the error tolerance is fulfilled.
  - **PID controller - proportional**. The default is 0.65.
  - **PID controller - integral**. The default is 0.05.
  - **PID controller - derivative**. The default is 0.05.
  - **Target error estimate**. The default is 0.1.
  - Select the **Anderson acceleration** checkbox to activate Anderson acceleration for the pseudo time-stepping method.
  - Select the **Override Jacobian update for steps** checkbox to override updates of the Jacobian for the segregated steps. The **CFL threshold** value (default: 100), which is the value of the CFL number where overriding of the Jacobian update becomes active. That is, the overriding becomes active for larger CFL numbers than the threshold. From the **Jacobian update** list, choose **On first iteration** (the default) or **Minimal**, which updates the Jacobian at least once and then only when the nonlinear solver fails during parameter stepping. It reuses the Jacobian for several nonlinear systems whenever deemed possible.
- **Anderson acceleration**, which is a nonlinear convergence acceleration method that uses information from previous Newton iterations to accelerate convergence. The Anderson acceleration method is primarily intended for acceleration of nonlinear iterations in transport problems involving, for example, crosswind diffusion stabilization. It is useful is for solving linear or almost linear problems using the segregated solver, where convergence can be improved and the performance increased. You can control the number of iteration increments to store using the **Dimension of iteration space** field (default: 10) and the mixing parameter as a value between 0 and 1 using the **Mixing parameter** field (default: 1.0). The **Iteration delay** field (default 0) contains the number of iterations between pseudo time stepping becomes inactive and Anderson acceleration becomes active. Enter a threshold value in the **Threshold for Anderson step** field (default: 10). This threshold value controls if the Anderson step or the Newton step is used in the nonlinear step. If the norm of the new step is less than the threshold times the norm of the previous step, the Anderson step is used. Otherwise, the Newton step is used. Lowering the value for the **Threshold for Anderson step** can improve robustness at the price of performance.

  When used for pseudo time stepping, you can enter a **CFL threshold** value (default: 100), which is the value of the CFL number where Anderson acceleration becomes active and pseudo time stepping becomes inactive. You can also choose **Use PID controller** (the default) or **Lock target CFL number** from the **Above CFL threshold** list. Select **Lock target CFL number** if the solver should set the target CFL number once the threshold is reached, or select **Use PID controller** if the PID controller should still control the CFL number based on the error estimate.

RESULTS WHILE SOLVING

See Results While Solving in the Common Study Step Settings section. Also see Getting Results While Solving.

Segregated Step

The **Segregated Step** node ( ) handles settings for one substep of a segregated iteration. This attribute uses a damped version of Newton's method and can be used together with a Segregated attribute node.

For more background information about the method and termination settings, see The Segregated Solver and Damped Newton Methods.

GENERAL

Use the **Variables** list to specify variables to be solved for in this step.

By default, all field or state components are included. Select **Manual** from the **Components** list to specify which fields or states to include.

The variables are the ones that appear under the **Dependent Variables** node, and the components are the components listed by each of these (for instance, `u` is the variable and `u`, `v`, and `w` are the components for a Solid Mechanics model); see also the Field and State nodes.

Select a **Linear solver** for the linear systems associated with the quantities specified by **Variables**. The available solvers are attribute nodes of the types Direct and Iterative.

Jacobian matrices requested by the linear solver during solution can be stored in a *sparse* or a *filled* format, which you choose as **Sparse** or **Filled**, respectively, from the **Matrix format** list. The default setting is **Automatic**. In this case, the setting from the **Advanced** node is used.

In addition, you can choose a matrix-free format, which you choose as **Free**. The matrix-free representation allows evaluation of matrix-vector products without assembling the matrix. This can reduce the memory usage significantly for solver algorithms that only use the matrix to multiply a vector, specifically:

- The Iterative solver without preconditioner
- The Krylov Preconditioner without preconditioner

A warning is issued when the matrix-free format is used with other solvers. COMSOL Multiphysics then assembles the matrix when needed but does not store it between repeated requests from the solver algorithm. This may reduce peak memory usage at the cost of multiple assembly calls.

METHOD AND TERMINATION

See the Fully Coupled node's **Method and Termination** section for all settings except for the following, which has a slightly different behavior as described, and the residual smoothing (see below):

For a Time-Dependent Solver, if **Backtracking (Newton)** or **Constant (Newton)** is selected as the **Nonlinear method**, choose a **Jacobian update**: **Minimal** (the default), **On every iteration**, **On first iteration**, or **Once per time step**:

- **On every iteration** computes a new Jacobian for all iterations of Newton's method.
- **On first iteration** updates the Jacobian for the first subiteration for this segregated step.
- **Minimal** updates the Jacobian at least once and then only when the nonlinear solver fails during time stepping. It reuses the Jacobian for several nonlinear systems whenever deemed possible.
- **Once per time step** updates the Jacobian once per time step.

For a Stationary Solver or a parametric solver, if **Constant (Newton)** is selected as the **Nonlinear method**, choose a **Jacobian update**: **Minimal** (the default), **On every iteration**, or **Once first iteration**:

- **On every iteration** computes a new Jacobian for all iterations of Newton's method.
- **Minimal** updates the Jacobian at least once and then only when the nonlinear solver fails during parameter stepping. It reuses the Jacobian for several nonlinear systems whenever deemed possible.
- **On first iteration** updates the Jacobian for the first subiteration for this segregated step.

The pseudo time stepping settings are not applicable for this node.

Select the **Residual smoothing** checkbox to enable that the residual smoothing term is applied to the residual on each iteration in the pseudo time-stepping solver.

The value in the **Relaxation factor** field (default: 0.1) controls the magnitude of the residual smoothing term.

Sensitivity

A **Sensitivity** solver node ( ) solves a sensitivity analysis problem set up in The Sensitivity Interface.

Also see The Sensitivity Analysis Algorithm. Sensitivity analysis for time-dependent problems is available with the Optimization Module.

GENERAL

From the **Defined by study step** list, choose any applicable study step or choose **User defined** to define the following two settings in this node.

In the **Objective** field, specify the objective to use for the sensitivity analysis.

From the **Sensitivity method** list, choose one of the following options:

- **Adjoint** — The adjoint method solves for the derivatives of a single scalar objective function with respect to any number of sensitivity variables.
- **Forward** — The forward sensitivity method solves for the derivatives of all dependent variables and an optional scalar objective function with respect to a small number of sensitivity variables. For transient problems, you can specify the **Forward sensitivity rtol factor** and the **Forward sensitivity scaled atol** to control the accuracy of the backward time stepping.
- **Forward numeric** — This method is a variant of the forward sensitivity method where the right-hand side of the sensitivity problem is computed by numerical differentiation.

See also Choosing a Sensitivity Method. More settings appear when the **Sensitivity** solver node appears under a **Time-Dependent Solver** while the **Adjoint** or **Forward** method is chosen. Those settings are described in the Transient Adjoint paragraph of the Optimization Solver in the *Optimization Module User's Guide*.

If desired, select the checkboxes and modify the values for any of the method-dependent parameters that are available.

From the **Store sensitivity states** list, choose **On** (the default), or choose **Off** if you do not want to store them.

TRANSIENT ADJOINT

This section is only available when you have selected **Adjoint** as the sensitivity method, and the section is identical to Transient Adjoint section of the optimization solver.

ADVANCED

From the **Compensate for nojac terms** list, choose **Automatic** (the default), **On**, or **Off**.

- With **Automatic**, the software tries to assemble the complete Jacobian if an incomplete Jacobian has been detected. If the assembly of the complete Jacobian fails or in the case of nonconvergence, a warning is written and the incomplete Jacobian is used in the sensitivity analysis for stationary problems. For time-dependent problems, an error is returned.
- With **On**, the software tries to assemble the complete Jacobian if an incomplete Jacobian has been detected. If the assembly of the complete Jacobian fails or in the case of nonconvergence, an error is returned.

If you get a warning about an incomplete Jacobian, you can then avoid that warning choosing **Off** from this list. With that setting, the software does not attempt to assemble the complete Jacobian (the incomplete Jacobian is used immediately).

From the **Adjoint solution** choose **Initialize with zero solution** (the default) or **Initialize with forward solution**. The latter option can reduce the computational time, if the problem is self-adjoint and an iterative solver is used. This typically happens in linear structural mechanics when the total elastic strain energy variable (`Ws_tot`) is used as objective. The option only affects the adjoint problem of stationary solvers.

SOR

The **SOR** node (SOR) handles settings for the SOR (successive overrelaxation) iterative method. Right-click the Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver attribute nodes to add an **SOR** node.

See The SOR Method for more detailed information about this feature.

GENERAL

Settings When Used with Any Attribute Node

Use the **Solver** list to specify which variant of the SOR algorithm to use. Select:

- **SSOR** (the default) to use the symmetric SOR algorithm, which in each iteration performs one **SOR** sweep followed by one **SORU** sweep.
- **SOR** to use the forward SOR algorithm.
- **SORU** to use the backward SOR (SORU) algorithm.

Settings When Not Used with Coarse Solver

Enter the **Number of iterations** to perform when this node is used as a preconditioner or smoother. This setting is not considered when the attribute is used as a linear system solver (with the **Use preconditioner** option in the **Solver** list of the **Iterative** attribute node). The solver then iterates until the relative tolerance specified by the corresponding operation node is fulfilled rather than performing a fixed number of iterations.

Settings When Used With a Coarse Solver

If this node is used with a Coarse Solver, select a **Termination technique** to determine how to terminate the solver. Select **Fixed number of iterations** to perform a fixed number of iterations each time the **Coarse Solver** is used, or **Use tolerance** to terminate the **Coarse Solver** when a tolerance is fulfilled.

If **Fixed number of iterations** is selected, enter a value for the **Number of iterations** to perform. The default is 10.

If **Use tolerance** is selected, enter a value for each of the following:

- **Relative tolerance** to specify the termination tolerance. The default is 0.1.
- **Maximum number of iterations** that the solver is allowed to take. When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver is automatically stopped with an error message.

General Settings

Specify a scalar **Relaxation factor** ω. The allowed values of this factor are between 0 and 2 (default: 1). See About the Relaxation Factor for more information.

The **Blocked version** checkbox is selected by default and it uses a blocked version of the SOR method that is optimized for parallel computations. M is then constructed from a column-permuted version of A.

Select the **Reuse data** checkbox (selected by default) to reuse the data in the blocks that define the SOR method. If you have selected that checkbox, the **Reuse sparsity pattern** checkbox is available. It is elected by default to store the sparsity patterns of the assembled matrices and try to reuse them for successive assembly processes within the same solution process. In many cases, the sparsity pattern of the system matrices does not change from one nonlinear iteration or time step to the others. Reusing the sparsity pattern from the previous iteration or step can then improve the solution performance at the cost of a usually small amount of memory.

Settings with and Without a Coarse Solver

- If used with a Coarse Solver, select a **Termination technique**. These are described for the SCGS attribute under Settings When Used With a Coarse Solver.
- If a Coarse Solver is not used, enter the **Number of iterations** to specify a fixed number of iterations to perform when this attribute is used as a preconditioner or smoother (default: 2).

This setting is not considered when the attribute is used as a linear system solver (with the **Use preconditioner** option in the **Solver** list of the Iterative node). The solver then iterates until it has established convergence or has reached the maximal number of iterations as specified by the corresponding Iterative node, rather than perform a fixed number of iterations.

SOR Gauge

The **SOR Gauge** node ( ) handles settings for the SOR gauge iterative method. This is a method of SOR-type with added functionality, useful as preconditioner/smoother for, for example, 3D magnetostatics in the AC/DC Module discretized with vector elements. In short, the added functionality consists of divergence cleaning for degrees of freedom discretized with vector elements. This node can be used together with the Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver nodes.

Also see The SSOR Gauge, SOR Gauge, and SORU Gauge Algorithms.

MAIN

Settings When Used With Any Attribute Node

Use the **Solver** list to specify which variant of the SOR Gauge algorithm to use. Each variant first performs one ordinary SOR iteration followed by one or several divergence cleaning iterations. Select:

- **SSOR gauge** (the default) to perform an ordinary **SSOR** iteration followed by divergence cleaning.
- **SOR gauge** to perform an ordinary **SOR** iteration followed by divergence cleaning.
- **SORU gauge** to perform an ordinary **SORU** iteration followed by divergence cleaning.

Settings When Not Used with Coarse Solver

Enter the **Number of iterations** to perform when this node is used as a preconditioner or smoother. This setting is not considered when the attribute is used as a linear system solver (with the **Use preconditioner** option in the **Solver** list of the **Iterative** attribute node). The solver then iterates until the relative tolerance specified by the corresponding operation node is fulfilled rather than performing a fixed number of iterations.

Settings When Used With a Coarse Solver

If this node is used with a Coarse Solver, select a **Termination technique** to determine how to terminate the solver. Select **Fixed number of iterations** to perform a fixed number of iterations each time the **Coarse Solver** is used, or **Use tolerance** to terminate the **Coarse Solver** when a tolerance is fulfilled.

If **Fixed number of iterations** is selected, enter a value for the **Number of iterations** to perform. The default is 10.

If **Use tolerance** is selected, enter a value for each of the following:

- **Relative tolerance** to specify the termination tolerance. The default is 0.1.
- **Maximum number of iterations** that the solver is allowed to take. When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver is automatically stopped with an error message.

Specify a scalar **Relaxation factor** ω. The allowed values of this factor are between 0 and 2 (default: 1). See About the Relaxation Factor for more information.

The **Blocked version** checkbox is selected by default and it uses a version of the SOR Gauge method that is optimized for parallel computations.

Select the **Reuse data** checkbox (selected by default) to reuse the data in the blocks that define the SOR method. If you have selected that checkbox, the **Reuse sparsity pattern** checkbox is available. It is elected by default to store the sparsity patterns of the assembled matrices and try to reuse them for successive assembly processes within the same solution process. In many cases, the sparsity pattern of the system matrices does not change from one nonlinear iteration or time step to the others. Reusing the sparsity pattern from the previous iteration or step can then improve the solution performance at the cost of a usually small amount of memory.

Use the **Variables** list to specify variables to include in the divergence cleaning phase of an SOR Gauge iteration. By default, all vector degrees of freedom are included.

Settings with and Without a Coarse Solver

- If used with a Coarse Solver, select a **Termination technique**. These are described for the SCGS attribute under Settings When Used With a Coarse Solver.
- If a Coarse Solver is not used, enter the **Number of iterations** to specify a fixed number of iterations to perform when this attribute is used as a preconditioner or smoother (default: 2). In addition to the initial divergence cleaning, the method performs a number of cleaning iterations in each linear solver iteration. Control the number of such divergence cleaning iterations in the **Number of secondary iterations** field.

SECONDARY

Use the **Number of secondary iterations** field to specify the number of divergence cleaning iterations to perform for each main iteration (default: 1).

SOR Line

The **SOR Line** node ( ) handles settings for the SOR line iterative method. This is a method of SOR type with added functionality useful for, for example, anisotropic meshes. It is a block SOR solver, where the blocks are formed from lines of nodes that are relatively close to each other. In addition, ordinary SSOR iterations are performed for all degrees of freedom after the SOR Line iterations have been performed. This node can be used together with the Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver nodes. Also see The SOR Line Algorithm.

MAIN

Settings When Used With Any Attribute Node

From the **Sweep type** list, choose **SSOR** (the default), **SOR**, or **SORU**. This setting decides in which order the blocks are looped through. **SOR** means lexical order (or forward), the order they are stored, while **SORU** means the opposite (backward) order. **SSOR** means **SOR** followed by **SORU**. The sweep type also decides if SOR, SORU, or SSOR is used in the secondary iteration (called *SSOR update* when the algorithms are described).

Settings When Not Used with Coarse Solver

Enter the **Number of iterations** to perform when this node is used as a preconditioner or smoother. This setting is not considered when the attribute is used as a linear system solver (with the **Use preconditioner** option in the **Solver** list of the **Iterative** attribute node). The solver then iterates until the relative tolerance specified by the corresponding operation node is fulfilled rather than performing a fixed number of iterations.

Settings When Used With a Coarse Solver

If this node is used with a Coarse Solver, select a **Termination technique** to determine how to terminate the solver. Select **Fixed number of iterations** to perform a fixed number of iterations each time the **Coarse Solver** is used, or **Use tolerance** to terminate the **Coarse Solver** when a tolerance is fulfilled.

If **Fixed number of iterations** is selected, enter a value for the **Number of iterations** to perform. The default is 10.

If **Use tolerance** is selected, enter a value for each of the following:

- **Relative tolerance** to specify the termination tolerance. The default is 0.1.
- **Maximum number of iterations** that the solver is allowed to take. When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver is automatically stopped with an error message.

General Settings

Use the **Relaxation factor** field to specify a scalar relaxation factor that controls the damping of the block SOR smoothing steps. The allowed values of this factor are between 0 and 2 (default: 0.5). See About the Relaxation Factor for more information.

Use the **Line based on** list to control if the lines of nodes are based on the **Mesh** (the default) or on a **Matrix**. Also define the **Maximum line length** (default: 20). This values determines the maximum length of the lines in number of DOFs for each block.

Use the **Multivariable method** list to control the line updates:

- If **Uncoupled** is selected, each block SOR smoothing step updates a set of degrees of freedom with the same name that are located on a line.
- If **Coupled** is selected (the default), each block SOR smoothing step updates all degrees of freedom located on a line.

For smoothing of the turbulence variables K and ε, **Coupled** is recommended.

The **Blocked version** checkbox is selected by default and it uses a version of the SOR method that is optimized for parallel computations.

Select the **Reuse data** checkbox (selected by default) to reuse data in order to improve the efficiency of the SOR Line method. If you have selected that checkbox, these additional checkboxes are available:

- The **Reuse lines** checkbox is selected by default to also reuse the SOR lines of nodes. Note that when lines are reused as a performance enhancement, it is not fully certain that the optimal lines are used.
- The **Reuse sparsity pattern** checkbox is selected by default to store the sparsity patterns of the assembled matrices and try to reuse them for successive assembly processes within the same solution process. In many cases, the

sparsity pattern of the system matrices does not change from one nonlinear iteration or time step to the others. Reusing the sparsity pattern from the previous iteration or step can then improve the solution performance at the cost of a usually small amount of memory.

Settings With and Without a Coarse Solver

- If used with a Coarse Solver, select a **Termination technique**. These are described for the SCGS attribute under Settings When Used With a Coarse Solver.
- If a Coarse Solver is not used, enter the **Number of iterations** to specify a fixed number of iterations to perform when this attribute is used as a preconditioner or smoother (default: 2).

SECONDARY

Use the **Number of secondary iterations** field to specify the number of SSOR iterations to perform after the SOR Line iterations have been performed (default: 1).

Use the **Relaxation factor** field to specify a scalar relaxation factor that controls the damping of the SSOR updates for the iterations specified in the **Number of secondary iterations** field. The allowed values of this factor are between 0 and 2 (default: 0.7). See About the Relaxation Factor for more information.

SOR Vector

The **SOR Vector** node ( ) handles settings for the SOR vector iterative method. This is a method of SOR type with added functionality useful for electromagnetics problems involving the $\nabla \times (a\nabla \times .)$ curl-curl operator and where you use *vector elements* (available primarily for electromagnetic wave simulations in the RF Module). In short, the added functionality consists of performing SOR iterations on an auxiliary linear system in addition to the ordinary SOR iterations. This node can be used as preconditioner/smoother together with the Iterative, Krylov Preconditioner, Presmoother, Postsmoother, or Coarse Solver nodes. Also see The SOR Vector Algorithm.

MAIN

Settings When Used with Any Attribute Node

Use the **Solver** list to specify which variant of the SOR Vector algorithm to use. Select:

- **SSOR vector** to perform one ordinary SOR iteration on the main system followed by a number of SSOR iterations on an auxiliary (projected) system and then one ordinary SORU iteration. This is repeated in each SSOR vector iteration.
- **SOR vector** to perform one ordinary SOR iteration followed by a number of SOR iterations on an auxiliary system. This is repeated in each SOR vector iteration.
- **SORU vector** to perform a number of SORU iterations on an auxiliary system followed by one ordinary SORU iteration. This is repeated in each SORU vector iteration.

The algorithms perform these iterations to preserve symmetry as a preconditioner and also when used as symmetric presmoother and postsmoother in a multigrid setting.

Specify a scalar **Relaxation factor** ω. The allowed values of this factor are between 0 and 2 (default: 1). See About the Relaxation Factor for more information.

The **Blocked version** checkbox is selected by default and it uses a version of the SOR Vector method that is optimized for parallel computations.

Select the **Reuse data** checkbox (selected by default) to reuse the data in the blocks that define the SOR method. If you have selected that checkbox, the **Reuse sparsity pattern** checkbox is available. It is elected by default to store the sparsity patterns of the assembled matrices and try to reuse them for successive assembly processes within the same solution process. In many cases, the sparsity pattern of the system matrices does not change from one

nonlinear iteration or time step to the others. Reusing the sparsity pattern from the previous iteration or step can then improve the solution performance at the cost of a usually small amount of memory.

Use the **Variables** list to specify variables to be included in the auxiliary system of the SOR Vector method.

Settings with and Without a Coarse Solver

- If used with a Coarse Solver, select a **Termination technique**. These are described for the SCGS attribute under Settings When Used With a Coarse Solver.
- If a Coarse Solver is not used, enter the **Number of iterations** to specify a fixed number of iterations to perform when this attribute is used as a preconditioner or smoother (default: 2). Then use the **Number of secondary iterations** field to specify the number of iterations to perform the auxiliary system for each main iteration (default: 1).

Sparse Approximate Inverse (SAI)

The **Sparse Approximate Inverse (SAI)** node (SAI) is an attribute that handles the *sparse approximate inverse* (SAI or SPAI) preconditioner, pre- and postsmoother, and coarse solver. The SAI preconditioner is an explicit preconditioner that approximates the inverse of the system matrix and not the system matrix itself (which, for example, ILU and SOR do). The advantage of the SAI approach is that the preconditioner can be applied in terms of matrix-vector multiplications, which can be processed efficiently and in parallel. The construction can be costly, but it can be run in parallel providing good parallel scalability even for higher core counts. The SAI preconditioning efficiency is sometimes not as good as the one of ILU or SOR (in terms of reductions of the solver iteration count); however, the SAI preconditioner can be more problem-aware and can be fitted well to specific problems such as anisotropic grids and operators. The SAI preconditioner is useful in the context of BEM methods, for example. See The Sparse Approximate Inverse (SAI) Preconditioner for more information.

You can add an **Sparse Approximate Inverse (SAI)** node as a subnode to the following nodes in a solver sequence: **Iterative**, **Iterative** > **Krylov Preconditioner**, **Multigrid** > **Presmoother** and **Multigrid** > **Postsmoother,** and **Domain Decomposition (Schwarz)** > **Coarse Solver** and (for both Schwarz and Schur domain decomposition) **Domain Decomposition** > **Domain Solver**.

The **Settings** window includes the following section:

GENERAL

From the **Preconditioning** list, select **Automatic** (the default), **Left**, or **Right**. You can select a preconditioning from the left or right for a nonsymmetric matrix, for example, where a preconditioner from the right might not work well for left preconditioning and vice versa.

From the **Sparsity pattern based on** list, select **Matrix** (the system matrix and the default setting), or select **Power of matrix** to base the sparsity pattern on the power of the system matrix, which you specify as a positive integer in the **Order of power** field (default: 2).

The cost and preconditioning efficiency increases with the order of the power.

In the **Maximum column size factor** field, you can specify a maximum columns size factor (default: 5), to limit the maximum number of nonzero elements of each column in the SAI preconditioner matrix. This limitation can be important for BEM models with conditions at infinity.

From the **Preconditioner symmetry** list, choose **Automatic** (the default) to make the COMSOL Multiphysics software automatically determine and make use of symmetries in the preconditioner. Alternatively, you can enforce the symmetry characteristics of the preconditioner by choosing **Nonsymmetric**, **Symmetric**, or **Hermitian**.

Enter a fill ratio between 1 (the default) and 100 in the **Fill ratio** field (or use the slider underneath). The fill ratio determines how much a column is allowed to grow outside of the nonfill elements in the matrix pattern.

Specify the number of iterations for the SAI preconditioner in the **Number of iterations** field (default: 2).

Specify a scalar **Relaxation factor**. The allowed values of this factor are between 0 and 2 (default: 1). Enter a **Relaxation factor** to specify a scalar relaxation factor ω. The allowed values of this factor are between 0 and 2. The default is 1. See About the Relaxation Factor for more information.

The **Blocked version** checkbox is selected by default. The SAI preconditioner then searches for repeated sparsity patterns with respect to the columns during the setup phase. For the same pattern only, a single LSQ system is set up and solved for multiple right-hand sides instead of multiple distinct LSQs, thereby significantly reducing the setup overhead.

Sparse Localized Schur

The **Sparse Localized Schur** node ( ) is an attribute to a Schur Solver and to a Krylov Preconditioner added under a Schur Solver node. This node is added by default, together with a **Direct** solver subnode. The **Sparse Localized Schur** node (in contrast to the alternative Localized Schur node) filters out small matrix elements and can therefore use all solvers, which you can add by right-clicking the **Sparse Localized Schur** node if you want to use another solver than the default **Direct** solver.

Use the **Drop tolerance** field to tune the maximum allowed sizes of dropped (neglected) elements (default: 0.001). A smaller drop tolerance means that the sparse localized Schur solver drops fewer elements and so it becomes more accurate (if it is set to 0, the Sparse Localized Schur node behaves like the Localized Schur node). This leads to fewer iterations in the Schur solver, but memory requirements and preconditioning time increase. A larger drop tolerance means that the filtering drops more elements and so memory use and solution time decrease. In this case, however, the Schur solver becomes less accurate, which leads to more iterations, or, if the drop tolerance is too high, to no convergence at all. Often it is most efficient to use as high a drop tolerance as possible; that is, choose it so that the Schur solver barely converges.

Use the **Termination technique** list to select how to terminate the solver. Select:

- **Fixed number of iterations** (the default) to perform a fixed number of iterations each time the **Schur Solver** is used.
- **Use tolerance** to terminate the **Schur Solver** when a tolerance is fulfilled.
- **Iterations or tolerance** to terminate when the estimated tolerance is smaller than a specified tolerance or after a specified number of iterations, whichever comes first.

Further options that apply to the selection (as indicated at each bullet) made in the **Termination technique** list are:

- **Number of iterations** (available when **Termination technique** is set to **Fixed number of iterations** or **Iterations or tolerance**). Use this field to specify the fixed number of iterations to perform (default: 2).
- **Relative tolerance** (available when **Termination technique** is set to **Use tolerance** or **Iterations or tolerance**). Use this field to specify the termination tolerance (default: 0.1).
- **Maximum number of iterations** (only available when **Termination technique** is set to **Use tolerance**). Use this field to enter a maximum number of iterations that the solver is allowed to take (default: 10). When this number of iterations has been performed without reaching the tolerance specified in the **Relative tolerance** field, the solver automatically stops with an error message.

State

The **State** node (⋃) is an attribute node that handles settings for state variables. A state is composed of a set of ODE variables. Each state has a separate **State** node. This attribute is used together with the Dependent Variables node.

GENERAL

The **State Components** section displays the variable names for the state components. Also, when internal extra variables are used, these are displayed here as **Internal Variables**.

Use the **Solve for this state** checkbox to control whether to solve for the state or not. This setting is only available if the **Dependent Variables** node's setting **Defined by study step** is set to **User defined**. If the variable is not solved for, its values are determined by the settings in the **Values of Variables Not Solved For** section of the corresponding **Dependent Variables** operation node.

If this state is part of a physics for which a **Model Reduction** node is computing a reduced model that include reduction, you can choose a **Reduced Model** node from the **Reconstruction** list, if you want this state to use another reconstruction than the rest of the study. This setting is only available if the **Dependent Variables** node's setting **Defined by study step** is set to **User defined** and if the state is a dependent variable such as in an ODE.

Use the **Store in output** checkbox to control whether to store the variable in any output solution or not.

A variable can still be solved for despite not being stored in output and vice versa.

SCALING

Control the scaling of a variable with the **Method** list.

Specifying a **Method** for a variable here overrides the **Method** selected in the **Scaling** section of the corresponding **Variables** operation node unless **From parent** is selected.

Select:

- **Automatic** to get an automatically determined scaling.
- **From parent** to use the scaling type selected in the **Method** list in the **Scaling** section of the corresponding **Variables** operation node.
- **Initial value based** to get a scaling that is determined from the initial values. Use this if the components of the initial values give a good estimate of the order of magnitude of the solution.
- **Manual** to manually enter a scaling. Then enter a value in the **Scale** field.
- **None** to get no scaling.

Stationary Acceleration

The **Stationary Acceleration** subnode (◷) can be useful to accelerate the solution process for nonlinear problems with a time-periodic stationary solution. You can add it as a subnode to all Time-Dependent Solver and Time Discrete Solver nodes. Instead of time-marching the problem from start to finish, the Stationary Acceleration node solves for a number of periods and then extrapolates the solution forward in time based on the average solution and

the average time derivative. This solution process is repeated until the average time derivative has reached steady state.

The **Stationary Acceleration** node can be used to speed up the solution process for some types of plasma models, but it is not used by default for any physics interfaces.

STATIONARY ACCELERATION

- In the **Variables** list, add the dependent variable for which you want to use stationary acceleration. Click the **Add** button (+) to open an **Add** dialog that contains all dependent variables in the study. Select the variables that you want to add and then click **OK**. You can also delete variables from the list using the **Delete** button ( ).
- From the **Components** list, select the dependent variables for which the stationary acceleration performs the averaging and extrapolation. Select **All** (the default) to perform averaging and extrapolation for all variables, or select **Manual** to select the variables that you want to apply stationary acceleration from the list that appears.
- In the **Frequency** field, enter the frequency of the periodic solution. The default value, 13.56 MHz, is a frequency that is commonly used for plasma processes.
- In the **Stationary tolerance** field, enter the tolerance used to terminate the outer acceleration iterations, when the average time derivatives are small enough (default value: 0.01).
- In the **Number of extrapolation cycles** field, enter the number of periodic cycles used to extrapolate the solution (default value: 50). The higher this number is, the more the solution process is accelerated, but at the same time the process can lead to an unstable acceleration iteration process.
- In the **Number of period averaging cycles** field, enter the number of cycles over which the stationary acceleration takes the average (default value: 5).
- In the **Number of smoothing cycles** field (default value: 10), enter the number of cycles that the stationary acceleration solves for prior to starting the period averaging cycles of the acceleration scheme.

Stop Condition

The **Stop Condition** node ( ) stops the solver when any of the specified conditions are fulfilled. It is an optional attribute subnode to the Parametric, Time-Dependent Solver, Time Discrete Solver, and Plug Flow Solver nodes.

StopCondition in the *COMSOL Multiphysics Programming Reference Manual*.

STOP EXPRESSIONS

Use the table to specify expressions for the conditions that define when the solver should stop. The solver evaluates the active expressions after each time step or parameter step. The setting in the **Stop if** column of each expression determines how it is evaluated. For **True (>=1)** (the default), the stepping stops if the real part is greater or equal to one, which is useful when entering logic expressions that evaluate to a Boolean true or false (`comp1.EndTerminal(comp1.phis)<2.4`, for example). For **Negative (<0)**, the stepping stops if the real part of the expression becomes negative (`comp1.intop1(comp1.T)-360`, for example). Another example of a stop condition is `timestep<0.04`, which makes the solver stop when the internal time step drops below 0.04 s (when the time-dependent solver hits a sharp transient, for example). To use such logical expressions, use the **True (>=1)** setting. Use the **Active** column to control which stop conditions that are active by selecting or clearing the corresponding checkbox. The solver stops when any of the active conditions is fulfilled. Optionally, you can enter

a suitable **Description** for the stop condition. The description is included in the message that appears in a **Warning** node when the stop condition is fulfilled.

You need to use the COMSOL Multiphysics variable scoping and namespace to access variables defined under Component 1, for example, using `comp1.T` instead of just `T`, and so on. See Variable Naming Convention and Namespace.

STOP EVENTS

This section is available when the **Stop Condition** node is an attribute of the Time-Dependent Solver operation node. This is because events are only supported for time-dependent solvers. Events are then useful for stopping a simulation at the point where the event occurs, which is usually more exact than using a stop condition.

Use the **Implicit event** table to specify at which events the solver should stop. All implicit events defined in the model automatically appear in the table. The stepping stops when any event marked as active is triggered.

OUTPUT AT STOP

Select an option from the **Add solution** list to make the solver additionally store the corresponding solutions before and after the stop condition was fulfilled. Select:

- **No** (the default) to not store any additional solutions. The last solution stored is the one normally stored by the solver before the stop condition was fulfilled.
- **Step before stop** to store the last step taken by the solver before the stop condition was fulfilled. No solutions are stored after this point even if they normally would be.
- **Step after stop** to store the solver step at which the stop condition was fulfilled. Any solutions up to this point are also stored as they normally would be.
- **Steps before and after stop** to store all solutions that would be stored by **Step before stop** and **Step after stop**.

Which solutions are normally stored by the solver depends on the **Times to store** setting for the Time-Dependent Solver node and on the **Parameters to store** setting for the Parametric node.

An example of using **Step before stop** would be to make sure to capture the last state of a simulation before a certain condition has been fulfilled, without having to store all of the solver steps up until this point. The setting **Step after stop** would similarly be used to capture the first state fulfilling a certain condition. When both the state before and after the condition are of interest, use the setting **Step before and after stop** to capture the transition. If the stop condition was fulfilled by the reinitialization effect of an implicit event, **Step before stop** stores the solution before reinitialization and **Step after stop** stores the solution after reinitialization.

Select the **Add warning** checkbox to specify that the solver adds a warning when the solver has stopped due to a stop condition.

Time Parametric

The **Time Parametric** node ( ) is an attribute node that handles settings for parameter stepping to add parametric sweeps. For each set of parameter values, a time-dependent problem is solved.

This attribute can be used together with a Time-Dependent Solver or another time-dependent solver. The functionality is then similar to when Parametric is added as a subnode to a Stationary Solver, but continuation is not supported. The initial data is the same for all parameters.

TimeParametric in the *COMSOL Multiphysics Programming Reference Manual*.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step. Select **User defined** to modify the parameter table and sweep type.

Use the **Sweep type** list to specify the type of sweep to perform. The **Specified combinations** type (the default) solves for a number of given combination of values, while the **All combinations** type solves for all combination of values. Using all combinations can lead to a very large number of solutions.

Use the table with **Parameter name**, **Parameter value list**, and (optional) **Parameter unit** to specify parameter names, values, and units for the parametric solver. Use the **Add** button (+) to add a row to the table. Each row has one parameter name, a corresponding parameter value list, and an optional unit. The unit becomes orange if the unit that you specify does not match the unit given for the parameter where it is defined. For the **Specified combinations** sweep type, the list of values must have equal length. When you click in the **Parameter value list** column to define the parameter values, you can click the **Range** button ( ) to define a range of parameter values. The parameter unit overrides the unit of the global parameter. If no parameter unit is given, parameter values without explicit dimensions are considered dimensionless.

If more than one parameter name has been specified, the lists of parameter values are interpreted as follows: Assume that the parameter names are `p1` and `p2`, and that `p1` has the list 1 3 and `p2` has the list 2 4. For the **Specified combinations** sweep type, the solver first uses `p1` equal to `1` and `p2` equal to `2`. Thereafter, it uses `p1` equal to `3` and `p2` equal to `4`. And when the sweep type is **All combinations**, the solver uses the following order for the parameter combinations: 1 2, 1 4, 3 2, and 3 4.

An alternative to specifying parameter names and values directly in the table is to specify them in a text file. You can use the **Load from File** button ( ) to browse to such a text file. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window. The read names and values are appended to the current table. The format of the text file must be such that the parameter names appear in the first column and the values for each parameter appear row-wise with a space separating the name and values, and a space separating the values. Click the **Save to File** button ( ) to save the contents of the table to a text file (or to a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ *for* Excel®).

When loading and saving parameter table data using Excel®, the units in the **Parameter unit** column are included. The unit column is ignored when saving and loading parameter data to *.txt, *.csv, and *.dat files.

CLUSTER SETTINGS

Select the **Distribute parameters** checkbox to distribute the parameters on several computational nodes. If the problem is too large to run on a single node, you can enable the **Maximum number of groups** field to use the nodes' memory more efficiently. In this case the same parameter is solved for by several nodes that cooperate as if running a nondistributed sweep. The number of nodes that cooperate is equal to the maximum of the total number of nodes divided by the **Maximum number of groups** setting and 1. So if the total number of nodes is 12 and the **Maximum number of groups** is 3, 3 groups with 4 nodes each cooperate.

LEAST-SQUARES DATA

The section only appears if you are solving a time-dependent least-squares optimization problem.

Least-squares data are read from least squares objectives (either a file or a table), and the solver sequence is set up accordingly: If there is a least-squares objective containing parameter columns in a time-dependent study step, a

Time Parametric solver is set up, and the parameter names and values appear under **Parameters from least-square objectives**.

Parameter values corresponding to the same parameter names are merged between different objectives. If the **Use parameters from least-squares objectives** checkbox is selected (which is the default), user-defined parameter values are merged with corresponding merged data from objectives. For parameters that are defined only in objectives and not user defined (and vice versa), globally defined values are used. If the **Use parameters from least-squares objectives** checkbox is selected, the following settings are available:

- The **Create bounding box from the General parameter value lists** checkbox is selected by default to exclude values outside the bounding box.
- The **Add solution data points from the General Parameter value lists** checkbox is selected by default to control if data points should also be added to the solution process that is given in the **General** section that are not least-squares data. These points do not affect the solution process or the least-squares objectives but can be useful, for example, for postprocessing purposes or for model debugging.

If **Use parameters from least-squares objectives** is off, no least-squares parameters from files are used.

You can change the default values of the **Use parameters from least-squares objectives** and its associated settings only if **Defined by study step** is set to **User defined**.

Upper Limit

The **Upper Limit** node ( ) makes it possible to impose restrictions on degrees of freedom (field variables). These restrictions are checked after each substep of a segregated approach. The restriction is performed without any regards to the equations, so use this restriction with care. Enforcing an upper limit on a field variable can be useful to ensure that the field quantity does not exceed some limit, for example. Right-click a Segregated node to add an **Upper Limit** node.

UPPER LIMIT

By default, no variables have active upper limits. To activate upper limits for field variables, use the **Upper limits (field variable)** field to specify the variables and their scalar upper limits as space-separated pairs: *field_variable*_1 *limit_value*_1 *field_variable*_2 *limit_value*_2, and so on. For example, to impose an upper limit of 300 for the value of a field **u** in Component 1, enter `comp1.u 300`.

Vanka

The **Vanka** node ( ) handles settings for the Vanka iterative method. Formally, this method applies to saddle-point problems (that is, problems where the equilibrium solution is neither a maximum nor a minimum) as a preconditioner or smoother. The corresponding linear system matrix is indefinite and its diagonal often contains zeros. A typical example is the Navier–Stokes equations. Problems formulated with weak constraints are also of this type. In short, the method can be described as a block SOR method. Local coupling of certain degrees of freedom (typically the Lagrange multiplier degrees of freedom) determines the blocks. Ordinary SSOR iterations are performed for degrees of freedom not involved in the block method. This attribute node can be used together with the Iterative, Krylov Preconditioner, Presmoother, Postsmoother, and Coarse Solver attribute nodes.

For more detailed information about the Vanka method, see The Vanka Algorithm.

MAIN

Settings with and Without a Coarse Solver

- If used with a Coarse Solver, select a **Termination technique**. These are described for the SCGS attribute under Settings When Used With a Coarse Solver.
- If a Coarse Solver is not used, enter the **Number of iterations** to specify a fixed number of iterations to perform when this attribute is used as a preconditioner or smoother (default: 2).

Settings When Used with Any Attribute Node

From the **Sweep type** list, choose **SSOR** (the default), **SOR**, or **SORU**. This setting decides in which order the blocks are looped through. **SOR** means lexical order (or forward), the order they are stored, while **SORU** means the opposite (backward) order. **SSOR** means **SOR** followed by **SORU**. The sweep type also decides if SOR, SORU, or SSOR is used in the secondary iteration (called *SSOR update* when the algorithms are described).

Use the **Variables** list to specify variables to include in a Vanka block approach.

Use the **Block solver** list to specify how to solve the Vanka block linear systems:

- Select **Direct** (the default) to use a direct solver.
- Select **Direct, stored factorization** to store the factorization. Storing the factorization makes the solver faster because the factorization is then not performed every update, but the storage uses more memory. If two Vanka smoothers are used as a presmoother and postsmoother of a Multigrid solver, with similar enough settings, they share the same stored factorization, which means that they only use half the memory. With this option, you can choose the **Use approximate factorization** checkbox to reduce the memory consumption and use an approximate smoother suitable for saddle-point problems such as Stokes flow (Ref. 14). Use the **Use Schur complement approximation for block with size larger than** field (default value: 150) to specify a size so that the solver can continue to use stored LU factorizations as long as the blocks are not above that size.
- Select **Iterative, GMRES** to use the iterative method GMRES. When **Iterative, GMRES** has been selected from the **Block solver** list, the following options become available:
  - Use the **Tolerance** field to specify the termination tolerance of GMRES (default: 0.02).
  - Use the **Number of iterations before restart** field to specify how many iterations the solver should take between each restart (default: 100).

If you use the Vanka algorithm as preconditioner or as smoother to a multigrid preconditioner when GMRES, Conjugate gradients, BiCGStab, or TFQMR is used as the linear system solver, use the **Direct** or **Direct, stored factorization** option in the **Block solver** list to get a stationary preconditioner.

The **Iterative, GMRES** option can be useful if you use the FGMRES method as linear system solver because it can handle preconditioners that are not stationary. The **Iterative, GMRES** option can also be useful if you use the Vanka algorithm as a smoother to a multigrid solver because GMRES can be a bit faster than the direct solver.

Use the **Relaxation factor** field to specify a scalar relaxation factor ω. The allowed values of this factor are between 0 and 2 (default: 0.8). See About the Relaxation Factor for more information.

Select the **Blocked version** checkbox (selected by default) to use a version of the Vanka method that is optimized for parallel computations.

Select the **Reuse data** checkbox (selected by default) to reuse the data in order to increase the performance of the Vanka method.

SECONDARY

Use the **Number of secondary iterations** field to specify the number of SSOR iterations to perform for degrees of freedom not involved in the Vanka blocks.

Use the **Relaxation factor** field to specify a scalar relaxation factor for the iterations specified in the **Number of secondary iterations** field (default: 1). The allowed values of this factor are between 0 and 2 (default: 1). See About the Relaxation Factor for more information.

Velocity Solver

The **Velocity Solver** node ( ) is an attribute subnode used by the Block Navier–Stokes attribute node. This node does not have any settings. Right-click it to add a general preconditioner for the velocity block. By default, a **Direct** node for direct linear system solvers is the added as the preconditioner.

Solution Utility Nodes

The following sections describe the solver utility nodes (listed in Table 20-10) and the settings in detail.

TABLE 20-10: SOLUTION UTILITY NODES.

ICON	NAME	DESCRIPTION
	Adaptive Mesh Refinement (Utility Node)	Stores the solution on the finest mesh from a mesh refinement procedure.
	Assemble	Provides a way of accessing assembled matrices and vectors for further work in Java®.
	Combine Solutions	Combining solutions by concatenation or summation. Also available at the study level.
	Compile Equations	Compiles equations by specifying which study and study step to use and specifying representation of complex variables.
	Copy Solution	Copy the complete solution results from another solver, including all dependent variables.
	For and End For	Add a for loop to the solver sequence to iterate some solver commands.
	Input Matrix	Used to create the raw data of an assembled matrix or vector from Java®.
	Solution Store	Stores the solution at this point of the solver configuration also after the solver configuration has been computed.
	State Space	Provides a way of accessing state-space matrices for further work in Java.

About Solver Commands in the *COMSOL Multiphysics Programming Reference Manual.*

Adaptive Mesh Refinement (Utility Node)

The **Adaptive Mesh Refinement** ( ) utility node is added automatically (to an otherwise empty solver configuration) by the corresponding Adaptive Mesh Refinement (Time-Dependent Adaptation) attribute node. It is a container for a solution obtained using the attribute node. It is not possible to add this node manually, and it does not have any settings.

Assemble

The **Assemble** node ( ) provides access to the raw data of any assembled matrix or vector. Right-click the **Solution** node and select **Other** > **Assemble**. Select the appropriate checkboxes for the matrices and vectors you want to inspect or modify and save the model as a model file for Java®. You can also display the values of these system matrices in a table using the System Matrix node ( ) found under **Results** > **Derived Values**. The saved Java file now contains code for assembling the selected matrices and vectors that can be used to access the matrix rows, columns, values, and so forth. For information about the eliminated system, see Elimination Constraint Handling.

Note that some study types require that additional parameters are defined. In order to get the expected matrices, you have to specify these parameters manually. If you get an error about undefined variables, you can define the

variables in the Parameters node found under **Global Definitions**. Note that the value you set is the one that is used in the expressions where the variable is found. Some examples of variables that might be needed:

- `t`, the requested output time.
- `timestep`, the time step used by the solver, for time-dependent problems.
- `freq`, the frequency to assemble the problem for, for frequency-dependent problems.

There are also other variables that might be needed: `phase` (the phase), `niterCMP` (the nonlinear iteration number), and `CFLCMP` (a pseudo-time-stepping control variable).

ELIMINATED OUTPUT

In this section you can choose to output matrices and vectors that are passed to the linear solvers — that is, where constraints have been eliminated — by enabling one or several of the following checkboxes: **Eliminated load vector (Lc)**, **Eliminated stiffness matrix (Kc)**, **Eliminated damping matrix (Dc)**, **Eliminated mass matrix (Ec)**, **Constraint null-space basis (Null)**, **Constraint force null-space basis (Nullf)**, **Particular solution (ud)**, and **Scale vector (uscale)**.

NONELIMINATED OUTPUT

In this section you can choose to output matrices and vectors that the solver assembles before the elimination step by enabling one or several of the following checkboxes: **Load vector (L)**, **Stiffness matrix (K)**, **Damping matrix (D)**, **Mass matrix (E)**, **Constraint vector (M)**, **Constraint Jacobian (N)**, and **Constraint force Jacobian (NF)**.

OPTIMIZATION OUTPUT

In this section you can choose to output matrices and vectors assembled during optimization by enabling one or several of the following checkboxes: **Optimization constraint Jacobian (NP)**, **Optimization constraint vector (MP)**, **Lower bound constraint vector (MLB)**, and **Upper bound constraint vector (MUB)**.

ADVANCED

If you want to assemble an eigenvalue problem, you can set the **Eigenvalue name** (default: `lambda`) and the **Value of eigenvalue linearization point** by first selecting the **Set eigenvalue name** checkbox. The **Eigenvalue name** is the name of the eigenvalue variable and should therefore be changed if a nonstandard variable name has been used, for example in a user-defined equation. It can also be changed from the default if a specific variable should be treated as an eigenvalue. The **Value of eigenvalue linearization point** is not transformed; that is, it corresponds to selecting **None** in the **Eigenvalue transformation** list in an Eigenvalue Solver node.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

This section, which is initially empty, contains a log from the assembling Select the **Keep warnings in stored log** to keep warning messages in this log so that the information in those warnings is also available when reopening the model.

Assemble in the *COMSOL Multiphysics Programming Reference Manual.*

Compile Equations

In the **Compile Equations** ( ) node's **Settings** window, you specify which study and study step to use when computing the current solver configuration and compiling the equations to solve. The node displays the name of the selected study step: **Compile Equations: Stationary**, for example. Right-click this node and select **Statistics** to see the number of degrees of freedom for the solver (see The Statistics Page).

STUDY AND STEP

Specify the study in the **Use study** list and the study step in the **Use study step** list. By default, you get the parent study and its first study step.

Complex variables are by default represented by complex-valued degrees of freedom. By selecting the **Split complex variables in real and imaginary parts** checkbox, the representation of complex variables is changed to using separate real degrees of freedom for the real and imaginary parts. The split representation can improve convergence where nonanalytic functions of complex variables are used in equations. Using a split representation also makes it possible to avoid complex pollution (a small nonzero imaginary component) of real variables by specifying a *real* or *complex* value type for variables. If you use a split representation of complex variables, specify the value type of dependent variables in the **Discretization** sections in the **Settings** windows for the main physics nodes (to see this setting, click the **Show More Options** button ( ) and select **Advanced Physics Options** in the **Show More Options** dialog).

The split representation enables a correct evaluation of Jacobians for the following operators: `real`, `imag`, `conj`, `abs`, `arg`, and `realdot`.

You can choose a partitioning method from the **Partitioning method for distributed computing** list: **From parent** (the parent **Solution** node; this is the default setting), **Mesh ordering**, **Nested dissection**, **Weighted nested dissection**, or **Off**. See Cluster Computing Settings for more information.

GEOMETRIC ENTITY SELECTION

The default behavior is that you try to solve the problem for the full geometry. However, if you prefer, you can choose to solve only on a subset of the full geometry. To do this, change **Use entities** from **All** to **Selected** and add named selections to the **Selections** list using the **Add** button (+). The study will now compute using only the added selections, and everything outside those selections will be neglected.

LOG

Select the **Keep warnings in stored log** checkbox if you want to keep any warnings in the log.

Copy Solution

The **Copy Solution** node ( ) is a utility node whose purpose is to copy the complete solution results from another solver, including all dependent variables. Right-click the **Solution** node and select **Other** > **Copy Solution** to add a **Copy Solution** node anywhere in a solver configuration; the software can then copy the solution from another solver at that point of the sequence. By default, Copy Solution nodes get a name that shows the name of the solution that they copy, such as **Solution 1** (or **No Solution**).

The **Settings** window for the Copy Solution nodes contains the following section:

GENERAL

From the **Solution** list, choose the solution to copy (any available Solution or Solution Store node in the model). The default is **None**, which copies no solution.

Use this node only when you need a complete copy of the solution that will not be used for further computations. To copy the solution from another solver and use it for further computations, use the **Initial Values of Variables Solved For** and **Values of Variables Not Solved For** sections of the **Dependent Variables** node or the **Values of Dependent Variables** section of the study settings instead.

For and End For

From the **Programming** submenu for solver sequences, you can select **For** to add two nodes to the end of the sequence, a **For** node ( ) and an **End For** node ( ). You can then move these nodes where you want to create a for loop that iterates some part of the solver sequence. When the sequence is run, the for loop runs the nodes between the **For** and **End For** nodes a fixed number of steps. You can add more than one **For** node to create nested for loops. The model tree displays the loop structure by indenting the description text for the nodes. The for loops must be balanced; otherwise an error occurs. For loops can be useful, for example, for solving particle-field interactions in particle tracing by iterating between a stationary and a time-dependent solver.

The **End For** node has no settings. The **Settings** window for the **For** node contains the following setting:

GENERAL

Select an option from the **Defined by study step** list. The default is **User defined**. If any instances of the Bidirectionally Coupled Particle Tracing or Bidirectionally Coupled Ray Tracing study step are present in the study then they can also be selected from the list.

Select an option from the **Termination method** list: **Fixed number of iterations** (the default) or **Convergence of global variable**. For **Fixed number of iterations** enter a positive integer for the **Number of iterations** (default 5). Any nodes

between this **For** node and the following **End For** node will be repeated a number of times equal to the specified **Number of iterations**.

For **Convergence of global variable** enter the following:

- **Global variable** (default 1)
- **Relative tolerance** (default 0.001)
- **Relative tolerance threshold** (default 1)
- **Maximum number of iterations** (positive integer, default 25)
- **Minimum number of iterations** (positive integer, default 1)

At the end of each iteration, the relative error is

$$\text{err} = \frac{g_1 - g_0}{\max(g_1, g_t)}$$

where g_0 is the value of the global variable from the previous iteration, g_1 is the value of the global variable from the current iteration, and g_t is the **Relative tolerance threshold**. A new iteration of the loop is started if the iteration number is less than the **Maximum number of iterations**, and if either the relative error is less than the **Relative tolerance** or the iteration number is less than the **Minimum number of iterations**.

The Statistics Page

Use the **Statistics** page to view statistics about a solver, its dependent variables, and their number of degrees of freedom. This can be done before solving the problem and is useful for determining which variables are the most costly to compute and store. To open the **Statistics** page for a solver, right-click the Compile Equations node ( ) and select **Statistics**. This page contains the following section:

NUMBER OF DEGREES OF FREEDOM

Here you see a list of the dependent variables and their number of degrees of freedom (DOFs) as well as the total number of DOFs. The list includes both variables solved for and variables not solved for.

Computing this statistic requires a computation of the size of the assembled finite element model. This can take some time for large models.

Input Matrix

Use the **Input Matrix** node ( ) to create the raw data of an assembled matrix or vector from Java. Right-click the Eigenvalue Solver, Stationary Solver, or Time-Dependent Solver nodes and select **Input Matrix**. Select the appropriate checkboxes for the matrices and vectors you want to input and save the model as a file for Java. The saved Java file now contains code for inputting the selected matrices and vectors.

INPUT

In this section you can choose to input matrices and vectors that are passed to the linear solvers by enabling one or several of the following checkboxes: **Load vector, Stiffness matrix**, **Damping matrix**, **Mass matrix**, **Constraint vector**, **Constraint Jacobian**, and **Constraint force Jacobian**.

The matrices and vectors input using the **Input Matrix** node replace the corresponding matrices and vectors in the assembled system from the model in COMSOL Multiphysics.

- Elimination Constraint Handling
- InputMatrix in the *COMSOL Multiphysics Programming Reference Manual*

Solution Store

This is a utility node that makes it possible to access intermediate solution results. By default, the software only stores the solution at the last computed node of a solver configuration. Add a **Solution Store** node ( ) anywhere in a solver configuration to make the COMSOL software store the solution at that point of the sequence in addition to the solution at the last computed node. You can use the solution from a **Solution Store** node when analyzing the results and as initial values (via a study-type node) for other computations. By default, Solution Store nodes created under a **Parametric Solutions** node ( ) get a name that shows the values of the parameters used for the solution of a parametric sweep (for example, **Tinit=340, c0_pro=1400**).

The **Settings** window for the Solution Store nodes contains the following sections:

GENERAL

This section contains the name of the solver sequence that the **Solution Store** node is using.

LOG

This section is initially empty. It contains information if you use a **Solution Store** node to store parametric sweep data.

StoreSolution in the *COMSOL Multiphysics Programming Reference Manual.*

State Space

The **State Space** node ( ) provides access to the raw data of a PDE in state-space form. To create state-space data, right-click the solver node and select **Other** > **State Space**. Specify the input and output and the state-space matrices and vectors that you want to access. Then save the model as a file for Java®. The saved Java file contains code for assembling the selected matrices and vectors that can be used to access the matrix rows, columns, values, and so on.

INPUT

In the **Input parameters** field, enter all parameters that affect the model as space- or comma-separated entries.

OUTPUT

The state-space node assembles matrices that describe a model as a dynamic system when **Off** is selected from the **Static** list:

$$Mc\dot{x} = MAx + MBu$$
$$y = Cx + Du$$

If you select **On** from the **Static** list, a static linearized model of the system is described by

$$y = (D - C(MA)^{-1}MB)u$$

In the **Output expressions** field, enter all expressions that are to be evaluated as output from the model as space- or comma-separated entries. Select any of the **MA**, **MB**, **D**, and **C** checkboxes, and if **Static** is set to **Off**, any of the **Mc**, **Null**, **ud**, or **x0** checkboxes. **Null** is the PDE constraint null-space matrix, and **ud** is a particular solution fulfilling the constraints. **x0** is the initial data. The solution vector U for the PDE problem can then be written

$$U = \mathrm{Null}x + ud + u0$$

where $u0$ is the linearization point, which is determined by the current solution (that is, the solution computed by the previous feature in the sequence). The previous feature can, for example, be a solver or a Dependent Variable node. The Dependent Variable node gives control over which variables to solver for (compute the matrices for). The input linearization point is stored in the sequence after the state-space node is run.

For output expressions that are defined using time derivatives, the corresponding component in the output matrix C is always 0. In such cases, use the Modal solver instead.

CONSTANTS

In this section you can define constants that can be used as temporary constants in the solver. You can use the constants in the model or to define values for internal solver parameters. These constants overrule any previous definition (for example, from Global Definitions). The constant values are expressions and can, for example, include the `range()` operator, units, and global expressions. The constant name can be a new or an existing global parameter. The constant is temporary in the sense that it is only defined during the solver run. You cannot override parameters used in the following parts of the model:

- Mesh and geometry
- Selections
- Probes
- Functions
- Materials
- Pairs
- Solver sequences
- Parameter-dependent lists

Also, the Parametric and Time Dependent solvers overrule any definition of solver constants.

Constants settings for a solver node do not carry over to postprocessing.

Some examples of when it can be useful to define constants for a solver:

- When doing more advanced solver sequences, where constants need to be changed between calls (for example, in for-loops).
- When you do not want to change the global definition of a parameter or when you cannot or do not want to use a Parametric Solver feature.
- When you want to define auxiliary parameters that are part of the equations like `CFLCMP` or `niterCMP` and where the solver does not define these parameters.

Click the **Add** button (+) to add a constant and then define its name in the **Constant name** column and its value (a numerical value or parameter expression) in the **Constant value** column. By default, any defined parameters are first added as the constant names, but you can change the names to define other constants. Click **Delete** ( ) to remove the selected constant from the list.

LOG

This section, which is initially empty, contains a log from the run of the **State Space** node. This log is stored in the Model MPH-file. Select the **Keep warnings in stored log** to keep warning messages in this log so that the information in those warnings is also available when reopening the model.

	StateSpace in the *COMSOL Multiphysics Programming Reference Manual*.

Job Configurations

The **Job Configurations** node ( ) automatically appears if the Job node has content. Or to make it available in the context menu, click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog.

The following categories of job configurations each correspond to a node:

- Parametric Sweep, Function Sweep, and Material Sweep
- Batch
- Cluster Computing
- Optimization
- Design of Experiments and Uncertainty Quantification (see the *Uncertainty Quantification Module User's Guide*)
- Sequence

Most of these job configuration nodes share the common set of subnodes listed in Table 20-11. In addition, a Batch job configuration node has a default Batch Data subnode that in turn stores External Process nodes, which contain information about batch jobs. Cluster Computing job configuration nodes do not have any subnodes and must point to a Batch job configuration. Optimization job configuration nodes do not have any subnodes but include parametric jobs.

- Using a Job Configuration to Store Parametric Results on File
- Advanced Study Extension Steps

TABLE 20-11: PARAMETRIC AND BATCH SUBNODES.

ICON	NAME	DESCRIPTION
	Derived Value	Runs a Derived Values node.
	Evaluate Derived Values	Evaluate some or all Derived Values nodes.
	Export to File	Runs an Export node and saves it to a file.
	External Class	Runs the main method of an external compiled Java® class.
	External Process	A Batch subnode that contains information about the batch processes that have been started by the Batch (Job Configurations) node. Each External Process node is associated with a started batch job.
	Geometry	Runs a geometry sequence.
	Job	Runs a Parametric, Batch, or Cluster Computing job node.
	Mesh	Runs a meshing sequence.
	Plot Group	Runs a Plot Group node.
	Save Model to File	Stores a model in the state that it is at that point in the job configuration.
	Solution	Runs a solver configuration.

TABLE 20-12: JOB CONFIGURATIONS NODE - CONTEXT MENU OPTIONS.

ICON	NAME	DESCRIPTION
	Show Default Solver	Shows the default job configuration node (if any) that corresponds to the study step nodes in the study.
	Parametric Sweep (Job Configurations)	Adds a Parametric Sweep node, which can loop over a given set of parameters. For each set of parameters, it runs the sequence defined by its subnodes. You can combine the sequence with other Batch, Parametric, or Cluster Computing sequences in a hierarchical way by adding a job configuration that points to another node.
f(x)	Function Sweep (Job Configurations)	This is a special version of a parametric sweep that sweeps over functions defined under a Switch node that you add from Definitions > Functions.
	Material Sweep (Job Configurations)	This is a special version of a parametric sweep that sweeps over materials defined under a Switch node that you add under Materials.
	Batch (Job Configurations)	Adds a Batch node to run batch jobs. The Batch job has a special Batch Data subnode that collects External Process subnodes containing job status information.
	Cluster Computing (Job Configurations)	Adds a Cluster Computing node, which is useful when you want to submit a batch job to a job scheduler to run the model in distributed mode as a batch job.
	Optimization (Job Configurations)	This node can be added together with an Optimization study that is using a gradient-free optimization solver. It shows which parametric sweeps run during the optimization.
	Sequence	Runs job sequence steps just like the Parametric feature, but it only runs them once without any parameters or sweep. It is similar to the Batch feature, but does not create a batch job, it just runs the steps. You can use it to store models and results to file, for example.
	Delete Configurations	Deletes all jobs under the Job Configurations node.

* Optimization is an option with the addition of the Optimization Module.

Parametric Sweep (Job Configurations)

One of the main nodes is the **Parametric Sweep** ( ) job configuration, which can loop over a given set of parameters. For each set of parameters, it runs the sequence defined by its subnodes. You can combine the sequence with other Batch, Parametric, or Cluster Computing sequences in a hierarchical way by adding a job configuration that points to another node. You can, for instance, create a **Parametric Sweep** node that does a LiveLink™ update and then runs a **Cluster Computing** node that in turn runs a second **Parametric Sweep** sequence on another node.

A parametric sweep can contain steps to run all solutions, save the model to a file, and evaluate derived values, for example. You add those steps by right-clicking the **Parametric Sweep** node and selecting one of the following options:

- **Job**
- **Solution**
- **Other**
- **Save Model to File**, which saves the solved model to an MPH-file. See Save Model to File.
- **Results**

Job refers to another job that is to be run from this parametric sweep, while **Solution** (see Solution) runs a **Solution** node as available under the **Solver Configurations** node, available further up in the **Study** tree.

Under **Other**, you can choose **External Class** (see External Class), which calls an external Java® class file. Another option, **Method Call** (see Method Call), runs a model method. The **Geometry** (see Geometry), builds the **Geometry** node (runs the geometry sequence). This can be used, for example, in combination with a parametric sweep to generate a sequence of MPH-files with different geometry parameters. The **Mesh** option (see Mesh) builds the **Mesh** node (runs the meshing sequence).

Under **Results**, you can choose **Plot Group** (see Plot Group) to run all or a selected set of plot groups. This is useful for automating the generation of plot groups after solving. The **Derived Value** option is there for legacy reason, and it is instead recommended that you use the **Evaluate Derived Values** option (see Evaluate Derived Values), which evaluates nodes under **Results** > **Derived Values**. The option **Export to File** (see Export to File) runs any node for data export under the **Export** node.

GENERAL

Use the **Defined by study step** list to specify that the settings are synchronized with the corresponding study step.

You define the parameters in the **Parameter name** and **Parameter values** fields. The parameters can be loaded from file by clicking the **Read File** button when you have selected the file through the **Load Parameter Values** dialog, which you open by clicking **Browse**. You can add a **Stop condition** that is evaluated after each solution. The last solution, which breaks the stop condition, is discarded from the set of solutions returned (the **Parametric Solutions** node) but is included in probe table outputs. Once the condition evaluates to a negative value, the **Parametric** node is stopped. Select the **Keep solutions before and after stop condition** checkbox to store both solutions — before and after the stop condition has been satisfied — in the parametric solutions storage.

RESULTS WHILE SOLVING

See Results While Solving in the Common Study Step Settings section.

ERROR

Errors are usually stored in the **Error** table. If you want to get the error message at once, select the **Stop if error** checkbox. Select the **Postpone errors until end of sequence** checkbox to allow the sequence to continue even if an error is encountered. This is different from **Stop if error** where the sweep only continues with the next step if no error occurs. The **Postpone errors until end of sequence** option is, for instance, useful when you are interested in the solution even if there is an error.

CLUSTER SETTINGS

You can distribute the sweep on several computational nodes by selecting the **Distribute parameters** checkbox. If the problem is too large to run on a single node, enable the **Maximum number of groups** field to use the nodes' memory more efficiently. In this case, the same parameter is solved for by several nodes that cooperate as if running a nondistributed sweep. The number of nodes that cooperate is equal to the maximum of the total number of nodes divided by the **Maximum number of groups** setting and 1. So if the total number of nodes is 12 and the **Maximum number of groups** is 3, 3 groups with 4 nodes each cooperate.

LOG

Select the **Keep warnings in stored log** checkbox as needed.

An Integro-Partial Differential Equation: Application Library path **COMSOL_Multiphysics/Equation_Based/integro_partial**.

Using a Job Configuration to Store Parametric Results on File

Batch (Job Configurations)

The **Batch** ( ) job configuration is the main node for running batch jobs. Batch jobs run in separate processes. You can therefore continue working in the COMSOL Desktop once a batch job is run. Model changes in the COMSOL Desktop after the batch job is submitted do not affect the model in the batch job. The **Batch** job has a special Batch Data subnode, which collects External Process subnodes containing job status information.

As in the Parametric Sweep (Job Configurations) node, the batch job is defined by a number of subnodes (see below). The batch job then runs each subnode. Use the **Save as Default** button in the toolbar to save the current directory setting as the default directory for batch files.

A batch job can contain steps to run all solutions, save the model to a file, and evaluate derived values, for example. You add those steps by right-clicking the **Batch** node and selecting one of the following options:

- **Job**
- **Solution**
- **Other**
- **Save Model to File**, which saves the solved model to an MPH-file. See Save Model to File.
- **Results**

Job refers to another job that is to be run from this batch job, while **Solution** (see Solution) runs a **Solution** node as available under the **Solver Configurations** node, available further up in the **Study** tree.

Under **Other**, you can choose **External Class** (see External Class), which calls an external Java® class file. Another option, **Method Call** (see Method Call), runs a model method. The **Geometry** (see Geometry), builds the **Geometry** node (runs the geometry sequence). This can be used, for example, in combination with a parametric sweep to generate a sequence of MPH-files with different geometry parameters. The **Mesh** option (see Mesh) builds the **Mesh** node (runs the meshing sequence).

Under **Results**, you can choose **Plot Group** (see Plot Group) to run all or a selected set of plot groups. This is useful for automating the generation of plot groups after solving. The **Derived Value** option is there for legacy reason, and it is instead recommended that you use the **Evaluate Derived Values** option (see Evaluate Derived Values), which evaluates nodes under **Results** > **Derived Values**. The option **Export to File** (see Export to File) runs any node for data export under the **Export** node.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step.

Set the number of cores that the batch job should use in the **Number of cores** field if desired, by first selecting the corresponding checkbox. The default behavior is to use all available cores. If you set **Number of simultaneous** jobs to more than one, several jobs can run at once. When you are running more than one job at once, it is important that the product of **Number of cores** and **Number of simultaneous** jobs does not exceed the number of cores available on the computer. Otherwise you experience performance degradation. When you run multiple batch jobs on your computer, COMSOL Multiphysics makes sure this does not happen if you are using the automatic setting. If you have a multicore machine, you can change these settings to control the number of simultaneous processes that are allowed to run in the batch sweep and also how many cores each of them is allowed to use. If you have a six-core machine, for example, change the **Number of simultaneous jobs** to three and the **Number of cores** to two. This allows three parameters to be solved in parallel, where each solver process gets access to two cores. For simulations where each parameter represents a small computational problem, you can increase the number of simultaneous jobs to as

many cores as you have on your computer. For larger problems, keep this setting to one simultaneous job (the default setting) to fully utilize the multicore processing power of the solvers.

You can also control the number of simultaneous jobs from the **Batch Sweep** node' **Settings** window, in the **Study Extensions** section. In that case, the number of cores is automatically computed from the number of physical cores divided by the number of simultaneous jobs (for this to be automatic, you must not select the **Number of cores** checkbox).

Select the **Use graphics** checkbox when the batch process should run results nodes that create graphical contents such as exporting to file.

Enter the **Number of job restarts**. The default is 0. This is the maximum number of times the job can be restarted if it fails to complete.

Enter a value for the **Alive time (seconds)**. The default is 300 seconds. This is the longest time the process is allowed to run before it must inform that it is still running. Failure to do so means that the process is considered dead and a new process is started if the maximum number of job restarts is not reached.

You can set a **Start time** if you want the batch process to start at a later time. Select the hour (0–23 hours) to start the run from the **Start time** list, or select **Now** to start the batch process without a delay.

FILES

Set the **Filename** of the model. If the batch job is generated from a parametric sweep, a unique name that depends on the parameter names and values is created. The default is to overwrite any previous models with the same name. Disable the default by clearing the **Clear previous model** checkbox. Select the **Clear meshes** checkbox to clear the meshes before running the batch sweep. The default is to not clear the meshes. Select the **Clear solutions** checkbox to clear the solutions before running the batch sweep.

Specify the **Directory** to store the model. The directory refers to the location where the client (COMSOL Desktop) reads and writes data. Click **Browse** if you want to browse to a directory.

From the **Add parameters to filename** list, choose **Parameter name and value** (the default), or choose **Index**, which instead of parameter names and parameter values uses an index scheme `iX`, `iY`, …, where same indices relate to the same parameter value. This option gives much shorter filenames.

- If you are connected to a COMSOL Multiphysics server on another computer, you can control the working directory used by the COMSOL Multiphysics server if you select the **Specify server directory path** checkbox and enter the path to the server **Directory** or **Browse** for the path. Otherwise, a temporary directory on the COMSOL Multiphysics server is used to save files. The server directory path refers to the location where the COMSOL Multiphysics server reads and writes the corresponding data (assuming a client/server configuration).
- If the batch job has another path to the directory, you select the **Specify external COMSOL batch directory path** checkbox and enter the path to the batch **Directory** or **Browse** for the path. If the batch job has another path to the directory, you select the **Specify external COMSOL batch directory path** checkbox and enter the path to the batch **Directory** or **Browse** for the path. The external COMSOL batch directory path refers to the location where the batch process reads and writes the data.
- If COMSOL Multiphysics is installed in a different directory from where the batch job runs, enable the **Specify external COMSOL installation directory path** and specify the install directory (click **Browse** or enter the path to the **Directory**). This can occur if you are submitting jobs to a job scheduler with the **Cluster Computing** node.

Click the **Save As Default** button ( ) at the top of the **Settings** window to save the current directory setting as the default directory for batch files.

How to Specify Directory Paths for Batch Jobs and Cluster Jobs

Some examples of how to specify the paths for the directories where the batch job reads and writes data:

- If both the COMSOL Desktop and the cluster job use and have access to the same path, only set **Directory**.
- If the COMSOL Desktop submits a cluster job to a Windows HPC job scheduler, where the directory where the COMSOL Desktop stores its data is a local path to the COMSOL Desktop but a network path to the cluster job, specify the main **Directory** and a separate external COMSOL batch directory path, respectively.
- If you use a Windows client connected to a server running on a Linux server head node that in turn is submitting a job to a job scheduler, that setup then requires the main **Directory** (which is a local Windows path) and a server directory path (which is a Linux path on the head node). Most likely, an external COMSOL batch directory path is not needed in this case because it is likely that the cluster and the head node are using the same file system.
- With a COMSOL Desktop running on a remote machine, the main **Directory** path refers to the COMSOL Desktop path, and the external COMSOL batch directory path refers to a remote batch job or cluster job path.
- With a client/server configuration running on a remote machine, the main **Directory** path refers to the COMSOL Desktop path, the server directory path refers to the server path, and the external COMSOL batch directory path refers to the remote batch job or cluster job path.

To summarize: If the batch job and the COMSOL Desktop do not share the same view of the file system, you must specify at least the main **Directory** and the external COMSOL batch directory.

SYNCHRONIZATION

Select the **Synchronize solutions** checkbox to synchronize the solutions computed by the batch processes with the model. This allows additional postprocessing after the sweep has finished. The default is to disable solution synchronization. If desired, and the **Synchronize solutions** checkbox is selected, select the **Clear synchronization data** checkbox to clear synchronization files left by batch jobs. Log files, .status, .recovery, and batch job MPH-files are not removed. To save the model to file before removing all synchronization data, select the **Save model to file after synchronization is completed** checkbox. The filename is the same as the one used for making a backup.

Select the **Synchronize accumulated probe table** checkbox to synchronize the accumulated probes computed by the batch processes with the model. The accumulated probe synchronization is enabled by default. Select the **Output model to file** checkbox to enable that all batch processes save the models to file. In most cases, use the solution synchronization and probe synchronization functionality instead because otherwise the data ends up in one file for each process and cannot be postprocessed efficiently. Use the **Probes** list to select probes to update during the batch sweep. The default is **All**, which selects all probes for plotting and tabulation of probe data. Select **Manual** to open a list with all available probes. Use the **Move Up** (↑), **Move Down** (↓), **Delete** ( ), and **Add** (+) buttons to make the list contain the probes that you want to see results from while solving. Select **None** to disable probe updating for batch sweep.

When the **Synchronize solutions** checkbox is selected for some models, the batch sweep stores a large amount of files in the directory specified under **Cluster computer settings**. Those files are needed for the synchronization of the solutions.

Select the **Accumulated probe table** checkbox to activate the accumulation of probe updates for both the variation on the solver level (time, frequency, and so forth) and on the batch sweep level. Use the **Output table** to select where to put the data. Select the **Use all probes** checkbox if all the model probes should be accumulated in the table. If the checkbox is not selected, the probes selected from the **Probes** list are used.

CLIENT SETTINGS

The **Batch** node can also be used as a client to drive a server on another machine. You enable the client functionality by selecting the **Client** checkbox. You can then set the **Hostname** (default: localhost) and **Port number** of the server

for the batch job (default: 2036) to connect to. This number is the default port number. If the server you want to connect to is using another port, then edit this number accordingly.

Micromixer — Batch Version: Application Library path **COMSOL_Multiphysics/Cluster_and_Batch_Tutorials/micromixer_batch**.

The COMSOL Commands

Cluster Computing (Job Configurations)

The **Cluster Computing** ( ) job configuration is useful when you want to submit a batch job to a job scheduler or you want to run the model in distributed mode as a batch job. This node is created the first time you submit a job. If you want to change its settings before the first job submission, right-click the **Study** node and select **Show Default Solver**.

When you have specified the cluster computing settings, click the **Save as Default** button ( ) in the **Settings** window's toolbar to save the current setting as default.

These settings are saved to The Preferences Window in the **Multicore and Cluster Computing** section.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding **Cluster Computing** study step (see Cluster Computing), or select **User defined** to define cluster settings in the **Cluster Settings** section below.

From the **Batch job** list, select which batch job to submit. Click the **Go to Source** button ( ) to move to the **Settings** window for the selected **Batch** node.

CLUSTER SETTINGS

After making these settings, click the **Save as Default** ( ) button in the **Settings** window toolbar to save the current directory settings as the default preference.

Enter the **Number of nodes** (compute nodes; see Overview of Simulations on Shared- and Distributed-Memory Computers) to use (the default is 1 node). Available with **Preferences controlled** settings and for the **General**, **HPCS 2008/2012/2016**, and **SLURM** scheduler types.

Enter the **Number of processes on host**. The default is 1. Available with **Preferences controlled** settings and for the **General** and **SLURM** scheduler types.

Cluster Computing Settings

From the **Settings** list, choose **Preference controlled** (the default) to use settings from the **Cluster computing** part of the **Multicore and Cluster Computing** page in the **Preferences** window. Choose **User controlled** to enter the following cluster computing settings:

If you want to use a job scheduler or do some other operations before or after the job, you set the command line in the **Prepend command** and **Postpend command** fields. You can define a default command line with the system

properties `cs.precmd` and `cs.postcmd`. If the command line contains `{nn}` or `{perhost}`, they are replaced by the values in the **Number of nodes** field and **Number of processes on host** field, respectively.

Choose the **Scheduler type**: **General** (the default), **Microsoft® HPC Pack**, **OGS/GE**, **SLURM**, **PBS**, **IBM LSF®**, or **Not distributed**:

General

Select **General** (the default) to configure to run on many types of clusters and schedulers, including Linux clusters.

- The entry in the **Host file** field specifies the host file used for the job. If left empty, MPD looks for a file `mpd.hosts` in the Linux home directory.
- Select which bootstrap server should be used by MPI using the **Bootstrap server** setting.
- Specify the installation directory for the MPI in the **MPI directory** field. Click **Browse** to browse for a directory on the file system.
- If you must provide extra arguments to MPI, use the **Additional MPI arguments** field.

Microsoft® HPC Pack

Select **Microsoft® HPC Pack** to use the Microsoft HPC Pack job scheduler to submit the batch job.

- Select a **Node granularity**: **Node** (the default), **Socket**, or **Core**. **Node** allocates one process on each host, **Socket** allocates one process on each socket, and **Core** allocates one process on each core.
- The **Exclusive nodes** checkbox is selected by default. Keep it selected if a compute node is used exclusively for a job — that is, no other jobs can interfere. Click to clear it if you want to run on nodes shared by other users.
- Set the names of **Requested nodes** to use specified nodes only. The job scheduler only allocates jobs on the nodes listed by you.
- Enter the **Node group**. As above, but can use node group names if defined by the system administrator. The job scheduler only allocates jobs on the nodes belonging to the group.
- Enter the minimum required **Cores per node** — the number of concurrent threads per physical node. The default is 0, which means all cores. The job scheduler only allocates jobs to nodes with at least as many cores as set.
- Enter the minimum required **Memory per node (MB)**. The default is 0, which means no limit. The job scheduler only allocates jobs to nodes with at least as much memory as set.
- Enter the **Runtime (minutes)** before the job is canceled. The default is **Infinite**; that is, the job is never canceled.
- Select a **Priority** — **Highest**, **Above normal**, **Normal** (the default), **Below normal**, or **Lowest** — for the scheduled job based on the standard scheduler.

Under **Cluster computing settings**:

- If you want to include scheduler arguments, add them to the **Additional scheduler arguments** field (for example, for `mpiexec`).
- Specify the installation directory for the MPI in the **MPI directory** field. Click **Browse** to browse for a directory on the file system.
- If you must provide extra arguments to MPI, use the **Additional MPI arguments** field.

Under **Advanced**:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`, and it should only be changed if you submit your job from a different computer than the head node.
- The entry in the **User** field is the user account that COMSOL Multiphysics uses for submitting the job. You provide the password in a separate command window that opens at execution time with the possibility to save the credentials.

OGS/GE

Select **OGS/GE** to use the Open Grid Scheduler/Grid Engine job scheduler to submit the batch job.

When **OGS/GE** is selected:

- Select a **Slot granularity** — **Host**, **Slot**, or **Manual** — to specify if COMSOL Multiphysics should parallelize on the physical **Host** level or on the OGS/GE-allocated **Slot** level. For **Host** and **Slot**, specify the **Number of slots** to allocate. The **Manual** setting can be used to control the granularity more. In this case set the number of computational nodes to use in the **Number of nodes**. For **Slot** and **Manual**, the number of processes on each node is set in the **Number of processes on host** field; usually this is 1.
- Enter the **Number of processes on host** to set the number of processes on each host.
- The Sun Grid Engine priority is set in the **Priority value** field. The default is 0.

Under **Cluster computing settings**:

- If you want to include scheduler arguments, add them to the **Additional scheduler arguments** field (for example, for `mpiexec`).
- Select the **Bootstrap server** that should be used by MPI.
- Specify the installation directory for the MPI in the **MPI directory** field. Click **Browse** to browse for a directory on the file system.
- If you must provide extra arguments to MPI, use the **Additional MPI arguments** field.
- Enter the **Queue name** to set the name of the Sun Grid Engine.

SLURM

Select **SLURM** to use the SLURM job scheduler to submit the batch job.

When **SLURM** is selected:

- The **Exclusive nodes** checkbox is selected by default. Keep it selected if a compute node is used exclusively for a job — that is, no other jobs can interfere. Click to clear it if you want to run on nodes shared by other users.
- Set the names of **Requested nodes** to use specified nodes only. The job scheduler only allocates jobs on the nodes listed by you.
- Enter the minimum required **Memory per node (MB)**. The default is 0. The job scheduler only allocates jobs to nodes with at least as much memory as set.
- Enter the **Runtime (minutes)** before the job is canceled. The default is **Infinite**; that is, the job is never canceled.
- The SLURM priority value is set in the **Priority value** field. The default is 0.

Under **Cluster computer settings**:

- If you want to include scheduler arguments, add them to the **Additional scheduler arguments** field (for example, for `mpiexec`).
- Specify the installation directory for the MPI in the **MPI directory** field. Click **Browse** to browse for a directory on the file system.
- If you must provide extra arguments to MPI, use the **Additional MPI arguments** field.
- Enter the **Queue name** to set the name of the SLURM job scheduler.

Under **Advanced**:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`.
- The entry in the **User** field is the user account that the COMSOL software uses for submitting the job. You provide the password in a separate command window that opens at execution time with the possibility to save the credentials.

PBS

Select **PBS** to use a PBS-based (Portable Batch System) job scheduler to submit the batch job. When **PBS** is selected:

- Enter the minimum required **Memory per node (MB)**. The default is 0. The job scheduler only allocates jobs to nodes with at least as much memory as set.
- Enter the **Runtime (minutes)** before the job is canceled. The default is **Infinite**; that is, the job is never canceled.
- The PBS priority value is set in the **Priority value** field. The default is 0.

Under **Cluster computer settings**:

- If you want to include scheduler arguments, add them to the **Additional scheduler arguments** field (for example, for `mpiexec`). To designate nodes as exclusive, use the **Additional scheduler arguments** `-n`. This means that a compute node is used exclusively for a job — that is, no other jobs can interfere.
- Specify the installation directory for the MPI in the **MPI directory** field. Click **Browse** to browse for a directory on the file system.
- If you must provide extra arguments to MPI, use the **Additional MPI arguments** field.

Under **Advanced**:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`.
- The entry in the **User** field is the user account that the COMSOL software uses for submitting the job. You provide the password in a separate command window that opens at execution time with the possibility to save the credentials.

IBM LSF®

Select **IBM LSF®** to use an LSF-based (IBM® Platform Load Sharing Facility) job scheduler to submit the batch job. When **IBM LSF®** is selected:

Under **Cluster computer settings**:

- If you want to include scheduler arguments, add them to the **Additional scheduler arguments** field (for example, for `mpiexec`). To designate nodes as exclusive, use the **Additional scheduler arguments** `-n`. This means that a compute node is used exclusively for a job — that is, no other jobs can interfere.
- Specify the installation directory for the MPI in the **MPI directory** field. Click **Browse** to browse for a directory on the file system.
- If you must provide extra arguments to MPI, use the **Additional MPI arguments** field.

Under **Advanced**:

- The entry in the **Scheduler** field is the IP address of the enterprise adapter of the head node or the DNS name of the head node. The default is `localhost`.
- The entry in the **User** field is the user account that the COMSOL software uses for submitting the job. You provide the password in a separate command window that opens at execution time with the possibility to save the credentials.

Not Distributed

Select **Not distributed** when you want to submit a batch job to a job scheduler without running a distributed job.

REMOTE AND CLOUD ACCESS

See Remote and Cloud Access described for Cluster Computing.

Micromixer — Cluster Version: Application Library path **COMSOL_Multiphysics/Cluster_and_Batch_Tutorials/micromixer_cluster**.

Function Sweep (Job Configurations)

To display this option for Job Configurations, click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog.

The **Function Sweep** (f(x)) is a special version of a parametric sweep that sweeps over functions defined under a **Switch** node that you add from **Definitions** > **Functions**.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step. Click the **Go to Source** button ( ) to move to the **Settings** window for the selected study node.

Add information to the table for each column: **Switch** and **Case numbers**. Use the **Move Up** ( ), **Move Down** ( ), **Add** ( ), and **Delete** ( ) buttons under the table to organize the data.

Enter a **Stop condition**.

For the rest of the settings, see Parametric Sweep (Job Configurations).

Material Sweep (Job Configurations)

To display this option for Job Configurations, click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog.

The **Material Sweep** ( ) is a special version of a parametric sweep that sweeps over materials defined under a **Switch** node that you add under **Materials**.

GENERAL

Use the **Defined by study step** list to specify if the settings are synchronized with the corresponding study step. Click the **Go to Source** button ( ) to move to the **Settings** window for the selected study node.

Add information to the table for each column: **Switch** and **Case numbers**. Use the **Move Up** ( ), **Move Down** ( ), **Add** ( ), and **Delete** ( ) buttons under the table to organize the data.

Enter a **Stop condition**.

For the rest of the settings, see Parametric Sweep (Job Configurations).

Optimization (Job Configurations)

To display this option for Job Configurations, click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog.

The **Optimization** ( ) node needs an Optimization study to work. It works analogously to a Parametric Sweep node for parametric sweeps and is only available when you use a gradient-free optimization solver.

GENERAL

The **Parametric jobs** list shows which Parametric Sweep nodes that the optimization solver runs. Each time the optimization solver needs to evaluate the objective function, it sends a number of control parameter tuples to the parametric sweep node. The value in the **Maximum number of simultaneous objective evaluations** field in the Optimization study node controls the maximum number of tuples that can be sent to a Parametric Sweep.

You can use the **Move Up** ( ), **Move Down** ( ), **Delete** ( ), and **Add** ( ) buttons to modify the list of parametric sweeps.

LOG

The **Log** section contains solver log output from the latest optimization run. Select the **Keep warnings in stored log** checkbox if you want the warnings to remain in the log for troubleshooting or other use.

Sequence

To display this option, click the **Show More Options** button ( ) and select **Solver and Job Configurations** in the **Show More Options** dialog.

The **Sequence** node ( ) is generated automatically by a Study Reference when it is used without any Parametric Sweep study step. It then runs the referenced studies in sequence.

Use a **Sequence** node to run job sequence steps in the same way as with the Parametric Sweep feature. The feature only runs the steps once without any parameters or sweep. It is also similar to the **Batch** feature, but does not create a batch job. A sequence can contain steps to run all solutions, save the model to a file, and evaluate derived values, for example. You add those steps by right-clicking the **Sequence** node and selecting one of the following options:

- **Job**
- **Solution**
- **Other**
- **Save Model to File**, which saves the solved model to an MPH-file. See Save Model to File.
- **Results**

Job refers to another job that is to be run from this sequence, while **Solution** (see Solution) runs a **Solution** node as available under the **Solver Configurations** node, available further up in the **Study** tree.

Under **Other**, you can choose **External Class** (see External Class), which calls an external Java® class file. Another option, **Method Call** (see Method Call), runs a model method. The **Geometry** (see Geometry), builds the **Geometry** node (runs the geometry sequence). This can be used, for example, in combination with a parametric sweep to generate a sequence of MPH-files with different geometry parameters. The **Mesh** option (see Mesh) builds the **Mesh** node (runs the meshing sequence).

Under **Results**, you can choose **Plot Group** (see Plot Group) to run all or a selected set of plot groups. This is useful for automating the generation of plot groups after solving. The **Derived Value** option is there for legacy reason, and it is instead recommended that you use the **Evaluate Derived Values** option (see Evaluate Derived Values), which evaluates nodes under **Results** > **Derived Values**. The option **Export to File** (see Export to File) runs any node for data export under the **Export** node.

EXAMPLE: USING A JOB SEQUENCE TO PLAY A SOUND WHEN THE SIMULATION IS READY

Use a job sequence with two steps to run a solver configuration (typically corresponding to a study step) and then call a method that plays a sound.

1. For the method, called `playWav`, for example, add a single line of code like `playSound("success.wav");`.
2. Add a **Sequence** node, and by right-clicking it, add a **Solution** node and a **Method Call** node to the sequence.
3. In the **Settings** window for the **Solution** node, specify the solver configuration to run from the **Run** list (or use the default, **All**, which is identical to choosing a solver configuration if there is only one such configuration in the study.
4. In the **Settings** window for the **Method Call** node, choose the method with the call for playing the sound (`playWav`, for example) from the **Run** list.
5. In the **Settings** window for the corresponding **Sequence** node, click the **Run** button ( ) at the top of the window. The selected solver configuration in the **Solution** node is then run, and when the computation has ended, a sound is played by calling the method in the **Method Call** node.

Using a Job Configuration to Store Parametric Results on File

As an example of the use of a job configuration, right-click the **Job Configurations** ( ) node and add a Parametric Sweep (Job Configurations) to run a parametric study, storing the model and associated data and plots for each parameter step to individual files. This is useful if you, for example, want to:

- Avoid large model files while running large parametric sweeps.
- Store information in individual output files instead of in one large file.
- Control several file outputs directly from the COMSOL Desktop: Model MPH-files, data files (text files), and image files.

The following steps describe the most important parts of setting up a job configuration to accomplish the desired file output:

1. Start with a model that does not contain any parametric sweep and define your outputs. Then add them to the **Export** node (by right-clicking and adding **Data**, **Plot**, and image nodes as desired) and assign each data or plot output to a file.
2. Create a parametric sweep study by right-clicking the study node and adding a **Parametric Sweep**. Add the parameters you want to sweep over in Parameters under Global Definitions. Now add the parameters in **Parameter name** in the parametric sweep node you created and set the **Parameter values** you want to sweep over. In some cases COMSOL Multiphysics chooses to use the more efficient parametric solver when sweeping. Set the **Use parametric solver** under **Study Extensions** to **Off** if you want to avoid this. Use the **Keep solutions** setting **Only last** to conserve memory. In that case, use the Accumulated Probe table to store the data you want to use for later processing. You can also choose to store the models on file by enabling the **Save each solution as model file** and then entering a filename in the **Filename** field, or clicking **Browse** to choose a name and location for the model files. The models created during the simulation can then be found in a **Save model to File** node under **Job Configurations**. The default settings are configurable in the **Preferences** window.
3. If you want to create output files with the parametric sweep for further analysis, right-click the main study node and select **Show Default Solver**. Select the parametric node under **Job Configurations** that corresponds to the parametric sweep from which you want to export data. You can see which parametric sweep the node corresponds

to from the **Defined by study step** list. Note that if you run a stationary study, you need to switch off **Use parametric solver** in the **Study Extensions** section (see above) to get the node under **Job Configurations**.

- Right-click the **Parametric** node and select **Results** > **Plot Group** if you want to run a **Plot Group** for each parameter value in the sweep. In most cases use the **Plot** settings under **Results While Solving** (in the study step's **Settings** window) instead.
- Right-click the **Parametric** node and select **Results** > **Derived Value** to run a **Derived Values** node for each parameter value in the sweep. This functionality is similar to probes but is useful if you have already set up a **Derived Values** node that you want to use during the sweep. The values are stored in a table (similar to probes) for further processing.
- Right-click the **Parametric** node and select **Results** > **Export to File** if you want to export data to a file for each parameter value in the sweep, running an **Export** node under **Results**. Note that after the sweep, the files created are listed in the node and can be opened in a browser using the **Open** button.

Advanced Job Configurations

Because a job configuration defines a sequence of steps, you can create highly advanced models that use different solvers and sweeps as input to each other and perform different types of postprocessing during a sweep. Here are some suggestions:

- Create a parametric job configuration that uses two solvers. The first solver is used as input to the second solver. One way to create such a sweep is to create two studies. Let the second study use the first as input from the **Values of Dependent Variables**. Create a **Parametric Sweep** in the first study and select to keep **Only last** solution. Run **Show Default Solver** in both studies and enter the **Job Configurations** node of the first study. Right-click the **Parametric** node and add a **Solver**. Select the new solver and set it to run the second solver from the second study. Also check the **Keep all solutions** settings. Right-click the **Parametric** node and select **Run**. You can add further functionality to the sequence such as **Export to File** to suit your needs.
- Another possibility is to create a parametric sweep that runs a **Cluster Computing** node. This gives you similar functionality as the distributed parametric sweep, but the results are stored in separate files. Note that this requires several licenses, one for each process running simultaneously. One way to create this is to add a **Cluster Sweep** node by right-clicking the study. This node creates such a sweep automatically. It also sets up synchronization of solutions and accumulated probe tables when the synchronization is enabled. Another, more complicated, way is to add a **Cluster Computing** node by right-clicking the study. Note that you need the **Advanced Study Options** enabled. If you added the **Cluster Computing** node, then run **Show Default Solver** and select the **Job Configurations** node. Right-click and add a **Parametric** node. Right-click the new **Parametric** node and enable it. Right-click again and add a **Job** node. Set the job sequence to point to the **Cluster Computing** node. This sets up the new **Parametric** node to start a new process for each parameter. After you have set the parameters that you want to compute for, right-click and select **Run**. The resulting models are stored in **External Process** nodes under the batch job run by the cluster computing node. To get exported data during the runs, you can use the functionality **Export to File** described above or enable the synchronization of solutions and accumulated probe tables in the **Batch** node.
- Create a parametric sweep that runs a solver and a class file that uses the COMSOL API to modify the solution. This can be useful if you want COMSOL Multiphysics to communicate with another program. You do this by adding a **Parametric Sweep** node to the study that you want to use. Run **Show Default Solver** and enter the **Job Configuration**s node. Right-click the **Parametric** node and select **Other** > **External Class**. You can also modify the **Parametric** node by, for example, adding a **Stop condition**.

The default names for the nodes that you add under the **Parametric** node use a dynamic naming, so that the sequence that is run and, when applicable, the data storage node appear in the node name. By renaming the node to a user-defined name, you disable the dynamic naming.

Batch Data

The **Batch Data** node ( ) contains information about the batch processes that have been started by the Batch (Job Configurations) node ( ). Each process is represented by an External Process ( ) subnode. On the **Batch Data** node's **Settings** window, click the:

- **Attach Job** button ( ) in the **Settings** window toolbar to display the progress of all the external processes. The user interface enters a progress mode in order to follow the progress of the external processes.
- **Stop all Processes** button ( ) to send the stop command to unfinished jobs.
- **Cancel all Processes** button ( ) to send the cancel command to unfinished jobs.
- **Clear All Data** button ( ) to clear all data for all batch processes.

You can also right-click the **Batch Data** node and choose these options.

PROCESS STATUS

The **Filename** and **Client filename** fields contain the filenames of the files where the backup batch file is stored.

	Micromixer — Batch Version: Application Library path **COMSOL_Multiphysics/Cluster_and_Batch_Tutorials/micromixer_batch**.

Derived Value

The **Derived Value** node ( ) runs a Derived Values node defined in the **Results** branch of the model tree.

	Use the Evaluate Derived Values instead. The **Evaluate Derived Value** node replaces the **Derived Value** node and provides the same functionality in a more general way. The **Derived Value** node will be removed from the COMSOL Desktop in a future version.

To add this node, right-click the Parametric Sweep (Job Configurations) or Batch (Job Configurations) node and select it from the **Results** submenu.

	The computed value is stored in a **Result** table under the Derived Values node (see Derived Values, Evaluation Groups, and Tables).

GENERAL

You select the Derived Values node to run from the **Run** list. The default behavior (**All**) is to run all Derived Values nodes. The node label is therefore by default set to **All Derived Values**.

RESULT

The **Table** setting decides in which **Table** under **Results** to store the computed values. The default is **New** for a new table.

From the **Update table** list, select one of the following options to control the behavior of table updates:

- **Clear initial table** (the default)
- **Append data to table**
- **Clear table for every new parameter value**. This option clears the table for every parameter in the sweep.

The **Parameters** column in the **Result** table contains the parameters that computed the numerical value, the **Value** column contains the numerical value, and the **Derived values** column contains the name (tag) of the **Derived Values** node that computed the numerical value. The information about the derived values nodes is useful when you have selected **All** from the **Run** list and the computed values come from different **Derived Values** nodes. Click the **Save to File** button ( ) and the **Load from File** button ( ) to save and load parameters to and from a text file or, if the license includes LiveLink™ *for* Excel®, a Microsoft Excel® Workbook spreadsheet. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window.

Evaluate Derived Values

The **Evaluate Derived Values** node ( ) evaluates some or all Derived Values nodes defined in the **Results** branch of the model tree. To add this node, right-click the Parametric Sweep (Job Configurations) or Batch (Job Configurations) node and select it from the **Results** submenu.

The evaluated derived values are stored in a **Result** table under the Derived Values node (see Derived Values, Evaluation Groups, and Tables).

GENERAL

You select the Derived Values nodes to evaluate from the **Evaluate** list. The default behavior (**All**) is to evaluate all Derived Values nodes. The node label is therefore by default set to **Evaluate All Derived Values**. Select **Manual** to add more than one but not all Derived Values nodes to the list that appears.

RESULT

The **Store output** checkbox is selected by default to store the evaluated derived values in a table. Clear it if you do not want to store the derived values. If selected, choose **New** or any existing table as the table to use from the **Destination table** list. From the **Update destination** list, select one of the following options to control the behavior of table updates:

- **Clear initial table** (the default)
- **Append data to table**
- **Clear table for every new parameter value**. This option clears the table for every parameter in the sweep.

From the **Update table** list, choose one of the options described above for the table updates.

Clear the **Add parameters to description** checkbox if you do not want to include the parameters in the table description.

Export to File

The **Export to File** node ( ) runs an Export node defined in the **Export** branch of the model tree. The file is stored with a unique name that is generated from the current parameter values and the filename that the Export node has set. To add this node, right-click the **Parametric Sweep** or **Batch** job configurations node and select it from the **Results** submenu. Also see Exporting Data and Images.

GENERAL

Use the **Run** setting to select the Export node to run. The default behavior (**All**) is to run all Export nodes.

FILE

In the **File** section you set if the COMSOL software should overwrite files with the same name or if an error should occur, for example. If you clear the **Clear previous** checkbox, the job adds the values in each run instead of clearing the previous value.

From the **Add parameters to filename** list, choose **None** to use the same name for each parameter value (can be useful if you want to start batch jobs with different parameter values from the command line and use the resulting file for further postprocessing), choose **Parameter name and value** (the default) to add parameter names and values to the filename, or choose **Index**, which instead of parameter names and parameter values uses an index scheme `iX`, `iY`, …, where same indices relate to the same parameter value. The index option gives much shorter filenames.

OUTPUT

In the **Output** section you find the names of the files created during a sweep. You can select to **Open** a file by clicking the button. The file then opens in a web browser. The **Parameters** column in the **Output** table contains the parameter names, and the **Filename** column contains the corresponding filename and, if applicable, the database in which the file is stored.

External Class

The **External Class** node ( ) runs the main method of an external compiled Java class file. To add this node, right-click the Parametric Sweep (Job Configurations), Batch (Job Configurations), Function Sweep (Job Configurations), Material Sweep (Job Configurations), or Sequence node and select it from the **Other** submenu.

GENERAL

Before the external class is called, the system property `cs.currentmodel` is set to the name of the model that is calling the external class. You can set the name of the class file in the **Filename** field. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Edit Location** ( ) (if it is a database location),. **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

Arguments can be passed to the main method using the **Input** field.

External Process

The **External Process** nodes ( ) under a Batch Data node contain information about the batch processes that the Batch (Job Configurations) node has started. Each **External Process** node is associated with a started batch job.

On the **External Process** node's **Settings** window, you can click these buttons, which are also available on The External Process Window, where you can monitor this node's progress.

- **Attach Job** button ( ) in the **Settings** window toolbar displays the progress of all the external processes. The UI enters a progress mode in order to follow the progress of the external processes.
- **Stop All Processes** button ( ) sends the stop command to unfinished jobs.
- **Cancel All Processes** button ( ) sends the cancel command to unfinished jobs.
- **Clear Status** button ( ) clears the status of the selected job. Useful when the status indicates that the process is running but the process has failed.
- **Rerun Job** ( ) restarts the selected job.
- **Clear Data** ( ) to clear all data for one particular batch process.
- **Clear All Data** ( ) to clear all data for all batch processes.

After clicking the button, the status of the requested operation is viewed in the Process Status section.

You can also right-click the **External Process** node and choose these options, except those that handle all processes.

GENERAL

The **Start command** field contains the command that was used to start the batch job. The **Filename** field contains the filename of the model that is used in the batch job. Click **Open** when the batch job has finished to open the file.

PARAMETERS

Parameter names and **Parameter values** are listed in this section when available.

PROCESS STATUS

The log is updated when you choose **Update log**.

Method Call

The **Method Call** node ( ) runs a model method defined in a **Method Call** node under **Global Definitions** (see Method Calls). To add this node, right-click the Parametric Sweep (Job Configurations), Batch (Job Configurations), or Sequence node and select it from the **Other** submenu.

GENERAL

From the **Run** list, choose any available model method (or choose **None**). The sweep, batch job, or sequence will then run the method call as part of the job. The referenced Method Call is run during the study process or when the parent feature is explicitly run.

	When running model methods as part of a Batch feature or a cluster operation, model methods are limited to those that do not include user interface commands.

Geometry

The **Geometry** node ( ) runs a geometry sequence. To add this node, right-click the Parametric Sweep (Job Configurations), Batch (Job Configurations), or Sequence node and select it from the **Other** submenu.

GENERAL

Select the sequence to **Run** from the list. The default is to run **All** geometry sequences. If a specific geometry sequence is selected, you can click the **Go to Source** button ( ) to go to the **Geometry** node containing this sequence.

Job

You can add a **Job** node ( ) to run another job configuration. Right-click a Parametric Sweep (Job Configurations) or Batch (Job Configurations) to add the **Job** node.

GENERAL

Select the sequence to **Run** from the list. Recursive calls are detected and cause errors. Click the **Go to Source** button ( ) to go to the source job configuration node.

Mesh

The **Mesh** node ( ) runs a meshing sequence. To add this node, right-click the Parametric Sweep (Job Configurations), Batch (Job Configurations), or Sequence node and select it from the **Other** submenu.

GENERAL

Select the sequence to **Run** from the list. The default is to run **All** meshing sequences. Click the **Go to Source** button ( ) to go to the source meshing sequence.

Plot Group

The **Plot Group** node ( ) runs a sequence of plot groups, creating a plot in the Graphics window. To add this node, right-click the Parametric Sweep (Job Configurations) or Batch (Job Configurations) node and select it from the **Results** submenu. Also see Plot Groups and Plots.

GENERAL

Select the sequence to **Run** from the list. The default is to run **All** plot group nodes. Click the **Go to Source** button ( ) to go to the source plot. You can use an Export to File node to store the resulting plot in a file.

Save Model to File

The **Save Model to File** node ( ) stores a model in the state it is in at that point in the Batch or Parametric job configuration.

GENERAL

The **Overwrite previous model files** checkbox is selected by default. This means that previous models with the same name are overwritten. If a parametric sweep is running, the model is given a unique name based on the current parameter values.

From the **Add parameters to filename** list, choose **None** to use the same name for each parameter value, choose **Parameter name and value** (the default) to add parameter names and values to the filename, or choose **Index**, which instead of parameter names and parameter values uses an index scheme `iX`, `iY`, …, where same indices relate to the same parameter value. The index option gives much shorter filenames.

Enter a **Filename** including its network path, or click **Browse** to navigate to the location on your network where you want to store the model.

OUTPUT

The names of the saved models are stored in the table under **Output** where the **Filename** and **Parameters** are listed. Open a saved model in a new instance of COMSOL Multiphysics by selecting an **Open file** from the list or by clicking the **Open** button.

Solution

The **Solution** node ( ) runs a solver configuration for either a Parametric Sweep (Job Configurations) or Batch (Job Configurations).

GENERAL

Select the sequence to **Run** from the list. The default is to run **All** solver configurations. Click the **Go to Source** button ( ) to go to the source solver configuration.

OUTPUT

In this section you can control how the copy of the solutions are stored in the container. The container is a solver sequence that has Solution Store nodes. Each **Solution Store** node is the solution computed for one of the parameter tuples in the Parametric Sweep (Job Configurations). The name of the solution copy is generated from the current sequence name and parameter values. By default, the **Add solution to a container** checkbox is selected and the **Clear previous** list is set to **Clear container initially**. You can choose between **Clear container initially**, **Append solutions to**

container, or **Clear container for every new parameter value**. To prevent any modifications to the container, clear the **Add solution to a container** checkbox. Select the **Regenerate default solver sequence** checkbox to generate a new solver sequence for each parameter value. If the checkbox is cleared, the solver sequence is not changed.

SOLUTION

This section contains a table of parameters and solutions after running a batch job or a parametric sweep. In the **Parameters** column you find the parameters in the parametric sweep, for example, and the values for those parameters at that step in the sweep. The corresponding row of the **Solution** column contains the name of the solution that corresponds to that set of parameter values. Typically, **Solution Store** nodes store those solutions, which are also available from the **Solution** list in the Solution datasets.

Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis

In general, how the perturbation concept (and the study) is named is based on the application. For example, in the AC/DC Module and Semiconductor Module, it is referred to as *small-signal analysis*, whereas in the Structural Mechanics Module it is referred to as *prestressed analysis*. For the Battery Design Module, the Electrodeposition Module, and the Fuel Cell & Electrolyzer Module, the studies are called *AC impedance*. For the CFD Module, and fluid flow in general, the term *perturbation* is sufficient.

See these study types for details about availability by module and physics interface:

- Frequency-Domain Perturbation
- Small-Signal Analysis, Frequency Domain
- Prestressed Analyses Studies
- AC Impedance, Stationary
- AC Impedance, Time Dependent

For information about plotting results from this type of models, see Small-Signal Analysis, Prestressed Analysis, and Harmonic Perturbation Plot Settings.

- With the Acoustics Module and AC/DC Module, see *Loudspeaker Driver — Frequency-Domain Analysis*: Application Library path **Acoustics_Module/Electroacoustic_Transducers/loudspeaker_driver**.
- With the Structural Mechanics Module, see *Piezoelectric Tonpilz Transducer with a Prestressed Bolt*: Application Library path: **Structural_Mechanics_Module/Piezoelectric_Effects/tonpilz_transducer_prestressed**.
- With the AC/DC Module, see *Small-Signal Analysis of an Inductor*: Application Library path **ACDC_Module/Devices,_Inductive/small_signal_analysis_of_inductor**.

Frequency-Domain Perturbation Study Step

Usually, two different right-hand side contributions (or loads) must be defined for each step. The first step needs a stationary value for the contribution, and the second step needs the perturbed value for the contribution. The definition of these contributions differs between exclusive and contributing nodes, and this relates to the **Harmonic Perturbation** node, which can be added to a wide variety of physics interface nodes (for example, the **Electric Potential** and **Electric Ground** nodes for the **Electric Currents** interface).

For plot settings made available by using this study, see Small-Signal Analysis, Prestressed Analysis, and Harmonic Perturbation Plot Settings. Also see Frequency-Domain Perturbation.

Harmonic Perturbation — Exclusive and Contributing Nodes

A physics node that is exclusive has a **Harmonic Perturbation** subnode. This subnode adds harmonic perturbations to the right-hand-side contributions of its parent node (for example, a **Boundary Load** on the **Solid Mechanics**

interface or a **Terminal** node on the **Electric Currents** interface). In the **Settings** window, the perturbation is entered for these contributions, which is only used when you solve for a **Frequency-Domain Perturbation** study type. The parent node defines the stationary value for the contribution, which is not present for the **Frequency-Domain Perturbation** study.

Harmonic perturbation nodes have a tilde over the top of the node, as in this example of a boundary level node ( ).

Nodes that are contributing (typically sources) can add their contributions as a harmonic perturbation. To define the stationary value for the contribution, you can add another node of the same type with the harmonic perturbation setting cleared.

For exclusive loads, there is only one way of doing it due to the exclusivity — as a subnode. This subnode cannot, in general, be a full copy of the original node because only some subsets of data can be changed.

As an example (prescribed displacement in structural mechanics), the prescribed displacement must have the same local system and the harmonic perturbation can only be applied to degrees of freedom already prescribed in the parent node.

Also, all contributing nodes are free to use the full set of settings. A static point load can be at one point in the global direction, and a local system for the harmonic contribution can be used.

- Physics Exclusive and Contributing Node Types
- For different plot settings made available, see Small-Signal Analysis, Prestressed Analysis, and Harmonic Perturbation Plot Settings.
- For information about the `linper` operator, see linper. You can use it to indicate load terms that should be used by stationary solvers using harmonic linear perturbation.

Vibrating MEMS structures are often prestressed. For example, a cantilever structure could be prestressed by applying a DC voltage bias between the cantilever and a nearby ground plane; then vibrations could be driven at resonance by applying an additional AC bias. Another common example would be a clamped–clamped beam with a residual thermal stress.

21

Results Analysis and Plots

This chapter describes the functionality for visualization, analysis, and presentation of simulation results in COMSOL Multiphysics®.

In this chapter:

- Results Overview
- Configurations
- Datasets
- Derived Values, Evaluation Groups, and Tables
- Plot Groups and Plots
- Exporting Data and Images
- Reports and Presentations
- Printing and Capturing Screenshots
- Creating PowerPoint Presentations and Word Documents with Linked Tables and Images

Results Overview

About the Results Branch

The **Results** branch in the COMSOL Multiphysics model tree contains tools for postprocessing and analyzing the results from your simulations, including visualizations, animations, data analysis, data and image export, reports, and presentations. The main **Results** node contains all nodes that you create for such purposes. The **Settings** window contains the following sections: **Update of Plots** and **Save Data in the Model**.

UPDATE OF RESULTS

The default is to update all plots automatically when you, for example, recompute the solution, click the plot node, or change the color table for a plot. Select the **Only plot when requested** checkbox to keep the plots unchanged until you explicitly update the plot using the **Plot** button ( ). This can be useful, for example, for large models with complex plots where you do not want to update the plots directly when opening the model or when solving. A gray asterisk in the upper-right corner of the plot node's icon indicates that the plot is not updated ( ).

Even when the **Only plot when requested** checkbox is selected, some changed style settings, such as the color table, are updated when you click a plot node, for example. Changes to style settings do not require that the COMSOL Multiphysics software reevaluates the plot data.

Select the **Recompute all plot data after solving** checkbox to compute a solution and the data for the dependent plots in one step. This can be convenient when it takes a long time to generate the data for the plots.

Select the **Reevaluate all evaluation groups after solving** checkbox to update the values of all derived values in evaluation groups (see About Evaluation Groups) when the solver finishes. Such an automatic update makes it easier to manage the contents of the evaluation group tables as you know that the data is up to date. It can also be convenient to make the solution and evaluation into one single step.

Select the **Run all exports after solving** checkbox to let the COMSOL software run all data and image export features added under **Export** after computing the solution.

Changing the Automatic Update of Plots

There are preference settings that you can use to avoid automatic updates of plots when opening or creating models. Open The Preferences Window and click **Results**. On the **Automatic Update of Plots** subpage you can set the preferences to update result plots.

- Select the **Disable for new models** checkbox to always disable the automatic update of plots for new models that you create (corresponds to selecting the **Only plot when requested** checkbox).
- Select the **Disable for models loaded from file (override saved)** checkbox to always disable the automatic update of plots for models that you open from file, such as models in the Application Libraries. The automatic update of plots is then disabled initially, regardless of the setting in the model.

Clearing Plot Data

To activate automatic updates of plots for the current model (if it has been turned off), clear the **Only plot when requested** checkbox in the **Settings** window for the **Result** node.

If you want to access postprocessing variables or data export features, for example, when working with models created in earlier versions, you must first re-solve the model or update the solution.

SAVING PLOT DATA IN THE MODEL

It is possible to save plot data in the model. When you open such a model, the stored plot data is used instead of the plot data being recomputed. Saving the plot data in the model is useful for plots that take a long time to recompute but do not contain a large amount of data. Examples include 1D plots (for example, a plot of an entity over time, which can take some time to generate but correspond to very little plot data), far-field plots (each point on the plot corresponds to an integral over the geometry), and slice plots over BEM solutions.

From the **Save plot data** list, choose one of the following options:

- **Automatic** (the default), which saves plot data for plots that take a long time to recompute but do not contain a large amount of data.
- **On**, to always save plot data in the model.
- **Off**, to never save plot data in the model.
- **Manual**, to control the saving of plot data in the model for each plot group. If you choose **Manual**, the main plot group node's **Settings** window includes a **Save Data in the Model** section, where you select the **Save plot data** checkbox to save that plot group's plot data in the model (by default, the plot data is not saved).

If you have saved data in the model, you can clear it by right-clicking the **Results** node and choosing **Clear Plot Data** or by clicking the **Clear Plot Data** button ( ) on the **Results** ribbon toolbar.

THE MAIN RESULTS ANALYSIS AND VISUALIZATION TOOLS

The **Results** branch groups the tools into the categories. During results analysis and visualization, there are these main operation types:

- Configurations. Configurations define multiple or single solutions; that is, multiple or a single time, eigenvalue, or parameter value that you can use in subsequent plots, data evaluations, data export, and preferred units.
- Datasets. Datasets provide the source of data for plotting, for example, by indicating a solution and geometry or by transforming another dataset (for combining solutions or evaluating data along a cut line, for example).
- Derived Values, Evaluation Groups, and Tables. Derived values define the evaluation of integrals, maximum and minimum values, values of variables in points, and values of global variables. The evaluation results are stored in Table nodes under **Tables** and displayed in the **Table** window.
- Plot Groups and Plots. A plot group is a collection of plots to display simultaneously in the **Graphics** window. The plot groups include 1D plots (graphs), 2D plots (surface plots, for example), and 3D plots (volume plots, for example) with many different plot types and options. You can enable or disable plots in a plot group to determine the most applicable final image for your model or project. The physics interfaces create suitable default plots grouped in descriptive plot groups. Use a combination of datasets and plot groups to create cross-section plots.
- **Export** (see Exporting Data and Images): Export data, images, and animations from plot groups to files or use a player to visualize dynamic data.
- Reports and Presentations. Create reports as HTML and Microsoft® Word documents that contain settings, selections, comments, plots, and other information about the model for easy viewing.

For quick single-click access to the functionality in the **Results** branch, the **Results** toolbar is available for adding plot groups, datasets, data evaluation tools, reports, and other results and visualization tools. When you select a plot group, a plot group contextual toolbar, with the same name as the plot group, appears. From that toolbar you can, for example, add new plots to the plot group and control the window to plot in.

To display the **Views** node under **Results** ( ), click the **Show More Options** button ( ) and select **Views** in the **Show More Options** dialog. This is useful, for example, when 2D axisymmetric revolved plots or 2D cut plane plots for 3D models are created. For details, see User-Defined Views.

- Results Toolbar and Plot Group Contextual Toolbar
- Results in the *COMSOL Multiphysics Programming Reference Manual*

Common Results Node Settings

Under Results Overview, there are common sections in the **Settings** windows. Table 21-1 provides cross references to the information relevant to these nodes, although the same section can also be available for other nodes throughout COMSOL Multiphysics. For the **Coloring and Style** section, see Table 21-2.

COMMON BUTTONS IN THE SETTINGS WINDOWS

The following buttons are available in many of the **Settings** windows and are mostly self-explanatory. These are not explicitly described or explained for every node.

- In general, use the **Move Up** (↑), **Move Down** (↓), or **Delete** ( ) button and the fields under tables to edit the table contents. Or right-click a table cell and select **Move Up**, **Move Down**, or **Delete**.
- At any time during plot creation, click the **Plot** button ( ) to preview a dataset or plot. Or right-click the node and select **Plot**.
- Click the **Add to Selection** (+), **Remove from Selection** (−), and **Clear Selection** ( ) buttons when working with geometric entities in the selection windows and when required.
- Click the **Range** button ( ) to define a range.
- Click the **Go to Source** button ( ) to move to the node to which the selection in the list next to the button refers.
- Click the **Evaluate** button (=) or right-click the **Derived Values** node and select **Evaluate All** (=) or **Clear and Evaluate All** ( ).

- Going to the Source Node
- About Selecting Geometric Entities
- Entering Ranges and Vector-Valued Expressions

Selecting a Dataset for Plots and Postprocessing

Almost every plot type's **Settings** window includes a **Data** section where you select a **Dataset** from a list of available and applicable datasets. **From parent** (the default) means that the plot uses the same dataset as the plot group to which it belongs. Click the **Go to Source** button ( ) to move to the dataset node to which the selection in the list next to the button refers.

Under **Data**, select a **Dataset**. Select:

- **From parent** (the default) to use the same dataset as the plot group to which it belongs.
- A **Data/Solution** or **Data/Parametric Solution** dataset to visualize a quantity from that solution.
- Other applicable types of datasets for the plot. For a 1D plot, for example, you can use a **Cut Line** dataset to visualize a quantity along the cut line (a cross section) or a **Parametric Curve** dataset to visualize a quantity along the parametric curve.
- **None** to not use any of the available datasets.

For plots where the selected dataset has the same nontrivial parameter structure as the dataset used in the parent plot group (typically, a solution that contains solution data for more than one time, eigenmode, or parameter), you can choose from where to take the solution parameters. From the **Solution parameters** list, choose **Manual** to choose a time, eigenmode, or parameter using the settings described below, or choose **From parent** to use those values from the corresponding settings in the parent plot group. Using the settings from the plot group can make it easier to work with plot groups where multiple datasets are used.

In addition, other lists can appear underneath the **Dataset** list for parametric, time-dependent, eigenmode, and adaptive mesh refinement solutions, as well as for evaluation of derived values:

- For parametric solutions, choose a parameter from the **Parameter value** list or, if applicable, from the **Parameter selection** list or separate lists from a parameter switch (see Inputs for Parametric Solver and Parametric Sweep Studies below). For a material sweep or function sweep, use the **Switch** list to choose a material or function for which to plot the corresponding solution.
- For time-dependent solutions, choose the time of the solution to use from the **Time** list for 2D and 3D plots. In addition you choose **Interpolated** for specifying an interpolated time in the text field that appears. You can also choose **Last** for the last solution in the list of times. It can be useful, for example, in models where the number of time steps depends on a parameter in a parametric sweep. For 1D plots and data evaluation, choose from the **Time selection** list: **All** to use all time steps, **First**, **Last**, **From list** to select from a list of all time steps, **Manual** to enter a range of times as indices directly, or **Interpolated** to enter **Times**.
- For eigenmode solutions, choose the eigenmode or eigenvalue of the solution to use from the **Eigenmode** or **Eigenvalue** list. For 1D plots and data evaluation, choose from the **Eigenmode selection** or **Eigenvalue selection** list: **All** to use all eigenmodes, **First**, **Last**, **From list** to select from a list of all eigenmodes, or **Manual** to enter a range of eigenmodes as indices directly.
- For solutions using adaptive mesh refinement (selecting a **Solution** dataset for the adaptive mesh refinement solutions), choose a refinement level from the **Parameter selection (Refinement level)** list. Level 0 is the base level (no mesh adaptation), and the highest level represents the final adaptive mesh refinement solution. For 1D plots and data evaluation, choose from the **Parameter selection (Refinement level)** list: **All** to use all refinement levels;

First, **Last**, or **From list** to select from a list of all refinement levels; or **Manual** to enter a range of refinement levels as indices directly.

	Datasets

	In **Parameter value** and **Time** lists with more than 100 parameter values or time steps, the values are grouped in sets of 100 for a better overview. Expand the section for the value that you want to plot a solution for.

Inputs for Parametric Solver and Parametric Sweep Studies

This information is useful when defining plots or derived values for **Parametric Solver** and **Parametric Sweep** studies using the settings in the **Data** section.

When setting parameters for parametric sweep studies in a node under **Results**, the available settings depend on the problem type. For a time-dependent parametric simulation, for example, you can select both time steps and parameter values. Similarly, an eigenvalue or eigenmode problem contains both eigenvalues or eigenmodes and parameter settings. In parametric sweeps, the time and eigenvalue settings are referred to as the inner solutions. Thus, in a graph plot for a parametric eigenvalue solution, for example, the axis source data for the x-axis data controls whether you want the inner solutions (eigenvalues) or outer solutions (parametric solutions) on the x-axis.

For **Parametric Solver** and **Parametric Sweep** studies, the **Parameter selection** or **Parameter values** list includes options for selecting solutions using the associated parameter values. For a parameter switch, there are lists (with the names of the corresponding **Parameters** nodes) of parameters for all parameter cases in all **Parameters** nodes that are included in the switch.

Any or all of the time steps can be selected from the **Time selection** list, or select **Interpolated** to get the same interpolated times for every parameter. Similar selections are available for eigenvalues and their associated eigenmodes.

- If **Interpolated** times is selected, enter **Times** or click the **Range** button ( ) to select and define specific times.
- If **Manual** times is selected, enter **Time indices** or click the **Range** button ( ) to select and define specific times.
- When available, from the **Table columns** list, select **Inner solutions** or **Outer solutions**. These options are available when there is a Parametric Sweep problem with dynamic inner solutions (that is to say, time, eigenvalue, or parametric solutions).
  - If **Inner solutions** is selected, when the **Evaluate** button ( ) is clicked, the results table displays the *dynamic value* (for example, time, eigenvalue, or parametric) solutions in rows.
  - If **Outer solutions** is selected, when the **Evaluate** button ( ) is clicked, the results table displays the *parameters* in rows.

	• Entering Ranges and Vector-Valued Expressions • Derived Values, Evaluation Groups, and Tables

Entering Axis Data for a Dataset

Revolution 1D and 2D datasets: Specify the revolution axis or point by a method based on the space dimension.

- For a **Revolution 1D** dataset, enter a value in the coordinate field to specify the revolution point.

- For a **Sector 2D** dataset, enter values for both the **x** and **y** coordinates (SI unit: m).
- For a **Mirror 2D**, **Revolution 2D**, or **Sector 3D** dataset, from the **Axis entry method** list, select **Two points** to enter the revolution axis by specifying two points or **Point and direction** to specify the axis by specifying one point and a direction vector.
  - If **Two points** is selected, enter coordinates in the **Point 1** and **Point 2** fields for **x** and **y** coordinates for the 2D datasets and for **x**, **y**, and **z** coordinates for the 3D dataset (SI unit: m).
  - If **Point and Direction** is selected, enter **Point** and **Direction** vectors for **x** and **y** coordinates for 2D datasets and for **x**, **y**, and **z** coordinates for the 3D dataset (SI unit: m).

Expressions and Predefined Quantities

When plotting and evaluating results, the COMSOL Multiphysics software provides a large number of predefined quantities that are specific to the physics interfaces in the model; mathematical functions and operators; and general quantities for the geometry, coordinate systems, and mesh.

The COMSOL Multiphysics software does not limit the results calculations to predefined quantities; you can plot and evaluate any function by entering the corresponding expression. You can combine numbers, parameters, mathematical constants, physical constants, variables, mathematical functions, unary operators, and binary operators. The **Expression** field or list is available for most plot types as well as for integration and data display and evaluation. You can enter any expression directly in the field or insert variables from a list of predefined quantities that you open by pressing Ctrl+Space or by clicking the **Insert Expression** ( ) button below the table.

You can also use Ctrl+Space to access predefined quantities in many text fields for preprocessing functionality such as definitions of parameters and variables, geometry and mesh features, and physics settings.

In the **Settings** window for many nodes under **Derived Values**, for example, you can enter and evaluate multiple expressions in the **Expressions** section:

- Click the **Replace Expression** ( ) button to select a predefined quantity from the tree of expressions that opens and then replace the contents of the current row in the **Expression** table with the corresponding variable. For postprocessing features where you input an array of expressions (for example, Global plots and most numerical evaluation features), choose **All expressions in this group** for groups with many related quantities such as vector and tensor components to add all quantities in the group to the table of expressions.
- Click the **Add Expression** ( ) button to add the corresponding variable to the next row in the **Expression** table. Otherwise, this option is similar to the **Replace Expression** option.
- The **Unit** for the expression appears automatically if you replace or add a predefined expression. You can click in the unit's text field and type a compatible unit for the quantity if there is no unit defined or if you want to change the unit. If you use an incompatible unit, it is ignored and replaced by the default unit.
- Click in the **Description** field in a row to enter a description (or edit the default) for the corresponding expression.

Use the **Move Up** ( ), **Move Down** ( ), **Delete** ( ) buttons and the fields under tables to edit the table contents. Or right-click a table cell and select **Move Up**, **Move Down**, or **Delete**. In addition, use the **Clear Table** button ( ) to clear the entire table and the **Insert Expression** button ( ) to insert an available model variable or expression into the current expression field at the cursor position.

In the **Expression** sections, in the **Settings** windows for plot nodes, for example, you can:

- Click the **Replace Expression** ( ) button to select a predefined quantity from the tree of expressions that opens and then replace the contents of the **Expression** field with the corresponding variable.

- Click the **Insert Expression** ( ) button to insert the corresponding variable at the current position in the **Expression** field (you can also use Ctrl+Space).
- Select a **Unit** from the list. You can select from a predefined number of applicable units for the quantity that the variable represents, but you can also click in the unit's text field and type any compatible unit for that quantity to use a unit that is not in the list (for example, `mi/h` for miles per hour as a unit for a velocity quantity).
- Select the **Description** checkbox to enter a description (or edit the default).

When applicable, use the **Plot Previous Expression** ( ) and **Plot Next Expression** ( ) buttons to step through all expressions available in the same group of expressions at the lowest level of expressions that you can choose from in the tree of expressions that opens when clicking the **Insert Expression** or **Replace Expression** button.

When there are parameters that can affect the plotted quantities, they are listed under **Parameters** with their name value, unit, and description. You can change the values of the parameters to plot quantities using a specific set of parameter values. Click the **Insert Expression** button ( ) at the bottom of the section or press Ctrl+Space to insert a predefined expression or variable into the selected cell in the **Value** column.

PREDEFINED QUANTITIES

The predefined quantities that you get access to by clicking one of the above buttons are divided into categories based on where in the model they belong:

- A **Built In** group with built-in functions and operators:
  - A list of available **Mathematical Functions** such as trigonometric functions.
  - A list of available **Operators**, divided into **Differentiation**; **Evaluation**; **Expressions**; **Integral, average, and sum**; **Linearization**, **Other**; and **Scoped evaluation**.
- A **Model** group with quantities and variables related to the model:
  - For **Component 1** (and any other components in the model), each physics interface has its own list of predefined quantities. In addition, there is a **Definitions** list with variables for coordinate systems and user-defined variables, a **Geometry** list with geometry variables local to the component such as normal and tangent components, and, if applicable, a **Global** list with global (scalar) quantities defined by the physics interfaces.
  - A **Geometry** list with geometry variables such as the spatial coordinates and the domain index.
  - A **Global Definitions** list with user-defined parameters and variables and a variable for the number of DOFs.
  - A **Mesh** list with mesh variables such as element size and element quality.
  - A **Solver** list with variables for the time, eigenvalue, and frequency (when applicable).

Double-click or press Enter to add the selected predefined quantity to the active text field.

Type a filter text in the text field at the top of the list of predefined expressions to filter the list to only include the quantities that match the filter text. Using a filter text can help you find a predefined quantity of interest without having to search through the full list of quantities. You can type the name of the predefined expression (for example, `atan2`) or the description (for example, `inverse tangent`) in the filter text for the **Insert Expression** and **Replace Expression** lists to search for a specific predefined expression. When you type Ctrl+Space in a text field, you can filter the list using the name of the predefined expression.

EVALUATION OF UNDEFINED QUANTITIES

During the evaluation of expressions, by default COMSOL Multiphysics does not report partially undefined quantities, and the program plots a quantity where it is defined. The plot is empty where the plotted data is

undefined or “not-a-number” (NaN). The plot is also empty where the plotted data quantity is infinity or negative infinity. If a results quantity is undefined everywhere, an error occurs for all plot types.

EVALUATION ON LOWER GEOMETRY DIMENSIONS

For variables defined on a higher geometry dimension such as domains, evaluating such variables on a lower dimension such as boundaries, the returned value is the mean value, if the values for the variable differ on the different sides of the boundary (such as the upside and downside of an interior boundary). Use the up and down operators to evaluate the variable on one side of the boundary.

ACCESSING OTHER SOLUTIONS THAN THE SELECTED SOLUTION

When you use the names of the dependent variables in a results expression, COMSOL Multiphysics uses the solution associated with the selected parameter value; eigenvalue; or time for a parametric analysis, eigenvalue analysis, or time-dependent analysis, respectively. To access other solutions in the model, use the `with` operator.

PROCESSING SOLUTIONS WITH A STORED LINEARIZATION POINT

If the solution being processed has a stored linearization point (such as for a harmonic perturbation or a small-signal analysis), several options are available for how to evaluate the expression in the **Expression evaluated for** list.

SPECIFYING A COORDINATE SYSTEM FOR VECTOR PLOTS

For vector plots based on some specific datasets, it is possible to choose a global Cartesian or a local cylindrical or cut-plane coordinate system to evaluate vectors in revolutions of axisymmetric models.

Vector Plots of Revolutions of 2D Axisymmetric Geometries

A **Coordinate system** list is available in the **Expression** section for plots that use a Revolution 1D or Revolution 2D dataset that has the default axis settings and points to a Solution, Mesh, Shell, or Layered Material dataset for an axisymmetric geometry. It is also available for plots using a Mirror dataset applied on a Revolution 2D dataset. From that list, choose **Global Cartesian** to enter a vector in the global Cartesian coordinate system or **Cylindrical** to enter a vector in a cylindrical coordinate system, which can be more convenient for a revolved (and possibly mirrored) axisymmetric geometry. The **Coordinate system** list is available for these plot types, when applicable:

- Arrow plots (**Arrow Volume**, **Arrow Surface**, and **Arrow Line**)
- **Deformation** subnodes
- Principal stress/strain plots (**Principal Stress Volume**, **Principal Stress Surface**, and **Principal Stress Line**)
- Scatter plots (**Scatter Volume** and **Scatter Surface**)
- **Streamline** plots

2D Vector Plots on Cut Planes

A **Coordinate system** list is available in the **Expression** section for 2D vector plots (**Arrow Surface** plots, for example) that use a **Cut Plane** dataset that points to a 3D Solution or Mesh dataset. From that list, you can choose **Cut Plane** to enter a 2D vector in the local cut-plane coordinates, or **Global Cartesian** to enter a 3D vector in the global Cartesian coordinate system.

Defining Plane Data for a Dataset

Select a **Plane type**: **Quick** (the default) to specify planes orthogonal to the coordinate axes or **General** to specify general planes. The **Plane type** consists of the sets of planes orthogonal to the coordinate axes applicable for the model geometry — for example, **xy-planes**, **yz-planes**, and **zx-planes** in 3D.

If **Quick** is selected:

- From the **Plane** list, select **xy-planes**, **yz-planes** (the default), **zx-planes**, **yx-planes**, **zy-planes**, or **zx-planes** as the set of planes orthogonal to the coordinate axes applicable for the model geometry. Specify the transverse coordinate by entering the location along the transverse coordinate axis.
- Enter the x-, y-, or z-coordinate in the field based on the **Plane** selection:
  - If **xy-planes** or **yx-planes** is selected, enter the **z-coordinate** (SI unit: m).
  - If **yz-planes** or **zy-planes** is selected, enter the **x-coordinate** (SI unit: m).
  - If **zx-planes** or **xz-planes** is selected, enter the **y-coordinate** (SI unit: m).

If **General** is selected:

- Select a **Plane entry method**: **Three points** or **Point and normal vector**. Enter **x**, **y**, and **z** coordinates.

  For the **Mirror 3D** dataset, select **Three points** to enter the mirror axis by specifying three points or **Point and normal** to specify the mirror axis by specifying one point and a normal vector:
  - If **Three points** is selected, enter **Point 1**, **Point 2**, and **Point 3** in the **x**-, **y**-, and **z**-coordinate fields (SI unit: m).
  - If **Point and normal vector** is selected, enter **Point** (SI unit: m) and **Normal vector** (dimensionless) data in the **x**-, **y**-, and **z**-coordinate fields.

For the **Cut Plane** dataset, select the **Additional parallel lines** checkbox to define multiple planes for plotting or evaluation, for example. Enter **Distances** from the original line in the field, or click the **Range** button ( ) to define a range of distances for additional cut planes. The **Distances** field refers to a direction that is normal to the cut plane.

Phase Settings in Plots

The **Phase** section is only available if at least one physics or multiphysics interface in the model includes a phase.

From the **Solution at angle (phase)** list, choose **From dataset** (the default, with the angle from the dataset added), **Custom per plot**, to specify the phase individually for each plot in the plot group, or **Manual**, to add a user-defined phase (in degrees) in the **Phase** field below, or use the slider underneath to specify a phase between 0 and 360 degrees.

Plot Array Settings for Plot Nodes

When you have enabled the plot array functionality by selecting the **Enable** checkbox in the **Plot Array** section in a 2D or 3D plot group node, you can control the behavior of each plot in the plot group using the settings in the **Plot Array** sections that appear. See Plot Array for the plot group settings for creating plot arrays.

By default, the **Belongs to array** checkbox is selected, so that all plots in the plot group are part of the plot array. Clear this checkbox to exclude that plot from the plot array. If desired, select the **Manual indexing** checkbox to rearrange the plots in the plot array. You can use the indexing to create "holes" (extra displacement) in the array, for example. For a linear array, enter the 0-based index in the **Index** field. For a square plot array, enter 0-based index values in the **Row index** and **Column index** fields. If you do not use a manual indexing, the plots in the plot array are ordered as the order of the plot nodes in the plot group.

The **Apply to dataset edges** checkbox is selected by default; clear that checkbox to exclude the dataset edges.

Plot Titles for Plot Groups and Plots

Every plot group and plot type have a **Title** section where the **Title type** is selected and set. The options are **Automatic** (the default), **Custom** (if available), **Manual**, **Label**, or **None**. An **Automatic** title is generated based on the type of plot or plots selected. Select **Label** to make the title display the plot group's label. Select **None** for no title. Select **Custom**

to add existing information combined with custom prefix and suffix text to the title as described below, or select **Manual** to enter free text in the field, including optional evaluation of variables, include the current date and time and the filename (see Manual Plot Titles below).

NUMBER FORMATS

For all title types (except **None**) in the plot groups' settings, you can choose the following formats from the **Number format** list:

- **Default**: Numerical values that come from the solvers are presented as-is. Numbers formatted during postprocessing use the **Output display precision** preference setting.
- **Automatic**: All numbers are formatted using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Engineering**: All numbers are formatted using engineering notation (such as `31.416E-6`; it is similar to scientific notation but with the powers of ten as multiples of three) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Scientific**: All numbers are formatted using scientific notation (such as `3.1416E-5`) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Stopwatch**: All numbers are formatted in decimal notation with a specified number of integer digits and decimals, which you enter in the **Number of integer digits** field (default: 3) and **Number of decimals** field (default: 2), respectively. Unnecessary zeros are always shown. For example, with the default settings, 17.1 would be formatted as `017.10`. The specified number of integer digits is not respected if the number is too large or if it is NaN or Inf. Select the **Always show the sign** checkbox to keep the width from changing for a sequence that includes both positive and negative values. Select the **Always show the imaginary part** checkbox to keep the width from changing for a sequence that includes both real numbers and numbers with a nonzero imaginary part.
- **Scientific stopwatch**: All numbers are formatted in scientific notation with one integer digit and a specified number of decimals and exponent digits. For example, with the default settings, 17.1 would be formatted as `1.71E1`. The settings are the same as for the **Stopwatch** format, with the addition of an **Always show the sign of the exponent** checkbox. Select it to keep the width from changing for a sequence that includes both positive and negative exponents.

CUSTOM PLOT TITLES

Solution

These settings are only available for the main plot groups. Under **Solution**, select the checkboxes as needed.

- Select **Dataset** to include details about the dataset used for the plot.
- Select **Phase** to include information about the phase (when applicable).
- Select **Solution** to include the details about the solution (the time step or parameter values, for example) for the plot (when applicable).
- Select **Filename** to include the name of the MPH-file for the model that the plot belongs to.
- Select **Date** to include the current date (using a format like **Nov 7, 2016**, for example).
- Select **Time** to include the current time (using a format like **4:47:48 PM**, for example).

The title includes dataset settings taken from a plot if there is exactly one dataset that is taken from a plot, and the plot group's dataset is not used anywhere. The plot group's dataset has precedence over the plots' datasets.

Type and Data

Under **Type and data**, select the checkboxes as needed.

- Select **Type** to include the plot type in the title.

- Select **Description** to include the variable details.
- Select **Expression** to include the variable expression in the title.
- Select **Unit** to include the variable unit.

User

Under **User**, enter text as needed:

- Enter text in the **Prefix** field to add free text at the front of any Solution title text string. For example, if all the **Dataset**, **Phase**, and **Solution** checkboxes are selected, this text is first.
- Enter text in the **Suffix** field to add free text at the end of any Solution title text string. For example, if all the **Dataset**, **Phase**, and **Solution** checkboxes are selected, this text is at the end of this information.

Layout

The **Use parameter indicator for solution and phase** checkbox is selected by default to display the solutions time, parameter value, or phase for the currently selected plot in the upper-left corner of the **Graphics** window.

MANUAL PLOT TITLES

For all manual plot titles, enter the plot title in the **Title** field. If the title is longer than the available width in the plot window, the title is automatically wrapped to another line. You can also use newline (carriage return) in the **Title** field to add new lines in the plot title. You can also use these two formatting modes for adding mathematical expressions to plot titles:

- Using LaTeX Display math mode. To do so, put `\[ \]` around the LaTeX mathematical expression in the **Title** field. This mode uses more vertical space for the math expression. For example, to plot the expression

$$u + \frac{\log x^2}{4\pi}$$

  add the following LaTeX text to the **Title** field: `\[u+\frac{\log x^2}{4 \pi}\]`
- Using LaTeX Inline math mode: To do so, put `\$ \$` around the LaTeX mathematical expression in the **Title** field. This mode is meant to be included in line in the text (in normal LaTeX) and has a more compact presentation. To use the same mathematical expression as in the other mode, add the following LaTeX text to the **Title** field: `\$u+\frac{\log x^2}{4 \pi}\$`

See also Mathematical Symbols and Special Characters for information about available LaTeX characters.

The LaTeX formatting modes are also available for color legend titles in plots.

In the **Title** section for plot groups, you can use these additional settings for including the date, the time, the filename, or values of scalar variables, for example:

The **Parameter indicator** field contains a parameter indicator, such as the time for the current plot of a time-dependent solution, which appears in the upper-left corner of the **Graphics** window. You can edit the indicator if desired.

You can evaluate and display values in the title and the parameter indicator. You can type, for example, `eval(t,min)` to evaluate the time t (in minutes). In addition to available scalar variables in the model, you can use the following variables to display date, time, filename, and so on:

TABLE 21-3: VARIABLES FOR PLOT TITLES.

VARIABLE NAME	DESCRIPTION
FILENAME	The filename as the last part of the file path,
PATH	The full file path,
DATE	The current date, in the format Dec 8, 2016.

TABLE 21-3: VARIABLES FOR PLOT TITLES.

VARIABLE NAME	DESCRIPTION
TIME	The current time, in the format 10:56:59 AM.
YEAR	The current year.
MONTH	The current month as a two-digit number.
DAY	The current day of the month as a two-digit number.
HOUR, HOUR24	The current hour as a two-digit number between 0 and 23.
HOUR12	The current hour as a two-digit number between 0 and 11.
AMPM	The AM/PM marker (AM or PM).
MINUTE	The current minute as a two-digit number.
SECOND	The current second as a two-digit number.

For example, use `eval(DATE)` to include the current date in the plot title or parameter indicator.

You can also use `printf`-style number format specifiers of the form `%[`*`flags`*`][`*`width`*`][.`*`precision`*`]`*`type` as the last argument using the syntax `eval(`*`expr`*`,`*`unit`*`,`*`precision`*`)`, where the unit is optional. Allowed types are {`d`, `f`, `e`, `E`, `g`, `G`}. Two examples are `eval(pi,,%05d)`, which appears as `00003`, showing the number as a rounded integer with the width of 5 and zero padding, and `eval(pi*1e10,,%+.3e)`, which appears as `+3.142e+10`, a number with scientific format with 3 decimal values and with the sign of the number shown.

Using Special Formats and Symbols in Titles

Using Special Formats and Symbols in Titles

SUPPORT FOR FORMATTING AND SYMBOLS IN TEXTS

For the titles as well as the *x*-axis, *y*-axis, and *z*-axis labels, you can use formatted strings that include HTML tags, Greek letters, and mathematical symbols. The tables in the following sections provide information about supported format and symbols. In addition to ASCII characters, Greek letters, and the mathematical symbols listed in Table 21-9 and the following tables, the COMSOL Multiphysics software correctly displays any Unicode-based character that you paste into a title or label field.

To display a backslash (\) in, for example, a title, use `\backslash`.

HTML TAGS

You can use the following HTML tags in text strings for plot labels and titles:

TABLE 21-4: VALID HTML TAGS.

HTML TAG	DESCRIPTION
`<b> </b>`	Enclosed text is rendered using a bold font.
`<i> </i>`	Enclosed text is rendered using an italic font.
`<sub> </sub>`	Enclosed text is rendered in subscript with the enclosed text slightly lower than the surrounding text.
`<sup> </sup>`	Enclosed text is rendered in superscript with the enclosed text slightly higher than the surrounding text.

TABLE 21-4: VALID HTML TAGS.

HTML TAG	DESCRIPTION
<tt> </tt>	Enclosed text is rendered using a monospaced font.
<u> </u>	Enclosed text is underlined.

GREEK CHARACTERS

The texts in labels and titles in all plots support the following Greek character tags:

TABLE 21-5: VALID GREEK SYMBOL COMMANDS.

COMMAND	SYMBOL	COMMAND	SYMBOL
\ALPHA	Α	\alpha	α
\BETA	Β	\beta	β
\GAMMA	Γ	\gamma	γ
\DELTA	Δ	\delta	δ
\EPSILON	Ε	\epsilon	ε
\ZETA	Ζ	\zeta	ζ
\ETA	Η	\eta	η
\THETA	Θ	\theta	θ
\IOTA	Ι	\iota	ι
\KAPPA	Κ	\kappa	κ
\LAMBDA	Λ	\lambda	λ
\MU	Μ	\mu	μ
\NU	Ν	\nu	ν
\XI	Ξ	\xi	ξ
\OMICRON	Ο	\omicron	ο
\PI	Π	\pi	π
\RHO	Ρ	\rho	ρ
\SIGMA	Σ	\sigma	σ
\TAU	Τ	\tau	τ
\UPSILON	Υ	\upsilon	υ
\PHI	Φ	\phi	φ
\CHI	Χ	\chi	χ
\PSI	Ψ	\psi	ψ
\OMEGA	Ω	\omega	ω

MATHEMATICAL SYMBOLS

For texts in titles and axis labels, you can use the following mathematical symbols:

TABLE 21-6: VALID MATHEMATICAL SYMBOL COMMANDS.

COMMAND	SYMBOL	COMMAND	SYMBOL
\approx	≈	\bullet	•
\sim	~	\partial	∂
\prop	∝	\nabla	∇
\neq	≠	\prod	∏
\equiv	≡	\sum	∑
\lequal	≤	\sqrt	√

TABLE 21-6: VALID MATHEMATICAL SYMBOL COMMANDS.

COMMAND	SYMBOL	COMMAND	SYMBOL
\gequal	≥	\integral	∫
\ll	>>	\oplus	⊕
\gg	<<	\otimes	⊗
\plusmin	±	\larrow	←
\infinity	∞	\rarrow	→
\deg	°	\lrarrow	↔
\cdot	·	\ldarrow	⇐
\times	×	\rdarrow	⇒

Arrow Positioning

For **Arrow Surface** in 3D plot groups and **Arrow Line** in 3D and 2D plot groups:

Under **Arrow Positioning**, first select a **Placement** of the arrows: **Gauss points**, **Mesh vertices**, **Uniform**, or **Uniform anisotropic**.

- Select **Gauss points** to position the arrows in the elements' Gauss points when a solution is available. Also specify the order of the Gauss points in the **Gauss-point order** field (default: 1). A higher order increases the arrow density in each element.
- Select **Mesh vertices** for arrows positioned in the mesh vertices (that is, more densely placed arrows where the mesh density is high).
- Select **Uniform** (the default) for arrows positioned uniformly on the surface. Then enter the number of arrows to plot in the **Number of arrows** field (default: 200).
- Select **Uniform anisotropic** to position the arrows using an anisotropic density (that is, more arrows in some directions than in others). In addition to entering the number of arrows to plot in the **Number of arrows** field (default: 200), use the **x weight**, **y weight**, and (in 3D) **z weight** fields to give weights for the arrow density in the different directions (using positive scalar weights). The default weights are 1 in all directions. A higher value increases the arrow density in the corresponding direction.

For **Arrow Volume** in 3D plot groups and **Arrow Surface** in 2D plot groups:

Under **Arrow Positioning**, first select a **Placement** of the arrows: **Element centers**, **Mesh vertices**, or **Grid** (the default):

- Choose **Element centers** to position the arrows in the element centers; if desired, change the value in the **Maximum number of points** field (default: 100,000).
- For **Mesh vertices**, see above.
- For **Grid**, in the **x grid points**, **y grid points**, and **z grid points** fields, select an **Entry method**: **Number of points** or **Coordinates**:
  - If **Number of points** is selected, enter the number of **Points** in each direction (the default is 7 for Arrow Volume plots and 15 for Arrow Surface plots).
  - If **Coordinates** is selected, enter **Coordinates** (SI unit: m) or click the **Range** button ( ) to define a range of values.

Entering Ranges and Vector-Valued Expressions

Principal Components and Positioning

These sections are available for the Principal Stress Volume, Principal Stress Surface, and Principal Stress Line plots:

PRINCIPAL COMPONENTS

Under **Principal Components**, select a **Type** — **Principal stress** or **Principal strain** — to visualize either the principal stresses (the default) or the principal strains as vectors.

From the **Data** list, choose one of the available principal stresses or strains (depending on the type selected above); for example, **Solid mechanics: Principal stresses**. The principal values and directions are then defined based on the selected data. If you choose **Manual**, you can enter the following values and direction components:

- Under **Principal values**, enter information in the **First**, **Second**, and **Third Value** fields. The default are the three principal stresses (`solid.sp1`, `solid.sp2`, and `solid.sp3`, for example, for a Solid Mechanics interface; the prefix is the Name of the physics interface node), plotted using red, green, and blue arrows, respectively.
- Under **Principal directions**, enter information in the table under **First**, **Second**, and **Third** for the **X**, **Y**, and **Z** coordinate fields. The defaults are the directions (eigenvectors) for the first, second, and third principal stress.

For transient problems, enter a **Time**.

POSITIONING

For **Principal Stress Surface** in 3D plot groups and **Principal Stress Line** in 3D and 2D plot groups:

Under **Positioning**, first select a **Placement**: **Gauss points**, **Mesh elements**, **Uniform**, or **Uniform anisotropic**.

- Select **Gauss points** to position the principal stress symbols in the elements' Gauss points when a solution is available. Also specify the order of the Gauss points in the **Gauss-point order** field (default: 1). A higher order increases the principal stress symbol density in each element.
- Select **Uniform** (the default) for principal stress symbols positioned uniformly on the surface. Then enter the number of symbols to plot in the **Number of points** field (default: 200).
- Select **Uniform anisotropic** to position the principal stress symbols using an anisotropic density (that is, more symbols in some directions than in others). In addition to entering the number of principal stress symbols to plot in the **Number of points** field (default: 200), use the **x weight**, **y weight**, and (in 3D) **z weight** fields to give weights for the symbol density in the different directions (using positive scalar weights). The default weights are 1 in all directions. A higher value increases the symbol density in the corresponding direction.

For **Principal Stress Volume** in 3D plot groups and **Principal Stress Surface** in 2D plot groups:

Under **Positioning**, first select a **Placement**: **Element centers**, **Mesh vertices**, or **Grid** (the default):

- Choose **Element centers** to position the principal stress symbols in the element centers; if desired, change the value in the **Maximum number of points** field (default: 100,000).
- For **Mesh vertices**, see above.

- For **Grid**, in the **X grid points**, **Y grid points**, and **Z grid points** fields, select an **Entry method**: **Number of points** or **Coordinates**:
  - If **Number of points** is selected, enter the number of **Points** in each direction (the default is 7 for Principal Stress Volume plots and 15 for Principal Stress Surface plots).
  - If **Coordinates** is selected, enter **Coordinates** (SI unit: m) or click the **Range** button ( ) to define a range of values.

In the settings above, **X**, **Y**, and **Z** appear by default as the coordinate names if the plot uses data defined using the material frame. If the data is defined using a spatial frame, for example, **x**, **y**, and **z** appear instead.

Defining the Number of Levels

For Contour plots, Directivity plots, Isosurface plots, Contour datasets, and Isosurface datasets, under **Levels** and from the **Entry method** list, select **Number of Levels** or **Levels**.

If **Number of Levels** is selected, enter the total number of levels in the **Total levels** field (the default is 20 for plots and 5 for datasets). The **Round the levels** checkbox is selected by default to round the values of the levels. Otherwise, enter the values of the contour **Levels** or click the **Range** button ( ) to define a specific range of levels.

Selecting Color Tables

For many plot types you can select the color table to use for coloring the surfaces, boundaries, contours, streamlines, slices, and so on. These color tables use 1024 colors each. The best way to compare the color tables is to experiment with the options. For an overview of the color tables and what they look like for some typical plots, see Overview of Color Tables and Their Usage.

The classic versions of some color tables correspond to that same color table in COMSOL Multiphysics versions earlier than version 6.0 (for example, **RainbowClassic** correspond to the **Rainbow** color table in versions before 6.0. The new versions of these color tables are typically less saturated, more uniform, more smooth, and more balanced.

THE COLOR TABLE LIST

When you click the downward-facing arrow to the right in the **Color table** list ( ), a list of color tables appears. In that list you can choose a color table for the plot. You can also see what the color tables look like by clicking a color table; the plot is updated immediately to show the plot using that color table. The color tables are divided into the following categories:

- **Rainbow** ( ): The various Rainbow, Prism, Dipole, Spectrum, and Cyclic color tables.
- **Thermal** ( ): The various Thermal. GrayBody, HeatCamera, Inferno, Magma, and Plasma color tables.
- **Wave** ( ): The various Wave and Disco color tables
- **Traffic** ( ): The various Traffic color tables.
- **Natural** ( ): A large selection of color tables inspired by nature.
- **Aurora** ( ): The various Aurora and Twilight color tables.
- **Linear** ( ): The GrayScale, GrayPrint, Cividis, and Viridis color tables.
- **Geoscience** ( ): The Gaia and GaiaLight color tables.

There is also a **Recently used** section ( ), which contains the most recently used color tables. An **In model** section ( ) is also available if any custom color tables have been added to the model (and then appear as Color Table nodes under **Color Tables**).

	All color tables in the **Linear** and **Natural** categories are linear, but there are linear color tables in other categories as well (for example, Inferno, Magma, and Plasma). The diverging color tables in the **Natural** category each have linear sides around the center point.

Use the **Collapse All** ( ) and **Expand All** ( ) buttons in the lower-left corner of the list of color tables to open or close all categories.

Click the **Import** button ( ) to choose a color table file from the file system. That color table is then added to the list under **In model** and is selected as the color table to use. A corresponding Color Table node is also added under **Color Tables**.

To filter (search) the list of color tables, type a filter text in the text field at the top of the list of color tables. For example, type `dark` in the filter text field to show all dark versions of the color tables. Use an empty filter text field to restore the full list.

Double-click or press Enter to close the list and use the selected color table in the plot. Click the **Reset** button ( ) or press Esc to reset the color table to the one used before opening the list of color tables and close the list.

The following sections provide detailed information about the available color tables.

AURORAAUSTRALIS, AURORAAUSTRALISDARK, AURORABOREALIS, JUPITERAURORABOREALIS, AND TWILIGHT

The **AuroraAustralis** ( ), **AuroraAustralisDark** ( ), **AuroraBorealis** ( ), and **JupiterAuroraBorealis** ( ) color tables resemble the colors in the aurora australis (southern light), aurora borealis (northern light), and Jupiter's aurora, respectively. The AuroraAustralis color table spans from white through green and indigo to blue. The AuroraAustralisDark color is similar to AuroraAustralis but does not start with absolute white so that the end value's color is different from a white background. The AuroraBorealis color table also spans from white through green and indigo to blue but with a larger indigo portion. The JupiterAuroraBorealis color table spans from black through blue to white.

The **Twilight** ( ) color table uses colors associated with twilight (the illumination of Earth's lower atmosphere when the Sun is not directly visible), spanning colors from pink through white to blue.

CIVIDIS

The **Cividis** ( ) color table uses yellow and blue colors in a color table that is suited for normal vision, a deuteranomaly, or red-green colorblindness. It was created by Jamie Nuñez, Ryan Renslow, and Chris Anderton at the Biological Sciences Division of the Pacific Northwest National Laboratory (located in Richland, Washington state, United States).

CYCLIC AND CYCLICCLASSIC

The **Cyclic** ( ) and **CyclicClassic** ( ) color tables are useful for displaying periodic data. Examples are the phase variation of a propagating wave or its polarization angle. Another typical use case for Cyclic is the visualization of seemingly random data having many discrete levels (domain numbers, terminal numbers, port numbers, and so on). For these cases, Cyclic is convenient because of the large number of colors it contains. The colors begin with red, then pass through yellow, green, cyan, blue, magenta, and finally return to red.

DIPOLE AND DIPOLE DARK

Dipole ( ) has been developed for plots where the majority of the solution is close to zero (or centered around some meaningful reference point) and where, in some places, positive and negative excitations occur. Typical cases are the electric potential distribution around positively and negatively charged objects with the field relaxing to zero at infinity and the pressure distribution of an acoustic wave propagating in a large open space. For those cases, the scale tends to white in areas of relative inactivity, allowing for a good contrast with titles, legends, dataset edges, and other plot elements. This reasoning is similar to the one used for the Prism color table. The main difference is that Dipole is symmetric (or "diverging"), making it suitable for positive and negative scalar fields, whereas Prism is more suitable for vector field norms (which are positive only).

DipoleDark ( ) is similar but uses slightly darker colors.

You can use a combination of Dipole color tables to visualize streamlines, contour lines, and arrows using DipoleDark on top of a surface plot using Dipole.

If zero is an important reference point, but the minimum and maximum values do not have the same magnitude, consider combining the color scale with the **Scale** setting **Linear symmetric**. If you would like to use more colors for a small range around zero and less colors for the extremes, consider using the **Color table transformation** setting **Nonlinear symmetric**.

DISCO, DISCOCLASSIC, DISCODARK, AND DISCOLIGHT

The **Disco** ( ) and **DiscoClassic** ( ) color tables span from red through magenta and cyan to blue. Like Rainbow, Disco has not been optimized for a particular use case. Unlike Rainbow, however, it has a strongly nonsymmetric luminance curve. This makes it less suitable as a general-purpose tool. Disco is typically not the first choice, but when an illustration already contains variants of Rainbow — or when Rainbow needs to be avoided for other reasons — Disco may provide an attractive alternative. **DiscoDark** ( ) and **DiscoLight** ( ) are similar but use darker and lighter colors, respectively.

You can use a combination of Disco color tables to visualize streamlines or contour lines using DiscoLight on top of a surface plot using Disco. The same way, DiscoDark can be used to draw on top of Disco.

GAIA AND GAIALIGHT

The **Gaia** ( ) color table spans colors that make it suitable for plots related to topography and bathymetry. At its center the color table has a zero point, representing sea level. The bottom half is intended for depth measurements (below sea level), and the top half represents height measurements (above sea level). The colors resemble water, snow, and different kinds of soil or vegetation, for different levels of elevation. As a result, an elevation plot using this color table will start to look like a landscape. In order to allow for a higher level of detail close to sea level, the colors in the color table have been pushed to the center using a logarithmic map. The colors have been calibrated for central Europe, with the data ranging from –4 km depth to +4 km height. **GaiaLight** ( ) is similar but uses lighter colors.

You can use a combination of Gaia color tables to visualize streamlines or contour lines using GaiaLight on top of a surface plot using Gaia.

Oftentimes in topography and bathymetry applications, the actual data is presented using a Rainbow color table or similar, while the "landscape color table" is used to provide a certain context (or is added just for aesthetic reasons).

GRAYBODY AND GRAYBODYLIGHT

The **GrayBody** ( ) color table is based on the Planckian locus for blackbody radiation. It is useful within the context of metal processing, for example. **GrayBodyLight** ( ) is similar but uses lighter colors.

You can use a combination of GrayBody color tables to visualize streamlines or contour lines using GrayBodyLight on top of a surface plot using GrayBody.

GRAYSCALE AND GRAYPRINT

The **GrayScale** ( ) color table uses the linear gray scale from black to white — the easiest palette to interpret and order.

The **GrayPrint** ( ) color table varies linearly from dark gray (RGB: 0.95, 0.95, 0.95) to light gray (RGB: 0.05, 0.05, 0.05). Choose this color table to overcome two difficulties that the GrayScale color table has when used for printing on paper — it gives the impression of being dominated by dark colors, and white is indistinguishable from the background.

Gray scale plots are often easier to use for publication. People can also better perceive structural detail in a gray scale than with color.

HEATCAMERA AND HEATCAMERALIGHT

The **HeatCamera** ( ) and **HeatCameraLight** ( ) color tables resemble the typical scale used for thermography applications. Here, the lighter colors red, orange, and yellow correspond to higher temperatures (and more radiated heat). The purples and the blues refer to cooler temperatures and less radiation. HeatCamera is used as the default color table for plots involving one of the heat transfer physics interfaces. For a smoother and more perceptually uniform option, consider Inferno, Magma, or Plasma.

INFERNO, MAGMA, AND PLASMA

The **Inferno** ( ), **Magma** ( ), and **Plasma** ( ) color tables use a general bluish to reddish to yellowish color sequence, which is relatively friendly to common forms of color vision deficiencies. They are designed so that they are analytically perceptually uniform, both in regular form and when converted to black-and-white images. They were created by Stéfan van der Walt and Nathaniel Smith.

NATURAL

The color tables in this category are accurate in representing the underlying data because they have resolution along the entire range and do not introduce visual artifacts. They can thus be referred to as perceptually uniform. They are also intuitive to read because they vary from light to dark, representing data going from low to high values.

Having full resolution is important if you want to study variations along the entire data range. For example, this can facilitate the process of debugging a model because it can illustrate where potential singularities exist and thus inform about locations where mesh adjustments are needed. The resolution was tested with the test described here: https://colorcet.com/testimage/index.html.

Among the sequential tables in this category, there are those with few, similar hues, and those with several, different hues. A color table with few hues look less “banded”. Such tables can be helpful when studying subtle changes in local trends, because the global trends, enhanced by having several hues, are relatively weak. The color tables in the Natural category with few hues are: **Bryophyta** ( ), **Prionace** ( ), **Kyanite** ( ), **Amethyst** ( ), and **Garnet** ( ).

The ability to discern global trends in the data is enhanced by introducing several, less similar, hues. Color tables in the Natural category with several hues are: **Agama** ( ), **Algae** ( ), **Lichen** ( ), **Cynanthus** ( ), **Lagoon** ( ), **Pelagic** ( ), **Passiflora** ( ), **Acanthaster** ( ), **Baptisia** ( ), **Cerinthe** ( ),

Arctium ( ), **Iodinea** ( ), **Caissara** ( ), **Amber** ( ), **Metasepia** ( ), and **MetasepiaBlue** ().

A strategy worth trying when analyzing the results from a model is to visualize the same data with two different types of color tables: one single-hue table for improved local resolution and one with several different hues to discern global trends.

Some of the color tables end in white. They are useful when the lowest value, or the highest value if reversing the table, in the dataset is zero. These color tables are the following: **Lichen** ( ), **Lagoon** ( ), **Pelagic** ( ), **Kyanite** ( ), **Passiflora** ( ), **Acanthaster** ( ), **Cerinthe** ( ), **Amethyst** ( ), **Garnet** ( ), **Iodinea** ( ), **Caissara** ( ), and **Amber** ( ).

For datasets excluding zero, color tables without white could be more intuitive. For such cases, use one of these tables: **Agama**, ( ) **Algae** ( ), **Bryophyta** ( ), **Cynanthus** ( ), **Prionace** ( ), **Baptisia** ( ), **Arctium** ( ), **Metasepia** ( ), and **MetasepiaBlue** ( ).

When the data includes a reference value (for example, the sea level or the freezing point of water), and you want to clearly distinguish between data below and above this reference, use one of the diverging color tables. The color tables with dark center could be more intuitive than those with white, for nonzero reference points. All the diverging color tables have linear sides. The diverging color tables are the following: **Avicularia** ( ), **Stomatopoda** ( ), **Tectocoris** ( ), **Ranitomeya** ( ), **Ctenophora** ( ), **Crocus** ( ), **Darner** ( ), and **Melithaea** ( ).

A potential drawback with the color tables in this category (the Natural category) is their dark ends, making the maximum values less pronounced. The **Acanthaster** ( ) color table was developed for the purpose of highlighting the maximum value.

The number of tables developed of each type (sequential, diverging, single hue, multiple hues) makes them useful when comparing data of the same type but for different cases. For example, they could be used in array plots when comparing concentrations of different species in mass transfer interfaces or for different load cases in structural mechanics.

PRISM AND PRISMDARK

Prism ( ) is slightly similar to the **Rainbow** color table but includes a white tip and is brighter. It has been developed for plots where the majority of the solution is close to zero (typically at the outer perimeter of the modeling domain) and where, in some places, singularities or "hot spots" occur. This is especially true for electric and magnetic field norms in electromagnetic models, but may also occur for stress and strain norms in structural mechanics models, for example. For those cases, the scale tends to white in areas of relative inactivity, allowing for a good contrast with titles, legends, dataset edges, and other plot elements. This is the default color table for plots when using one of the structural mechanics physics interfaces. It is also used as the default option for plotting electric and magnetic field norms in the low-frequency electromagnetics interfaces.

PrismDark ( ) is similar but uses slightly darker colors. It can be used, in combination with Prism, to add arrows or streamlines on top of a plane, for instance. Close to the hot spots the contrast between the two color scales increases, and in the wake regions the contrast will fade.

You can use a combination of Prism color tables to visualize streamlines, contour lines, and arrows using PrismDark on top of a surface plot using Prism.

The hot spots typically use the top half of the scale. How much of the color scale that is used by the hot spots can be further fine-tuned using the **Color table transformation** options.

RAINBOW, RAINBOWCLASSIC, RAINBOWDARK, AND RAINBOWLIGHT

Rainbow ( ) is the default for most plots that support color tables. The colors range through shades of blue, cyan, green, yellow, and red. This color table is not optimized for a particular use case (nor is it perceptually uniform), but it is not really bad for most use cases either. Consequently, it serves very well as a general-purpose tool for quick result assessment. The disadvantage of this color table is that people with color vision deficiencies (affecting up to 10% of technical audiences) cannot see distinctions between reds and greens.

RainbowClassic ( ) is the rainbow color table used in versions of COMSOL Multiphysics earlier than version 6.0. Compared to RainbowClassic, the current Rainbow color table is less saturated, more uniform, more smooth, and more balanced.

RainbowDark ( ), **RainbowLight** ( ), and **RainbowLightClassic** ( ) are similar to Rainbow but use darker and lighter colors, respectively.

You can use a combination of Rainbow color tables to visualize streamlines or contour lines using RainbowLight on top of a surface plot using Rainbow. The same way, RainbowDark can be used to draw on top of Rainbow.

SPECTRUM, SPECTRUMCLASSIC, AND SPECTRUMLIGHT

Spectrum ( ) and **SpectrumClassic** ( ) are similar to the **Rainbow** color tables but include violet at the short-wavelength end of the visible spectrum. They also include richer shades of green and less yellow and cyan to more closely replicate the human perception of visible light. The saturation and hue distribution have been derived from the chromatic response of the CIE 1931 Standard Observer. The included wavelengths range from 415 nm to 660 nm. **SpectrumLight** ( ) is similar but uses lighter colors. You can use them with the Ray Optics Module, for example, to accurately visualize polychromatic light.

You can use a combination of Spectrum color tables to visualize streamlines or contour lines using SpectrumLight on top of a surface plot using Spectrum.

THERMAL, THERMALCLASSIC, THERMALDARK, THERMALLIGHT, THERMALLIGHTCLASSIC, THERMALWAVE, AND THERMALWAVEDARK

Thermal ( ) and **ThermalLightClassic** ( ) more or less resemble the radiation pattern of a glowing piece of metal, where lighter colors refer to higher temperatures. These color tables are not optimized for a particular use case, but they are not really bad for most use cases either: Like Rainbow, the serve very well as general-purpose tools. However, for a more accurate approximation of a radiating graybody, consider one of the GrayBody color tables instead.

ThermalLight ( ) is similar but use lighter colors. **ThermalDark** ( ) and **ThermalClassic** ( ) are similar but use darker colors.

You can use a combination of Thermal color tables to visualize streamlines or contour lines using ThermalLight on top of a surface plot using Thermal. The same way, ThermalDark can be used to draw on top of Thermal.

ThermalWave ( ) is designed for wave phenomena of a thermal nature. It is used in one of the default plots for the thermoviscous acoustics and linearized Navier–Stokes physics. The colors relate to orange and blue flames, and the luminance distribution is calibrated to be fully symmetric.

ThermalWaveDark ( ) is similar to ThermalWave but with darker colors, in particular in the center. The advantage is a stronger contrast and a more vibrant plot, and the disadvantage is that the darker colors do not contrast well with titles, legends, and dataset edges.

You can use a combination of ThermalWave color tables to visualize streamlines, contour lines, and arrows using ThermalWaveDark on top of a surface plot using ThermalWave.

TRAFFIC, TRAFFICCLASSIC, TRAFFICFLOW, TRAFFICLIGHT, AND TRAFFICLIGHTCLASSIC

The **Traffic** ( ) and **TrafficClassic** ( ) color tables span from green through yellow to red. **TrafficLight** ( ) and **TrafficLightClassic** ( ) are similar but use lighter colors. The **TrafficFlow** ( ) color table is specifically designed for visualizing mesh quality. The green half has a very soft gradient: All good mesh elements have about the same color when using a reversed TrafficFlow color table. This makes it much easier to focus on the mesh elements with a low quality.

You can use a combination of Traffic color tables to visualize streamlines or contour lines using TrafficLight on top of a surface plot using Traffic.

VIRIDIS

The **Viridis** ( ) color table uses a general bluish to greenish to yellowish color sequence, which is relatively friendly to common forms of color vision deficiencies. It is designed so that it is analytically perceptually uniform, both in regular form and when converted to a black-and-white image. It was created by Stéfan van der Walt and Nathaniel Smith.

WAVE, WAVECLASSIC, WAVELIGHT, WAVELIGHTCLASSIC

The **Wave** ( ) and **WaveClassic** ( ) color tables are useful for data that naturally has positive and negative attributes in addition to a magnitude. Like ThermalWave, Wave has two clearly distinct hues on both sides of the center to indicate “negative” (blue) and “positive” (red) values, and it has a symmetric luminance distribution. The Wave color table has been deliberately designed to be strongly nonlinear to support acoustic wave patterns with hotspots (singularities) and radiating point sources while also clearly resolving the far field. This color table is used as a default for many acoustics applications. Oftentimes, it is used together with the **Linear symmetric** setting in the **Scale** list for the color table scaling.

People with color vision deficiencies can interpret the Wave color table because it does not use red-green-gray distinctions, making it efficient for 99.98% of the population.

WaveLight ( ) and **WaveLightClassic** ( ) are similar but use lighter colors.

You can use a combination of Wave color tables to visualize streamlines or contour lines using WaveLight on top of a surface plot using Wave.

OVERVIEW OF COLOR TABLES AND THEIR USAGE

The following collages show related color tables used in the following cases:

- Smooth gradients — a general-purpose plot, showing an undistorted color table.
- Singularities — the majority of the solution uses the bottom half of the table, which represents a common plot in electromagnetics and structural mechanics models.
- Wake regions — the majority of the solution uses the top half of the table, which represents a common plot in CFD models.
- Propagating waves — the majority of the solution uses the center half of the table, which represents a common plot in acoustics, RF, and wave optics models.
- Mesh plot — a discontinuous plot, with a focus on the top half, which represents a common plot when finding mesh elements with a low quality.

The superscript 1 denotes color tables with the suffix Classic, which are copies of those used in COMSOL Multiphysics 5.6 and earlier versions.

When there are dark or light versions of a color table, you can use them to get nicely contrasting arrows, contours, or streamlines onto a surface plot that is using the basic version of that color table.

Color Tables and Color Themes in the *COMSOL Multiphysics Programming Reference Manual*.

Custom Color Tables

You can add custom color tables, stored as text fields with RGB data, to the Model Builder in the following ways:

- Click the **Import** button ( ) in the **Color Table** window and choose a color table text file from the file system (see The Color Table List).
- Add a **Color Table** node ( ) under **Color Tables** ( ), and then browse to a color table file on the file system or in a Model Manager database. See Color Table below.

If there are no custom color tables, select the **Color Tables** checkbox under **Results** in the **Show More Options** window to display the **Color Tables** node.

You can also add your own continuous color tables and discrete color tables that you store in the `data/colortables/` folder in the directory where COMSOL Multiphysics is installed or in the user settings directory `.comsol/v6.3` under your local home directory.

Color Table

You can add **Color Table** nodes ( ) under **Results** > **Color Tables** to define custom tables that you can access in the **Color Table** window (see The Color Table List). **Color Table** nodes are also added automatically when you import custom color tables using the **Color Table** window.

DEFINITION

From the **Data source** list, choose **Local table** (the default) or **File** as the source of the color table data:

- For a local table, you can edit the RGB values (0–1) in the **Red**, **Green**, and **Blue** columns. Use the buttons underneath the table to move, insert, or delete individual rows with RGB data, clear the entire table, or load or save the color table data from or to a file. The **Length** column is optional. In that column, you can add lengths as nonnegative scalar numbers to decide the relative length of each color segment in the color table. For continuous color tables, the last length is not used. If the **Length** column is left empty, all colors in the table get an equal length.
- For a color table from a file, enter the path and filename in the **Filename** field, or click **Browse** ( ) to browse to the file using the **Coordinate File** window that opens. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window to choose a file from a database, for example. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

From the **Type** list, choose **Continuous** (the default) or **Discrete** to interpret the color data as a continuous or discrete color table, respectively.

PREVIEW

This section contains a preview of the added color table.

Defining the Color and Data Ranges

Under **Range**, select the **Manual color range** and **Manual data range** checkboxes to manually override the color range and data range, respectively, with values in the **Minimum** and **Maximum** field, or use the sliders to control values that defined the range of the color legend and the data itself.

Defining the Coloring and Style

Depending on the plot type and space dimension, the following options are available and defined under **Coloring and Style**. The items are listed in alphabetical order.

ARROW BASE

Select **Tail** (the default) to position the arrow's tail at the arrow position, **Head** to position the arrow's head at the arrow position, or **Center** to position the center of the arrow at the arrow position.

ARROW LENGTH

Select an **Arrow length**:

- **Proportional** (the default), so that the length of the arrows is proportional to the magnitude of the quantity they represent.
- **Normalized**, so that all arrows have the same length.
- **Logarithmic**, so that the length of the arrows is proportional to the natural logarithm of the magnitude of the quantity they represent. This makes arrows representing small values relatively larger. The value in the **Range quotient** field (default: 100) determines the ratio between the smallest and largest values in the range of values for the logarithmic arrow length.

Number of Arrows

When **Uniform** or **Uniform anisotropic** is selected as the **Placement**, also specify the **Number of arrows** (default: 200).

ARROW SCALE FACTOR

Select the **Scale factor** checkbox to enter a scalar number to scale the arrows or use the slider to select.

ARROW TYPE

Select an **Arrow type**: **Arrow**, **Arrowhead**, or **Cone**. Also, for Arrow Volume, Arrow Surface, Arrow Line, Arrow Point, Point Trajectories, and Ray Trajectories plots, select **Double arrow** for a double arrow with two arrowheads, which can represent a moment or torque, for example. Arrowheads are not available for Principal Stress and Coordinate System plots. When selecting the **Ellipse** point style type in Point Trajectories and Ray Trajectories plots, you can select **None** from the **Arrow type** list to not display any arrows.

COLOR

Surface and Contour Plots

For surface and contour plots, for example, from the **Coloring** list select to use a **Color table** (see Coloring) or select **Uniform** to use a single color from the **Color** list. You can also select **Custom** to define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette.

Arrow Plots

For arrows, and unless a **Color Expression** subnode determines the arrow colors, select an arrow **Color** or select **Custom** to define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette.

Graph Plots — Colors and Color Cycles

For lines in graph plots, select a **Color**: **Custom**, **Cycle**, **Cycle (reset)**, **From theme**, **Black**, **Blue**, **Cyan**, **Gray**, **Green**, **Magenta**, **Red**, **White**, or **Yellow**.

If you select **Custom**, define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette. Choose or enter a line **Width** as a positive integer, or use the slider to select. By default, the line width is set a the **Default from preferences**, with the width from the preference setting shown in parentheses (default: 1). You specify the default line width as a positive integer on the **Graph Plots** page under **Results** > **Plots** in the **Preferences** window.

If you select **Cycle**, it cycles through all the colors; if you have more than one line plot in a plot group and want to cycle through the same set of colors, select **Cycle (reset)**. Also, choose **Default** (7 colors) or **Long** (19 colors) from the **Color cycle** list. Choosing **Long** can be useful if you plot many curves in a graph plot. The colors are defined in a text file, `Default.txt`. For information about the file format, see Color Tables and Color Themes in the *COMSOL Multiphysics Programming Reference Manual*.

If you select **From theme**, the line and maker color is taken from the selected color theme.

For **Error Bars** and **Graph Marker** subnodes, you can choose **From theme** to use the color from the color theme or **Custom** to define a custom color, or choose any of the predefined colors.

The Color Palette

In the color palette that opens, you can choose from a number of basic colors, or click **Define custom colors** to open a section where you can specify a specific color using sliders to define the R (red), G (green), and B (blue) components. You can also click one of the RGB values to enter a specific value (0–255). Additionally, it is possible to change the hue using the vertical color slider. To change the intensity and saturation, move the cursor in the larger area to the left of the color slider: move it up or down to add tint (more white) or shade (more black), respectively; move it to the left or right to add less or more saturation, respectively. Click **Add to custom colors** to add the new color to the set of available custom colors. The color palette in the cross-platform version of the COMSOL Desktop looks slightly different but provides similar functionality.

COLOR LEGEND

The **Color legend** checkbox is selected by default. Click to clear the checkbox if required. The legend position is determined by the settings in the **Color Legend** section in the Settings window for the parent Plot Group node.

You can adjust the default precision settings if required. Open The Preferences Window and open the **Graphics** > **Display Format** page. Under **Display Format (Maximum Number of Digits)**, in the **Color legend** field, enter an integer between 1 and 15 for the number of digits for the values displayed on the color legend. The default setting is 5 digits.

COLOR LEGEND TITLE

The **Color legend title** field in available if you have selected the **Show titles** checkbox in the **Color Legend** section of the settings for the parent **Plot Group** node. You can then add a title for the color legend, including LaTeX characters. See Manual Plot Titles for more information about LaTeX in titles. See also Mathematical Symbols and Special Characters for information about available LaTeX characters.

COLOR TABLE TRANSFORMATION

Choose one of the following options from the **Color table transformation** list:

- **None** (the default)
- **Reverse**, to reverse the color table
- **Nonlinear**
- **Nonlinear symmetric**

With the **Nonlinear** and **Nonlinear symmetric** settings you can select the **Reverse color table** checkbox if desired. You can also transform the color table to make it nonlinear. There is a parameter that controls how much the color table is transformed. Use the **Color calibration parameter** field or the associated slider to define a parameter value between –1.5 and 1.5. The **Nonlinear symmetric** setting is mainly useful when **Scale** is **Linear symmetric** and a symmetric color table such as Dipole or Wave is used. The reversal of the color table is applied before the nonlinear transformation, if used.

Color table transformations are mainly useful for rather moderate transformations of color tables. To deal with singularities or highly nonlinear expressions there are other approaches available:

- Specify a manual color range in the **Range** section.
- Use a logarithmic color scale (see Scaling).

COLOR TABLE TYPE

For **Surface** plots, choose **Continuous** (the default) or **Discrete** from the **Color table type** list. If you chose **Discrete**, specify the number of discrete color bands in the **Number of bands** field (default: 10).

COLORING

Select a **Coloring**: **Color table** (default), **Uniform**, or **Gradient**.

If **Color table** is selected, and if the default color table (**Rainbow** in most plots) is not suitable for the plot, try other options. See Selecting Color Tables for details.

If **Uniform** is selected, select a **Color** or **Custom** to choose a different color. For Line plots in 2D and 3D, you can also choose **From theme** to use the line color from the chosen color theme.

If **Gradient** is selected, define the coloring as a gradient between two colors, which you specify from the **Top color** and **Bottom color** lists.

Reverse Color Table

Select the **Reverse color table** checkbox to reverse the order of the colors in the color table (if **Coloring** is set to **Color table**).

Reverse Color Gradient

Select the **Reverse color gradient** checkbox to reverse the order of the colors in the color gradient (if **Coloring** is set to **Gradient**).

Selecting Color Tables

ELLIPSE AXIS EXPRESSIONS

Define the semi-major and semi-minor axes of the ellipse using vector expressions. For the **Semi-major axis expression** and **Semi-minor axis expression**, click the **Replace Expression** button ( ) to select a predefined expression

to replace the current expression, or press Ctrl+Space to insert a predefined expression (dimensionless). The expressions available are based on the physics interfaces used in the model. If the Geometrical Optics interface is used to compute ray intensity, the default expressions (typically `gop.pax`, `gop.pay`, and `gop.paz` for the semi-major axis and `gop.pbx`, `gop.pby`, and `gop.pbz` for the semi-minor axis) represent the shape and orientation of the polarization ellipse.

ELLIPSE ENTRY METHOD

Define the entry method for an ellipse as the point type from the **Ellipse entry method**: Choose **Number of ellipses** to enter a **Maximum number of ellipses**, or choose **Collection of times** to enter a number times in the **Times** field.

ELLIPSE SCALE FACTOR

Select the **Ellipse scale factor** checkbox to enter a scalar or use the slider to select.

FUNCTION TYPE

Available for Point Graph and Global 1D plots, you can choose **Continuous** (the default) or **Discrete** from the **Function type** list. Choose **Discrete** to plot global and point graphs as discrete values.

FIXED SIZE

Select the **Fixed size** checkbox to make the sphere radii have constant radius when zooming a plot using one of the following particle-style plot types that plot spheres in 2D and 3D: Particle Trajectories, Ray Trajectories, and Point Trajectories; Particle Tracing and Particle Tracing with Mass; Poincaré Map; and Phase Portrait.

FUNCTION

In a Table Surface plot, choose **Continuous** (the default) to consider the (x, y, data) triplets as samples of a function data = $f(x,y)$, where $f(x,y)$ is continuous, or choose **Discrete** to treat the samples as discrete and draw them as large pixels.

GRID

Select a **Grid**: **None** (the default), **Fine**, **Normal**, or **Coarse**. If **Fine**, **Normal**, or **Coarse** is selected, also choose a **Color** for the grid.

For the **Matrix Histogram** plot (available with the Fatigue Module), you can select the **Grid** checkbox to add a grid to the matrix histogram. Choose a color (default: gray) for the grid from the **Color** list.

INTERPOLATION AND NUMBER OF INTERPOLATED TIMES

Particle trajectories can appear jagged because the output times for the simulation are too few to result in a smooth plot. You can improve the particle trajectories by using a uniform interpolation of the data for the particle trajectories. From the **Interpolation** list, select **None** for no interpolation (the default), or select **Uniform** to use a uniform interpolation of the data using additional interpolated times defined in the **Number of interpolated times** field. The default is 100 interpolated times.

Interpolation of lines is only available for Particle Trajectories plots, which are available for use with Particle datasets created with the Particle Tracing Module.

LEGEND TYPE

For contour, isosurface, and directivity plots, the **Legend type** list is available. You can choose **Automatic** (the default for contour and directivity plots; not available for isosurfaces), **Filled** for a filled (joined) legend, or **Line** (the default

for isosurface plots), for a legend with separated lines for the levels. The **Automatic** setting provides a filled legend for filled contours and a line legend for line and tube contours.

	For isosurface plots using interactive levels, only legends with lines are applicable, and the **Legend type** is then not available.

LINE MARKERS OR MARKER TYPE

Select a **Marker** type: **None**, **Cycle**, **Cycle (reset)**, **Asterisk**, **Circle**, **Diamond**, **Plus sign**, **Point**, **Square**, **Star**, or **Triangle**.

If a marker is selected (excluding **None**), then from the **Positioning** list, select **Interpolated** (the default) or **In data points** or (for Line Graph, Radiation Pattern, and Through Thickness plots) **In evaluation points**. For **Interpolated**, enter the **Number** of markers to display (the default is 8; the maximum is 10,000 markers) or use the slider to select. If **In data points** is selected, the markers appear in the data points for the plot (which for a plot of a 1D solution are the mesh nodes).

	The line markers are only available for Histogram plots using a continuous function.

	If a graph plot contains isolated points, they appear as markers if the **Position** is set to **In data points** or **In evaluation points**; otherwise, isolated points are not visible when using markers.

LINE STYLE

The line styles available depend on the type of plot and the space dimension and include these options:

- From the **Line** list (for line graphs and point graphs, for example): **Cycle**, **Cycle (reset)**, **Solid**, **Dotted**, **Dashed**, or **Dash-dot**. If you select **Cycle**, it cycles through all the colors; if you have more than one line plot in a plot group and want to cycle through the same set of colors, select **Cycle (reset)**.
- From the **Line type** or **Type** list (for line, streamline, and particle trajectory plots, for example): **Line**, **Tube**, or **None** (**None** is not available for Line plots). For 3D Streamline, Particle Trajectories, Point Trajectories, and Ray Trajectories plots, **Ribbon** is also available. Ribbons are an alternative to tubes for visualization of, for example, the vorticity of a flow field.
  - If **Tube** is selected, enter a **Tube radius expression** (the radius of the tube); click the **Replace Expression** button ( ) to select a predefined expression to replace the current expression, or press Ctrl+Space to insert a predefined expression (SI unit: m). The default is 1 m.
  - If **Ribbon** is selected for streamlines, enter a width for the ribbons in the **Width expression** field; click the **Replace Expression** button ( ) to select a predefined expression to replace the current expression, or press Ctrl+Space to insert a predefined expression (SI unit: m). The default is 1 m. Select the **Width scale factor** checkbox to enter a user-defined scaling of the ribbons' width in the associated field. By default, the program scales the width automatically.
  - If **Ribbon** is selected for particle trajectories, specify a direction for the ribbons: At **Ribbon direction**, click the **Replace Expression** button ( ) to select a predefined expression to replace the current expression, or press Ctrl+Space to insert a predefined expression (SI unit: m). You can also edit the expressions in the **Direction, x-component**; **Direction, y-component**; and **Direction, z-component** fields. Select the **Width scale factor** checkbox to enter a user-defined scaling of the ribbons' width in the associated field. By default, the program scales the width automatically.

- In Particle Trajectories plots, you can also choose an interpolation from the **Interpolation** list: **None** (the default) or **Uniform**. For the uniform interpolation, specify the **Number of interpolated times** (default value: 100).
- For line plots where you specify the line width, enter a line **Width** or use the slider to select. The default, however, is **Default from preferences**, which takes the value, which is displayed in parentheses, from the **Line width** field in the **Preferences** window, under **Results** > **Plots** > **Graph Plots**. If a line plot (graph plot) contains isolated data points (for example, in a logarithmic plot where parts of the data cannot be plotted), those data points follow the line width down to a minimum size for the points. Such isolated data points are replaced with line markers, if markers are used and plotted in the data points.

PLOT ALONG LINES WHEN ANIMATING

If the plan is to create an **Animation** report, select the **Plot along lines when animating** checkbox. This is useful for Particle Trajectories, Particle Tracing, Particle Tracing with Mass, and Point Trajectories plots.

POINT MOTION

Select a **Point motion** to specify what should happen **When particles leaves domain**: **Stick to boundary** (to plot the points on the boundary at the exit point) or **Disappear** (to not render these points at all).

For static fields, specify the **End time** in the **Advanced** section. It is possible that all particles have left the domain at the selected time. In that case, all points appear at the outflow boundary if **Stick to boundary** is selected, and no points appear if **Disappear** is selected. To make the points appear, specify an earlier end time.

POINT RADIUS

Enter a **Point radius expression**; click the **Replace Expression** button ( ) to select a predefined expression to replace the current expression, or press Ctrl+Space to insert a predefined expression (SI unit: m). The default is 1 mm.

POINT STYLE

Under **Point style**, select a **Type**: **Point**, **None**, **Comet tail**, **Arrow**, or **Ellipse**. If **Point** or **Comet tail** is selected, enter a Point Radius and Radius Scale Factor.

Comet tail and **Arrow** are available with the **Particle Tracing**, **Particle Tracing with Mass**, **Particle Trajectories**, **Point Trajectories**, and **Ray Trajectories** plots. All of them except **Point Trajectories** and **Ray Trajectories** require a license for the Particle Tracing Module. See Particle Tracing, Particle Tracing with Mass, Particle Trajectories, and Point Trajectories. The **Ray Trajectories** plot requires a license for the Acoustics Module or the Ray Optics Module.

Comet tail plots provide a convenient way to indicate the direction of travel of particles at a given point in time. The tail of the comet typically points in the opposite direction to the particle velocity; visually, it is the same as the tail of a comet approaching the sun.

These additional settings are available when **Comet tail** is selected: Tail and Tail Components and Tail Scale Factor.

Ellipse is available with the **Particle Trajectories**, **Point Trajectories**, and **Ray Trajectories** plots in 3D.

Ellipses provide a convenient way to visualize the polarization of rays. The eccentricity of the ellipse indicates the degree to which it is linearly or circularly polarized. For elliptical and circular polarization, arrows on the perimeter of the ellipse can be used to distinguish between left- and right-handed polarization.

RADIUS SCALE FACTOR

Select the **Radius scale factor** checkbox to enter a scalar number for the scale factor for a tube radius in a line plot, for example.

RANGE QUOTIENT

If **Logarithmic** is selected as the arrow length, enter a **Range quotient**, which is the ratio between the maximum arrow length and the arrow length below which no arrow is drawn. The default is 100.

ROUNDED END CAPS

The **Rounded end caps** checkbox is selected by default to smoothen the transition using a hemispherical head when a 2D or 3D **Line** plot with **Tube** selected as the **Line type** uses a radius expression that varies along the length. Clear this checkbox if you, for example, want to show the cross-sectional variation along the length using an equivalent radius expression. This setting is also available for **Tube Data** plots created using the COMSOL API.

SCALE FACTOR

Enter a **Scale factor** for the arrows using a positive scalar number in the field or by using the associated slider (for scale factors between 0 and 1).

SCALING

From the **Scale** list, choose **Linear** (the default), **Linear symmetric**, or **Logarithmic**. Select **Linear symmetric** to obtain a color range centered around zero for a color table or color gradient. This setting is useful for visualizing wave-like solutions with zero bias. Selecting **Logarithmic** can make it easier to interpret the results when plotting expressions that have value ranges that cover multiple magnitudes.

TAIL AND TAIL COMPONENTS

Define the length and direction of the comet tail as a vector expression. For the **Tail expression**, click the **Replace Expression** button ( ) to insert a predefined expression into the **Tail, x-component**; **Tail, y-component**; and **Tail, z-component** (for 3D plots) fields. The expressions available are based on the physics interfaces used in the model. The default expressions (typically `pt.nvx`, `p.nvy`, and `pt.nvz`) represent the negative of the particle velocity.

TAIL SCALE FACTOR

Select the **Tail scale factor** checkbox to enter a scalar number between 0 and 1 or use the slider to select.

TYPE

Select **Curve** or **Solid** from the **Type** list for the type of histogram to plot when the **Function** list under **Output** is set to **Discrete**. Select **Solid** for filled histogram bins.

WIREFRAME

To plot only on the visualization mesh, select the **Wireframe** checkbox, and then click **Plot** ( ). This displays the surface plot as a triangular grid.

Defining Element Filters

For Mesh and Volume plots, you can specify the elements to display under **Element Filter**. Without filtering, the plots display all elements. Using element filters, you can highlight elements based on, for example, their mesh quality, size, or location.

To define an element filter, select the **Enable filter** checkbox and select a **Criterion**: **Logical expression** (the default), **Random**, or **Expression**. For Mesh plots, **Worst quality**, **Best quality**, and **Size** are also available, which filters mesh elements with the worst element, best quality, or size, respectively. When you choose **Size**, the fraction that you specify is the fraction with the smallest elements. For example, a fraction of 0.1 plots the smallest 10% of the elements.

- If **Expression** or **Logical expression** is selected, enter an **Expression** in the text field. For example, an expression can be `abs(x-y)` to plot a fraction of elements closest to the line $y = x$ (that is, the fraction that you specify is the fraction where the expression evaluates to the smallest values). An example of a logical expression is

`(h>0.1)&&(h<0.4)`, which shows the elements with an element size between 0.1 and 0.4 (`h` is the predefined variable for the mesh element size). Another example is `x>0`, which plots elements in the right half-plane only. The expression can include unit syntax such as `y<50[cm]`. Click the **Replace Expression** ( ) button to select a predefined quantity and replace the entire contents of the **Expression** field with the corresponding variable as the only expression.

- If **Random**, **Expression**, **Worst quality**, **Best quality**, or **Size** is selected, specify the **Fraction** of elements (0–1) to show (the default is 1, which means that all elements are included).

Defining Shrinking of Elements

For Mesh and Volume plots, under **Shrink Elements**, enter an **Element scale factor** between 0 and 1 to scale elements in the mesh plot when applicable. The default value is 1, which means no shrinking. Using a smaller value shrinks the size of the elements in the plot accordingly. This effect can be useful for visualizing individual elements and for looking at interior elements in a volume plot.

Entering Quality Settings for Plot Settings Windows

Many plots have a **Quality** section where you can specify all or some of the plot resolution, to enforce continuity, smoothing, the use of accurate derivative recovery, and the use of derivatives. The steps for this section vary slightly based on the plot but are basically as follows.

1 Under **Quality**, select a plot **Resolution**: **Extra fine**, **Finer**, **Fine**, **Normal** (the default), **Coarse**, **No refinement**, or **Custom**. A higher resolution means that elements are split into smaller patches during rendering. The **Finer**, **Fine**, **Normal**, **Coarse** use heuristics to determine a suitable resolution. For **Custom**, enter a positive integer (default: 1) in the **Element refinement** field. A higher value means higher resolution. The refinements is done by subdividing the element edges. See the following figure, which shows the refinement levels 1, 2, and 3:

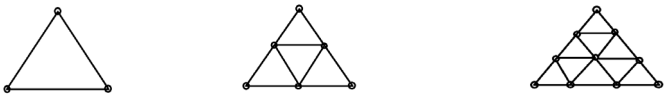

Figure 21-1: Element refinement levels 1 (left), 2 (middle), and 3 (right).

For new plots, you can also specify a preference for the resolution on the **Results>Plots** page in the **Preferences** window.

Custom refinement applies to the base dataset. The number of elements in the model can therefore increase radically if the plot uses, for example, a revolve dataset because the refinement is applied to the solution dataset.

2 To enforce continuity on discontinuous data, under **Quality**, from the **Smoothing** list, select:

- **None**: to plot elements independently.
- **Inside material domains** (the default): to smooth the quantity within domains shared by the same material but not across material boundaries. Here, *material* is interpreted in a wider sense than just a physical material.

Some physics interfaces implement material groups, which are sets of domains that are considered as being suitable for internal smoothing.

- **Internal**: to smooth the quantity inside the geometry, but no smoothing takes place across borders between domains with different settings.
- **Everywhere**: to apply smoothing to the entire geometry.
- **Expression**: to use an expression to indicate where smoothing should occur. Enter an expression in the **Expression** field such that smoothing occurs where the expression is continuous. The default expression is `dom`, the domain variable, which is equivalent to the **Internal** smoothing. You can also — in a surface plot, for example — use `material.domain`, which is an indicator variable for domains that share the same material (see Material Group Indicator Variables) and is equivalent to the **Inside material domains** setting.

The smoothing is done so that if there are two different values in points with the same coordinates, the plotted value is the mean of those two values.

For all **Smoothing** settings except **None**, you can specify a smoothing threshold by choosing **Manual** from the **Smoothing threshold** list and specify a value in the **Threshold** field. The default is **None**, for no smoothing threshold.

The default, **Inside material domains**, is to smooth the quantity except across borders between domains with different materials, where there is often a sharp transition from one material to another or between different types of physics. See the screenshots below that shows a material discontinuity where smoothing everywhere blurs the border (left) whereas smoothing inside material domains (right) keeps the material discontinuity intact. In these plots, no refinement is used to show the smoothing effect more clearly.

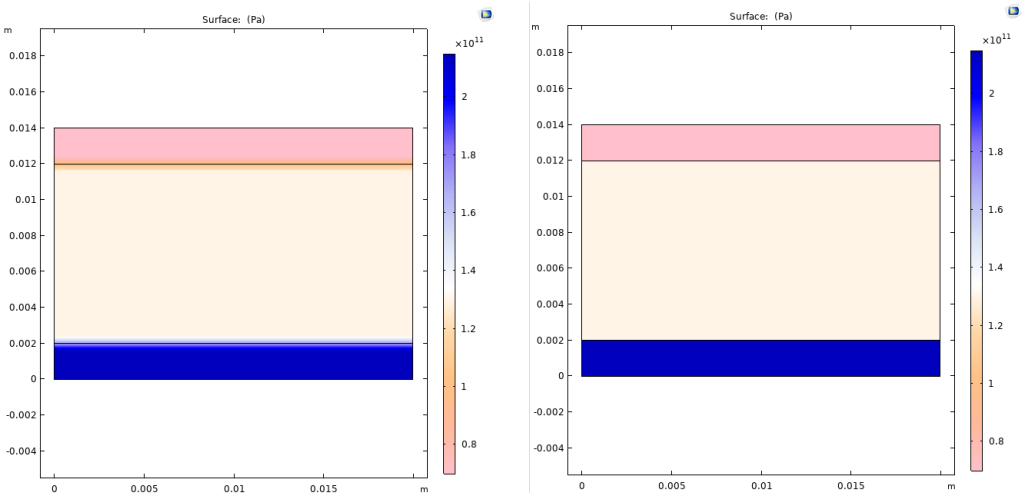

Figure 21-2: Smoothing everywhere (left) versus smoothing inside material domains (right).

3 Under **Quality**, the **Recover** default is **Off** because the accurate derivative recovery takes processing time. This recovery is a polynomial-preserving recovery that recovers fields with derivatives such as stresses or fluxes with a higher theoretical convergence than smoothing (see Polynomial-Preserving Derivative Recovery below).

To use accurate derivative recovery, from the **Recover** list, select:

- **Within domains**: to perform recovery inside domains.
- **Everywhere**: to apply recovery to all domain boundaries.

The **Recover** option only affects variables that are defined on domains.

4 The **Use derivatives** checkbox is selected by default, when available. Clear it if you do not want to use space derivatives for a smoother plot, but doing so usually improves the plot quality.

POLYNOMIAL-PRESERVING DERIVATIVE RECOVERY

Plotting and evaluating stresses or fluxes boils down to evaluating space derivatives of the dependent variables. By default, computing a derivative like ux or uxx (first and second derivatives of u with respect to x) is done by evaluating the derivative of the shape functions used in the finite element approximation. These values have poorer accuracy than the solution u itself. For example, uxx is identically 0 if u is defined using linear elements. COMSOL Multiphysics evaluates the derivatives (and u itself) using a polynomial-preserving recovery technique by Z. Zhang (see Ref. 1). The recovery is only applied on variables that are discretized using Lagrange shape functions.

The polynomial-preserving recovery is a variant of the superconvergent patch recovery by Zienkiewicz and Zhu that forms a higher-order approximation of the solution on a patch of mesh elements around each mesh vertex. For regular meshes, the convergence rate of the recovered gradient is $O(h^{p+1})$ — the same as for the solution itself. Near boundaries, the accuracy is not as good, and it might even be worse than without recovery. Results evaluation is about 2–5 times slower when using polynomial-preserving derivative recovery.

By default, the accurate derivative recovery smooths the derivatives within each group of domains with equal settings. Thus, there is no smoothing across material discontinuities. You find the setting for accurate derivative recovery in the plot node's **Settings** windows' **Quality** section. Due to performance reasons, the default value for **Recover** list is **Off** (that is, no accurate derivative recovery). Select **Within domains** to smooth the derivatives within each domain group (that is, groups of domains with equal settings). Select **Everywhere** to smooth the derivatives across the entire geometry.

Inheriting Style Options

All 2D and 3D plot types (except Mesh) have the **Inherit Style** section. Use this functionality to maintain a consistent style between plots.

After there is more than one plot in a plot group, the **Plot** list makes these plots available to select the attributes you want to maintain between plots. For any plot with this section, and if the checkbox is applicable to the plot type, all checkboxes are selected by default. The available attributes vary based on the plot type and include:

- Arrow scale factor
- Background color
- Color
- Color and data range
- Deform scale factor
- Ellipse scale factor
- Frame
- Height scale factor
- Ribbon width scale factor
- Point radius scale factor
- Tail scale factor
- Transparency
- Tube radius scale factor

The default **Plot** selected is **None**, which means that styles are not inherited for any plots. If you want to inherit a style, add and select an available plot from the **Plot** list. All attributes automatically inherit the style from the selected plot. To prevent a plot attribute from being inherited, clear the checkbox or select **None** from the **Plot** list.

Integration Settings for a Derived Value

Select a **Method**: **Auto** (the default), **Integration**, or **Summation**.

- **Auto** — the default method, which computes the integral for fields by numerical integration and for reaction forces by summation. Predefined quantities for reaction forces use summation instead of integration. Also, if an expression is specified for the integrand using the `reacf` operator, the automatic setting chooses the summation method.
- **Integration** — the standard numerical integration method (quadrature).
- **Summation** — a summation method is useful for calculating reaction forces. The summation method finds all nodes on the boundary, evaluates the expression in the nodes, and sums up the values. Reaction force variables are predefined in the structural mechanics interfaces.

The COMSOL Multiphysics software determines an appropriate **Integration order** for the expression when you use integration. To change the order, select the checkbox and enter an integer (0 or larger; default: 4). The COMSOL Multiphysics software performs the integration elementwise using numeric quadrature of the selected order.

2D Axisymmetric Models

For 2D axisymmetric models, **Volume Integration** and **Surface Integration** are available and active by default. COMSOL Multiphysics multiplies the expression (integrand) with `2*pi*r` prior to integration to compute the corresponding volume or surface integral if you do the next step.

- For **Surface Integration**, the **Compute volume integral** checkbox is selected by default.
- For **Line Integration**, the **Compute surface integral** checkbox is selected by default.

Reaction force variables in axisymmetric models include the $2\pi r$ factor, so summation over them always gives you the revolved surface force or volume force.

Data Series Operation Settings for Derived Values

These settings are available in the **Data Series Operation** section for most evaluation types under **Derived Values** and **Evaluation Group** nodes.

NORMALIZATION

You can use this list to normalize the values within each column of the data table for the evaluation. The following operators are available from the **Normalization** list. Select:

- **None** (the default) to not apply any normalization.
- **First** to normalize with respect to the first value within each column; that is, the first value is set to 1.
- **Last** to normalize with respect to the last value within each column; that is, the last value is set to 1.
- **Maximum absolute value** to normalize with respect to the maximum absolute value within each column; that is, the table value that is the maximum absolute value is set to 1. This normalization preserves the sign of negative numbers and the argument of complex-valued numbers.

If the expression that was evaluated has a valid unit, then normalization changes the unit of the expression to dimensionless.

TRANSFORMATION

In addition to performing the averaging on each solution in a data series (from a parametric or Time Dependent study) an operation can be applied such as the integral or maximum of the averaged quantity for the data series so that the result is, for example, the integral or maximum of the averaged quantity for each step in the data series. The following operators are available from the **Transformation** list. Select:

- **None** (the default) to not apply any data series operation.
- **Average** to evaluate the average of the data series.
- **Maximum** to evaluate the maximum of the data series. If **Maximum** is selected, select an option from the **Find maximum of** list: **Real part** or **Absolute value**.
- **Minimum** to evaluate the minimum of the data series. If **Minimum** is selected, select an option from the **Find minimum of** list: **Real part** or **Absolute value**.
- **Integral** to evaluate the integral of the data series.
- **RMS** (the *root mean square* or *quadratic mean*).
- **Standard deviation**.
- **Variance**.

For the **Maximum** and **Minimum** transformations of values for a time-dependent or parametric simulation, select the **Include Time** (or some parameter instead of **Time** for parametric simulations) checkbox to include the time or parameter value for which the maximum or minimum occurred.

For the **Average**, **Integral**, **RMS**, **Standard deviation**, and **Variance** transformations, there is also a **Method** list available for choosing one of the following computational methods:

- **Auto** (the default): The automatic method uses integration whenever it is possible; otherwise, it uses summation.
- **Integration**: Compute the values using integration (treating the data as samples of a continuous function; see note below).
- **Summation**: Compute the values using summation of the data values. Summation can be useful when there are parameters on the rows, or different load cases, which you want to compute a linearly sum for rather than an integral.

For the **Integral** transformation, you can also select the **Cumulative** checkbox to get cumulative integration of the table values.

The data series operations treat the data points as samples of a continuous function if the rows of a table, when evaluated without a data series operation, come from a transient or parametric solver (not if they come from an outer parametric sweep). The average, integral, standard deviation, variance, and RMS values, when you use integration, are all computed by performing one or more integrations of this continuous function using the trapezoidal method. The results are consistent with viewing the data series as samples of a continuous function but are not consistent with viewing the data points as discrete samples. For such cases, use summation instead.

For details about the solvers and studies, including the availability by module, see Harmonic Perturbation, Prestressed Analysis, and Small-Signal Analysis.

Solutions computed for a harmonic perturbation study step (for example, the second step of a small-signal analysis or prestressed analysis) consist of two separate parts: the linearization point and the perturbation solution. These parts can be combined in a number of different ways when evaluating an expression. This is controlled by the **Expression evaluated for** list, which appears in many postprocessing nodes if the selected dataset is based on the result of a harmonic perturbation:

EXPRESSION EVALUATED FOR

Select an option from the **Expression evaluated for** list: **Static solution**, **Harmonic perturbation**, **Total instantaneous solution**, **Average for total solution**, **RMS for total solution**, or **Peak value for total solution**. Each option is described below.

See Built-In Operators for information about the operators described in this section.

For the correct evaluation of small-signal lumped parameters like electric impedance and inductance, understanding the `lindev` operator is mandatory; see the note at the end of the Harmonic Perturbation section.

Static Solution

The expression is evaluated by taking the values of any dependent variables from the linearization point part of the solution. This is achieved by wrapping the expression in the `linpoint` operator.

Harmonic Perturbation

If **Harmonic perturbation** is selected, the **Compute differential** checkbox is also available. If the checkbox is not selected (the default), the expression is evaluated by taking the values of any dependent variables from the harmonic perturbation part of the solution.

If the **Compute differential** checkbox is selected, the differential of the expression with respect to the perturbation is computed and evaluated at the linearization point. This is achieved by wrapping the expression in the `lindev` operator. For expressions that are linear in the solution, the two options are the same.

Do not select the **Compute differential** checkbox when evaluating predefined or user-defined small-signal lumped parameters.

Lumped parameters are in general defined as a ratio of an applied excitation to a measured response; for example, electric impedance is the ratio of an applied voltage to the resulting current. In a small-signal sense such quantities must be defined using the `lindev` operator as, for example, `lindev("voltage")/lindev("current")`. Some physics interfaces provide built-in postprocessing variables for lumped parameters that use this type of definition. When wrapping such an expression or related variable once more in the `lindev` operator, the result is wrong (zero).

Total Instantaneous Solution

The expression is evaluated by adding the linearization point and the harmonic perturbation and taking the real part of this sum. This is achieved by wrapping the expression in the `lintotal` operator. The phase and amplitude of the harmonic perturbation part can be set in the corresponding dataset.

Average for Total Solution

This is the same as evaluating for **Total instantaneous solution** and then averaging over all phases of the harmonic perturbation. This is achieved by wrapping the expression in the `lintotalavg` operator.

RMS for Total Solution

This is the same as evaluating for **Total instantaneous solution** and then taking the RMS over all phases of the harmonic perturbation. This is achieved by wrapping the expression in the `lintotalrms` operator.

Peak Value for Total Solution

This is the same as evaluating for **Total instantaneous solution** and then taking the maximum over all phases of the harmonic perturbation. This is achieved by wrapping the expression in the `lintotalpeak` operator.

EXAMPLE: EVALUATING STRESSES IN A PRESTRESSED ANALYSIS

To illustrate the effect of the different **Expression evaluated for** settings, consider a prestressed solid mechanics model. The solution has been obtained by first computing a prestressed state, in a Stationary study step, and then adding a small harmonic perturbation on top of the stationary solution, using a Frequency Domain, Perturbation study step. The linearization point solution, $\mathbf{u}_0$, is therefore the stationary displacements from the prestress step, and the harmonic perturbation part of the solution, $\mathbf{u}_p$, is the small complex-valued harmonic displacements induced by the harmonic perturbation step. The instantaneous displacements are therefore

$$\mathbf{u}(t) = \mathbf{u}_0 + \text{real}(\mathbf{u}_p e^{i\omega t})$$

A common measure of the equivalent stress level in a solid is the von Mises stress, σ_e. This is a nonlinear function of the strain and therefore of the displacements. Assuming that the harmonic perturbation is small, the von Mises stress can be linearized around the linearization point

$$\sigma_e(t) = \sigma_e(\mathbf{u}_0 + \text{real}(\mathbf{u}_p e^{i\omega t})) \approx \sigma_e(\mathbf{u}_0) + \nabla\sigma_e(\mathbf{u}_0) \cdot \text{real}(\mathbf{u}_p e^{i\omega t}) = \sigma_{e0} + \text{real}(\sigma_{ep} e^{i\omega t}) \quad (21\text{-}1)$$

where the gradient is taken with respect to the solution degrees of freedom. Now suppose you evaluate the von Mises stress using each of the available options for **Expression evaluated for**:

Static solution: Evaluating using the static solution returns the von Mises stress from the prestress step, σ_{e0}.

Harmonic perturbation, Compute differential on: Evaluating using the harmonic perturbation solution with the **Compute differential** option selected returns the complex-valued amplitude of the linearized change in von Mises stress, σ_{ep}, due to the harmonic perturbation. For a perturbation that is small compared to the linearization point, the von Mises stress varies harmonically

$$\sigma_e(t) \approx \sigma_{e0} + \text{real}(\sigma_{ep} e^{i\omega t})$$

while for a large perturbation, the stress variation is no longer harmonic, due to its nonlinearity.

Harmonic perturbation, Compute differential off: Evaluating using the harmonic perturbation solution with the **Compute differential** option cleared returns the von Mises stress expression evaluated by substituting the complex perturbation solution, $\mathbf{u}_p$. This number, $\sigma_e(\mathbf{u}_p)$, is essentially a nonsensical value because it involves products of complex-valued amplitudes.

Total instantaneous solution: Evaluating using the total instantaneous solution option returns the von Mises stress expression evaluated using the total solution at the phase, θ, specified in the current dataset:

$$\sigma_e(\theta) = \sigma_e(\mathbf{u}_0 + \text{real}(\mathbf{u}_p e^{i\theta}))$$

Average for total solution: The average for the total solution is computed over one period by varying the phase, θ, in the interval [0, 2π]:

$$\sigma_e^{\text{mean}} = \frac{1}{2\pi}\int_0^{2\pi} \sigma_e(\mathbf{u}_0 + \text{real}(\mathbf{u}_p e^{i\theta}))d\theta$$

RMS for total solution: The RMS value for the total solution is computed over one period by varying the phase, θ, in the interval [0, 2π]:

$$\sigma_e^{\text{RMS}} = \sqrt{\frac{1}{2\pi}\int_0^{2\pi} \sigma_e(\mathbf{u}_0 + \text{real}(\mathbf{u}_p e^{i\theta}))^2 d\theta}$$

Peak value for total solution: The peak value for the total solution is computed as the maximum of $\sigma_e(\theta)$ for any phase θ in the interval [0, 2π].

Extra Time Steps for Trajectory Plots and Intersection Point Datasets

For trajectory plots, such as Particle Trajectories and Ray Trajectories, it is often useful to plot the particle or ray positions at specific times other than the time steps stored in the solution. This is often the case when particles or rays are reflected at boundaries; the exact reflection times are usually not known in advance, so they cannot be specified in the settings for a transient study step and must be computed instead. Similarly, intersection point datasets are not guaranteed to find all intersections close to wall bounces.

The **Extra Time Steps** section is always available in Intersection Point 2D and Intersection Point 3D datasets. It also appears in when a plot supports the rendering of particle or ray positions at time steps other than those stored in the solution. The plot must refer to a valid **Particle** or **Ray** dataset.

Select an option from the **Maximum number of extra time steps rendered** list: **None**, **All** (the default), **Specified number of times**, or **Proportional to the number of solution times**. For **None** the trajectories are only plotted at the stored solution times.

For **Specified number of times** enter a nonnegative integer for the **Maximum number of extra time steps**. The default is 100. This value is the total number of extra time steps, typically corresponding to reflection or velocity reinitialization times, that can be plotted along each trajectory in addition to the stored solution times.

For **Proportional** to the number of solution times enter a nonnegative integer for the **Proportionality factor**. The default is 1. The maximum number of extra times shown in the trajectory plot is the product of the proportionality factor and the number of stored solution times shown in the plot.

Node Properties for Reports and Presentations

When applicable, the **Node Properties** section provides settings for including the node properties for all model nodes. Select the checkboxes **Include author**, **Include date created**, and **Include application version** (for the report **Root** node) or **Include version** (for other report nodes) to include those properties. For **Comments**, the default setting (the report **Root** node excepted) — **From referenced node** — takes the comments from the node in the model; select **Custom** to add other comments or **None** for no comments.

In reports, each comment line becomes a separate paragraph. In presentations, each line becomes a separate list item (if there is only one line, no bullet is shown). You can use bullet lists (the default; preceded by one or more

asterisks for subbullet levels, *) and numbered list (preceded by one or more hash signs, #). Use the **Increase Bullet-List Level** ( ), **Increase Numbered-List Level** ( ), and **Decrease List Level** ( ) buttons as required to manage the list levels. Also, use the other text formatting options as desired. See Custom Report, Documentation, and Presentation Components for more information.

Images for Reports and Presentations

For details about the **Images** section settings, see the Images subsection under The Report Node and The Presentation Node, respectively. When the **Images** section appears in report and presentation Section nodes (templates excepted) or subnodes that generate image output, it contains settings that allow overriding those of the global report or presentation for individual report or presentation nodes, or in templates, for specific feature types, such as **Geometry** or **Plot Group** nodes.

In the **Size** list, you can choose between the **From report** or **From presentation**, **From parent** (the default), and any of the available size settings.

In the **Type** list the default setting is again **From parent**. Choose **From report** or **From presentation** to bypass any overrides in parent Section nodes or any of the supported types.

In the **Color theme** list, you can choose between **From report** or **From presentation**, **From parent** (the default), and using a custom color theme for the current node or (in templates) node type.

Finally, the **Background** list allows you to customize the background settings.

Slide Layouts (Presentations Only)

For details about the **Slide Layouts** section settings, see the Slide Layouts subsection under The Presentation Node. The **Slide Layouts** section appears in presentation subnodes that can generate image output as well as in regular (that is, nontemplate) presentation Section nodes. It contains the following lists where you can customize settings for the current node or, in templates, the current feature type:

- **Title and content**
- **Two content**
- **Content with image layout**
- **Slide with image only**

In all four cases, the default value is **From parent**. In addition to the settings described in The Presentation Node section, you can also choose **From presentation** to bypass any overrides of the settings in parent Section nodes.

Through-Thickness Location for Layered Materials and Shells

The **Through-Thickness Location** section is available in the Settings windows for **Line Average**, **Surface Average**, **Line Integration**, **Surface Integration**, **Line Maximum**, **Surface Maximum**, **Line Minimum**, and **Surface Minimum** nodes under **Derived Values**, when a Layered Material or Shell dataset is selected. It is also available for **Line Graph**, **Point Graph**, **Point Evaluation**, and **Point Matrix Evaluation** nodes when a Layered Material or Shell dataset is selected, but the **Location input** list is not available, and the local z-coordinate can only be a scalar for **Point Evaluation** and **Point Matrix Evaluation** nodes.

THROUGH-THICKNESS LOCATION

To determine the value of the evaluation, a through-thickness location is required.

From the **Location input** list, choose **From dataset** (the default) or **Manual**. For **Manual**, select a **Location definition**: **Reference surface** (the default), **Physical**, or **Relative**.

Once **Reference surface** is selected, the through-thickness location is taken from a layered material definition specified under **Materials** in a **Layered Material Link** or **Layered Material Stack** node, or in a **Material** node that represents a single-layer material.

Enter one or more values for a **Local z-coordinate** for the **Physical** option or **Local z-coordinate [-1,1]** for the **Relative** option. The bottom, middle, and top through-thickness location of a layered material, having a total thickness d, can be defined as follows:

- Bottom: 0 (Physical) or −1 (Relative)
- Middle: $d/2$ (Physical) or 0 (Relative)
- Top: d (Physical) or 1(Relative)

Click the **Range** button ( ) to define a range of local z-coordinates using the **Range** dialog.

Most of the variables defined on a layered material are available only on the surfaces and not directly available on lower dimensions (edges or points). In order to plot or evaluate such variables on lower dimensions, use the `mean()` operator once or twice depending on you are evaluating on edges or points, respectively. For instance, to evaluate the `lshell.disp` variable for the total displacement on edges, use the expression `mean(lshell.disp)`. Similarly, to evaluate the same variable on points, use the expression `mean(mean(lshell.disp))`.

About Integration Orders

The *integration order* affects the accuracy of computations involving integration and quadrature formulas, but it also important to consider its interplay with interpolation between meshes and different types of datasets for results evaluation.

What integration method that is used depends on what type of dataset that is used. Solution and Mesh datasets use Gauss quadrature. Cut and Shell datasets also use a variant of Gauss quadrature. Other datasets use a trapezoidal method.

For example, the integration order under the volume integral operator does represent the order of the polynomial that the scheme would integrate exactly in a mathematical sense.

Regardless of if you use a Join dataset approach or the `withsol` operator to combine two solutions, the same type of integration is used. So, when performing this operation with a Join dataset or the `withsol` operator, first an interpolation or extrapolation from one mesh to the other is performed, and then an integration is performed using the quadrature integration method in **Derived Values** > **Volume Integration**. When using the `withsol` operator you can use additional input arguments to control exactly for which parameters the operation is taking place.

If the two input datasets to a Join dataset are found to have different meshes during evaluation, then the points in `dataset2` are mapped to `dataset1` where interpolation takes place.

Datasets that use the trapezoidal method use the integration order to define the mesh refinement to use when evaluating. The expression is evaluated, and then the trapezoidal method is used. The refinement has the same interpretation as in plots: A refinement of 1 means that the evaluation will use the finite-element mesh. For a refinement of N, each edge of the finite-element mesh is split into N subedges. This will lead to N–1 internal points being added along each edge, and there will also be internal points added to triangles, tetrahedra, and so on. The number of refinement elements will be a factor of N^{edim} elements larger than the number of original elements; here `edim` is the element dimension used when evaluating (edge = 1, surface = 2, and volume = 3). This is a valid integration method, but it is not as accurate as Gauss quadrature.

Configurations

Configurations are used to specify, for example, graph plot style settings or a solution tuple describing the times for which a solution should be plotted and evaluated. You can then use such a configuration in plot groups, evaluation groups, and data export. In this section:

- Adding Configurations
- Graph Plot Style
- Multiselect Solution
- Single-Select Solution
- Preferred Units

Adding Configurations

To add configurations, right-click the **Results** node and choose **Configurations** ( ) and then **Graph Plot Style**, **Multiselect Solution**, **Single-Select Solution**, or **Preferred Units**. The **Graph Plot Style** node contains line styles, line markers, legends, and other graph plot style settings, whereas for **Multiselect Solution** and **Single-Select Solution** nodes, the former is useful for plots and data evaluations where you can use multiple times, eigenvalues, or parameter values, and the latter is useful for plots and data evaluations that use a single time, eigenvalue, or parameter value.

A **Configurations** node is then added with a **Graph Plot Style**, **Multiselect Solution**, **Single-Select Solution**, or **Preferred Units** subnode. To add additional configurations, right-click the **Results** node or the **Configurations** node and choose another **Graph Plot Style**, **Multiselect Solution**, or **Single-Select Solution** to add it as a new configuration. There can only be a single **Preferred Units** node. You can also add configuration nodes from the **Configurations** menu in the **Definitions** section on the **Results** ribbon toolbar.

When you have defined configurations, you can use them and select applicable configurations in the **Settings** windows for plot groups, evaluations groups, and data export nodes, for example. You then do not have to redefine which settings or solutions to use in each plot, data evaluation, or data export.

Graph Plot Style

Add a **Graph Plot Style** node ( ) to specify the line style, line makers, and legends to use in graph plots. To use it in graph plots, select a **Graph Plot Style** configuration from the **Configuration** list in the **Style Configurations** section in **1D Plot Group**, **Polar Plot Group**, and **Smith Plot Group** nodes. You can add a **Graph Plot Style** node from the context menu when right-clicking graph plot nodes in a 1D plot group, taking the graph plot style settings from that graph plot.

COLORING AND STYLE

Under **Line style**:

From the **Line** list, select **Cycle**, **Cycle (reset)**, **Solid**, **Dotted**, **Dashed**, or **Dash-dot**. If you select **Cycle**, it cycles through all the colors; if you have more than one line plot in a plot group and want to cycle through the same set of colors, select **Cycle (reset)**.

From the **Color** list, choose one of the following line color options: **Custom**, **Cycle**, **Cycle (reset)**, **From theme**, **Black**, **Blue**, **Cyan**, **Gray**, **Green**, **Magenta**, **Red**, **White**, or **Yellow**. If you select **Custom**, define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette. If you select **Cycle**, it cycles through all the colors; if you have more than one line plot in a plot group

and want to cycle through the same set of colors, select **Cycle (reset)**. Also, choose **Default** (7 colors) or **Long** (19 colors) from the **Color cycle** list.

Choose or enter a line **Width** as a positive integer (default: 1). You can also choose **Default from preferences**, with the width from the preference setting shown in parentheses (default: 1). You specify the default line width as a positive integer on the **Graph Plots** page under **Results** > **Plots** in the **Preferences** window.

Under **Line markers**, you can specify the following settings:

Select a **Marker** type: **None**, **Cycle**, **Cycle (reset)**, **Asterisk**, **Circle**, **Diamond**, **Plus sign**, **Point**, **Square**, **Star**, or **Triangle**.

If a marker is selected (excluding **None**), then from the **Positioning** list, select **Interpolated** (the default) or **In data points**. For **Interpolated**, enter the **Number** of markers to display (the default is 8; the maximum is 10,000 markers) or use the slider to select. If **In data points** is selected, the markers appear in the data points for the plot (which for a plot of a 1D solution are the mesh nodes).

LEGENDS

Under **Include in automatic mode**, choose which of the following information to include in the automatic legends (not all types are available for all plot types that support legends):

- **Label**
- **Point**
- **Solution**
- **Description**
- **Expression**
- **Unit**
- **Headers**, for column headers.

By default, only the **Point**, **Solution**, and **Headers** checkboxes are selected.

Under **Prefix and suffix**, add a prefix and suffix in the **Prefix** and **Suffix** fields, if desired. You can also define a **Precision** as a positive integer (default: 3).

Multiselect Solution

Add a **Multiselect Solution** node ( ) to select multiple times, eigenvalues, or parameter values to use in a graph plot, for example, or any other plot or data evaluation that support multiple solutions.

From the **Solution** list, choose an available **Solution** dataset from which to pick the solution values. Choose **None** to not use any solution data.

From the **Time selection** (for example) list, choose **All**, **First**, **Last**, **From list**, **Manual**, or **Interpolated**. For **From list**, you can choose from a list that appear. For **Manual**, enter indices for the solutions to include. For **Interpolated**, enter values in the span of times (the **Interpolated** option is not available for eigenvalues or parameters).

There can be multiple selection list for nested parametric simulations such as a parametric sweep for a time-dependent study.

You can choose **Multiselect Solution** nodes by choosing **From configurations** and the select it from the **Configurations** list in the **Data** section in applicable plot groups' settings.

Single-Select Solution

Add a **Single-Select Solution** node ( ) to select a time, eigenvalue, or parameter value to use in a plots or data evaluations that use a single solutions.

From the **Solution** list, choose an available **Solution** dataset from which to pick the solution values. Choose **None** to not use any solution data.

From the **Time**, **Eigenvalue**, or **Parameter value** list, choose a time, eigenvalue, or parameter value to use in plots, data evaluations, or data export nodes.

There can be multiple selection lists for nested parametric simulations such as a parametric sweep for a time-dependent study.

You can choose **Single-Selection Solution** nodes by choosing **From configurations** and the select it from the **Configurations** list in the **Data** section in applicable plot groups' settings.

Preferred Units

Add a **Preferred Units** node ( ) to choose properties for which you want to use another preferred unit by default under **Results** rather than the default unit from the unit system in the model. You can only add one **Preferred Units** node.

UNITS

Click the **Add Physical Quantity** button ( ) to open the **Physical Quantity** dialog, where you can select a physical quantity from the **General**, **Acoustics**, **Electromagnetics**, **Solid Mechanics**, and **Transport** sections. You can also type a filter text in the text field at the top of the dialog to search for available physical quantities. Click **OK** to add the selected physical quantity to the table above. You can only add a physical quantity to the table once, so already added physical quantities are then no longer available in the **Physical Quantity** dialog.

In the table, the physical quantity, its default unit from the unit system, and the preferred unit appears in the **Quantity**, **Unit**, and **Preferred unit** columns, respectively. From the lists in the **Preferred unit** column, choose the preferred unit that you want to use for each added physical quantity. The preferred units are used in subsequent plots, derived values, and other results features. Click the **Apply** button ( ) at the top of the **Settings** window to directly apply the preferred units to all of the results features that have settings for choosing a unit.

Click the **Delete** button ( ) to remove the selected physical quantity from the table. Click the **Clear Table** ( ) button to clear the entire table.

Select the **Apply conversions to expressions with the same dimensions** checkbox to apply the preferred unit and convert values accordingly for physical quantities and expressions that share the same dimensions (that is, the same dimensional formula, such as ML^2T^{-2} for work and energy).

Once a preferred unit is applied, deleting the unit entry or node or undoing the preferred units change action does not automatically result in reverting to the older unit state. To change the units to the original state, you have to add or change the units manually for the affected results from their respective nodes.

Datasets

About Datasets

Datasets refer to the source of data for creating **Plots** and **Reports**. It can be a **Solution**, a **Mesh**, or some transformation or cut plane applied to other datasets — that is, you can create new datasets from other datasets. You add datasets to the **Datasets** branch ( ) under **Results**.

All plots refer to datasets; the solutions are always available as default datasets. Characteristics of a dataset include:

- A visualization mesh
- Mapping to a previous dataset (except for solutions and meshes)
- Ability to refer the evaluation to the previous dataset

The base dataset maps to a solution and geometry or some other source of data. An example of a transformation dataset is Revolution 2D, which sweeps a 2D dataset into 3D.

	Cut Point, Cut Line, Cut Plane, Edge 2D, Edge 3D, and Surface datasets are used in combination with plot groups and Line, Point, and Surface graphs to create cross-sectional plots and plots for data in points, along lines and edges, and on cut planes and surfaces.

	Integration over solution datasets (or using the Integration coupling operator) uses the most accurate integration method (Gaussian quadrature) whereas most other datasets use less accurate integration methods (typically the trapezoid method) because they do not operate on original elements of the finite element mesh.

	Datasets such as Mirror mirror vectors (used in, for example, arrow plots, streamline plots, and deformations) but not scalars.

By default, all datasets are generated when you compute a solution. To only generate datasets for components that are solved for, select the **Automatically generate datasets only for components solved for** checkbox on the **Results** > **Datasets** page in the **Preferences** window.

ADDING A DATASET TO THE MODEL BUILDER

In the **Model Builder** under **Results** ( ), right-click **Datasets** ( ) and select an option from the context menu. Continue defining each dataset as described. See Table 21-7 for links to all the types of datasets.

	• See Dataset Types and Attributes for links to the dataset descriptions. • Named Selections • Meshing • Introduction to Solvers and Studies

	Depending on the physics interface included in the model, not all dataset types in the following table may be available. To see all dataset types, select the **All Dataset Types** checkbox in the **Show More Options** dialog.

EXPORTING DATA FROM DATASETS

For most datasets, you can right-click the dataset node and choose **Add Data to Export**. A Data node is then added under **Results** > **Export**, where you can define the content and format for the data output and export it to a file.

For datasets that also include a mesh, such as Solution and Mesh datasets, you can also right-click the dataset and choose **Add Mesh to Export**. A Mesh (Export) node is then added under **Results** > **Export**, where you can define the content and format for the mesh data output and export it to a file.

Dataset Types and Attributes

The following tables list the available dataset types, including links to the description of the properties and settings of the dataset and the available dataset attributes:

TABLE 21-7: DATASET TYPES.

LINK	DESCRIPTION AND PLOT USE
Array 1D, Array 2D, and Array 3D	Create 1D, 2D, and 3D arrays of other datasets, so that you can plot the same data in multiple locations as an array of plots.
Array Factor	Define array factors for use in setting up simplified models for radiation pattern plots in RF simulations of antenna arrays.
Average and Integral	Creates a dataset that computes the average of another dataset, for example to plot the average.
Beam	To analyze beams by providing a 3D representation of the beams, with a correct visualization of their shape. The dataset forms a 3D mesh and evaluates expressions for all vertices of the mesh. It can handle variations in the shape of the cross section along the beam's length.
Contour (Dataset)	To analyze on 2D contour lines. Use this dataset for 2D arrow plots, 2D line plots, and 1D global plots.
Cut Line 2D and Cut Line 3D	To create lines through 2D and 3D geometry to visualize along the line. Use this dataset to create 2D or 3D cross-section line plots.
Cut Plane	Plots on cut planes are made on 3D datasets and can be visualized in either 2D or 3D plot groups.
Cut Point 1D, Cut Point 2D, and Cut Point 3D	Plot and evaluate a value in a certain point along time or along a parametric solution. Use this dataset to create 1D, 2D, or 3D cross-section point plots.
Edge 2D and Edge 3D	Plot and evaluate a value along a boundary (edge) in 2D or an edge in 3D. Use this dataset to create plots for data on edges.
Embed 1D and Embed 2D	To embed 1D data in 2D and 2D data in 3D.

TABLE 21-7: DATASET TYPES.

LINK	DESCRIPTION AND PLOT USE
Extrusion 1D and Extrusion 2D	To extrude data in postprocessing from 1D to 2D and from 2D to 3D.
Filter	To filter data using a lower bound, upper bound, or both a lower and upper bound.
Grid 1D, Grid 2D, and Grid 3D	Create a dataset that can evaluate functions or expressions from a solution dataset on a created domain with a grid.
Intersection Point 2D and Intersection Point 3D	Enable evaluation of expressions at the intersection points of particle or ray trajectories and a surface and evaluate intersection points with a more general surface. Requires the Particle Tracing Module or Ray Optics Module.
Isosurface (Dataset)	To visualize isosurfaces in 3D. Use this dataset to create arrow surface plots, surface plots, and contour plots. In addition, the contour dataset can be applied to the isosurface dataset.
Join	To join the solution data from two Solution datasets. This makes it possible to evaluate and plot the difference between two solutions, for example.
Kernel Density Estimation	To compute the kernel density estimation (KDE) from a table with data.
Layered Material	To create a volume/domain (3D) dataset for a layered shell physics defined using a surface/boundary (2D) geometry and a built-in extra dimension (1D) geometry. Use this dataset to plot or evaluate layered shell quantities on a domain level or its lower dimensions. Requires the AC/DC Module, Composite Materials Module, or Heat Transfer Module.
Maximum and Minimum	Creates a dataset that computes the maximum or minimum of another dataset.
Mesh (Dataset)	To make a mesh available for visualization and results analysis. Use a Mesh node in a plot group to get the actual plot.
Mirror 2D and Mirror 3D	To extend a solution defined on one side of an axis to the other side of the axis. Useful for visualization of a solution to an axisymmetric problem or plane of reflection.
Parametric Curve 2D and Parametric Curve 3D	To visualize data along a general parametric curve in 2D or 3D. Use this dataset to create a line plot in its original dimension and as a line graph plot in 1D.
Parametric Surface	To visualize data on a general parametric surface. Use this dataset with a surface plot in its original dimension and as any plot type in 2D.
Parametric Extrusion 1D and Parametric Extrusion 2D	To extend another dataset by using a parameter, such as time, as a dimension.

TABLE 21-7: DATASET TYPES.

LINK	DESCRIPTION AND PLOT USE
Particle (Dataset)	To visualize particle traces computed by a Particle Tracing interface. Requires the Particle Tracing Module.
Particle Bin	To organize particles into groups and treating each group as a single entity for the purpose of using other particle postprocessing features. Requires the Particle Tracing Module.
Partition	To partition a domain with respect to a set of isolevels and add elements corresponding to the isosurfaces or contours.
Pipe	To analyze pipes by providing a 3D representation of the pipes, with a correct visualization of their shape. The dataset forms a 3D mesh and evaluates expressions for all vertices of the mesh. It can handle variations in the shape of the cross section along the pipe's length.
Ray (Dataset)	To visualize ray traces computed by a Geometrical Optics or Ray Acoustics interface. Requires the Ray Optics Module or the Acoustics Module.
Ray Bin	To organize rays into groups and treating each group as a single entity for the purpose of using other ray tracing features. Requires the Ray Optics Module or the Acoustics Module.
Receiver 2D and Receiver 3D	To visualize the impulse response for a ray acoustics simulation of, for example, room acoustics or underwater acoustics. Requires the Acoustics Module.
Response Spectrum 2D and Response Spectrum 3D	To perform a response spectrum analysis (a modal-based method for estimating the structural response to a transient, nondeterministic event). Requires the Structural Mechanics Module.
Revolution 1D and Revolution 2D	Use a revolution dataset to visualize a 2D or 1D axisymmetric solution in 3D and 2D, respectively.
Sector 2D and Sector 3D	To exploit symmetries in the model to reduce the model size and then, if needed, use rotations and reflections to plot the solution for the entire geometry.
Shell	To visualize the top and bottom surfaces of a shell in 3D. Requires the Structural Mechanics Module.
Solution	To make solutions available for visualization and results analysis. Solvers create Solution datasets automatically.
Spatial FFT	To convert a spatial solution to the frequency domain using FFT.
Surface (Dataset)	Plot and evaluate a value on surfaces (boundaries) in 3D. Use this dataset to create plots for data on surfaces.

TABLE 21-7: DATASET TYPES.

LINK	DESCRIPTION AND PLOT USE
Time Average and Time Integral	To compute the time average or time integral of time-dependent data from another dataset.
Transformation 2D and Transformation 3D	To perform a rotation or other affine transformation of data from another dataset.

TABLE 21-8: DATASET ATTRIBUTES.

DATASET ATTRIBUTE	DESCRIPTION	ADD TO THESE DATASET TYPES
Selection (Dataset Attribute)	Add a selection of geometric entities for which to include the data.	Solution, Mesh, and other datasets that contain data defined in the model.
Mesh Import Parameters	Choose a parameter for solution data in models with inner and outer solutions.	Filter and Partition

Common Results Node Settings

Array 1D, Array 2D, and Array 3D

Select an **Array 1D** ( ), **Array 2D** ( ), or **Array 3D** ( ) dataset, found under the **More Datasets**, **More 2D Datasets**, and **More 3D Datasets** submenus, to create an array of data for plots based on another dataset. Right-click an **Array 1D**, **Array 2D**, or **Array 3D** dataset node to add a **Selection** subnode if desired. The **Array 1D**, **Array 2D**, and **Array 3D** nodes' **Settings** windows include the following sections:

DATA

From the **Dataset** list, choose the dataset that you want to duplicate into an array. The list includes all available datasets that are compatible with the Array dataset (1D datasets for Array 1D, 2D datasets for Array 2D, and 3D datasets for Array 3D).

INPUT

In this section you define the part of space that the array is created from. From the **Method** list, select **Automatic** (the default) to use the bounding box of the source dataset as input. Alternatively, select **Manual** to specify the part of space manually:

- Under **Size**, define the dimensions of the input space in the **x**, **y** (2D and 3D), and (3D only) **z** fields (the names of the space coordinates can vary).
- Under **Position**, define the base point for the input space. From the **Base** list, select **Corner** (the default) or **Center** to use a location at the lower-left corner or the center as the base position. Then enter the base position in the **x**, **y**, and (3D only) **z** fields (the names of the space coordinates can vary).

ARRAY SIZE

Here you specify the size of the array as the number of cells in each direction. From the **Array type**, choose **Linear**, **Rectangular** (2D only), or **Three-dimensional** (3D only). For **Linear**, enter the number of cells as a positive integer in the **Size** field. You specify the distance between each cell in the **Displacement** section below. For **Rectangular** and **Three-dimensional**, you specify the number of cells as positive integers in each i direction in the **x size**, **y size** (2D and

3D), and **z size** (3D only) fields. For 1D, enter the number of cells in the **x size** field (the names of the space coordinates can vary).

DISPLACEMENT

In this section you specify the displacement used to separate each cell in the array. From the **Method** list, select **Automatic** (the default) to a displacement that is the same as the size defined in the **Input** section. This means that to create an array of cells that have the same size as the bounding box of the underlying dataset, you can use **Automatic** both here and in the **Input** section. Alternatively, select **Manual** to specify the displacement manually by entering displacement distances in the **x**, **y** (2D and 3D), and **z** (3D only) fields (the names of the space coordinates can vary). The displacement cannot be smaller than the size of the input cell.

ROTATION

This section is only available for 2D and 3D Array datasets and only when the **Array type** setting is **Linear**.

Specifying a rotation can be useful for modeling cables, for examples. For 3D **Array** datasets, choose one of the following settings:

- **X-axis**
- **Y-axis**
- **Z-axis** (the default)
- **Cartesian**. When you choose this option, specify the rotation axis in the **x**, **y**, and **z** fields below.
- **Spherical**. When you choose this option, specify the rotation axis in the θ and φ fields below.

In the **Angle increment** field, enter the angle (in radians) with which the rotation will be incremented for each array item that is added.

In 3D, under **Point on axis of rotation**, enter the coordinates for a point on the axis in the **x**, **y**, and **z** fields (SI unit: m).

In 2D, under **Center of rotation**, enter the coordinates for a point on the axis in the **x** and **y** fields (SI unit: m).

ADVANCED

If needed, you can define variables for the array dataset. Select the **Define variables** checkbox to define the following variables:

- Under **Space variables**, you create variables that evaluate to the coordinates in the dataset's coordinate system. Enter variable names in the **x**, **y** (2D and 3D), and **z** (3D only) fields (the names of the space coordinates can vary).
- Under **Cell variables**, you create integer variables that identify the current cell in the array. For example, the 3D cell with variable values (0, 0, 0) corresponds to the underlying dataset's cell. Enter variable names in the **x**, **y**, and **z** (3D only) fields (the names of the space coordinates can vary).

Select the **Floquet-Bloch periodicity** checkbox if you want to incorporate phase changes from Floquet-Bloch periodicity. The Floquet-Bloch periodicity corresponds to the relation

$$u(r+R) = u(r)\,e^{-ikR}$$

where R is the lattice vector, and k is the wave number. For Array datasets, the lattice vector when evaluating in a cell of the array is the displacement from the base cell. You define the Floquet-Bloch periodicity using the

components of the wave vector **k** (SI unit: 1/m) in the **x**, **y** (2D and 3D), and **z** (3D only) fields under **Wave vector**. The wave vector can be complex, and you can use this to model gains and losses over an array.

Clear the **Check for overlap between cells** checkbox to make it possible to, for example, create a hexagonal lattice by composing two linear arrays. It also makes it possible to create rectangular lattices where the unit cells are not rectangles. To create such lattices, you have to create an array of arrays, where you in the outer array specify the right shift.

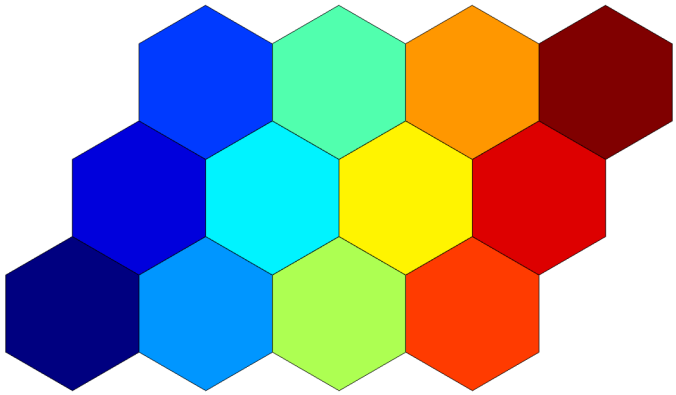

Figure 21-3: A hexagonal lattice created using two Array 2D datasets, where the "outer" dataset's setting has turned off the check for overlap between cells.

Array Factor

Select an **Array Factor** ( ) dataset, found under the **More Datasets** submenu, to define array factors for use in radiation pattern plots in RF simulations of antenna arrays, simplifying the analysis for a periodic antenna array. You can choose an Array Factor dataset as the dataset for the input data in **Radiation Pattern** plots.

DATA

Select a **Dataset** for the data to be the input to the average factor computation.

ARRAY DEFINITIONS

Use the settings in this section to define the array for the array factors.

From the **Plane** list, choose the plane for the array factor: **xy-plane** (the default), **yz-plane**, or **zx-plane**.

From the two columns (for example, **x** and **y**, if **xy-plane** was selected), enter the following properties, which are used when transforming the expression under **Evaluation**:

- **Array size**: Enter the array size as positive integers in the plane directions.
- **Phase shift**: Enter the phase shift (in radians) in the plane directions, which can use a parameter for the steering angle to sweep over a number of such angles.
- **Displacement**: Enter the displacements in the plane directions for the distances between the arrays as factors of the array wavelength (typical values would be close to 0.5).

EVALUATION

Use the settings in this section to define the function to evaluate for the array factor.

In the **Function** field, enter an expression to evaluate, typically `emw1.af3`, using the `af3` function for a uniform three-dimensional array factor (requires a license for the RF Module).

From the **Scale** list, choose **Linear** (the default) or **dB** for a decibel scale.

Select the **Normalization** checkbox if you want the evaluation to be normalized with respect to the number of power inputs, which can be, for example, a single power input or one power input for each antenna in the antenna array.

With a license for the RF Module, see *Modeling of a Phased Array Antenna* for an example of the use of an Array Factor dataset: Application Library path **RF_Module/Antenna_Arrays/microstrip_patch_antenna_periodic**.

Average and Integral

Select an **Average** (AV) or **Integral** ($\int du$) dataset, found under the **More Datasets** submenu, to compute the average or integral of another dataset, for example, to plot the average or integral.

DATA

Select a **Dataset** for the data to compute the average or integral. To compute the average or integral for a **Solution** dataset, use a **Selection** to define the geometric entity (point, boundary, edge, or domain) to integrate over. Right-click the dataset and choose **Selection**.

SETTINGS

Select an integration **Method**: **Auto** (the default), **Integration**, or **Summation over nodes**.

- **Auto** — Computes the integral for fields by numerical integration and for reaction forces by summation. Predefined quantities for reaction forces use summation instead of integration. Also, to specify an expression for the integrand, use the `reacf` operator, and the automatic setting chooses the summation method.
- **Integration** — the standard numerical integration method (quadrature).
- **Summation over nodes** — a summation method useful for computing reaction forces. The summation method finds all nodes on the boundary, evaluates the expression in the nodes and sums up the values. Reaction force variables are predefined in the structural mechanics interfaces. This is selected instead of Integration for reaction forces when the automatic selection of integration method is active.

For **Integration order**, the COMSOL Multiphysics software determines an appropriate integration order for the expression when you use integration. The default is 4. Select the checkbox to make a different entry in the field (as an integer that is 0 or larger). COMSOL Multiphysics then performs the integration elementwise using numeric quadrature of the selected order.

Select a **Geometry level** — **From dataset** (the default), **Volume**, **Surface**, **Line**, or **Point**. The default means the highest geometry dimension for the data in the dataset; typically volumes in 3D, surfaces in 2D, and lines in 1D.

If the dataset represents data for a 1D or 2D axisymmetric geometry, the **Compute surface integral** (1D axial symmetry) and **Compute volume integral** (2D axial symmetry) checkboxes are selected by default to compute an average or integral that takes the axial symmetry into account. COMSOL Multiphysics then multiplies the expression (integrand) with `2*pi*r` prior to integration to compute the corresponding volume or surface integral.

For an integral evaluation dataset example, see *Flow Past a Cylinder*: Application Library path **COMSOL_Multiphysics/Fluid_Dynamics/cylinder_flow**.

Beam

Use a **Beam** ( ) dataset, selected from the **More Datasets** submenu, for visualizing beams in a model by providing a 3D representation of the beams, with a correct visualization of their shape. The dataset forms a 3D mesh and

evaluates expressions for all vertices of the mesh. It can handle variations in the shape of the cross section along the beam's length.

Go to Common Results Node Settings for links to information about the **Data** section.

BEAM PHYSICS

From the **Physics interface** list, choose **All** (the default) to use beam physics from all applicable physics interfaces, or choose any applicable physics interface. **All** is useful to visualize the 3D geometry (while evaluating a trivial expression like `0`), but that option will fail to evaluate variables that are defined locally inside each physics interface. **Selection** subnodes can also be used to select the edges that the intended physics is using.

CROSS SECTION

Enter a scaling of the beam as a scalar value in the **Scale** field (default: 1).

Enter a refinement as an integer between 1 and 5 in the **Refinement** field (default: 2).

SPACE VARIABLES

In this section, you create variables that evaluate to the coordinates in the dataset's coordinate system. Enter variable names in the **x′**, **y′**, and **z′** fields (the default names of the space coordinates are `beam1x`, `beam1y`, and `beam1z`, respectively, for the first **Beam** dataset).

Beam datasets require the Structural Mechanics Module.

Contour (Dataset)

Use a **Contour** ( ) dataset, selected from the **More 2D Datasets** submenu, for results evaluation on 2D contour lines. Contour lines cannot be parameterized in general, so only 2D arrow plots, 2D line plots, and 1D global plots can be used to visualize the dataset. Only 2D datasets can be used.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, and **Levels**.

Cut Line 2D and Cut Line 3D

Use a **Cut Line 2D** ( ) or **Cut Line 3D** ( ) dataset to create lines through 2D or 3D geometries to visualize along the line. All plots and results analysis nodes available in 1D are available for cut line datasets as well as 3D plots and results analysis nodes for edges. These datasets are also used to create cross-section line plots. The resolution of cut lines is controlled by the resolution of the underlying mesh and by the resolution setting in the **Quality** section in plots. If you need full control over the resolution, use a Parametric Curve dataset (see Parametric Curve 2D and Parametric Curve 3D). Right-click a **Cut Line 2D** or **Cut Line 3D** dataset node to add a **Selection** subnode if desired.

Go to Common Results Node Settings for links to information about the **Data** section.

LINE DATA

Use **Line entry method** to specify the cut line either by **Two points** or by a **Point and direction**. If **Two points** is selected, enter **x** and **y** coordinates (2D) or **x**, **y**, and **z** coordinates (3D) in the **Point 1** and **Point 2** fields ((SI unit: m). If **Point and direction** is selected, enter **x** and **y** coordinates (2D) or **x**, **y**, and **z** coordinates (3D) in the **Point** (SI unit: m) and **Direction** fields.

The **Bounded by points** checkbox is selected by default to constrain the line between the defined points.

From the **Snapping** list, choose **None** for no snapping (the default), **Snap to closest boundary** to snap the cut lines to the closest boundary in the geometry, or **Snap to closest edge** (Cut Line 3D only) to snap the cut lines to the closest edge in the geometry. Use this option when evaluating a variable that is available on boundaries but not in domains, for example. Otherwise, leave the snapping off (the default setting, **None**) to avoid the additional computational cost. However, snapping always happens if the underlying dataset has a shell geometry.

For **Cut Line 2D**, also select the **Additional parallel lines** checkbox to define multiple lines for plotting or evaluation, for example. Then enter **Distances** from the original line in the field. The **Distances** field refers to a direction that is normal to the cut line and rotated 90 degrees counterclockwise relative to the cut line's direction. For example, if the cut line is from (0, 0) to (1, 0), then the distances are along the vector (0, 1) from any point on the cut line.

ADVANCED

Under **Space variable**, you can change the name of the space variable for the cut line's coordinate from its default value (`cln1x`, for example). The space variable name shows in the **Table** window when displaying the data. For Cut Line 2D nodes, normal variables are created, and under **Normal variables**, you can change the default names (`cln1nx` and `cln1ny`, for example) in the **nx** and **ny** fields. Tangent variables are also created for Cut Line 2D and Cut Line 3D nodes. Under **Tangent variables**, you can change the default names (`cln1tx`, `cln1ty`, and `cln1tz`, for example, in 3D) in the **tx**, **ty**, and **tz** fields. The normal and tangent vectors defined using these variables have unit length.

For a Cut Line 3D example, see *Thin-Film Resistance*: Application Library path **COMSOL_Multiphysics/Electromagnetics/thin_film_resistance**.

Cut Plane

For plots on cut planes, use **Cut Plane** datasets ( ), which are made on 3D datasets and can be visualized in either 2D or 3D plot groups. All plots and results analysis nodes available in 2D are available for cut plane datasets as well as for surfaces in 3D. The cut plane corresponds to an orthogonal 2D coordinate system embedded in 3D. This dataset is used to create 3D cross-section surface plots. Right-click the **Cut Plane** dataset node to add a **Selection** subnode if desired

Go to Common Results Node Settings for links to information about these sections: **Data** and **Plane Data**.

ADVANCED

Under **Space variables**, you can change the name of the space variables **x** and **y** for the cut plane's coordinates from their default values (`cpl1x` and `cpl1y`, for example). These names appear as column titles for the coordinate columns in the **Table** window when displayed in numerical results from a Cut Plane dataset.

Under **Normal variables**, if desired, edit the variable names for the components of the normal vector — **nx**, **ny**, and **nz**. The default names are `cpl1nx`, `cpl1ny`, and `cpl1nz`, respectively.

If you have the:

- AC/DC Module and the Particle Tracing Module, see *Magnetic Lens*: Application Library path **ACDC_Module/Electromagnetics_and_Particle_Tracing/magnetic_lens**.
- Fuel Cell & Electrolyzer Module, see *Mass Transport Analysis of a High Temperature PEM Fuel Cell*: Application Library path **Fuel_Cell_and_Electrolyzer_Module/Fuel_Cells/ht_pem**.
- CFD Module, see *Airflow over an Ahmed Body*: Application Library path **CFD_Module/Verification_Examples/ahmed_body**.
- Chemical Reaction Engineering Module, see *Laminar Static Mixer*: Application Library path **Chemical_Reaction_Engineering_Module/Mixing_and_Separation/laminar_static_mixer**.
- Particle Tracing Module, see *Ideal Cloak*: Application Library path **Particle_Tracing_Module/Tutorials/ideal_cloak**.

Cut Point 1D, Cut Point 2D, and Cut Point 3D

Use a **Cut Point 1D** ( ), **Cut Point 2D** ( ), or **Cut Point 3D** ( ) dataset to plot and evaluate a value in certain points along time or along a parametric solution and to create cross-sectional point plots. The choice of 1D, 2D, or 3D only controls the type of input the dataset accepts. For example, a Cut Point 1D can only be added to 1D datasets and a Cut Point 2D can only be added to 2D datasets. Any of these can be used to make a point graph plot along time and so forth and for point evaluations.

Add a **Cut Point 1D** dataset for points as cross-section data. Add a **Cut Point 2D** or **Cut Point 3D** dataset to, for example, plot the values in certain points along time or along a parametric solution and use the dataset in its original dimension. Useful ways to visualize and display data in cut points are through **Point Evaluation** nodes ( ) under **Derived Values** and **Point Graph** nodes ( ) under **1D Plot Group** nodes.

Go to Common Results Node Settings for links to information about the **Data** section.

POINT DATA

To specify the point data coordinates using the **Entry method** list:

- Select **Coordinates** (the default) to enter the coordinates. For Cut Point 1D, enter **x** coordinates; for Cut Point 2D, enter **x** and **y** coordinates; and for Cut Point 3D enter **x**, **y**, and **z** coordinates.
- Select **From file** to enter or browse to a text file with the cut point data. Enter the path and filename in the **Filename** field, or click **Browse** ( ) to browse to the file using the **Coordinate File** window that opens. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ). You can use text files (*.txt) or, if the license includes LiveLink™ for Excel®, Microsoft Excel Workbook files (*.xlsx). The file format is such that each row contains N coordinates for an N-dimensional cut point. That is, each row contains coordinate values like the following example, for a 3D case:

```
x0 y0 z0 …
x1 y1 z1 …
```

…

For text files, you can use any of the following characters to separate the coordinates: space, comma, semicolon, or a tab character. Empty lines and lines that begin with a percent (%) character are ignored.

- Select **Grid** to enter grid coordinates for gridded data. For Cut Point 1D, enter **x** coordinates; for Cut Point 2D, enter **x** and **y** coordinates; and for Cut Point 3D, enter **x**, **y**, and **z** coordinates.
- Select **Regular grid** to specify the number of points in each direction. Enter **Number of x points**, **Number of y points** (Cut Point 2D and 3D), and **Number of z points** (Cut Point 3D only). The default value is 10 points in each direction.

From the **Snapping** list, choose **None** for no snapping (the default), **Snap to closest boundary** to snap the selected points to the closest boundary in the geometry, or **Snap to closest edge** (Cut Point 3D only) to snap the selected points to the closest edge in the geometry. Use this option when evaluating a variable that is available on boundaries but not in domains, for example. Otherwise, leave the snapping off (the default setting, **None**) to avoid the additional computational cost.

THROUGH-THICKNESS LOCATION

This section is only available for Cut Point 3D datasets that refer to a Layered Material dataset and where **Snapping** is set to **Snap to closest boundary** or **Snap to closest edge**.

Select a **Location definition**: **Reference surface** (the default), **Physical**, or **Relative**.

Once **Reference surface** is selected, the through-thickness location is taken from a layered material definition specified in a **Layered Material Link**, **Layered Material Stack**, or **Material** node (defined as a single-layer material) under **Materials**.

Enter one or more values for a **Local z-coordinate** for the **Physical** option or **Local z-coordinate [-1,1]** for the **Relative** option. The bottom, middle, and top through-thickness location of a layered material, having a total thickness d, can be defined as follows:

- Bottom: 0 (Physical) or −1 (Relative)
- Middle: $d/2$ (Physical) or 0 (Relative)
- Top: d (Physical) or 1(Relative)

Click the **Range** button ( ) to define a range of local z-coordinates using the **Range** dialog.

ADVANCED

By default, the Cut Point datasets create a point number variable so that you can refer to that variable in a Point Graph, for example, where you want to plot some quantity at those cut points. The default variable name is typically `cpt1n`, for the first Cut Point dataset. Enter another variable name in the **Point number variable** field if desired.

For a Cut Point 1D example, and if you have the Plasma Module, see *Benchmark Model of a Capacitively Coupled Plasma*: Application Library path **Plasma_Module/Capacitively_Coupled_Plasmas/ccp_benchmark**.

For a Cut Point 2D example, see *Steady-State 2D Heat Transfer with Conduction*: Application Library path **COMSOL_Multiphysics/Heat_Transfer/heat_convection_2d**.

For a Cut Point 3D example, and if you have the:

- MEMS Module, see *Prestressed Micromirror*: Application Library path **MEMS_Module/Actuators/micromirror**.
- Microfluidics Module, see *Star-Shaped Microchannel*: Application Library path **Microfluidics_Module/Fluid_Flow/star_chip**.
- RF Module, see *Microwave Oven*: Application Library path **RF_Module/Microwave_Heating/microwave_oven**.

Edge 2D and Edge 3D

Use an **Edge 2D** ( ) or an **Edge 3D** ( ) dataset to plot and evaluate a value along an edge (boundary) in 2D or an edge in 3D. Create a line graph or any other plot type in a **1D Plot Group** to plot data along an edge using one of these datasets. Use an **Edge 2D** dataset to plot values on boundaries (edges) in a 2D geometry. Use an **Edge 3D** dataset to plot values on edges in a 3D geometry.

Go to Common Results Node Settings for links to information about these sections: **Data** and **Selection**.

ADVANCED

Select the **Reverse direction** checkbox if desired, to flip the direction of the edge.

Embed 1D and Embed 2D

Use an **Embed 1D** ( ) or **Embed 2D** ( ) dataset to embed 1D data into 2D (as a line in 2D) and 2D data into 3D (as a 2D surface in 3D), respectively. You can use an Embed 2D dataset to plot 3D arrows for a 2D solution, for example. Add these datasets by right-clicking the **Datasets** node and choose them from the **More Datasets** and **More 2D Datasets** submenus.

Go to Common Results Node Settings for links to information about the **Data** section. The dataset can be any dataset with an output dimension equal to the embed dataset's dimension.

MAPPING

In this section you determine the mapping from the lower to the higher space dimension in which the data from the lower one should be embedded.

From the **Mapping mode** list, choose **Auto** (the default) or **Manual**. For **Auto**, all higher-dimensional coordinates are set to 0. For **Manual**, you can define the mapping using the **x'**, **y'**, and (2D only) **z'** fields under **Output space expressions**. The default expressions, in 2D, are `X`, `Y`, and `0`, respectively, which is the same as the **Auto** mapping; that is, the embedded surface is located in the *xy*-plane, at $z = 0$.

ADVANCED

In this section you can see and edit the names of the space variables for the embedded geometry. Under **Space variables**, edit the default names `emb1x`, `emb1y`, and (2D only) `emb1z` in the **x'**, **y'**, and (2D only) **z'** fields if desired. You can use those variables when creating plots for the embedded data in the higher space dimension.

Extrusion 1D and Extrusion 2D

Use an **Extrusion 1D** ( ) or an **Extrusion 2D** ( ) dataset to extrude data in postprocessing from 1D to 2D and from 2D to 3D, respectively. Using these datasets, you can solve a problem more efficiently in a lower dimension and then extrude it for postprocessing, if the geometry is such that a linear extrusion is suitable.

Go to Common Results Node Settings for links to information about the **Data** section. The dataset can be any dataset with an output dimension equal to the extrusion dataset's dimension.

EXTRUSION

Use the **y minimum** and **y maximum** (for **Extrusion 1D** nodes) or **z minimum** and **z maximum** (for **Extrusion 2D** nodes) fields to define the range of the extrusion.

The value in the **Resolution** field is the number of layers added. The default is 10 layers; you must use at least 2.

You define the name of the variable in the extrusion direction in the **y variable** (for **Extrusion 1D** nodes) or **z variable** (for **Extrusion 2D** nodes) field. For the extrusion datasets, you can use the extrusion variable in the expressions that are being evaluated.

Under **Embedding** (**Extrusion 2D** nodes only), specify the extrusion direction using the **Map plane to** list, where you can choose **xy-plane** (the default), **xz-plane**, or **yz-plane**. Select the **Separate levels** checkbox for plotting data for each equidistant point in time, for example.

ADVANCED

This section is only available in Extrusion 2D datasets.

If needed, specify a value (SI unit: rad/m) in the **Out-of-plane wave number** field (default: 0). Doing so can be useful when postprocessing solid mechanics models with a specified out-of-plane mode extension.

For an Extrusion 2D example, and if you have the Structural Mechanics Module and the Wave Optics Module, see *Stress–Optical Effects with Generalized Plane Strain*: Application Library path **Structural_Mechanics_Module/Stress-Optical_Effects/stress_optical_generalized**.

Filter

Add a **Filter** ( ) node from the **Datasets** menu to create a dataset that filters data from another dataset using a lower or upper bound or both a lower and an upper bound. You also specify the expression that specify what part of the data that you want to filter. It is also possible to use a Filter dataset as the source for a mesh import (see Importing Meshes). It is then the result of the evaluation of the Filter dataset that is used. If needed, right-click to add a Mesh Import Parameters subnode.

Right-click the **Filter** node or click the **Attributes** menu in the **Results** toolbar to choose **Create Mesh in New Component** or **Create Mesh Part**. In both cases, an **Import** node is added to import the geometry that is the result of the filtering as a mesh from the dataset, in a new model component or as a mesh part, respectively.

Click the **Plot** button ( ) to visualize the filter dataset in a plot.

DATA

From the **Dataset** list, select a dataset that contains the data that you want to filter.

EXPRESSION

Enter or choose an expression for the quantity for which you want to apply a filter. See Common Results Node Settings for links to more information about the **Expression** section.

FILTER

From the **Bounds** list, choose the bounds for the filtering of the expression: **Lower** (the default), **Upper**, or **Lower and upper**. Depending on the chosen bounds, enter values for the bounds in the **Lower bound** and **Upper bound** fields.

Select a **Geometry level**: **Taken from dataset** (the default), **Volume**, **Surface**, **Line**, or **Point**. The default means the highest geometry dimension for the data in the dataset: typically volumes in 3D, surfaces in 2D, and lines in 1D. Select the **Propagate to lower dimensions** checkbox to make a geometry level of volumes, for example, also include their adjacent surfaces, lines, and points.

EVALUATION

Select a data **Smoothing** method — **None**, **Inside material domains** (the default, for smoothing within domains shared by the same material but not across material boundaries), **Inside geometry domains** (for smoothing within each geometry domain but not across interior boundaries), **Everywhere**, or **Expression**. If you choose **Expression**, enter an expression in the **Expression** field such that smoothing occurs where the expression is continuous. The default expression is `dom`, the domain variable, which is equivalent to the **Internal** smoothing. You can also — in a surface plot, for example — use `material.domain`, which is an indicator variable for domains that share the same material (see Material Group Indicator Variables) and is equivalent to the **Inside material domains** setting. For all **Smoothing** methods except **None**, you can also choose smoothing threshold, if needed. From the **Smoothing threshold** list, select **None** (the default), or select **Manual** to enter a relative smoothing threshold value (default: 0.1) in the **Threshold** field. The **Use derivatives** checkbox controls whether cubic (Hermite) interpolation is used when applying the filter and is selected by default. It can give a better-looking plot for most expressions.

Grid 1D, Grid 2D, and Grid 3D

Adding a **Grid 1D** (—), **Grid 2D** ( ), or **Grid 3D** node ( ) from the **More Datasets**, **More 2D Datasets**, or **More 3D Datasets** submenus creates a dataset that can evaluate functions or other datasets on a domain with a grid, including global functions also where there is no domain mesh; for example, you can evaluate BEM and far-field operators. All functions in the same list as the selected function can be evaluated. The domain is an interval for Grid 1D, a rectangle for Grid 2D, and a block for Grid 3D. The domain does not need to have the same dimension as the number of arguments to the function. To plot functions, use a line graph in 1D, for example, by pointing to the Grid 1D dataset in a 1D Plot Group (or similarly for Grid 2D and Grid 3D). Grid datasets always use the spatial frame when evaluating outside the meshed domain.

Click the **Plot** button ( ) to visualize the grid dataset in a plot.

DATA

From the **Source** list, select **Dataset** (the default) to evaluate an expression based on a solution dataset or select **Function** to evaluate a function.

For datasets, select an available solution dataset from the **Dataset** list, or select **None** to not use any dataset. It is only possible to evaluate globally defined expressions and expressions that depend on spatial coordinates. Using the `at`*`i`* operator with the extra argument `'mi'`, you can also access domain variables defined on domains where the grid points are located.

For functions, select the function to create a dataset for from the **Function** list: **None**, **All**, or any of the defined functions in the model. Select **All** to make the Grid dataset point to all functions in the list rather than to a specific function, which can be useful, for example, to plot several functions together in the same plot group.

For functions, there is also a **Refresh** button that you can click to update the source for functions that read files (Elevation, Image, and Interpolation).

The plot of the grid data uses the number of points specified in the **Resolution** section below, mixing uniformly distributed points with points taken from the function, including local minima and maxima.

PARAMETER BOUNDS

Available fields are based on the dimension of the Grid dataset. Enter a name for the parameter in the **Name** field. The **First parameter**, **Second parameter** (Grid 2D and Grid 3D), and **Third parameter** (Grid 3D only) default names are `x`, `y`, and `z`, respectively. For each parameter, enter a **Minimum** lower bound (the defaults are 0) and a **Maximum** upper bound (the defaults are 1) for the first; first and second; or first, second, and third dimension of the domain depending on the dimension.

GRID

Enter a **Resolution** (Grid 1D), **x resolution** and **y resolution** (Grid 2D), or **x resolution**, **y resolution**, and **z resolution** (Grid 3D). The resolution is the number of points into which each dimension is discretized. The defaults are `1000` (Grid 1D), `100` (Grid 2D), and `30` (Grid 3D), and the valid range is between 2 and 1,000,000 points.

A high resolution might require significant computational resources. For **Grid 1D** nodes, the **Adaptive** checkbox is selected by default to enable downsampling of 1D datasets by removing unnecessary evaluation points, which can improve graph plots in some cases.

From the **Point distribution** list, select **Uniform** (the default) for a uniform, linear point distribution, select **Exponential** for an exponential point distribution, or select **Mixed uniform/exponential**, which is an exponential distribution (uniform in logarithmic space) followed by a uniform distribution. The mixed distribution guarantees that the maximum relative distance between consecutive evaluation points is small regardless of whether the x-axis is linear or logarithmic.

ADVANCED

In this section, you can define auxiliary variables and their units. The auxiliary variables have the same value ranges as the parameters in the dataset, but it is possible to control their units explicitly. If activated, you can choose an auxiliary variable from the **Insert Expression** and **Replace Expression** menus for the x-axis expression in a **Function** plot, for example.

Select the Define auxiliary variables checkbox to define auxiliary variable for a grid dataset. Then enter names and units in the **Auxiliary variable** and associated **Unit** fields, under **First parameter** and **Second parameter** for Grid 2D datasets and under **First parameter**, **Second parameter**, and **Third parameter** for Grid 3D datasets.,

For an example of a 1D grid dataset and with the AC/DC Module, see *A Geoelectrical Forward Problem*: Application Library path **ACDC_Module/Devices,_Resistive/geoelectrics**.

Intersection Point 2D and Intersection Point 3D

Use an **Intersection Point 2D** ( ) or **Intersection Point 3D** ( ) dataset, found under the **More 2D Datasets** and **More 3D Datasets** submenus, to enable evaluation of expressions at the intersection points of particle or ray trajectories and a surface or to evaluate intersection points with a more general surface. You can use the Intersection Point datasets with the following plot nodes and derived value nodes: Particle Trajectories and Ray Trajectories; Particle

and Ray (1D plots); Particle Evaluation and Ray Evaluation; Point Trajectories; Histogram; Phase Portrait; Optical Aberration; and Aberration Evaluation.

Go to Common Results Node Settings for links to information about this section: **Data**. The dataset must point to a Particle or Ray dataset. For information about the **Extra Time Steps** section, see Extra Time Steps for Trajectory Plots and Intersection Point Datasets,

CURVE

This section is only available for Intersection Point 2D datasets.

From the **Curve type** list, you can specify that the intersection of the particle or ray trajectories with one of the following curves is taken:

- **Line** (the default)
- **Circle**
- **Semicircle**
- **General**

For each of these surface types, additional settings are available.

Line

For **Line** as the curve type, choose one of the following options from the **Line entry method** list:

- If you choose **Two points**, enter the coordinates of the two points that define the line in the **x** and **y** columns for **Point 1** and **Point 2**. If you want the line to be bounded by the points instead of extended beyond both points, select the **Bounded by points** checkbox (selected by default).
- If you choose **Point and directions**, enter the **x** and **y** coordinates for a point under **Point** and the **x** and **y** components of a direction vector under **Direction**.

If you want to create additional lines that are parallel to the line you defined, select the **Additional parallel lines** checkbox and enter the distances between each line in the **Distances** field, or click the **Range** button ( ) to define a range of distances.

Circle

For **Circle** as the curve type, you define the circle by entering its center coordinates in the **x** and **y** fields under **Center** and the radius in the **Radius** field.

Semicircle

For **Semicircle** as the curve type, you define the semicircle by entering its center coordinates in the **x** and **y** fields under **Center**, an axis direction in the **x** and **y** fields for the axis vector components under **Axis direction**, and the radius in the **Radius** field. The axis direction defines the extent of the semicircle as the segments of the circle perimeter where the scalar product with the axis direction vector is positive. For example, with the default axis direction $(0, 1)$, the semicircle consists of the circle perimeter where $y > 0$.

General

For defining a general curve, you enter a curve expression $F(\mathbf{r})$. The intersection points will be evaluated on the curve $F(\mathbf{r}) = 0$.

SURFACE

This section is only available for Intersection Point 3D datasets.

From the **Surface type** list, you can specify that the intersection of the particle or ray trajectories with one of the following surfaces is taken:

- **Plane** (the default)
- **Sphere**
- **Hemisphere**
- **General**

For each of these surface types, additional settings are available.

Plane

For **Plane** as the surface type, choose one of the following options from the **Plane type** list:

- If you choose **General** (the default), see the settings for the available plane entry methods below.
- If you choose **Quick**, you can choose one of **xy-planes**, **yz-planes**, **zx-planes**, **yx-planes**, **zy-planes**, or **xz-planes** from the **Plane** list. Depending on the selected plane's orientation, you can enter the **x-coordinate**, **y-coordinate**, or **z-coordinate** as an offset for the plane (default: 0).

For a **General** plane type, also choose one of the following options from the **Plane entry method** list:

- If you choose **Three points**, enter the coordinates of the three points that define the plane in the **x**, **y**, and **z** columns for **Point 1**, **Point 2**, and **Point 3**.
- If you choose **Point and normal**, enter the **x** and **y** coordinates for a point under **Point** and the **x** and **y** components of a direction vector under **Direction**.

If you want to create additional surfaces (planes) that are parallel to the plane you defined, select the **Additional parallel planes** checkbox and enter the distances between each plane in the **Distances** field, or click the **Range** button ( ) to define a range of distances.

Sphere

For **Sphere** as the surface type, you define the sphere by entering its center coordinates in the **x**, **y**, and **z** fields under **Center** and the radius in the **Radius** field.

Hemisphere

For **Hemisphere** as the surface type, you define the hemisphere by entering its center coordinates in the **x**, **y**, and **z** fields under **Center**, an axis direction in the **x**, **y**, and **z** fields for the axis vector components under **Axis direction**, and the radius in the **Radius** field. The axis direction defines the extent of the hemisphere as the parts of the sphere's surface where the scalar product with the axis direction vector is positive. For example, with the default axis direction (0, 0, 1), the hemisphere consists of the part of a full sphere where $z > 0$.

General

For a general surface, you enter a surface expression $F(\mathbf{r})$. The intersection points will be evaluated on the surface $F(\mathbf{r}) = 0$.

ADVANCED

Under **Space variables** (Intersection Point 3D only), you can change the name of the space variables **x** and **y** for the intersection surface's coordinates from their default values (`ip1x` and `ip1y`, for example).

Under **Normal variables**, enter or edit the variable names for the components of the normal vector — **nx**, **ny**, and **nz** (Intersection 3D) or **nx** and **ny** (Intersection Point 2D). The default names are `ipl1nx`, `ipl1ny`, and `ipl1nz`, respectively.

Select an option from the **Interpolation between time steps** list: **Linear** (the default) or **Cubic**. If the expressions being evaluated at the intersection point are differentiable, the **Cubic** interpolation method will take into account the

derivatives of these expressions at the time steps before and after the intersection point is reached. This allows expressions that do not vary linearly over time to be interpolated more accurately.

Intersection Point 2D and **Intersection Point 3D** datasets require the Particle Tracing Module or the Ray Optics Module.

Isosurface (Dataset)

Use an **Isosurface** ( ) dataset, found under the **More 3D Datasets** submenu, to visualize isosurfaces in 3D. Isosurfaces cannot be parameterized in general so use this dataset to create arrow surface plots, surface plots, and contour plots. The contour dataset can be applied to the isosurface dataset.

- Go to Common Results Node Settings for links to information about the **Data**, **Expression**, and **Levels** sections.
- Datasets

Join

Use a **Join** ( ) dataset to combine the solutions from two datasets. The Join dataset makes it possible to compare solutions from two datasets — for example, to evaluate and visualize the difference between two solutions to the same problem using two different meshes in a mesh convergence study or to create the sum over a parametric sweep that contains a few solutions. The Join dataset has predefined methods to combine the solutions to get the difference, norm of difference, product, quotient, or sum of the two solution datasets. In addition, two predefined "operators", `data1` and `data2`, correspond to the solution data in the first and second Solution dataset, respectively, and make it possible to compare, for example, solutions from different but compatible models or to combine the two solution datasets using a method other than the ones that you can select directly.

You can also use the `withsol` operator in a plot expression, for example, to combine solutions from different solver sequences. See `withsol` for more information.

When combining data from two meshes, the Join dataset searches for the points of one mesh in the other; the results are then combined. Note that this process is not symmetric.

Right-click a **Join** dataset node to add a **Selection** subnode if desired and if its two source datasets use the same geometry.

DATA 1 AND DATA 2

Select a dataset as `data1` and another dataset as `data2` from the **Data** lists in the **Data 1** and **Data 2** sections, respectively.

Select which solutions to use from the **Solutions** lists:

- Select **All** (the default) to use all solutions in the dataset.
- Select **One** to use one of the available solutions in a time-dependent, parametric, or eigenvalue solution from the list of solutions that appear underneath the **Solutions** list.

The following dataset combinations support the option to include all solutions from both datasets:

- Both datasets point to the same solution.
- Both datasets point to two different stationary solutions.
- Both datasets point to two different time-dependent solutions.

COMBINATION

In the **Method** list, select a method for combining the datasets:

- Select **Difference** (the default) to combine the datasets using a difference: `data1-data2`.
- Select **Norm of difference** to combine the datasets as `abs(data1-data2)`, where `data1` and `data2` are the results of evaluating the expression in the two source datasets. For complex-valued data, this corresponds to the Euclidean norm of the difference.
- Select **Explicit** to combine the datasets using an explicit expression with the "operators" `data1` and `data2` in, for example, a plot node's **Expression** field. This can be useful to compare two different dependent variables in two different datasets such as two solutions from two different models using the same geometry. For example, to plot the sum of the variable `u` from the first dataset and the variable `v` from the second dataset, times two, type `2*(data1(u)+data2(v))`. The scope for `data1` is the model to which the solution dataset under **Data 1** belongs, and similarly for `data2`.
- Select **General** to combine the datasets using a general expression in `data1` and `data2` that you type into the **Expression** field. The default, `data1-data2`, is identical to the **Difference** method. This method is useful for combining datasets with similar solution data (from a mesh convergence study, for example) using a method other than a difference, product, quotient, or sum.
- Select **Product** to combine the datasets using a product: `data1*data2`.
- Select **Quotient** to combine the datasets using a quotient: `data1/data2`.
- Select **Sum** to combine the datasets using a sum: `data1+data2`.

If you choose **Difference**, for example, an operation such as `sin(u)` for the **Join** dataset is equivalent to `sin(data1(u))-sin(data2(u))`. If you want to evaluate or plot `sin(u)` as the operator applied to the difference itself, for example, choose **Explicit** and use `sin(data1(u)-data2(u))` as the expression to evaluate or plot.

It can happen that the geometries in the two datasets do not match. In such cases, for example, **Join** datasets that contain data from a domain cannot be selected in a point plot. Also, selections are not supported when using **Join** datasets.

If you only want to compare the values of integrals over datasets, then you can achieve this using the **Transformation type** set to **Difference** in an **Evaluation Group** node, which provides better accuracy.

Kernel Density Estimation

Use a **Kernel Density Estimation** ( ) dataset, found under the **More Datasets** submenu, to take a table and compute the kernel density estimation (KDE), which is a nonparametric way to estimate the probability density function of a random variable.

DATA

From the **Dimension** list, choose a space dimension for the data: **1** (the default), **2**, or **3**.

From the **Source** list, choose **Table** (the default) or **Evaluation Group**, and then choose the table or evaluation group from the **Table** or **Evaluation group** list below.

Under **Columns**, choose which columns that should represent the coordinate values (1–3, depending on the chosen dimension) from the **x-coordinates**, **y-coordinates**, and **z-coordinates** list.

KERNEL

From the **Kernel type** list, choose which kernel to use: **Gaussian** (the default) or **Parabolic (Epanechnikov)**.

For the Gaussian (normal) kernel, the kernel $K_h(x)$ is computed as

$$K_h(x) = \frac{1}{h\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x}{h}\right)^2}$$

For the parabolic (Epanechnikov) kernel, the kernel $K_h(x)$ is computed as

$$K_h(x) = \begin{cases} \frac{3}{4h}\left(1 - \left(\frac{x}{h}\right)^2\right), & |x/h| \le 1 \\ 0, & |x/h| > 1 \end{cases}$$

The Epanechnikov kernel is optimal in a mean square error sense, although the loss of efficiency is small for the Gaussian (normal) kernel.

From the **Bandwidth** list, choose how to specify the bandwidth: **Auto (Silverman's rule of thumb)** (the default), to compute the bandwidth automatically using Silverman's rule of thumb, or **Manual**, to specify the bandwidth h as a scalar value in the case of 1 dimension. For 2 and 3 dimensions, specify the matrix components of the bandwidth H. The bandwidth matrix H must be symmetric, invertible (nonsingular), and positive definite.

Silverman's rule of thumb is designed to be used for the Gaussian kernel and cannot be expected to work similarly in other cases.

ADVANCED

Under **Input variables**, you can edit the names of the input variables that are created in the **x**, **y**, and **z** (depending on the dimension).

From the **Resolution** list, choose **Automatic** (the default) to use an automatically determined resolution, or choose **Manual** to define the resolution as a positive integer larger than 1 (default: 10) in the **x resolution**, **y resolution**, and **z resolution** fields (depending on the dimension).

Under **Output variable**, you can edit the name of the out variable for the KDE value in the **KDE value** field.

Layered Material

Use a **Layered Material** ( ) dataset, found under the **More Datasets** submenu, to create a volume or domain (3D) dataset corresponding to a layered shell physics defined using a surface or boundary (2D) geometry and a built-in

extra dimension (1D) geometry. This dataset is used to plot or evaluate the quantities on a domain level or its lower dimensions.

The Layered Material dataset requires the AC/DC Module, Composite Materials Module, Heat Transfer Module, Porous Media Flow Module, or Structural Mechanics Module. See the documentation for those products for more information about modeling using layered materials.

DATA

Select a **Dataset** that corresponds to a layered shell physics to create a volume or domain dataset. By default, a Layered Material dataset is active on all boundaries. Right-click the dataset and select **Add Selection** in order to restrict the selection and plot or evaluate quantities only on specified selection.

LAYERS

Select an **Evaluate in**: **Node points** (the default), **Interfaces**, or **Layer midplanes**.

In case **Node points** is selected, a domain dataset is created and a surface plot using this dataset plots on the exterior boundaries of the layered shell domain. In order to have better visualization inside a layered shell, select the **Separate levels** checkbox. This setting creates slices on the node points in the through-thickness direction. Increase the **Refinement** (default: 1) to have more evaluation points in the through-thickness direction.

In case **Interfaces** or **Layer midplanes** is selected, slices are created in the domain either at the interface between the two successive layers or in the middle of each layer, respectively.

Specify **Scale** (default: 1) to increase the thickness of a layered shell keeping the other geometric dimensions unchanged. This is particularly useful to analyze the through-thickness behavior in thin layered shells.

Under **Layer selection**, choose the layers or interfaces to include in the dataset. Select the **User all layers** checkbox if desired. If that checkbox is not selected and model contains several shells, then you can specify what shell to make layer or interface selections for from the **Layered material** list. Then, in case **Mesh vertices** or **Layer midplanes** are selected, choose the layers to include in the dataset. In case **Interfaces** is selected, then under **Interface selection**, choose the layer interfaces to include in the dataset. In both cases, all layers or layer interfaces are selected by default.

In all cases, use the **Save Layers to File** ( ), **Load Layers to File** ( ), **Set All** ( ), **Clear All** ( ), **Copy Selection** ( ), and **Paste Selection** ( ) buttons as desired for making the desired selection of layers or layer interfaces.

Maximum and Minimum

Select the **Maximum** evaluation (MAX) or **Minimum** evaluation (MIN) dataset, found under the **More Datasets** submenu, to create a dataset that computes the maximum or minimum of another dataset.

DATA

Select a **Dataset** for the data to compute the maximum or minimum. To compute the maximum or minimum for a **Solution** dataset, use a **Selection** to define the geometric entity (point, boundary, edge, or domain) to integrate over. Right-click the dataset and select **Selection**.

SETTINGS

Select a **Geometry level**: **Taken from dataset** (the default), **Volume**, **Surface**, **Line**, or **Point**. The default means the highest geometry dimension for the data in the dataset: typically volumes in 3D, surfaces in 2D, and lines in 1D.

Select the evaluation point type from the **Point type** list:

- **Lagrange points** (the default) to evaluate the maximum or minimum value in the Lagrange points. Select a **Lagrange order** (default: 5; the Lagrange order is the number of partitions of an element edge) to adjust the accuracy of the minimum or maximum values.
- **Mesh vertices** to evaluate the maximum or minimum value in the mesh vertices of the extended mesh.
- **Integration points** to evaluate the maximum or minimum value in the integration points. Select an **Integration order** (default: 4) to adjust the accuracy of the minimum or maximum values.

Mesh (Dataset)

Add a **Mesh** ( ) dataset to make a mesh available for visualization and results analysis, typically for mesh-related quantities such as the mesh element quality, which is possible to plot using a mesh dataset without computing a solution. Use a **Mesh** node in a plot group to get a plot of the actual mesh. You can right-click the **Mesh** dataset node to add a **Selection** subnode if desired or to add **Data** or **Mesh** subnodes under **Export**.

MESH

Select the **Mesh** to use as the data from the list. The list includes meshes in the model, including possible meshes created for extra dimensions by the physics interfaces (listed as **Derived Mesh**, for example).

The setting in the **Geometry shape function** list determines the shape function and order of the curved mesh elements that determine the geometry shape. Select one of the following geometry shape functions: **Linear Lagrange**, **Quadratic Lagrange**, **Cubic Lagrange**, **Quartic Lagrange**, **Quintic Lagrange**, **Sextic Lagrange**, **Septic Lagrange**, **Linear serendipity**, **Quadratic serendipity**, **Cubic serendipity**, or **Quartic serendipity**. The default geometry shape function is **Linear Lagrange**, but if you, for example, want to use the curved skewness mesh quality measure, then you need to use a higher-order geometry shape function.

Mirror 2D and Mirror 3D

Use a **Mirror 2D** ( ) dataset to extend a solution defined on one side of an axis to the other side of the axis. This can be useful for visualization of a solution to an axisymmetric problem. Use a **Mirror 3D** ( ) dataset to extend a solution defined on one side of a plane to the other side of a plane. They are selected from the **More 2D Datasets** and **More 3D Datasets** submenus. Right-click a **Mirror 2D** or **Mirror 3D** dataset node to add a **Selection** subnode if desired.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Axis Data** (Mirror 2D), and **Plane Data** (Mirror 3D).

	Generally, operations on vector quantities using the mirror dataset work if you use the Mirror dataset directly from the plot but do not work if you use it indirectly with another dataset in between. For example, use a mirror of a cut dataset operation order rather than a cut of a mirror.

ADVANCED

Select the **Define variables** checkbox to create a **Positive side indicator** variable. The default, `mir1side`, is 1 in the original domain and 0 in the mirror. Use the **Positive side indicator** variable in the **Expression** section of a plot **Settings** window to exclude quantities from the mirror side. Under **Space variables**, enter or edit the variable names for the mirrored coordinate system. Enter or edit the **x**, **y**, and **z** (Mirror 3D only) variable names in the respective fields. The default names are `mir1x`, `mir1y`, and mir1z, respectively.

From the **Vector transformation** list, choose **Symmetric** (the default) or **Antisymmetric**. The symmetric transformation negates the vector component orthogonal to the symmetry axis or plane. The antisymmetric transform negates the vector components parallel to the symmetry axis or plane. The latter option can be useful for visualizing models with odd symmetry.

The **Vector transformation** setting only affects how vector entities are transformed by the Mirror dataset (for example, for arrow plots, streamline plots, and **Deformation** subnodes). It does not have any effect in scalar plots such as surface plots.

If desired, select the **Remove elements on the symmetry plane** checkbox to not include and elements that lie on the symmetry plane.

- For a Mirror 3D example, and with the Chemical Reaction Engineering Module, see *Steam Reformer*: Application Library path **Chemical_Reaction_Engineering_Module/Reactors_with_Porous_Catalysts/steam_reformer**.
- For a Mirror 2D example, and with the Plasma Module, see *DC Glow Discharge*: Application Library path **Plasma_Module/Direct_Current_Discharges/positive_column_2d**.

Parametric Curve 2D and Parametric Curve 3D

Use a **Parametric Curve 2D** ( ) or **Parametric Curve 3D** ( ) dataset to visualize data along a general parametric curve. Visualize the parametric curve as a line plot in its original space dimension (2D or 3D) and as a line graph plot in 1D. Parametric Curve datasets always use the spatial frame when evaluating outside the meshed domain. Select these options from the **More 2D Datasets** and **More 3D Datasets** submenus.

Go to Common Results Node Settings for links to information about the **Data** section.

PARAMETER

Enter a **Name** and the **Minimum** and **Maximum** range of the parameter curve. You can use numbers, parameters, and solution-dependent expressions for the range limits.

EXPRESSIONS

Enter functions for the coordinates of the parameter. For Parametric Curve 2D, enter values in the **x** and **y** fields. For Parametric Curve 3D, enter values in the **x**, **y**, and **z** fields.

If the expressions contain any global parameters, you must do an update of the current solution or re-solve the model before using the dataset.

If you want to evaluate an expression defined globally where there is also no domain mesh, select the **Only evaluate globally defined expressions** checkbox. It is then possible to, for example, postprocess a BEM model without a domain mesh inside the domain. The expressions that you can evaluate with this setting can be functions of the space variables and the domain variable `dom`.

In 3D, select the **Snap to closest boundary** checkbox to snap the selected points to the closest boundary in the geometry. Use this option when evaluating a variable that is available on boundaries but not in domains. Otherwise,

leave the snapping off (the default setting) to avoid the additional computational cost. However, snapping always happens if the underlying dataset has a shell geometry.

RESOLUTION

Enter the number of subdivisions of the parameter range. The default **Resolution** is 1000, and the valid range is between 2 and 1,000,000 subdivisions. A high resolution might require significant computational resources.

ADVANCED

Tangent variables are created for these dataset. Under **Tangent variables**, you can change the default names (`pc1tx`, `pc1ty`, and `pc1tz`, for example, in 3D) in the **tx**, **ty**, and **tz** fields. The tangent vectors defined using these variables have unit length.

For a Parametric Curve 3D example, and with the Heat Transfer Module, see *Radiative Heat Transfer in Finite Cylindrical Media*: Application Library path **Heat_Transfer_Module/Verification_Examples/cylinder_participating_media**.*Results Analysis and Plots*

Parametric Surface

Use a **Parametric Surface** ( ) dataset, selected from the **More 3D Datasets** submenu, to visualize data on a general parametric surface. Parametric Surface datasets always use the spatial frame when evaluating outside the meshed domain. You can visualize the parametric surface as a surface plot in its original dimension and as any plot type in 2D.

Go to Common Results Node Settings for links to information about the **Data** section.

PARAMETERS

Enter a **Name** and a range of the parameter in the **Minimum** and **Maximum** fields for both the **First parameter** and **Second parameter** fields. You can use numbers, parameters, and solution-dependent expressions for the range limits.

EXPRESSIONS

Enter functions for coordinates of the two parameters in the **x**, **y**, and **z** fields.

If the expressions contain any global parameters, you must do an update of the current solution or re-solve the model before using the dataset.

If you want to evaluate an expression defined globally where there is also no domain mesh, select the **Only evaluate globally defined expressions** checkbox. It is then possible to, for example, postprocess a BEM model without a domain mesh inside the domain. The expressions that you can evaluate with this setting can be functions of the space variables and the domain variable `dom`.

RESOLUTION

Enter the number of subdivisions of the parameter ranges. The default **Resolution** is 200, and the valid range is between 2 and 1,000,000 subdivisions. A high resolution might require significant computational resources.

Parametric Extrusion 1D and Parametric Extrusion 2D

Use a **Parametric Extrusion 1D** ( ) or **Parametric Extrusion 2D** ( ) dataset to extend another dataset by using a parameter, such as time, as a dimension. Select these from the **More Datasets** and **More 2D Datasets** submenus.

SETTINGS

From the **Level transformation** list, select **None** (the default) to use no transformation of the extrusion level, or select **Expression** to enter an expression in the **Transformation expression** field. The default expression is `level`, which is a predefined variable for the extrusion level (that is, no transformation). You can instead use an expression that is a function of `level`, such as `log10(level)` for a logarithmic transformation to create a directivity plot, for example.

Select the **Level scale factor** checkbox to edit the field. The default factor value is 1. The level scale factor applies to the transformed levels. The **Separate levels** checkbox is selected by default for plotting data for each equidistant point in time, for example.

Go to Common Results Node Settings for links to information about the **Data** section.

For a 1D Parametric Extrusion example, see *The KdV Equation and Solitons*: Application Library path **COMSOL_Multiphysics/Equation_Based/kdv_equation**.

Particle (Dataset)

Use a **Particle** ( ) dataset, selected from the **More Datasets** submenu, to visualize particle traces computed by a Particle Tracing Module interface. The Particle dataset is automatically created when solving a model containing one of the Particle Tracing Module interfaces if the **Generate default plots** option is selected in the **Study**. Selections can be added to the particle dataset, which makes it possible to compute, for example, the number or fraction of particles in a given domain or on a given boundary during results processing. You can visualize the particles using a plot of the particle trajectories in the original dimension, as a Poincaré map, or as a 2D phase portrait.

PARTICLE SOLUTION

Select a **Solution** from the list of solution data. Select a **Particle geometry specification**: **Manual** (the default) or **From physics interface**. If any particle trajectories have been solved for, then instead **From physics interface** is the default and an applicable particle tracing physics interface is selected from the **Physics interface** list (see below).

If **Manual** is selected, the **Particle geometry** and **Position-dependent variables** text fields become available. In the **Particle geometry** field, enter the name of the variable for the particle geometry. This corresponds to the hidden geometry on which the particle degrees of freedom are computed. When the Particle dataset is generated from the default plots, the correct name for the particle geometry is filled in automatically. The particle geometry takes the name `pgeom_<id>`, where `<id>` is the Name for the specific Particle Tracing interface node.

In the **Position-dependent variables** field, enter the names of the dependent variables for the particles' position using commas to separate the variables. Like the particle geometry, the names of the particle degrees of freedom are filled in automatically when the particle dataset is generated from the default plots. The names correspond to the particle position degrees of freedom with the component name prepended. For example, for a 3D component, with name `comp1` and dependent variables `qx`, `qy`, and `qz` for the physics interface, the correct expression to enter is `comp1.qx`, `comp1.qy`, and `comp1.qz`.

If **From physics interface** is selected, select the **Physics interface** from which the particle geometry and the names of the particle position degrees of freedom are defined. Only physics interfaces that can create a valid particle geometry are shown.

Particle datasets require the Particle Tracing Module.

If you have the AC/DC Module and the Particle Tracing Module, see *Magnetic Lens*: Application Library path **ACDC_Module/Electromagnetics_and_Particle_Tracing/magnetic_lens**.

Particle Bin

Use a **Particle Bin** ( ) dataset, selected from the **More Datasets** submenu, to organize particles into groups and treating each group as a single entity for the purpose of using other particle postprocessing features. This dataset always takes a Particle (Dataset) as input.

EXPRESSION

See Expressions and Predefined Quantities for information about the settings for defining an expression to be evaluated. The value of this expression is used as a criterion for organizing particles into bins. The options in the **Bins** section below determine how the value of this expression is organized into subintervals.

Then, if this dataset is used in place of a Particle (Dataset) in any other Results feature, all particles in each bin are replaced by a single macroparticle having position and other properties that are the average over all particles in the bin.

BINS

Choose one of the following from the **Entry method** list: **Limits**, **Number of bins** (the default), or **Tolerance**.

- For **Limits**, enter a list of values directly, or use the **Range** button ( ). All particles whose expressions evaluate to a number between the same limits, are put into the same bin.
- For **Number of bins**, enter the **Number of bins**. The default is 10. Then select one of the following from the **Distribution** list: **Equal number of particles** or **Equal bin width**. The limits for each bin are computed so that they lie between the largest and smallest values of the expression over all particles.
- For **Tolerance** enter the **Tolerance**. Particles are typically placed in the same bin if the difference between their expression values is less than the tolerance. This is a convenient option when the value of the expression should take on any of a large number of discrete values, since you can simply specify a small tolerance and then a single bin is created for each discrete value.

Particle Bin datasets require the Particle Tracing Module.

Partition

Use a **Partition** dataset ( ), select from the **More Datasets** submenu, to partition a domain with respect to a set of isolevels and add elements corresponding to the isosurfaces or contours. It is also possible to use a Partition dataset as the source for a mesh import (see Importing Meshes). It is then the result of the evaluation of the Partition dataset that is used. If needed, right-click to add a Mesh Import Parameters subnode.

Right-click the **Partition** node or click the **Attributes** menu in the **Results** toolbar to choose **Create Mesh in New Component** or **Create Mesh Part**. In both cases, an **Import** node is added to import the geometry that is the result of the partitioning as a mesh from the dataset, in a new model component or as a mesh part, respectively.

Go to Common Results Node Settings for links to information about the **Data** and **Expression** sections.

PARTITION

From the **Entry method** list, choose **Number of levels** (the default) and then enter the total number of levels in the **Total levels** field (default: 1) and clear or select the **Round the levels** checkbox (selected by default) if desired. Alternatively, choose **Levels** and then enter the desired isolevels in the **Levels** field.

By default, the **Geometry level** list is set to **From dataset**. If desired, choose **Volume**, **Surface**, **Line**, or **Point** instead. The **Propagate to lower dimensions** checkbox is selected by default; clear it if you do not want the partitioning to propagate.

EVALUATION

Select a data **Smoothing** method — **None**, **Inside material domains** (the default, for smoothing within domains shared by the same material but not across material boundaries), **Inside geometry domains** (for smoothing within each geometry domain but not across interior boundaries), **Everywhere**, or **Expression**. If you choose **Expression**, enter an expression in the **Expression** field such that smoothing occurs where the expression is continuous. The default expression is `dom`, the domain variable, which is equivalent to the **Internal** smoothing. You can also — in a surface plot, for example — use `material.domain`, which is an indicator variable for domains that share the same material (see Material Group Indicator Variables) and is equivalent to the **Inside material domains** setting. For all **Smoothing** methods except **None**, you can also choose smoothing threshold, if needed. From the **Smoothing threshold** list, select **None** (the default), or select **Manual** to enter a relative smoothing threshold value (default: 0.1) in the **Threshold** field. The **Use derivatives** checkbox controls whether cubic (Hermite) interpolation is used when applying the filter and is selected by default. It can give a better-looking plot for most expressions.

ADVANCED

Under **Advanced**, define the name of the **Part variable**: By default, it is `part1part`. It evaluates to 0, 1, and so on for the parts that the geometry is split into. For example, you can create a surface plot of `part1part` to visualize that numbering.

Pipe

Use a **Pipe** ( ) dataset, selected from the **More Datasets** submenu, for visualizing pipe networks by providing a 3D representation of the pipes, with a correct visualization of their shape. The dataset forms a 3D mesh and evaluates expressions for all vertices of the mesh. It can handle variations in the shape of the cross section along the pipes' length. The pipes must have a defined cross section in the physics interfaces, and it must be a 3D model if you want to use it directly. For a 2D pipe model, you can use an Embed 2D dataset and then refer to that dataset in the Data section.

Go to Common Results Node Settings for links to information about the **Data** section.

PIPE PHYSICS

From the **Physics interface** list, choose **All** (the default) to use pipe physics from all applicable physics interfaces, or choose any applicable physics interface. **All** is useful to visualize the 3D geometry (while evaluating a trivial

expression like 0), but that option will fail to evaluate variables that are defined locally inside each physics interface. **Selection** subnodes can also be used to select the edges that the intended physics is using.

CROSS SECTION

Enter a scaling of the beam as a scalar value in the **Scale** field (default: 1).

Enter a refinement as an integer between 1 and 5 in the **Refinement** field (default: 2).

If desired, you can change the value in the **Walls relative tolerance** field (default: 10^{-4}). This value is used for the definition of the internal walls inside pipes and must be greater than a similar value defined in the physics.

SPACE VARIABLES

In this section, you create variables that evaluate to the coordinates in the dataset's coordinate system. Enter variable names in the **x′**, **y′**, and **z′** fields (the default names of the space coordinates are `pipe1x`, `pipe1y`, and `pipe1z`, respectively, for the first **Pipe** dataset).

Ray (Dataset)

Use a **Ray** dataset ( ), selected from the **More Datasets** submenu, to visualize ray traces computed by a Geometrical Optics or Ray Acoustics interface. The Ray dataset is automatically created when solving a model containing one of the interfaces if the **Generate default plots** option is selected in the **Study**. Selections can be added to the Ray dataset, which makes it possible to compute, for example, the number or fraction of rays in a given domain or on a given boundary during results processing.

RAY SOLUTION

Select a **Solution** from the list of solution data. Select a **Ray geometry specification**: **Manual** (the default) or **From physics interface**. If any ray trajectories have been solved for, then instead **From physics interface** is the default and an applicable Geometrical Optics or Ray Acoustics interface is selected from the **Physics interface** list (see below).

If **Manual** is selected, the **Ray geometry** and **Position-dependent variables** text fields become available. In the **Ray geometry** field, enter the name of the variable for the ray geometry. This corresponds to the hidden geometry on which the ray degrees of freedom are computed. When the Ray dataset is generated from the default plots the correct name for the ray geometry is filled in automatically. The ray geometry takes the name `pgeom_<id>`, where `<id>` is the name for the specific physics interface node.

In the **Position-dependent variables** field, enter the names of the dependent variables for the rays' position using commas to separate the variables. Like the ray geometry, the names of the ray degrees of freedom are filled in automatically when the Ray dataset is generated from the default plots. The names correspond to the ray position degrees of freedom with the component name prepended. For example, for a 3D component, with name `<comp1>`, and **Dependent Variables** `qx`, `qy`, and `qz` for the physics interface, the correct expression to enter is `comp1.qx`, `comp1.qy`, and `comp1.qz`.

If **From physics interface** is selected, select the **Physics interface** from which the ray geometry and the names of the ray position degrees of freedom are defined. Only physics interfaces that can create a valid ray geometry are shown.

Ray datasets require the Ray Optics Module or Acoustics Module.

Ray Bin

Use a **Ray Bin** ( ) dataset, selected from the **More Datasets** submenu, to organize rays into groups and treating each group as a single entity for the purpose of using other ray tracing features. This dataset always takes a Ray (Dataset) as input.

EXPRESSION

See Expressions and Predefined Quantities for information about the settings for defining an expression to be evaluated. The value of this expression is used as a criterion for organizing rays into bins. The options in the **Bins** section below determine how the value of this expression is organized into subintervals.

Then, if this dataset is used in place of a Ray (Dataset) in any other Results feature, all rays in each bin are replaced by a single ray having position and other properties that are the average over all rays in the bin.

BINS

Choose one of the following from the **Entry method** list: **Limits**, **Number of bins** (the default), or **Tolerance**.

- For **Limits**, enter a list of values directly, or use the **Range** button ( ). All rays whose expressions evaluate to a number between the same limits, are put into the same bin.
- For **Number of bins**, enter the **Number of bins**. The default is 10. Then select one of the following from the **Distribution** list: **Equal number of particles** or **Equal bin width**. The limits for each bin are computed so that they lie between the largest and smallest values of the expression over all rays.
- For **Tolerance** enter the **Tolerance**. Rays are typically placed in the same bin if the difference between their expression values is less than the tolerance. This is a convenient option when the value of the expression should take on any of a large number of discrete values, since you can simply specify a small tolerance and then a single bin is created for each discrete value.

Ray Bin datasets require the Ray Optics Module or Acoustics Module.

Receiver 2D and Receiver 3D

Use a **Receiver 2D** ( ) or **Receiver 3D** dataset ( ), selected from the **More 2D Datasets** submenu and the **More 3D Datasets** submenu, respectively, to collect the data necessary to visualize the impulse response for a Ray Acoustics simulation (of room acoustics, for example), using an **Impulse Response** plot node in a 1D plot group. The **Impulse Response** node uses the data from a **Receiver** dataset as input.

See Common Results Node Settings for links to information about the **Data** section.

RECEIVER

The receiver is specified as a sphere with a radius, located at a center position (the microphone needs to have a certain finite size such that there is a reasonable probability of rays interacting with it).

Under **Center**, specify the **x**, **y**, and (3D only) **z** coordinates for the center of the receiver.

Under **Radius**, specify the radius of the receiver. From the **Radius input** list, choose **Variable size (large room volume)** to determine the radius using an expression (see below), or choose **Fixed size** to enter a value for the radius in the **Radius** field (SI unit: m).

The following expression determines the radius R of the receiver in room acoustics applications:

$$R = \log_{10}(V) d_{\mathrm{SR}} \sqrt{\frac{4}{N}}$$

where you enter the values for the **Number of rays**, N; **Room volume**, V (SI unit: m^2); and **Source-receiver distance**, d_{SR} (SI unit: m), to determine the radius. This computed receiver size is optimized for modeling of large rooms. However, it will return a different value for each source-receiver pair if there are multiple sources and receivers present in the simulation, and it will not necessarily correspond to the dimensions of a listener.

DIRECTIVITY

From the **Directivity type** list, choose **Omnidirectional** (the default), **User defined (dB)**, or **User defined (linear)** too enter a directivity expression in the **Expression** field either as a gain in dB or a linear gain. The linear gain option also allows the input to be negative, which corresponds to a shift in phase. Click the **Replace Expression** ( ) button to choose an expression from available predefined expressions.

EXTRA TIME STEPS

An impulse response plot requires a precise evaluation of arrival times. You can control the added extra time steps from the **Maximum number of extra time steps rendered** list:

- Choose **All** (the default) to render all extra time steps. This setting is the preferred and most efficient.
- Choose **Specified number of times** to enter a maximum number of steps in the **Maximum number of extra time steps** field (default: 100).
- Choose **Proportional to the number of solution times** to enter a factor in the **Proportionality factor** field. The proportionality factor is a positive integer.
- Choose **None** to not add any extra time steps.

ADVANCED

From the **Interpolation between time steps** list, you can choose to use a **Linear** interpolation (the default) or a **Cubic** interpolation, which can be more exact but requires a larger computational effort.

Under **Normal variables** and **Other variables**, if desired, you can change the default names of the created variables for the normal directions (**nx**, **ny**, and, in 3D, **nz**) and for the **Distance traveled** by a ray inside the receiver, the **Volume** of the receiver, the **Directivity**, and the **First ray arrival time**.

Receiver datasets require the Acoustics Module.

Response Spectrum 2D and Response Spectrum 3D

Use a **Response Spectrum 2D** ( ) or **Response Spectrum 3D** ( ) dataset selected from the **More 2D Datasets** and **More 3D Datasets** submenus, respectively, to perform a response spectrum analysis for a structural mechanics model. A response spectrum analysis is a modal-based method for estimating the structural response to a transient, nondeterministic event. Typical applications are designing against earthquakes and shocks.

DATA

The input to a response spectrum is the results from an eigenfrequency computation, which you choose as one of the existing solution datasets from an eigenfrequency study, available in the **Eigenfrequency dataset** list.

When you have selected a value other than **None** from the **Mass correction** list, you also need to include a number of stationary load cases. In those cases, also choose an applicable solution from the **Missing mass load cases dataset**

list. Computing the stationary load cases used here requires a special technique, as described in Performing a Response Spectrum Analysis in the *Structural Mechanics Module User's Guide*.

It is also possible to sum the response spectrum results with a stationary solution. If the checkbox **Add static solution** in the **Static Solution** section is selected, then you can also select a **Static solution** dataset.

SPECTRA

In this section you specify the spectra used as loading for the response spectrum evaluation ("design response spectra"). The spectra must be defined as functions under either the **Global** node or under **Definitions** in a component. Spectra are commonly provided as functions of either natural frequency or period time. This is just an inversion of the abscissa, but you have the option to use either form.

From the **Spectrum type** list, choose a type for the spectrum: **Pseudoacceleration spectrum** (the default), **Displacement spectrum**, or **Pseudovelocity spectrum**.

From the **Depends on** list, choose **Frequency** (the default) or **Period time** to specify how the spectrum function is defined.

	The functions you reference for the spectra are taken as entered, without any unit conversions. Thus, it is not meaningful to modify the unit fields available in the settings for many types of functions. The argument to the function is always either seconds or Hertz, depending on the choice in the **Depends on** list.

In a **Response Spectrum 2D** node, also specify the following settings:

- From the **Horizontal spectrum** list, choose any available user-defined function that represents the horizontal response spectrum.
- From the **Vertical spectrum** list, choose any available user-defined function that represents the vertical response spectrum.

In a **Response Spectrum 3D** node, also specify the following settings:

- From the **Primary horizontal spectrum** list, choose any available user-defined function that represents the primary horizontal spectrum. As a default, the primary spectrum acts along the global X-axis.
- From the **Secondary horizontal spectrum** list, choose any available user-defined function that represents the secondary horizontal spectrum. The secondary horizontal spectrum acts in a direction orthogonal to the primary horizontal spectrum. This option is only available when the **Spatial combination** method is **SRSS** or **Percent method**.
- In the **Primary axis rotation** field, enter a primary axis rotation (in degrees). This is the counterclockwise rotation in the XY-plane from the X-axis to the direction in which the primary horizontal spectrum acts. The allowed range is 0–90 degrees. This option is only available when the **Spatial combination** method is **SRSS** or **Percent method**.
- From the **Vertical spectrum** list, choose any available user-defined function that represents the vertical spectrum.

COMBINATION

The combination of the modes in the response spectrum method is in general done in two passes. First, all modes are combined into a response for each spatial direction of excitation, and then the result for the two or three directions are combined into a final result. There are, however, also evaluation methods where the total result is computed directly.

From the **Spatial combination** list, choose one of the following combination methods:

- The **SRSS** method (the default). This combination method uses the square root of the sum of the squares.

- The **Percent method**. In this method, the contribution from the worst direction is taken at full value, whereas the two (in 2D: one) other contributions are reduced. There are two variants in commonly in use, the 40% (100-40-40) method and the 30% (100-30-30) method. You enter the percentage for the reduced contributions in the **Weight factor for smaller response** field (default: `40[%]`).
- The **CQC3** method (for **Response Spectrum 3D** datasets only). The CQC3 method extends the CQC (complete quadratic combination) principles to the spatial combination. In the CQC3 method, the modal and spatial combination are performed simultaneously. When you have selected this method, enter a **Secondary horizontal spectrum scale factor** (default: 0.5). In this method, the secondary horizontal spectrum is taken to differ from the primary horizontal spectrum only by this constant scalar factor. Also, select the **Augment with rigid response** checkbox to include the rigid response if desired.
- The **SRSS3** method (for **Response Spectrum 3D** datasets only). The SRSS3 method is a special case of the CQC3 rule, in which the mode correlation is ignored. This method has the same additional settings as the CQC3 method.

For the **SRSS** and **Percent method** options, you need to decide on a method for the modal combination. From the **Mode combination** list, choose a method for combining the modes:

- The **CQC (Der Kiureghian)** method uses CQC (complete quadratic combination) with a Der Kiureghian correlation coefficient determining the degree of interaction between the modes. The coefficient depends on the damping and spacing between the frequencies.
- The **Absolute value sum** method uses the sum of absolute values of the modes. This is a highly conservative method since it assumes that all modes reach their peak values at the same time.
- The **SRSS** (square root of sum of squares) method does not include any interaction between the modes and is applicable only when the eigenfrequencies for the used modes are well spaced.
- The **Double sum (Rosenblueth)** method uses a double sum with a Rosenblueth correlation coefficient. This method resembles the CQC method in that the coupling between the modes depends on the damping and eigenfrequency spacing, but it also takes the duration of the event into account.
- The **Grouping method** uses a scheme where grouping of modes are created based on the proximity eigenfrequencies. Within each group, the modes are assumed to interact completely, while there is no interaction between modes in different groups.
- The **Ten percent method** assumes that modes interact if their natural frequencies differ by less than 10%.

Depending on the method that you have selected from the **Mode combination** list, the following additional settings are available:

Enter a **Damping ratio** (as a value between 0 and 1; the default is 0.05) for the CQC3, CQC (Der Kiureghian), and Double sum (Rosenblueth) methods. For the latter, also enter a time of duration (in seconds) in the **Time of duration** field (default: 0).

Select the **Use absolute value for coupling terms** checkbox to use a more conservative assumption that the combination of two modes always gives a positive contributions to the total response. Without this assumption, the signs of the modal contributions are respected. This setting is available for **CQC (Der Kiureghian)**, **Grouping method**, and **Ten percent method**. For the **Double sum (Rosenblueth)** method, you can select the corresponding **Use absolute value for coupling terms (NRC RG 1.92 Rev. 1)** checkbox. Later versions of NRC RG 1.92 state that the sign of the

contribution should be respected, so this option is available only for compatibility with the first version of this regulatory guide.

Respecting the sign of the coupling contributions is strictly speaking correct only when the result quantity is a linear function of the eigenmodes. This includes components of displacement, velocity, and acceleration vectors, as well as components of stress and strain tensors.

Nonlinear quantities like total displacement and equivalent stress measures are always positive irrespective of the sign of the underlying mode shapes, so for such quantities you should consider selecting the **Use absolute value for coupling terms** checkbox in order to ensure a conservative result.

For all mode combination methods, the following settings are available:

From the **Rigid modes** list, choose **None** (the default), **Gupta**, or **Lindley-Yow**. Some standards require a classification of the modes based on the natural frequency, where modes of with higher frequencies ("rigid modes") are assumed to have a higher degree of correlation to each other. For the two methods that address this, Gupta and Lindley-Yow, additional settings are available:

Specify a **Frequency limit for pure periodic modes** (SI unit: 1/s). The default is 0. This is the frequency below which the modes are assumed to be fully periodic, and thus have the least degree of correlation. For the Lindley-Yow method, modes can be fully periodic even at higher frequencies, since there is an additional requirement stating that the acceleration spectrum must be monotonically decreasing before modes are considered to have a rigid part.

Specify a **Frequency limit for pure rigid modes** (SI unit: 1/s). The default is 0. For the Gupta method only. This is the frequency above which the modes are assumed to follow the base support acceleration as a rigid body, even if there can be some amplification.

Specify a **Zero period acceleration frequency** (SI unit: 1/s). The default is 0. This is the frequency above which there is no periodic response, and the acceleration is equal to that of the excitation. For the Gupta method, this value is ignored, unless you also select to use the missing mass method.

In general, a mode superposition using a limited number of modes will miss some mass. With the assumption that the higher-order modes do not have any dynamic amplification, it is possible to device a correction by solving some extra static load cases, containing the acceleration excitation acting on the "lost mass".

From the **Mass correction** list, choose one of the following options:

- **None** (the default).
- **Missing mass method**. In this model, the missing mass is computed from the eigenmodes as a distributed field over the structure, which can be seen as mass density distribution. This mass density is then used in stationary analysis to compute the extra displacements at a certain frequency. When you select this option, you must also select a stationary study in the **Missing mass load cases dataset** list.
- **Static ZPS method** (for Lindley-Yow only). In this method, there is no need to actually deduce the true missing mass. According to the Lindley-Yow method, all rigid modes have the acceleration at the zero period acceleration frequency, S_{ZPA}. This acceleration is given to the whole structure. The static load cases are thus just pure gravity loads but scaled by S_{ZPA} instead of the acceleration of gravity. When you select this option, you must also select a stationary study in the **Missing mass load cases dataset** list.

STATIC SOLUTION

Select the **Add static solution** checkbox to add another solution to the response spectrum results. The most common case would be the contribution from a self-weight load case. You can, however, add any type of real-valued solution, for example, a certain time step from a time-dependent study, or the solution for a certain parameter in a stationary study having an auxiliary sweep.

When **Add static solution** is selected, you select the dataset containing the static solution in the **Data** section.

The response spectrum solution does not contain any direction information – it is always positive. The actual sign of any quantity is unknown. It is important that the summation with the static solution is done using appropriate assumptions about interaction. Select a **Sign of response spectrum solution** — **Same as static solution**, **Positive**, or **Negative**. In most cases, summing with the same sign for the static solution and the response spectrum solution will give the most conservative value.

Response Spectrum 2D and **Response Spectrum 3D** datasets require the Structural Mechanics Module.

- For information about how to set up studies for response spectrum analysis, see Performing a Response Spectrum Analysis in the *Structural Mechanics Module User's Guide*.
- The expressions used for the various evaluation options are described in Response Spectrum Analysis Theory in the *Structural Mechanics Module User's Guide*.

When you use a **Response Spectrum 2D** or **Response Spectrum 3D** dataset, any result quantity that is defined for the underlying eigenfrequency study is available. Not all variables are meaningful, though. All results from a response spectrum analysis are by definition positive; the evaluation methods contain absolute values or RMS-like operations. This has important implications for the interpretation of the results, for example

- If the sign of your result quantity is important for the conclusions, you need to manually consider also the case of a negative value.
- It is not meaningful to evaluate a quantity that is not proportional to the mode amplitude. This does, however, not mean that you are limited to linear quantities; equivalent stresses like von Mises and Tresca are nonlinear, but they are still proportional to the mode amplitude.
- It is not meaningful to show deformation or vector plots of response spectrum results.

Revolution 1D and Revolution 2D

Use a **Revolution 1D** dataset to visualize a 1D axisymmetric ( ) solution in 2D. All plot types in 3D or 2D are available for visualization through the revolution dataset. Use a **Revolution 2D** dataset to visualize a 2D ( ) solution in 3D. All plot types in 3D or 2D are available for visualization through the revolution dataset. Right-click a **Revolution 1D** or **Revolution 2D** dataset node to add a **Selection** subnode if desired.

See Common Results Node Settings for links to information about the **Data** and **Axis Data** sections.

REVOLUTION LAYERS

From the **Number of layers** list, choose **Normal** (the default), **Fine**, **Coarse**, or **Custom**. The predefined settings adapt the number of layers to the chosen revolution angle, which minimizes the time to plot the revolved geometry for revolution angles that are less than 360 degrees. If **Custom** is selected, enter the number of **Layers** about the revolution axis (default value: 50).

For all choices, enter the **Start angle** (SI unit: deg) for the revolved model. The default is 0 degrees. Enter the **Revolution angle** (SI unit: deg) to revolve the model to see into the geometry in degrees. The default is 360 degrees, that is, a full revolution. Enter negative values to revolve the model in the opposite direction. An axisymmetric

geometry in the *rz*-plane is projected to the *xy*-plane and then rotated about the *y*-axis or to the *xz*-plane and then rotated about the *z*-axis using the start angle and revolution angle.

By default, a revolution that is not a full 360 degrees uses end caps to close the revolved geometry. Clear the **Add end caps if the revolution is not full** checkbox to leave the geometry open, without end caps.

ADVANCED

For **Revolution 2D**, from the **Map plane to** list, select a plane to map the axisymmetric solution to — **xy-plane** (the default) to map the *rz*-plane to the *xy*-plane and then rotate it about the *y*-axis, or select **xz-plane** to map the *rz*-plane to the *xz*-plane and then rotate it about the *z*-axis.

For **Revolution 1D** and **Revolution 2D**, select the **Define variables** checkbox to create variable names for the space and angle variables in the revolved geometry. Then under **Space variables**, enter or edit the variable names for the revolved coordinate system. Enter or edit the **x**, **y**, and **z** (Revolution 2D only) variable names in the respective fields. The default names are `rev1x`, `rev1y`, and `rev1z`, respectively.

Under **phi**, enter or edit the variable name for **phi**. Phi is the name of the angle variable in the revolved coordinate system. The default name is `rev1phi`.

For example, the angle variables can be useful to enter Cartesian components of axisymmetric vector fields (such as `ht.tfluxr*cos(rev1phi)` for the *x*-component of a heat flux from a 2D axisymmetric heat transfer model, where `ht.tfluxr` is the radial component of the total heat flux).

You can also enter the **Azimuthal mode number** as an integer. The default is 0. You can also use a mode number that is defined as a parameter or a variable.

Use the azimuthal mode number to control the source dataset and evaluate it with different phases.

Sector 2D and Sector 3D

Use the **Sector 2D** ( ) and **Sector 3D** ( ) datasets, selected from the **More 2D Datasets** and **More 3D Datasets** submenus, to make it possible to plot the solution for the full geometry while reducing computation time and memory requirements for complex geometries by exploiting sector symmetries. The geometry must be of a type that can be transformed through the use of rotation or reflection (mirroring). Rotation and reflection are only available when using an even number of sectors. It is also possible to invert the phase (change the sign) when rotating or reflecting.

For example, suppose that there are *N* sectors in a geometry. A Sector dataset first evaluates the input expressions in the source dataset, creates *N* copies (one for each sector of the geometry), maps and interpolates the data, and transforms the expression components that correspond to vector fields.

Right-click a **Sector 2D** or **Sector 3D** dataset node to add a **Selection** subnode if desired.

Go to Common Results Node Settings for links to information about these sections: **Data** and **Axis Data**.

SYMMETRY

In the **Number of sectors** field, enter any integer greater than or equal to 2 (the default is 2) to define the number of sectors in the full geometry. From the **Sectors to include** list, choose **All** (the default) to use all specified sectors evenly distributed. If you want to use fewer sectors than what you specified in the **Number of sectors** field, choose a range of sectors using the **Start sector** field (default: 0, for the first sector) and the **Number of sectors to include**

field (default: the number of sectors, so that you get the same plot as if using **All**). You can use these settings to only plot a fraction of the sectors in order to see the solution inside of the resulting geometry.

When the **Number of sectors** entered is an even number, select a **Transformation**: **Rotation** (the default) or **Rotation and reflection**. For an uneven number of sectors, only rotation is available and it requires no additional user input.

If **Rotation and reflection** is selected:

- For **Sector 2D**, enter **x** and **y** coordinates for the **Direction of reflection axis**.
- For **Sector 3D**, enter **x**, **y**, and **z** coordinates for the **Radial direction of reflection plane**.

ADVANCED

Select the **Define variables** checkbox to create variables for the **Sector number** and the **Space variables**:

- The **Sector number** is an integer number from 0 to the number of sectors minus 1. Each sector has a unique sector number: 0, 1, 2, and 3 for a sector dataset that includes four sectors, for example. The default variable for the sector number is `sec1number`, where `sec1` is the dataset node's tag.
- The **Space variables** evaluate to the coordinate after the transformation (as opposed to x, y, and z, which evaluate to the coordinates in the underlying dataset). The default variable names (the number of which are based on space dimension) are `sec1x` for the x coordinate, `sec1y` for the y coordinate, and `sec1z` for the z coordinate.

When the **Define variables** checkbox is selected, the input expression is enabled once for each sector, something that increases evaluation time by roughly a factor of the number of sectors (N). If the input expression being evaluated contains any of the space variables, then this evaluated mode is enabled automatically.

Azimuthal Mode Number

When the **Number of sectors** is odd or **Rotation** is selected as the **Transformation** (cyclic symmetry), also enter the **Azimuthal mode number** as an integer. The default is 0. You can also use a mode number that is defined as a parameter or a variable.

Use the azimuthal mode number to control the source dataset and evaluate it with different phases for the different sectors. If the mode number is k, then the phase shifts with $-2\pi ik/N$ for sector i.

Invert Phase When Rotating and Invert Phase When Reflecting

These checkboxes are available in various combinations as follows:

- When **Rotation** is selected as the **Transformation** and the **Number of sectors** is a multiple of 2 (an even number), select the **Invert phase when rotating** checkbox to make the phase of the solution change between consecutive sectors.
- When **Rotation and Reflection** is selected as the **Transformation** and the **Number of sectors** is a multiple of 2 (an even number), select the **Invert phase when reflecting** checkbox to make the phase change between consecutive sectors. When the **Number of sectors** is a multiple of 4, select the **Invert phase when rotating** checkbox to make the phase change between consecutive sectors.

Shell

Use the **Shell** ( ) dataset is available in 3D and 2D axisymmetry, under the **More 3D Datasets** submenu, to simultaneously visualize the top and bottom surfaces of a shell using, for example, surface and arrow plots. The main purpose is to give a representation which matches the physical thickness of a shell. The results displayed on the two sides will be different as long as the selected quantity has an explicit dependence on the thickness. Right-click the **Shell** node to add a **Selection** subnode if desired.

DATA

Select the Solution dataset to use for the shell postprocessing from the **Dataset** list. Only 3D and 2D axisymmetric Solution datasets that contain one or more surfaces are available.

LAYERS

In order to have better visualization inside a layered shell, select the **Separate levels** checkbox. This setting creates slices on the mesh nodes in the through-thickness direction. Increase the **Refinement** (default: 1) to have more evaluation points in the through-thickness direction.

In this section, you further specify the parameters for the top and bottom surfaces:

Top Parameters

Under **Top parameters**, enter the following parameters that control the evaluation of the top surface:

- The local z-coordinate, in the range [−1, 1], for thickness-dependent results. Usually the value should be set to 1.
- The components of the reference point for moment computations.

Bottom Parameters

Under **Bottom parameters**, enter the parameters that control the evaluation of the bottom surface (similar to those for the top surface). The local z-coordinate should usually have the value −1.

POSITION

Under **Orientation**, enter the **X-component**, **Y-component**, and **Z-component** for the components of the displacement direction vector, such as the global normal vector components `nx`, `ny`, and `nz` or the shell normal components, such as `shell.nlX`, `shell.nlY`, and `shell.nlZ`. This is the direction in which she displayed boundary is offset from the meshed boundary.

Under **Displacement of normals**, enter the **X-component**, **Y-component**, and **Z-component** for the displacements of normals (default: 0). Here you can enter an additive correction to the shell's orientation, which should be applied when evaluating in the spatial frame.

Under **Distance**, enter a value for the displacement magnitude in the **Distance** field. For example, `shell.z_offset+0.5*shell.z*shell.d`, which is an offset, if using, plus half the shell thickness. The local z-coordinates, as given in the **Layers** section, are inserted in the distance expression in order to position the top and bottoms surfaces. The surface is offset in the direction given under **Orientation**. By using distance values larger that the actually shell thickness, it is possible to enhance the result presentation for very thin shells.

ADVANCED

In this section, you can adjust the area and length scale factors, if desired. Doing so could be useful to take into account the fact that the area scale is not the same for both surfaces created by revolving a line, for example. By default, the values in the **Area scale factor** and **Line scale factor** fields are set by the physics interface.

Shell datasets require the Structural Mechanics Module.

Solution

The **Solution** ( ) datasets make solutions available for visualization and results analysis. Solvers automatically create **Solution** datasets. By default, the name of the Solution dataset nodes include the name of the study with the solution that the dataset refers to (for example, **Study 2/Solution**), but you can rename them if you want to.

Right-click to select **Remesh Deformed Configuration** if the model contains mesh deformation. You can also right-click to add a **Selection** subnode if desired or to add **Data** or **Mesh** subnodes under **Export**.

Solution datasets do not contain the solution but refer to a solution stored in a solver node.

SOLUTION

- Select a **Solution** to make available for visualization and results analysis.
- If there is more than one Component, select the geometry to perform visualization and results analysis for by selecting the corresponding **Component** from the list. If you want to plot solutions in a different component, right-click the **Solution** dataset node and select **Duplicate** ( ). Select another component from the **Component** list in the duplicated **Solution** dataset node, and then refer to that dataset in the plot groups where you want to plot the solution for that component's geometry.
- Select the **Frame** to evaluate the coordinates in: **Mesh**, **Material**, **Geometry**, or **Spatial**. The default in most cases is the Material frame, and this rarely needs to be changed. This frame selection is used for all results evaluations that use the solution dataset.
- Enter a value for the **Solution at angle (phase)** (SI unit: deg). The default is 0 degrees and evaluates complex-valued expressions by multiplying the solution in the solution dataset by a factor of `exp(i*pi*phase/180)` prior to expression evaluation.
- Enter a **Scale factor** (the default is 1; that is, no scaling) to multiply the solution by a real-valued scale factor.

- Deformed Configuration
- Remeshing a Deformed Mesh

Spatial FFT

Use a **Spatial FFT** ( ) dataset to compute the spatial Fourier transform of a variable or expression. You can add a **Spatial FFT** dataset by right-clicking the **Datasets** node and choose **Spatial FFT** from the **More Datasets** submenu.

DATA

From the **Dataset** list, choose the dataset to use a the input for the spatial FFT.

TRANSFORMATION

Click the **Preview Spatial Samples** button to get a plot of the spatial resolution in the Graphics window.

From the **Resolution** list, choose **Automatic** (the default) to have the spatial sampling resolution set up automatically, or choose **Manual** to specify the sampling resolution using integers larger than 2 in the $\mathbf{N}_x$, $\mathbf{N}_y$, and (in 3D) $\mathbf{N}_z$ fields under **Sampling resolution**.

From the **Layout** list under **Spatial layout**, choose **Normal** (the default), **Periodic**, or **Use zero padding**. For the last layout option, specify paddings as integer values (zero or larger) in the **x padding**, **y padding**, and (in 3D) **z padding** fields.

If the geometry is a unit cell of a periodic pattern, the last samples of each dimension must be ignored to make the samples periodic. To have more resolution in the frequency domain you then need to pad the spatial domain with zeros. This option should be used when the transformation is followed by frequency domain filtration that helps having higher resolution in the frequency domain.

Under **Fourier space variables**, the default variable names for the $\mathbf{f}_x$, $\mathbf{f}_y$, and (in 3D) $\mathbf{f}_z$ Fourier space variables are `sfft1fx`, `sffft1fy`, and `sfft1z` for a **Spatial FFT I** dataset. If desired, enter other variable names.

From the **Domain** list, choose **Frequency** (the default), corresponding to the spatial frequencies, or **Index**, having the axes values as the 0-based DFT indices. The following equation describes the DFT transform:

$$X_{k_1, k_2, \ldots, k_d} = \sum_{n_1=0}^{N_1-1} \left(\omega_{N_1}^{k_1 n_1} \sum_{n_2=0}^{N_2-1} \left(\omega_{N_2}^{k_2 n_2} \cdots \sum_{n_d=0}^{N_d-1} \omega_{N_d}^{k_d n_d} \cdot x_{n_1, n_2, \ldots, n_d} \right) \right)$$

where $\omega_{N_l} = \exp(-i2\pi/N_l)$.

In the equation for the DFT transform above, d can be up to 3 as it is the dimensionality of the Fourier space. The k_i indices are integers that are the indices of the transformed space corresponding to the axis values when **Domain** is set to **Index**. If you set **Domain** to **Frequency**, the axis values are shifted and scaled to match spatial frequencies.

The **Mask DC** checkbox is selected by default to set the DC value (zero frequency component) to zero. This is usually necessary because this value is too high and overwhelms the rest of the spectrum. If you want to include the DC value, clear this checkbox.

Select the **Backward transformation** checkbox to run use the opposite sign convention used for electromagnetic waves, for example. $\omega_{N_l} = \exp(i2\pi/N_l)$ is then used, which is the convention used for electromagnetic waves.

QUALITY

From the **Resolution** list, choose **Extra fine**, **Finer**, **Fine**, **Normal** (the default), **Coarse**, **No refinement**, or **Custom**. A higher resolution means that elements are split into smaller patches during rendering. If you chose **Custom**, enter a refinement as a positive integer pin the **Element refinement** field.

If you have the Structural Mechanics Module, see *Wave Propagation in Rock Under Blast Loads*:
Application Library path **Structural_Mechanics_Module/Elastic_Waves/blasting_rock**.
If you have the Wave Optics Module, see *Fresnel Lens*:
Application Library path **Wave_Optics_Module/Verification_Examples/fresnel_lens**.

Surface (Dataset)

Use a **Surface** ( ) dataset to visualize data on surfaces (boundaries) of a 3D geometry. Refer to this dataset to plot and evaluate a value on a surface using a 2D plot group and a **Surface** or **Contour** plot, for example.

PARAMETERIZATION

Specify how to parameterize the surface. Choose from one of these options in the **x- and y-axes** list to specify what the local *x*- and *y*-axes represent:

- **Surface parameters** (the default) uses parameters of the 3D surface, computed using the average normal and by choosing the 2D axes using a set of geometrical rules.
- **xy-plane**, **yz-plane**, **zx-plane**, **yx-plane**, **zy-plane**, and **xz-plane** are the local *x*- and *y*-axes representing the global *xy*-plane, *yz*-plane, *zx*-plane, *yx*-plane, *zy*-plane, and *xz*-plane, respectively.
- If **Expression** is selected, enter any expression, including the global spatial coordinates, for example, in the **x-axis** and **y-axis** fields. The default values are **x** and **y**, respectively.

ADVANCED

Select the **Define variables** checkbox to create space variables for the surface. If needed, change the names of the space variables in the **x** and **y** fields.

Time Average and Time Integral

Select a **Time Average** ($\overline{AV}_t$) or **Time Integral** ($\int dt$) dataset, found under the **More Datasets** submenu, to compute the time average or time integral of some time-dependent data in another dataset, for example, to compute time averages or time integrals.

DATA

Select a **Dataset** for the data to compute the time average or time integral. To compute the time average or time integral for a dataset with time-dependent data, select times to include in the average or integral from the **Time selection** list: **All** (the default) to use all time steps, **First** to use the first time step only, **Last** to use the last time step only, **From list** to select from a list of all time steps, **Manual** to enter a range of times as indices directly, or select **Interpolated** to enter **Times**.

SETTINGS

If desired, clear the **Interpolate between stored time steps** checkbox to improve performance by disabling interpolation between stored time steps. If the checkbox is selected, you can specify the following properties:

Enter a relative tolerance in the **Tolerance** field (default: 0.001).

In the **Minimum interval length** field, enter a minimum interval length as a number relative to the length of the time interval (default: 10^{-4}). The data is evaluated at least at every stored time step regardless of the value of the minimum interval length.

Transformation 2D and Transformation 3D

Use a **Transformation 2D** ( ) or **Transformation 3D** ( ) dataset to use a rotation or other affine transformation of the underlying 2D or 3D geometry. Right-click the **Datasets** node and choose these datasets from the **More 2D Datasets** and **More 3D Datasets** submenus, respectively. The supported transformations are scaling, rotating, and moving (translating), performed in that order.

In general, scaling, rotating, and moving are not commutative; that is, the order of these operations matter. If you want to perform transformations in another order, use several Transformation datasets in succession, where each Transformation dataset only carries out one type of transformation and uses the dataset as its input.

DATA

From the **Dataset** list, choose the dataset to use as input for the transformation.

TRANSFORMATION

From the Transformation type list, choose **Structured** (the default) for a structured transformation where you specify separate scaling, rotation, and translation (moving) of the geometry, or choose **General** for a general transformation using base vectors (a translation matrix) and a translation vector.

Settings for a Structured Transformation

Select the **Scale** checkbox if you want to scale the geometry, and then enter scale factors in the **x**, **y**, and **z** (3D only) fields.

Select the **Rotate** checkbox if you want to rotate the geometry.

- Then, in 3D only, choose the type of rotation axis from the **Axis type** list: **X-axis**, **Y-axis**, **Z-axis**, **Cartesian**, or **Spherical**. For **Cartesian**, specify the axis in the **x**, **y**, and **z** fields below. For **Spherical**, specify the θ and φ angles.
- Specify the rotation angle in the **Angle** field.
- Specify the center of rotation in the **x**, **y**, and **z** (3D only) fields under **Center of rotation**.

Select the **Move** checkbox if you want to move (translate) the geometry, and then enter translations in the **x**, **y**, and **z** (3D only) fields.

ADVANCED

If desired, you can edit the names of the created space variables for the transformed geometry in the **x**, **y**, and **z** (3D only) fields.

Selection (Dataset Attribute)

For datasets that contain data defined in the model, such as **Solution** datasets ( ) and **Mesh** datasets ( ), you can add a selection so that the results and plots use a subset of the geometry. As an alternative, you can add **Selection** subnodes to some of the plot nodes; see Selection (Plot Attribute).

To add a **Selection** subnode to a dataset:

- In the **Results** toolbar, click **Attributes** > **Selection** ( ).
- Under **Results** > **Datasets**, right-click a dataset and choose **Selection** ( ).

In the **Selection** subnode ( ), select the geometric entities for which you want to include data in the dataset using the **Graphics** window and the settings under **Geometric Entity Selection** in the **Selection** subnode's **Settings** window. Select the **Propagate to lower dimensions** checkbox to make a selection of domains, for example, also include their adjacent boundaries, edges, and points. This can be convenient when using Surface plots on the boundaries of a 3D geometry, for example.

Mesh Import Parameters

For **Filter** ( ) and **Partition** ( ) datasets, you can add a **Mesh Import Parameters** subnode ( ) to control for which solution parameters, when the solution data contains inner or outer solutions, that are used for data transferred from a Filter or Partition dataset to a mesh or mesh part.

To add a **Mesh Import Parameters** subnode:

- In the **Results** toolbar, click **Attributes** > **Mesh Import Parameters** ( ) when a **Filter** or **Partition** dataset is selected.
- Under **Results** > **Datasets**, right-click a **Filter** or **Partition** dataset and choose **Selection** ( ).

The Settings window for the **Mesh Import Parameters** subnode includes the following section:

DATA

If the model includes a solution that contains inner or outer solutions, you can choose which solution to pass on to a mesh or mesh part; for example, it can be a **Time** or **Load case** list.

There is also **Remesh a Deformed Configuration** for a dataset. See Deformed Configuration.

Derived Values, Evaluation Groups, and Tables

About Derived Values

You can integrate or compute the average, maximum, or minimum of any quantity to compute derived quantities such as total flux; charges; inductances; reaction forces; and average, maximum, and minimum values. You can also measure geometric quantities such as volumes, surfaces, and distances.

Use **Derived Values** ( ) to define evaluations of numerical results — globally, in a point, or integrated quantities. The values appear in a table in the **Table** window, where you have different options for the precision and notation of the numerical values (see The Table Window and Tables Node below). For 2D and 3D plots, you can also get numerical results directly in a table by clicking the plot. The same functionality is available for **Evaluation Group** nodes ( ), which provide a clearer connection to the results table and more flexible data handling (see About Evaluation Groups below). You can also add evaluation groups and derived values nodes as result templates (see Adding and Creating Result Templates) by right-clicking an **Evaluation Group** or derived values node and choosing **Add as Result Template**.

For all derived values, you can also apply an operator on a data series (from a parametric or Time Dependent study) to compute, for example, the temporal average of a quantity in a point of the domain for which a time-dependent solution is computed. In addition to the average, you can also compute the integral, maximum, minimum, RMS (root mean square), standard deviation, or variance of the data series. The derived values nodes use datasets (typically solution datasets) that provide the data from which the derived values are computed. If needed, specify the frame and geometry to use in the dataset's **Settings** window.

	Depending on the physics interface included in the model, not all derived values (numerical evaluation) types may be available. To see all numerical evaluation types, select the **All Numerical Evaluation Types** checkbox in the **Show More Options** dialog.

	For evaluating derived values in a batch job for cluster computing, for example, see Evaluate Derived Values.

For 3D and 2D models, the numerical value of the current plot can be displayed by clicking anywhere in the model geometry.

For a 3D model, the value is for the point where a ray projected from the point clicked hits the geometry.

COMSOL Multiphysics displays the value at that point along with the point's coordinates in a row in an **Evaluation 2D** or **Evaluation 3D** table in the **Table** window. Each click adds a row to the table. From the **Table** window, you can plot or copy the table data to a clipboard like any other table.

- See Derived Value Types for links to the datasets.
- Common Results Node Settings

About Evaluation Groups

An evaluation group is analogous to a plot group: It has zero or more numerical evaluation nodes (all evaluation nodes that are also available under **Derived Values**) as subnodes. The **Evaluation Group** node contains common settings and also acts as the table to which its subnodes evaluate. The values in an evaluation group's table can be reevaluated automatically when solving (see Update of Results). For information about the available evaluation nodes, see Derived Value Types. For information about the evaluation group tables, see The Table Window and Tables Node. To add an **Evaluation Group** node ( ), right-click the main **Results** node and select **Evaluation Group**. Then right-click the **Evaluation Group** node to add the evaluation nodes to be evaluated within that evaluation group. You can evaluate all nodes under an **Evaluation Group** node by right-clicking them or by clicking the **Evaluate** button ( ).

Also, for evaluation nodes under an **Evaluation Group** node where the selected dataset has the same nontrivial parameter structure as the dataset used in the parent evaluation group (typically, a solution that contains solution data for more than one time, eigenmode, or parameter), you can choose from where to take the solution parameters. From the **Solution parameters** list in the evaluation node, choose **Manual** to choose a time, eigenmode, or parameter using the settings described below, or choose **From parent** to use those values from the corresponding settings in the parent evaluation group. Using the settings from the evaluation group can make it easier to work with evaluation groups where multiple datasets are used.

From the **Evaluation Group** contextual ribbon toolbar, you can also add evaluation nodes and evaluate them. In addition, you can create graph plots and surface plots by clicking the **Graph Plot** ( ) and **Surface Plot** buttons, respectively; click the **Clear** button ( ) to clear the selected evaluation group; and click the **Copy to Table** button ( ) to copy the selected evaluation group to a table.

The **Evaluation Group** node's **Settings** window contains the following sections:

DATA

In this section you define the data to use for the evaluations. See Common Results Node Settings for more information.

If you have defined a compatible configuration (see Configurations), which is typically a Multiselect Solution, the you can choose **From configuration** from the **Solution parameters** list (the default is **Manual**). With **From configuration**, choose a compatible configuration from the **Configuration** list to use its settings for the solution parameters such as time, eigenvalue, or parameter values to use.

STORAGE

You can also store the evaluation group's table data on the file system instead of, or in addition to, storing it in the model. Select a way to store the table data from the **Store table** list:

- Select **In model** (the default) to store the table data in the model.
- Select **On file** to store the table data in the model to a file that you select by first clicking **Browse** or enter into the **Filename** field. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).
- Select **In model and on file** to store the table data both in the model and on the file system.

For the storage in the model, specify the buffer size in the **Maximum number of rows** field. The default for new evaluation group tables is taken from the **Default maximum number of rows** field on the **Results** > **Tables** page in the **Preferences** window (factory setting: 10,000 rows). If the table size exceeds that number of rows, the software removes rows from the top. If you use a large number, most table data will fit in the table without being truncated.

The row limit applies to table data in the model only and not to tables with data stored in a file.

If you change the storage format to or from storage on file, then click **Update** ( ) in the **Storage** section's header to refresh the contents of the table.

TRANSFORMATION

You can make a transformation of the evaluations in the evaluation group.

Select the **Transpose** checkbox to transpose the data in the **Evaluation Group** window so that the table presentation contains row headers instead of column headers.

From the **Type** list, choose one of the following transformation types:

- **None**, for no transformation.
- **Sum**, for the sum of all evaluations.
- **Average**, for the average of all evaluations.
- **Difference**, for the difference of all evaluations (`evaluation1–evaluation2–evaluation3`, and so on)
- **General**, for a general expression, which can include global parameters and mathematical and physical constants, for example. Enter the expression for the general transformation in the **Expression** field. To refer to the evaluated results in the subnodes listed in the table below (in the **Feature** column), use the corresponding tags listed in the table's **Tag** column. For example `pi*pev1/pev2` for pi (π) times a quotient (ratio) of the values from the **Point Evaluation 1** and **Point Evaluation 2** subnodes. The expression is evaluated elementwise.

When the **Type** list is not **None**, select the **Keep child nodes** checkbox to include the evaluation of the child nodes in the evaluation of the transformation of those values.

FORMAT

Use the **Include parameters** list to control which parameters value columns to include in the evaluation group's table: Use **Automatic** (the default) to include the parameter value columns are included for the first active evaluation subnode, which is a good choice if all evaluation subnodes have the same parameter value columns. Otherwise, use **On** to include all parameter value columns, or use **Off** to include no parameter value columns.

You can choose to concatenate the contributions from the evaluation features horizontally or vertically. From the **Concatenation** list, choose **Horizontal** (the default) or **Vertical**.

The **Table** window displays the results from integral and variable evaluations defined in Derived Values nodes or by probes and stored in Table nodes. It can also display results from nodes under Evaluation Group nodes as an **Evaluation Group** window (see About Evaluation Groups). You can control the formatting, add row numbers, create plots, and export and copy the data in tables (see below).

See Table for information about the **Settings** window.

A **Tables** subbranch ( ) is found under the **Results** main branch and contains all tables defined in the model. Table nodes can also result from evaluating Derived Values. When you select a Table node to display, the window name changes to the name of the Table (**Table 1**, as in Figure 21-4, for example).

- For Windows users, from the **Home** toolbar, select **Windows** > **Table**.
- For cross platform (macOS and Linux) users, select **Windows** > **Table**.

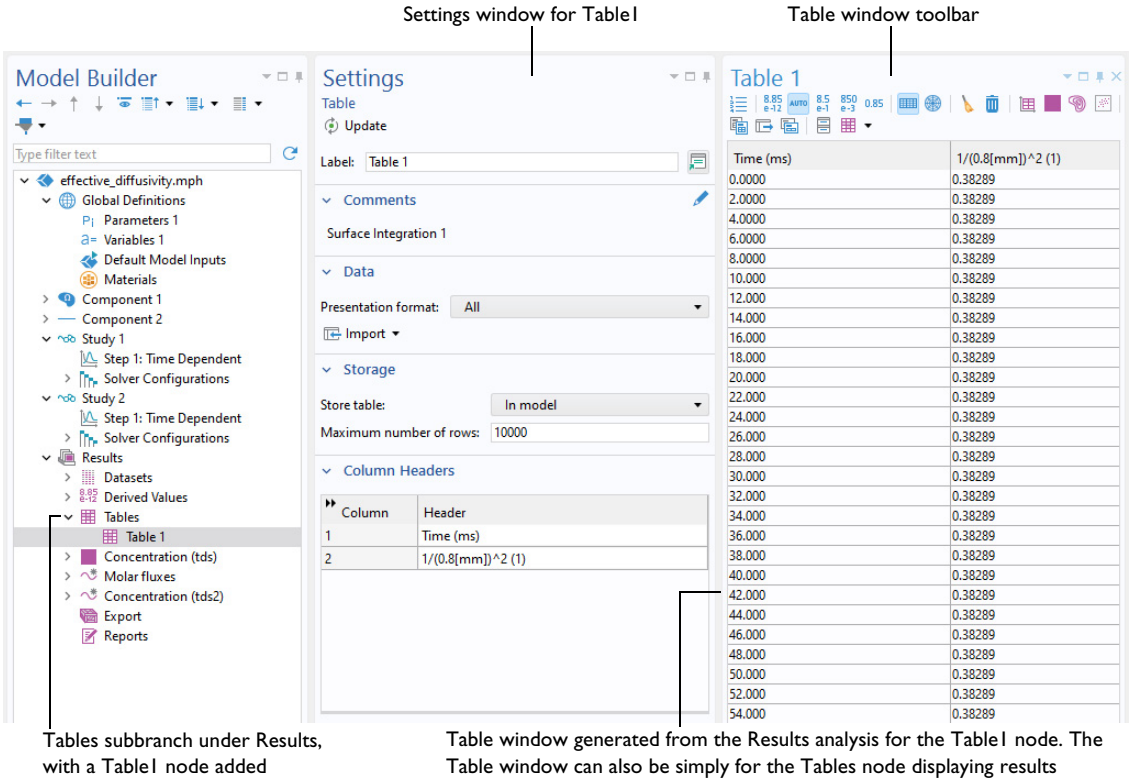

Figure 21-4: An example of the Tables subbranch with a Table node, and the associated settings and Table windows.

You can control the default values for new tables on the **Results** > **Tables** page in the **Preferences** window for the following table properties: default maximum number of rows, maximum filled matrix size, and display precision.

TABLE WINDOW TOOLBAR AND MENU OPTIONS

When a **Table** ( ) is generated and displays in the **Table** window, a variety of editing options are available as listed in Table 21-9 and shown in Figure 21-4. For the different notation options, only one of them can be selected. Likewise, only one of the two forms for displaying complex-valued numbers can be selected, and those forms are

only applicable if the table contains some complex-valued numbers with nonzero imaginary part. In addition, you can use Table Histogram plots to create histograms from tables and evaluation groups.

TABLE 21-9: TABLE WINDOW EDITING BUTTONS.

BUTTON	NAME	DESCRIPTION
	Settings	Open the Table's Settings window.
	Full Precision	Click to display as many significant digits as possible. Integers appear without decimal parts, and nonintegers are shown with roughly 16 significant digits.
	Automatic Notation	This is the default notation, where numbers are formatted in either regular or scientific notation depending on which gives the shortest representation.
	Scientific Notation	The scientific notation, such as `3.1416E-5`, can be easier to read than decimal notation for tables containing values on different scales.
	Engineering Notation	The engineering notation, such as `31.416E-6`, is similar to scientific notation but with the powers of ten as multiples of three.
	Decimal Notation	The decimal notation uses only decimal representation of the numbers, such as `0.000031416`. Small numbers can get long representations because of leading zeros, and large numbers may appear with excess precision.
	Rectangular Complex Number	Display complex-valued numbers as the real part + the imaginary part followed by *i* (the imaginary unit), such as `2.451+0.657i`.
	Polar Complex Number	Display complex-valued numbers using a polar form, consisting of an absolute value or modulus and an angle, such a `0.0786∠-45°`.
	Show Row Numbers	Display row numbers for the table rows in the leftmost column.
	Clear Table	Click to clear the data from the table, but keep the table itself. Click the Evaluate button (=) in the Settings window for the derived values node to regenerate the table data.
	Delete Table	Click to delete the table. There is no undo. If required, click the Evaluate button (=) in the Settings window for the derived values node to regenerate the table data to regenerate the table.
	Table Graph	Click to plot the table as a **Table Graph** plot in the **Graphics** window.
	Table Surface	For tables with filled data, click to plot the table as a **Table Surface** plot in the **Graphics** window.
	Table Contour	For tables with filled data, click to plot the table as a **Table Contour** plot in the **Graphics** window.
	Copy Table and Headers to Clipboard	Click the button or right-click anywhere in the table and select this option from the context menu. You can then paste the table's data and headers in a spreadsheet, for example.
	Export	Click to export the table to a text file in a spreadsheet format or to a Microsoft® Excel Workbook (*.xlsx) if the license includes LiveLink™ *for* Excel®. When saving to a Microsoft Excel Workbook, an Excel Save dialog opens where you can specify the sheet and range and whether to overwrite existing data and include a header.
	Copy Table and Headers to PowerPoint and Word	Click to copy the table and its headers to Microsoft® PowerPoint and Microsoft® Word.
	Display Table	Click to display a menu of available tables to display.

TABLE 21-9: TABLE WINDOW EDITING BUTTONS.

BUTTON	NAME	DESCRIPTION
	Delete Column	Right-click a column header or anywhere in the table, and select **Delete Column**. There is no undo. If required, click the **Evaluate** button (=) to regenerate the table.
	Delete Rows	Right-click in the table and select **Delete Rows** or press Del to delete selected rows in the table. There is no undo. If required, click the **Evaluate** button (=) to regenerate the table.
	Copy Cell to Clipboard	Right-click anywhere in the table and select this option from the context menu to copy the contents of the selected cell to the clipboard.
	Copy Selection to Clipboard	Select the rows to copy, then right-click anywhere in the table and select this option from the context menu, or press Ctrl+C.
	Copy Selection and Headers to Clipboard	Select the rows to copy, then right-click anywhere in the table and select this option from the context menu.
	Copy Table to Clipboard	Right-click anywhere in the table and select this option from the context menu.
	Copy Table and Headers to Clipboard	Right-click anywhere in the table and select this option from the context menu.
	Copy Column to Clipboard	Right-click anywhere in the table and select this option from the context menu to copy the selected column to the clipboard.
	Copy Column and Header to Clipboard	Right-click anywhere in the table and select this option from the context menu to copy the selected column and its header to the clipboard.
	Copy Table and Headers to PowerPoint and Word	Right-click anywhere in the table and select this option from the context menu (on Windows only) to copy the table and its headers in a way that it will remain linked to the model for future updates after pasting it into a Microsoft® PowerPoint presentation or Microsoft® Word document. See Creating PowerPoint Presentations and Word Documents with Linked Tables and Images for more information on how to insert and update tables in a presentation.
	Copy Selected Rows to New Parameter Case	Right-click anywhere in the table and select this option from the context menu (when applicable) to copy the selected rows to a new parameter case (a **Case** node under **Global Definitions** > **Parameters**), which can be useful, for example, when rebuilding the geometry using optimal parameter values found by an optimization solver.

For a surface integration example that includes tables, see *Effective Diffusivity in Porous Materials*: Application Library path **COMSOL_Multiphysics/Diffusion/effective_diffusivity**.

- Results Analysis and Plots
- Derived Values, Evaluation Groups, and Tables

The same derived values functionality is available under **Evaluation Group** nodes ( ). Evaluation groups provide a clearer connection to the results table and more flexible data handling.

In the **Model Builder**, under **Results**, right-click **Derived Values** ( ). Select an option from the list and continue defining each derived value (see Table 21-10). All of these nodes for various derived values, except where noted, are also available as evaluation nodes under an **Evaluation Group** node. Also, as evaluation nodes, the default settings in the **Dataset** list is **From parent**, which is not available for the corresponding nodes under **Derived Values**.

TABLE 21-10: DERIVED VALUE TYPES (EVALUATION NODES).

LINK TO SECTION	DESCRIPTION
Point Evaluation	To evaluate expressions or variables defined in a point.
Global Evaluation	To evaluate the numerical value of a global variable.
Global Matrix Evaluation	To define the evaluation of the numerical values for a global matrix variable such as S-parameters in a model with several ports activated as a parametric sweep and a frequency-domain study. Not available as an evaluation node in an evaluation group.
Point Matrix Evaluation	To define the evaluation of the numerical values for a matrix variable, such as anisotropic material data in some points in the model. Not available as an evaluation node in an evaluation group.
System Matrix	To evaluate an Assemble or Modal node to a table. Not available as an evaluation node in an evaluation group.
MORE DERIVED VALUES SUBMENU	This submenu contains additional derived value nodes: Particle Evaluation, Ray Evaluation, Aberration Evaluation, and Global Evaluation Sweep.
Particle Evaluation	To evaluate an expression for all, or a subset of, the particles in a particle tracing model.
Ray Evaluation	To evaluate an expression for all, or a subset of, the rays in a Ray dataset.
Aberration Evaluation	To compute Zernike coefficients for Zernike polynomials that correspond to various types of monochromatic aberration in ray optics.
Global Evaluation Sweep	To vary a small number of model parameters as a sweep during postprocessing (for postprocessing of reduced models, for example)
AVERAGE SUBMENU	Volume Average, Surface Average, and Line Average
Volume Average	To evaluate an average over a set of domains in 3D models.
Surface Average	To evaluate an average over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
Line Average	To evaluate an average over a set of domains in 1D, boundaries in 2D, or edges in 3D.
INTEGRATION SUBMENU	Volume Integration, Surface Integration, and Line Integration
Volume Integration	To evaluate an integral over a set of domains in 3D models.
Surface Integration	To evaluate an integral over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
Line Integration	To evaluate an integral over a set of domains in 1D, boundaries in 2D, or edges in 3D.
MAXIMUM SUBMENU	Volume Maximum, Volume Minimum, Surface Maximum, Surface Minimum, Line Maximum, and Line Minimum
Volume Maximum	To evaluate the maximum over a set of domains in 3D models.
Surface Maximum	To evaluate the maximum over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
Line Maximum	To evaluate the maximum over a set of domains in 1D, boundaries in 2D, or edges in 3D.
MINIMUM SUBMENU	Volume Maximum, Volume Minimum, Surface Maximum, Surface Minimum, Line Maximum, and Line Minimum
Volume Minimum	To evaluate the minimum over a set of domains in 3D models.

TABLE 21-10: DERIVED VALUE TYPES (EVALUATION NODES).

LINK TO SECTION	DESCRIPTION
Surface Minimum	To evaluate the minimum over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
Line Minimum	To evaluate the minimum over a set of domains in 1D, boundaries in 2D, or edges in 3D.
MEASURE SUBMENU	Volume Measurement, Surface Measurement, Line Measurement, Distance Measurement, and Mass Properties
Volume Measurement	To evaluate the volume over a set of domains in 3D models.
Surface Measurement	To evaluate the surface area over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
Line Measurement	To evaluate the length of lines over a set of domains in 1D, boundaries in 2D, or edges in 3D.
Distance Measurement	To evaluate the distance between two points in the model geometry.
Mass Properties	To evaluate mass properties (volume, mass, and center of mass) in the model geometry.

Volume Average, Surface Average, and Line Average

The derived average values are useful for calculating averaged quantities for each solution in a dataset (a time-dependent solution, for example). Also apply an integral, maximum, or other operation to compute the maximum of an averaged quantity, for example.

Under **Results**, right-click **Derived Values** ( ) or any **Evaluation Group** node ( ), and from the **Average** submenu select:

- **Volume Average** ( ) to evaluate an average over a set of domains in 3D models. The result of the evaluation is stored in a **Table** node and displayed in the **Table** window.
- **Surface Average** ( ) to evaluate an average over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
- **Line Average** ( ) to evaluate an average over a set of domains in 1D, boundaries in 2D, or edges in 3D.

Go to Common Results Node Settings for information about these sections: **Data**, **Selection**, **Through-Thickness Location**, **Expressions**, **Integration Settings**, and **Data Series Operations**.

For a line average example, see *Tubular Reactor with Nonisothermal Cooling Jacket*: Application Library path **COMSOL_Multiphysics/Chemical_Engineering/tubular_reactor**.

Volume Integration, Surface Integration, and Line Integration

The derived integration values are useful for calculating integrated quantities for each solution in a dataset (a time-dependent solution, for example). Also apply an average, maximum, or other operation to compute the average of an integrated quantity, for example.

Under **Results**, right-click **Derived Values** ( ) or any **Evaluation Group** node ( ), and from the **Integration** submenu select:

- **Volume Integration** ( ) to evaluate an integral over a set of domains in 3D models. The result of the evaluation is stored in a **Table** and displayed in the **Table** window.

- **Surface Integration** (∬) to evaluate an integral over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
- **Line Integration** (∫) to evaluate an integral over a set of domains in 1D, boundaries in 2D, or edges in 3D. Integrate over any dataset of the right dimension. For example, make a volume integration of a 2D revolved dataset or a surface integration of a cut plane.

DATA

In the **Data** section you define the data for the integration.

From the **Dataset** list, choose **None**, **From parent** (the default), or any applicable dataset.

Depending on the type of data, a **Solution parameters** list can appear, with the options **From parent** or **Manual**. If you choose **Manual**, then other lists, such a s **Parameter selection** and **Time selection**, will be available for choosing solution parameters to include in the integration.

Also, in datasets from models that contain parametric sweeps, a **Table columns** list is available for choosing table columns to include:

- **Data only** (the default)
- **Inner solutions** (such as time steps)
- **Outer solutions** (such as the parametric solutions)
- The parameter names in the sweep

Go to Common Results Node Settings for information about these sections: **Selection**, **Through-Thickness Location**, **Expressions**, **Integration Settings**, and **Data Series Operation**.

For volume integration examples, and if you have the:

- AC/DC Module, for both a volume and surface integration example, see *Eddy Currents*: Application Library path **ACDC_Module/Introductory_Electromagnetics/eddy_currents**.
- RF Module, see *Microwave Oven*: Application Library path **RF_Module/Microwave_Heating/microwave_oven**.

For a surface integration example see *Effective Diffusivity in Porous Materials*: Application Library path **COMSOL_Multiphysics/Diffusion/effective_diffusivity**.

For line integration examples, and if you have the:

- AC/DC Module, see *An RFID System*: Application Library path **ACDC_Module/Introductory_Magnetostatics/rfid**.
- CFD Module, see *Capillary Filling — Level Set Method*: Application Library path **CFD_Module/Multiphase_Flow/capillary_filling_ls**.
- Microfluidics Module, see *Capillary Filling — Level Set Method*: Application Library path **Microfluidics_Module/Two-Phase_Flow/capillary_filling_ls**.
- Heat Transfer Module, see *Radiation in a Cavity*: Application Library path **Heat_Transfer_Module/Verification_Examples/cavity_radiation**.

Volume Maximum, Volume Minimum, Surface Maximum, Surface Minimum, Line Maximum, and Line Minimum

The derived maximum and minimum values are useful for calculating maximum or minimum quantities for each solution in a dataset (a time-dependent solution, for example). Also apply an average, maximum (or minimum), or other operation to compute the maximum or minimum over the entire dataset for a quantity, for example.

Under **Results**, right-click **Derived Values** ( ) or any **Evaluation Group** node ( ), and from the **Maximum** or **Minimum** submenus select:

- **Volume Maximum** (MAX) or **Volume Minimum** (MIN) to evaluate a maximum or minimum value over a set of domains in 3D models. The result of the evaluation is stored in a **Table** and displayed in the **Table** window.
- **Surface Maximum** (MAX) or **Surface Minimum** (MIN) to evaluate a maximum or minimum value over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
- **Line Maximum** (MAX) or **Line Minimum** (MIN) to evaluate a maximum or minimum value over a set of domains in 1D, boundaries in 2D, or edges in 3D.

CONFIGURATION

Choose whether to find the maximum or minimum of the real part or the absolute value, which are different for complex-valued data. Choose **Real part** (the default) or **Absolute value** from the **Find maximum of** or **Find minimum of** list.

Select the evaluation point type from the **Point type** list, if the maximum or minimum is taken for a geometry entity level that is lower than for the data in the dataset; otherwise, specify an **Element refinement** (default: 5):

- **Lagrange points** (the default) to evaluate the maximum or minimum value in the Lagrange points. Select a **Lagrange order** (default: 5; the Lagrange order is the number of partitions of an element edge) to adjust the accuracy of the minimum or maximum values.
- **Mesh vertices** to evaluate the maximum or minimum value in the mesh vertices of the extended mesh.
- **Gauss points** to evaluate the maximum or minimum value in the Gauss points (integration points). Select an **Integration order** (default: 4) to adjust the accuracy of the minimum or maximum values.

Select the **Include position** checkbox to also tabulate the position coordinates for the maximum or minimum.

	Go to Common Results Node Settings for information about these sections: **Data**, **Selection**, **Through-Thickness Location**, **Expressions**, and **Data Series Operation**.

	For a volume maximum example, and if you have the Nonlinear Structural Materials Module, see *Polynomial Hyperelastic Model*: Application Library path **Nonlinear_Structural_Materials_Module/Hyperelasticity/polynomial_hyperelastic**.

Volume Measurement, Surface Measurement, Line Measurement, Distance Measurement, and Mass Properties

The derived measurement values are used for computing a volume, surface area, or line length for the geometry in a dataset. Also apply an average, maximum (or minimum), or other operation to compute the surface area over the entire dataset for a quantity, for example.

Under **Results**, right-click **Derived Values** ( ) or any **Evaluation Group** node ( ), and from the **Measure** submenu select:

- **Volume Measurement** ( ) to evaluate the volume over a set of domains in 3D models. The result of the evaluation is stored in a **Table** and displayed in the **Table** window.
- **Surface Measurement** ( ) to evaluate a surface area over a set of domains in 2D, 2D axisymmetric, or boundaries in 3D.
- **Line Measurement** ( ) to evaluate the length of lines over a set of domains in 1D, boundaries in 2D, or edges in 3D.
- **Distance Measurement** ( ) to evaluate the distance between two points in the model geometry.

Go to Common Results Node Settings for information about these sections: **Data**, **Selection**, and **Data Series Operation**. For the **Distance Measurement**, select exactly two points.

- **Mass Properties** ( ) to evaluate mass properties: volume, mass, and center of mass. The settings for this node include an **Evaluation Settings** section, where you select, under **Contribution**, which mass properties to include and, under **Unit**, their respective units. You can also select an **Integration order** checkbox and specify the integration order in the associated text field.

For **Mass Properties**, only Solution and Mesh datasets based on a 3D component are supported. For Mesh datasets, it is only possible to compute the volume (clear the **Mass** and **Center of mass** checkboxes).

MEASUREMENT SETTINGS

This section contains settings for the measurement tools:

- From the **Unit** list, select a compatible unit for the measurement (default SI units: m^3 for volumes, m^2 for surface areas, and m for lengths of lines and distances).
- If you want to add a custom description, select the **Description** checkbox and enter a description in the associated text field.
- From the **Frame** list, select a frame for the measurement. The default is **Spatial** for a spatial frame. Choose **From dataset** to use the frame used in the dataset.
- For the **Integration order**, when available, the COMSOL Multiphysics software determines an appropriate integration order for the expression when you use integration. The default is 4. Select the checkbox to make a different entry in the field (as an integer that is 0 or larger). COMSOL Multiphysics then performs the integration elementwise using numeric quadrature of the selected order.
- For axisymmetric models, the **Compute volume of revolved geometry** checkbox (for surface measurements) and **Compute area of revolved geometry** checkbox (for line measurements) are selected by default.

Point Evaluation

Use **Point Evaluation** ( ) to define the evaluation of a variable or an expression in a point. The result is stored in a **Table** node and displayed in the **Table** window.

- Go to Common Results Node Settings for information about these sections: **Data**, **Through-Thickness Location**, **Expressions**, and **Data Series Operation**.
- Table

SUMMATION

Use this section to compute the sum or average over the points. From the **Type** list, select one of these options:

- **None** (the default) to not do any summation.
- **Sum** to compute the sum of the values.
- **Average** to compute the average value.

Global Evaluation

Use a **Global Evaluation** ( ) to define the evaluation of the numerical value of a global variable.

- Go to Common Results Node Settings for information about these sections: **Data**, **Expressions**, and **Data Series Operation**.
- Table

Global Matrix Evaluation

Use a **Global Matrix Evaluation** ( ) to define the evaluation of the numerical values for a global matrix variable such as S-parameters in a model with several ports activated as a parametric sweep and a frequency-domain study. The **Table** window then displays all values for all frequencies in a parametric sweep.

- Go to Common Results Node Settings for information about the following sections: **Data**, **Through-Thickness Location**, and **Expression**. For the expression, you can only choose from available matrix variables.
- Table

DATA SERIES OPERATION

Select an option for operations on the data series for the inner parameters — typically a frequency sweep or time series from a study — and the outer parameters — the parametric sweep (for ports in electromagnetics, for example) — from the **Inner parameters** and **Outer parameters** lists:

- Select **None** to use the computed value as it is (the default).
- Select **Average** to use the average of the computed values for the inner solutions or the outer solutions.
- Select **Sum** to use the sum of the computed values for the inner solutions or the outer solutions.

For structured sweeps where the two innermost columns are both inner and both outer, these lists have dynamic labels such as **Outer parameter (PortName)** for a sweep over **PortName**.

The **Ignore NaN** checkbox is selected by default to ignore NaNs in the data for an inner or outer data series operations. If you want to keep values that are NaN, clear this checkbox. This setting is useful when solving a parametric sweep that computes a single column of the matrix variable at each step, such as when running a Port or Terminal sweep in the AC/DC Module or the RF Module. If the **Ignore NaN** checkbox is selected, the columns not computed in each step (that are filled with NaN) are ignored when evaluating the complete matrix.

TRANSFORMATION

This section allows specifying a transformation to be applied on the evaluated matrix. The result of the transformation is displayed in the **Table** window. Select a **Transformation** for the matrix. If **None** is selected, the evaluated matrix is displayed. If **Inverse** is selected, the inverse of the evaluated matrix is displayed.

The additional transformations available in the list (such as **From S to Z**) can be used in electrical applications to transform between different lumped parameter matrices of the system, such as the system's impedance matrix, $\mathbf{Z}$; admittance matrix, $\mathbf{Y}$; and S-parameter matrix, $\mathbf{S}$. These matrices are computed in Port or Terminal sweeps (using the AC/DC Module or the RF Module), and are related by simple transformations,

$$Z = Y^{-1}$$
$$Z = Z_0(1+S)(1-S)^{-1}$$
$$S = Y_0(Z-1)(Z+1)^{-1}$$

where Z_0 is the characteristic impedance and Y_0 the characteristic admittance of the ports or terminals. In general, only one of the three matrices is computed by the physics interface and becomes available for evaluation.

Choose the appropriate transformation to compute and display one of the other two matrices. If the transformation requires it, specify a **Characteristic impedance** (SI unit: Ω) or **Characteristic admittance** (SI unit: S).

You can also make a transformation from Maxwell capacitance to mutual capacitance or vice versa by selecting **From Maxwell to mutual** or **From mutual to Maxwell**, and from an inverse Maxwell capacitance to mutual capacitance by selecting **From inverse Maxwell to mutual** (the inverse Maxwell capacitance is the output from sweeps over lumped parameters in electromagnetics). The relationship between the Maxwell capacitance matrix MA and the mutual capacitance matrix MU is that MU_{ij} is equal to $\sum_{k=1\ldots n} \mathrm{MA}_{ik}$ if $i=j$, or equal to $-\mathrm{MA}_{ij}$ otherwise.

The transformation operations are only applicable for square matrices.

Particle Evaluation

Use a **Particle Evaluation** ( ) derived values node to define the evaluation of the numerical value of quantities computed by one of the particle tracing interfaces. This feature requires the Particle Tracing Module. To add this node, right-click the **Derived Values** node or any **Evaluation Group** node and choose **Particle Evaluation** from the **More Derived Values** menu.

- See Common Results Node Settings for information about these sections: **Data** and **Expression**. The dataset must be a Particle (Dataset). If no **Particle** dataset is available then the only option is **None**.
- Derived Values, Evaluation Groups, and Tables

EVALUATION

To specify the particles to evaluate the expression for, the **Particles to evaluate** list contains the following options:

- Select **All** (the default) to evaluate the expression for all particles in the simulation.

- Select **Fraction** to evaluate for a fraction of all particles. Enter a scalar value between 0 and 1 in the **Fraction of particles** field. The default value is 1, which means that the evaluation includes all particles.
- Select **Number** to specify a number of particles to evaluate for in the **Number of particles** field. The default value is 100 particles. If the particle simulation contains fewer particles than the specified number, all particles are included.

The Results Table

Click the **Evaluate** button (=) or right-click the **Derived Values** node and select **Evaluate All** (=) or **Clear and Evaluate All** (=).

The first column in the table is a list of the **Time** values selected from the **Data** section. There are *N* additional columns, where *N* is the number of particles chosen in the **Evaluation** section.

The values in each column correspond to the supplied **Expression** for all the selected **Time** values. Each column contains *M* rows, where *M* is the number of **Time** values selected in the **Data** section. By default four digits are displayed; click the **Full precision** button (8.85 e-12) to display as many significant digits as possible. If required, the precision level can be changed from The Preferences Window under **General**.

Point Matrix Evaluation

Use a **Point Matrix Evaluation** ( ) to define the evaluation of the numerical values for a matrix variable, such as an anisotropic material property or coordinate system transformation matrix in a point. The **Table** window then displays all values for each selected point and, for example, for each parameter value if the solution includes a parametric sweep.

- Go to Common Results Node Settings for information about these sections: **Data** and **Expression**. For the expression, you can only choose from available matrix variables.
- Table

SELECTION

Select the points where you want to evaluate the matrix using the selection tools in this section. See About Selecting Geometric Entities.

DATA SERIES OPERATION

Select an option for operations on the data series for the inner solutions — typically a frequency sweep or time series from a study — and the outer solutions — the parametric sweep (for ports in electromagnetics, for example) — from the **Inner solutions** and **Outer solutions** lists:

- Select **None** to use the computed value as it is (the default).
- Select **Average** to use the average of the computed values for the inner solutions or the outer solutions.
- Select **Sum** to use the sum of the computed values for the inner solutions or the outer solutions.

The **Ignore NaN** checkbox is selected by default to ignore NaNs in the data for an inner or outer data series operation. If you want to keep values that are NaN, clear this checkbox.

Ray Evaluation

Use a **Ray Evaluation** (8.85) derived values node to evaluate a quantity computed by the Geometrical Optics or Ray Acoustics interface. This feature requires the Ray Optics Module or the Acoustics Module. This feature requires

the Particle Tracing Module. To add this node, right-click the **Derived Values** node or any **Evaluation Group** node and choose **Ray Evaluation** from the **More Derived Values** menu

- See Common Results Node Settings for information about these sections: **Data** and **Expression**. The dataset must be a Ray (Dataset). If no **Ray** dataset is available then the only option is **None**.
- Derived Values, Evaluation Groups, and Tables

EVALUATION

To specify the rays to evaluate the expression for, the **Rays to evaluate** list contains the following options:

- Select **All** (the default) to evaluate the expression for all rays in the simulation.
- Select **Fraction** to evaluate for a fraction of all rays. Enter a scalar value between 0 and 1 in the **Fraction of rays** field. The default value is 1, which means that the evaluation includes all rays.
- Select **Number** to specify a number of rays to evaluate for in the **Number of rays** field. The default value is 100 rays. If the ray simulation contains fewer rays than the specified number, all rays are included.

The Results Table

Click the **Evaluate** button (=) or right-click the **Derived Values** node and select **Evaluate All** (=) or **Clear and Evaluate All** (=).

The first column in the table is a list of the **Time** values selected from the **Data** section. There are *N* additional columns, where *N* is the number of rays chosen in the **Evaluation** section.

The values in each column correspond to the supplied **Expression** for all the selected **Time** values. Each column contains *M* rows, where *M* is the number of **Time** values selected in the **Data** section. By default four digits are displayed; click the **Full precision** button (8.85 e-12) to display as many significant digits as possible. If required, the precision level can be changed from The Preferences Window under **General**.

Aberration Evaluation

Use the **Aberration Evaluation** (8.85) derived values node to compute a list of Zernike coefficients for Zernike polynomials that correspond to various types of monochromatic aberration that arise when electromagnetic rays are focused by a system of lenses and mirrors. An Intersection Point 3D dataset (see Intersection Point 2D and Intersection Point 3D) pointing to a Ray (Dataset) dataset must be used. The dataset must point to an instance of the Geometrical Optics interface in which the optical path length is computed. To add this node, right-click the **Derived Values** node or any **Evaluation Group** node and choose **Aberration Evaluation** from the **More Derived Values** menu.

In addition, in the **Settings** window for the Intersection Point 3D dataset, **Hemisphere** must be selected from the **Surface type** list. The **Center** of the hemisphere corresponds to the focus and the **Axis direction** points from the focus toward the center of the exit pupil in the focusing system.

The **Aberration Evaluation** derived values node is available with the Ray Optics Module.

FILTERS

Use the options in the **Filters** section to exclude some rays from the calculation of the Zernike coefficients.

- Select the **Filter by wavelength** checkbox to exclude all rays except those of a specified vacuum wavelength. If this checkbox is selected, enter a **Wavelength** (default: 632.8 nm) and a **Tolerance** (default: 1 nm). If the difference

between the specified wavelength and the vacuum wavelength of a ray exceeds this tolerance, then the ray will be ignored.

- Select the **Filter by release feature index** checkbox to exclude all rays except those released by a specific physics feature. Then enter an integer value for the index; the default is 1. This field is 1-indexed, meaning that 1 corresponds to the first ray release feature, 2 is the second ray release feature, and so on.
- Select the **Filter by number of reflections** checkbox to include rays only if they have reflected a specified number of times. Then enter an integer for the number of reflections; the default is 0. For this option to work correctly, it is necessary to select the **Count reflections** checkbox in the settings for the Geometrical Optics interface, before running the study.
- Select the **Filter by additional logical expression** checkbox to include rays if they satisfy another user-defined expression. The expression is considered to be true if it returns a nonzero value. The default expression is 1, which would cause all rays to be included.

ZERNIKE COEFFICIENT CALCULATION

The optical path difference among all rays that pass through the exit pupil is computed. Then a linear least-squares fit is used to express the optical path difference as a linear combination of a standard set of orthogonal polynomials on the unit circle, called *Zernike polynomials*. The polynomials are scaled by the coefficients that are computed by the least-squares fit, called the *Zernike coefficients*.

Select the **Length unit** in which the Zernike coefficients will be given. The default is the micron (μm). This input is disabled if the model is dimensionless.

Select an option from the **Maximum polynomial order** list: **2**, **3**, **4**, or **5** (the default).

A list of Zernike polynomials and their derivation, properties, and references are included in the Ray Optics Modeling chapter of the *Ray Optics Module User's Guide*.

Global Evaluation Sweep

Use the **Global Evaluation Sweep** ( ) derived values node to vary a small number of model parameters as an evaluation sweep during postprocessing. A global evaluation sweep can be useful for postprocessing of reduced models, for example. To add this node, right-click the **Derived Values** node or any **Evaluation Group** node and choose **Global Evaluation Sweep** from the **More Derived Values** or **More Evaluations** menu, respectively.

- See Common Results Node Settings for information about the **Data** and **Expressions** sections.
- Model Reduction

PARAMETERS

Use the **Sweep type** list to specify the type of sweep to perform. The **Specified combinations** type (the default) sweeps over a number of given combinations of values, while the **All combinations** type sweeps over all combinations of values. Using all combinations can lead to a very large number of sweeps.

Use the table with **Parameter name** and **Parameter value list** to specify parameter names and values for the global evaluation sweep. Use the **Add** button (+) to add a row to the table. Each row has one parameter name, a corresponding parameter value list, and an optional unit. The unit becomes orange if the unit that you specify does not match the unit given for the parameter where it is defined. For the **Specified combinations** sweep type, the list of values must have equal length. When you click in the **Parameter value list** column to define the parameter values, you can click the **Range** button ( ) to define a range of parameter values. The parameter unit overrides the unit of the global parameter. If no parameter unit is given, parameter values without explicit dimensions are considered

dimensionless. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons as needed. In addition, use the **Clear Table** button ( ) to clear the entire table. Click the **Range** button ( )when the focus is in a **Parameter value list** cell to define a list of parameter values using the **Range** dialog.

The list of parameters in the **Parameter name** column contains parameters from **Parameters** nodes where the **Show in parameter selections** checkbox is selected.

If more than one parameter name have been specified, the lists of parameter values are interpreted as follows: Assume that the parameter names are `p1` and `p2`, and that `p1` has the list `1 3` and `p2` has the list `2 4`. For the **Specified combinations** sweep type, the solver first uses `p1` equal to `1` and `p2` equal to `2`. Thereafter, it uses `p1` equal to `3` and `p2` equal to `4`. And when the sweep type is **All combinations**, the sweep uses the following order for the parameter combinations: 1 2, 1 4, 3 2, and 3 4.

System Matrix

Use a **System Matrix** ( ) derived values node to evaluate a matrix defined in an **Assemble** or **Modal Solver** node to a table.

SOLUTION

Select a **Solution** from the list to specify which **Solver** branch to tabulate the system matrix for. From the **Solver feature** list, select the **Assemble** or **Modal Solver** node that computes the system matrix.

OUTPUT

Select a **Matrix**: **Stiffness matrix** (the default), **Damping matrix**, **Mass matrix**, or any other system matrix that the selected **Assemble** or **Modal Solver** node computes.

First select the system matrices to assemble or compute in the **Settings** window for the **Assemble** or **Modal Solver** node and then compute the solution so that the solver stores these system matrices. Selecting a system matrix that has not been computed and stored results in an error.

Select a **Format**: **Sparse** (the default) or **Filled**. The system matrices can become very large but are usually sparse (most matrix elements are zero). If **Filled** is selected, the preference setting for the maximum filled matrix size (the default is 100) on the **Results** > **Tables** page in the **Preferences** window prevents the creation of a table with a very large matrix. Typically, when this is an Assemble node, a filled matrix output can only be used for very small models or when using reduced matrices.

When the System Matrix is a Modal Solver, the matrices of interest are typically small and filled.

- Introduction to Solvers and Studies and Solution Utility Nodes
- Derived Values, Evaluation Groups, and Tables

Table

Tables can store the results of **Derived Values** and results from probes, for example. The results are displayed in the **Tables** window, which by default is located below the **Graphics** window.

If you make any changes to the Table settings, click the **Update** button ( ) at the top of the **Settings** window.

A **Table** node is added under **Tables**. Click the node to display a table with the selected integration node's description and values in the **Table** window.

You can use Table Graph and Table Surface nodes to plot the data in the tables.

The Table Window and Tables Node

There are three ways to evaluate a **Derived Values** node and put the result in a **Table**:

- Click the **Evaluate** button (=) found in the top-left corner of, for example, a **Settings** window for **Volume Integration**, **Surface Integration**, or **Line Integration**.
- In the **Model Builder**, right-click the specific **Derived Values** node (for example, **Volume**, **Surface**, or **Line Integration**) and select **Evaluate**.
- In the **Model Builder**, right-click the **Derived Values** node, and select **Evaluate All** (=) to evaluate all the **Derived Values** nodes. This appends the results to any existing tables. Select **Clear and Evaluate All** ( ) to first clear the affected tables and then evaluate all the **Derived Values** nodes.

In addition, you can specify the output table for data from a probe in the **Table and Windows Settings** section of the probe **Settings** window. Also, for nested parametric sweeps, you can add an accumulated probe table, which provides a matrix of values where the rows and columns represent two independent parameters.

To delete all tables, right-click the main **Tables** node and select **Delete All** ( ). To clear the contents of all tables, right-click the main **Tables** node and select **Clear All**.

DATA

If applicable (for accumulated probe tables, for example) select a data format from the **Presentation format** list: **All** (the default) or **Filled**:

- **All** displays all data in the table. For many tables, that is the only available format.
- Select **Filled** to create a matrix of data from, for example, a nested parametric sweep with independent parameters.

The table itself can be filled regardless of the settings in the **Presentation format** list.

Filled tables can only be produced by studies that have **All combinations** selected in their parametric sweeps. The filled tables make it possible to retrieve data for a pair of parameters on a matrix format and can be used to make response surface plots, for example. You can get filled tables from some probes or from using derived values when all solutions are selected. Basically, you get filled tables when the input parameters in a parametric sweep (such as time) represent a full outer product. In some cases, such as eigenvalue solutions or if the solver is interrupted, the data is not filled. Also, if you modify the table by, for example, evaluating more than once into the same table or delete columns, the table data is no longer filled.

For a **Filled** presentation format, under **Column headers**, select a **Column description** (in addition to the parameter values): **None**, **From data** (the default), or **Manual**. If you select **Manual**, type the description in the **Description** field; that description is then added to the parameter values in the header of each column.

Under **Filled data structure**, select the parameters to use for the rows and the columns from the **Rows** and **Columns** lists, and select the data (probed quantity, for example) to use in the table from the **Data** list. These settings are available when the table is filled, also when the presentation format is set to **All**.

Click the **Import** button to import data from, for example, a spreadsheet. In the **Import** dialog that opens, select a data file to import. You can import data from text files (*.txt), CSV files (*.csv), and data files (*.dat). If the license includes LiveLink™ *for* Excel®, you can also import data from a Microsoft Excel® file (some or all of *.xlsx, *.xls, *.xlsb, *.xlsm). The supported Excel file formats depend on whether Excel is installed or not (see Supported Microsoft Excel File Types in the *COMSOL Multiphysics Programming Reference Manual*).

The imported data replaces any existing data in the table.

You can import data in multiple **Table** nodes to plot exported solution data from different models in the same graph. To do so, after importing the data, create a 1D Plot Group and then add Table Graph nodes that point to each of the tables.

STORAGE

You can also store the table data on file instead of, or in addition to, storing it in the model. Select a way to store the table data from the **Store table** list:

- Select **In model** (the default) to store the table data in the model.
- Select **On file** to store the table data in the model to a file that you select by first clicking **Browse** or enter into the **Filename** field. This makes it possible to, for example, keep track of more data using probes while solving without having to put all the data in the model. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Edit Location** ( ) (if the location is a database), **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).
- Select **In model and on file** to store the table data both in the model and on file.

For the storage in the model, specify the buffer size in the **Maximum number of rows** field. The default for new tables is taken from the **Results** > **Tables** page in the **Preferences** window (factory setting: 10,000 rows). If the table size exceeds that number of rows, the software removes rows from the top. If you use a large number, most table data will fit in the table without being truncated.

The row limit applies to table data in the model only and not to tables with data stored on a file.

COLUMN HEADERS

You can specify the headers for each column in the table when the presentation format is set to **All**. In the **Header** column, enter the header that you want to use for the corresponding column. When you import table data from a file, COMSOL Multiphysics uses the contents of the last comment row preceding the data to create column headers, which you can edit if desired. For comma-separated data and column headers, the CSV (comma-separated) data file format (.csv files) works best. If a CSV file contains exactly one row without data preceding the data, and the nondata row contains the right number of columns, the import interprets the contents of that row as column headers.

LOCATION IN USER INTERFACE

To add a **Table** node, if not already created, right-click the **Tables** ( ) node and select **Table**. You can also add a table by clicking the **Evaluate (New Table)** button ( ), which is in the top-left corner of, for example, a **Settings** window for **Volume Integration**, **Surface Integration**, or **Line Integration**. This evaluates the node and stores the result in a new table. This button is also used as the **Evaluate** button.

Plot Groups and Plots

About Plot Groups

A plot group contains one or more plots (for example, combining a surface plot and a streamline plot) using the same or separate datasets, such as a solution. All active plots in a plot group appear in the same plot window. You can define plot groups for 1D, 2D, 3D, polar, and Smith plots (requires the RF Module or the AC/DC Module) and then create an individual or a series of plots in a plot group. You can use several plot groups of the same type in a model and plot them in the Graphics window or in another plot window that you can add if needed. Information in the form of data and images can be used to generate a report or presentation or be exported.

Attributes can also be added as subnodes to a plot to modify the plot's behavior — **Deformation** ( ) attributes deform a plot (to illustrate, for example, structural deformation) and **Transformation** ( ) attributes to transform (move, scale, and rotate) a plot; **Color Expression** ( ) attributes modify the color of a plot; filtering to only include parts of the plot is available using the **Filter** ( ) attribute; **Selection** ( ) attributes limit the plot to a selected subset of the geometry; and **Export Expressions** ( ) attributes can add quantities to the data export for streamline, radiation pattern, and trajectories plots. Add a **Material Appearance** ( ) attribute to include material appearances in postprocessing plots or a **Transparency** ( ) attribute to display 3D plots and 2D plots using a height expression using transparency. A **Height Expression** ( ) attribute can also be added to some 2D plots. For volume and surface plots in 2D and 3D you can embed an **Image** ( ). You can add **Marker** ( ) and **Graph Marker** ( ) attributes to add markers for indicating minimum and maximum values, for example, to 2D and 3D plots and 1D graph plots, respectively.

You can also select appropriate color tables for the plots' color expressions based on your audience and what you plan to do with the final analysis.

The physics interfaces create suitable default plots for visualizing the results for the particular physics or application. The default plots appear in plot groups with descriptive names. You can modify and delete these plots and plot groups and add additional plots to existing or new plot groups. To disable the default plots for a study, clear the **Create default plots** checkbox in the **Study Settings** section in the main **Settings** window for a **Study** node. You can also add plot groups as result templates (see Adding and Creating Result Templates) by right-clicking a plot group node and choosing **Add as Result Template**.

ADDING PLOTS TO PLOT GROUPS

Under **Results** ( ) in the **Model Builder**, right-click the **Plot Group** node and select an option from the context menu to plot the graphs listed in Table 21-11. Each plot group can have several plots combined to create a meaningful representation of the data.

When the plot type is defined, click the **Plot** button ( ), press F8, or right-click the node and select **Plot**. The plot displays in the window selected from the **Plot window** list. To plot results in another window, right-click the plot group node or the plot node and select a plot window from the **Plot In** submenu.

- At any time during plot creation, click the **Plot** button ( ) to visualize a dataset or plot.
- When you are working with **Functions**, you can also click the **Create Plot** button ( ) to create a customized plot of the function under **Results**, including default plot groups and plots.
- The time-related settings only display on the interfaces for time-dependent models.

- See Plot Types for a summary of the available plot types, including links.
- Results Toolbar and Plot Group Contextual Toolbar
- Creating Cross-Section Plots and Combining Plots

Depending on the physics interface included in the model, not all plot types in the table below may be available. To see all plot types, select the **All Plot Types** checkbox in the **Show More Options** dialog. To see the Particle Tracing and Particle Tracing with Mass plot types, you must first select the **All Plot Types** checkbox.

COPYING PLOT DATA TO THE CLIPBOARD AND TO TABLES

For plots in plot groups, you can right-click the plot node and choose **Copy Plot Data to Clipboard** ( ). The plot data is then directly available on the clipboard so that it can be pasted into a document or spreadsheet without the need to add an **Export** > **Data** node.

For 1D plots, you can right-click the plot node and choose **Copy Plot Data to Table** ( ). The plot data is then available in a new **Table** node and its associated **Table** window.

The time-related settings only display for time-dependent models.

SHOWING COORDINATES OF GRAPH PLOTS

For graph plots in 1D plot groups, you can get information, in a tooltip, about the x- and y-coordinate values for the graph when hovering over it with the mouse. The tooltip also contains information about the line style, in the upper-left corner, and the time or parameter value, for example, that the graph represents, in the upper-right corner. The tooltip appears by default; click the **Enable Tooltip** button ( ) in the **Graphics** window toolbar to disable it.

GETTING GENERAL INFORMATION ABOUT PLOTS

If desired, all plot nodes' **Settings** windows can include an **Information** section, which includes information about the plotting time, memory usage, and the number of points and elements in the plot. To include the **Information** section, select the **Plot Information Section** checkbox under **Results** in the **Show More Options** dialog and then click **OK**. The same information can also appear in the **Log** window, if you first select the **Log plot information** checkbox on the **Log and Messages** page under **User Interface** in the **Preferences** window and then click **OK**.

Plot Types

The following table lists the available plot types and their attributes, including links to the description of the properties and settings. Table 21-12 below it lists the plot attributes: subnodes that you can add to certain plot types to modify or enhance the plot.

TABLE 21-11: PLOT TYPES.

NAME AND LINK	DESCRIPTION	PLOT ATTRIBUTES
Admittance Graph	Plot an admittance graph as a Smith plot. This plot requires the RF Module, AC/DC Module, MEMS Module, or Plasma Module.	Color Expression, Filter
Annotation	Add annotations to plots.	Deformation, Transformation, Transparency (3D only), Visual Effects (3D only)
Annotation Data	Plot raw point, text, and color data as annotations in 2D or 3D. Only available through the COMSOL Multiphysics API.	Transparency

TABLE 21-11: PLOT TYPES.

NAME AND LINK	DESCRIPTION	PLOT ATTRIBUTES
Arrow Data	Plot raw point, vector, and color data as arrows in 2D or 3D. Only available through the COMSOL Multiphysics API.	Material Appearance, Transparency (3D Only), Visual Effects (3D only)
Arrow Line	Plot a vector quantity as arrows on lines or edges (3D).	Color Expression, Deformation, Filter, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Arrow Point	Plot a vector quantity as arrows at points.	Color Expression, Deformation, Filter, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Arrow Surface	Visualize a vector quantity in arrows.	Color Expression, Deformation, Filter, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Arrow Volume	Visualize a vector quantity as arrows in a volume.	Color Expression, Deformation, Filter, Material Appearance, Selection, Transformation, Transparency, Visual Effects
Contour (Plot)	Visualize a scalar quantity as a contour plot.	Color Expression, Deformation, Filter, Height Expression (2D only), Marker, Transformation, Selection, Transparency (3D and 2D with Height Expression only), Visual Effects (3D and 2D with Height Expression only)
Contour Series	Visualize a varying quantity (over time, for example) as a series of contour plots.	Color Expression, Deformation, Filter, Height Expression (2D only), Marker, Selection, Transformation, Transparency (3D and 2D with Height Expression only), Visual Effects (3D and 2D with Height Expression only)
Coordinate System Volume, Coordinate System Surface, Coordinate System Line, and Coordinate System Point	Plot coordinate systems for 2D and 3D models. Found on the More Volume Plots, More Surface Plots, More Line Plots, and More Point Plots submenus, respectively.	Deformation, Filter, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Directivity	Plot the directivity as a plot for speakers, for example. This plot requires the Acoustics Module.	None
Function	Plot a function as a graph plot (1D), surface plot (2D), or slice plot (3D).	Filter (2D and 3D only), Height Expression (2D only), Transparency (2D with Height Expression and 3D only), Visual Effects (2D with Height Expression and 3D only), Error Bars (1D only)
Global	Plot a global scalar quantity as a function of time or a parameter.	Color Expression, Comparison, Error Bars, Filter, Graph Marker
Histogram	Plot a histogram showing the distribution of a quantity.	Filter, Height Expression (2D only), Transparency (with Height Expression only), Visual Effects (with Height Expression only)

TABLE 21-11: PLOT TYPES.

NAME AND LINK	DESCRIPTION	PLOT ATTRIBUTES
Image	Plot an image on the surface of a 2D or 3D geometry.	Deformation, Material Appearance, Transformation, Transparency (3D only), Visual Effects (3D only)
Impedance Graph	Plot an impedance graph as a Smith plot. This plot requires the RF Module, AC/DC Module, MEMS Module, or Plasma Module.	Color Expression, Filter
Impulse Response	Plot an impulse response plot. This plot requires the Acoustics Module.	Color Expression, Energy Decay
Interference Pattern	This plot shows the intensity on a cut plane resulting from the interference of multiple rays passing through the cut plane.	None
Isosurface (Plot)	Plot a scalar quantity as an isosurface plot.	Color Expression, Deformation, Filter, Marker, Material Appearance, Selection, Transformation, Transparency, Visual Effects
Isosurface Series	Visualize a varying quantity (over time, for example) as a series of isosurface plots.	Color Expression, Deformation, Filter, Marker, Selection, Transformation, Transparency, Visual Effects
Joint Probability Distribution	Plot joint probability distributions.	None
Layered Material Slice	Plot a layered material quantity as a slice plot at a specified through-thickness location. This plot requires the AC/DC Module, Composite Materials Module, Heat Transfer Module, or Structural Mechanics Module.	Deformation, Filter, Marker, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Line	Plot a quantity on lines — that is, boundaries in 2D or edges in 3D.	Deformation, Filter, Selection, Marker, Material Appearance, Height Expression (2D only), Transformation, Transparency (3D and 2D with Height Expression only), Visual Effects (3D and 2D with Height Expression only)
Line Data	Plot raw point, element, and color data as a line in 2D or 3D. Only available through the COMSOL Multiphysics API	Marker, Material Appearance, Transparency (3D only), Visual Effects (3D only)
Line Graph	Plot a scalar quantity along a geometric line. The line can be an edge in the geometry, a parametric curve, or a cut line.	Color Expression, Comparison, Filter, Graph Marker
Line Segments	Add line segments to 1D plots.	None
Matrix Histogram	Plot a precomputed matrix as a 2D histogram. For rainflow counting, for example, to be able to visualize how the stress amplitudes and mean stresses are distributed. This plot requires the Fatigue Module.	Filter, Height Expression, Transparency (with Height Expression only), Visual Effects (with Height Expression only)
Max/Min Volume, Max/Min Surface, Max/Min Line, Max/Min Point	Plot the maximum and minimum of an expression and the points where they are attained within the geometry. Found on the More Volume Plots, More Surface Plots, More Line Plots, and More Point Plots submenus, respectively.	Deformation, Filter, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)

TABLE 21-11: PLOT TYPES.

NAME AND LINK	DESCRIPTION	PLOT ATTRIBUTES
Mesh (Plot)	To display a mesh.	Deformation, Filter, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Multislice	Display a scalar quantity on slices in multiple directions inside a 3D domain. Found on the More Surface Plots submenu.	Deformation, Filter, Marker, Material Appearance, Selection, Transformation, Transparency, Visual Effects
Nyquist	Display a Nyquist plot, which shows the magnitude and phase of a frequency response.	Color Expression, Filter
Octave Band	Display an octave band plot to represent a frequency response in frequency bands.	Graph Marker
Optical Aberration	Display a linear combination of Zernike polynomials based on the optical path difference of light rays as they are focused by a system of lenses and mirrors. This plot requires the Ray Optics Module.	Height Expression, Transparency (with Height Expression only), Visual Effects (with Height Expression only)
Particle (Plot)	Plot a particle variable versus time for all particles, or plot one particle property versus another at a set of time steps. Available with 1D Plot Groups. This plot requires the Particle Tracing Module.	Color Expression, Filter
Particle Tracing	Visualize the trajectory of a massless particle subject to a flow field. Found on the More Point Plots submenu.	Color Expression, Deformation, Transformation, Transparency (3D only), Visual Effects (3D only)
Particle Tracing with Mass	Make a particle tracing plot considering the particle's mass. Found on the More Point Plots submenu.	Color Expression, Deformation, Transformation, Transparency (3D only), Visual Effects (3D only)
Particle Trajectories and Filter for Particle Trajectories	Visualize the trajectories of particles computed by one of the Particle Tracing physics interfaces. This plot requires the Particle Tracing Module.	Color Expression, Deformation, Export Expressions, Filter, Material Appearance, Transformation, Transparency (3D only), Visual Effects (3D only)
Pellets	Visualize pellets as spheres or slices in 3D.	Deformation, Transformation, Transparency, Visual Effects
Phase Portrait	Visualize particle traces using a phase portrait in 2D. Found under the More Surface Plots submenu. This plot requires the Particle Tracing Module.	Color Expression, Material Appearance
Poincaré Map	Visualize particle traces as a Poincaré map in 2D, 2D axial symmetry, and 3D. Found on the More Surface Plots or More Volume Plots (3D) submenu. This plot requires the Particle Tracing Module.	Color Expression, Material Appearance, Transparency (3D only), Visual Effects (3D only)
Point	Plot points in 2D and 3D.	Deformation, Export Expressions, Filter, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)

TABLE 21-11: PLOT TYPES.

NAME AND LINK	DESCRIPTION	PLOT ATTRIBUTES
Point Data	Plot raw point, element, and color data as points in 2D or 3D. Only available through the COMSOL Multiphysics API.	Marker, Material Appearance, Transparency (3D only), Visual Effects (3D only)
Point Graph	Visualize the value in a point along time or a parameter value. The point can be a point in the geometry or a cut point.	Color Expression, Comparison, Error Bars, Filter, Graph Marker
Point Trajectories and Filter for Point Trajectories	Visualize the trajectories of points in 3D. Found on the More Point Plots submenu.	Color Expression, Deformation, Export Expressions, Filter, Material Appearance, Transformation, Transparency (3D only), Visual Effects (3D only)
Polarization	Plot the polarization state for diffraction orders, simulated for periodic structures.	Color Expression
Principal Stress Volume	Plot principal stress and strain in structural mechanics models. Found on the More Volume Plots submenu.	Color Expression, Deformation, Filter, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Principal Stress Surface	Plot principal stress and strain in structural mechanics models. Found on the More Surface Plots submenu.	Color Expression, Deformation, Filter, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Principal Stress Line	Plot principal stress and strain in structural mechanics models. Found on the More Line Plots submenu.	Color Expression, Deformation, Filter, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Radiation Pattern	Plot the value of a global variable for the radiation pattern of an electromagnetic or acoustic pressure field, for example.	Deformation, Export Expressions, Graph Marker (1D only), Material Appearance, Transformation (2D and 3D only), Transparency (3D only), Visual Effects (3D only)
Ray (Plot) and Filter for Ray and Ray Trajectories	Plot a ray variable versus time for all rays, or plot one ray property versus another at a set of time steps. Available with 1D Plot Groups. This plot requires the Ray Optics Module or the Acoustics Module.	Color Expression and Filter
Ray Trajectories and Filter for Ray and Ray Trajectories	Visualize the trajectories of rays computed by the Geometrical Optics interface or Ray Acoustics interface. This plot requires the Ray Optics Module or the Acoustics Module.	Color Expression, Deformation, Export Expressions, Filter, Material Appearance, Transformation, Transparency (3D only), Visual Effects (3D only)
Reflection Graph	Plot a reflection graph as a Smith plot. This plot requires the RF Module, AC/DC Module, MEMS Module, or Plasma Module.	Color Expression, Filter
Scatter Surface Scatter Surface and Scatter Volume	Scatter surface plots, found on the More Volume Plots (3D) and More Surface Plots (3D) submenus, visualize a scalar quantity as scattered spheres or disks. The radius of the spheres can be proportional to the value of a quantity.	Material Appearance

TABLE 21-11: PLOT TYPES.

NAME AND LINK	DESCRIPTION	PLOT ATTRIBUTES
Scatter Volume Scatter Surface and Scatter Volume	Scatter volume plots can be used as alternatives to arrow plots for scalar quantities or when to get a feeling for how entities correlate.	Material Appearance, Transparency, Visual Effects
Slice	Display a scalar quantity on slices inside a 3D domain.	Deformation, Filter, Marker, Material Appearance, Selection, Transformation, Transparency, Visual Effects
Sobol Index	Plot Sobol indices. This plot requires the Uncertainty Quantification Module.	None
Spot Diagram	Display the positions of rays as they intersect an image plane. This plot includes some capability to automatically identify the image plane and compute the intersection points of rays that cross it.	Color Expression
Streamline	Plot a vector field as a streamline plot.	Color Expression, Deformation, Export Expressions, Filter, Material Appearance, Selection, Transformation, Transparency (3D only), Visual Effects (3D only)
Streamline Multislice	Plot a vector field as a streamline plot on surfaces in 3D.	Color Expression, Deformation, Export Expressions, Filter, Material Appearance, Selection, Transformation, Transparency, Visual Effects
Streamline Surface	Plot a vector field as a streamline plot on surfaces in 3D.	Color Expression, Deformation, Export Expressions, Filter, Material Appearance, Transformation, Transparency, Visual Effects
Surface (Plot)	Display a quantity on a 2D domain or a 3D boundary.	Deformation, Filter, Height Expression (2D plots only), Image, Marker, Material Appearance, Selection, Transformation, Transparency (3D and 2D with Height Expression only), Visual Effects (3D and 2D with Height Expression only)
Surface Data	Plot raw point, element, and color data as a surface in 2D or 3D. Only available through the COMSOL Multiphysics API.	Marker, Material Appearance, Transparency (3D only), Visual Effects (3D only)
Surface Slit	Display a quantity by evaluating one expression on one side and another expression on the other side on a 3D boundary.	Deformation, Filter, Marker, Material Appearance, Selection, Transformation, Transparency, Visual Effects
Table Annotation	Add annotations from a table to a plot.	Transparency (3D only), Visual Effects (3D only)
Table Contour	Plot contours based on values from a table.	Height Expression, Marker, Material Appearance, Transparency (with Height Expression only), Visual Effects (with Height Expression only)
Table Graph and Filter for Table Graph	Table plots display data from a table with one line per output column.	Error Bars, Filter, Graph Marker
Table Histogram	Plot a histogram showing the distribution of a quantity from a table or evaluation group.	Height Expression (2D only), Transparency (with Height Expression only), Visual Effects (with Height Expression only)
Table Point	Plot points in a table in a 2D plot.	Marker

TABLE 21-11: PLOT TYPES.

NAME AND LINK	DESCRIPTION	PLOT ATTRIBUTES
Table Surface	Used with 2D plot groups to visualize the data in a table that represents a matrix of values that are functions of two independent parameters.	Height Expression, Marker, Material Appearance, Transparency (with Height Expression only), Visual Effects (with Height Expression only)
Through Thickness	Display the through-thickness variation of a layered shell quantity at specified points. This plot requires the AC/DC Module, Composite Materials Module, Heat Transfer Module, or Structural Mechanics Module.	Color Expression, Filter
Tube Data	Plot raw point, element, and color data as a tube in 2D or 3D. Only available through the COMSOL Multiphysics API.	Marker, Transparency (3D only), Visual Effects (3D only)
Volume	To display a quantity inside a 3D domain.	Deformation, Filter, Image, Marker, Material Appearance, Selection, Transformation, Transparency, Visual Effects
Waterfall	Create a waterfall diagram, which is a plot that can illustrate how an expression depends on two parameters in a sweep. Found on the More Point Plots submenu,	Color Expression, Material Appearance, Transparency, Visual Effects
Whirl	Display a plot of the mode shapes of a rotor rotated about the rotor axis at discrete rotation intervals. This plot type, found on the More Line Plots submenu, requires the Rotordynamics Module.	Color Expression, Material Appearance, Transparency, Visual Effects
CROSS SECTION PLOTS		
*1D, 2D, and 3D Cross-Section Point Plots	A point cross-section plot makes it easy to view an expression at an arbitrary set of spatial coordinates and results in a line plot.	
*2D Cross-Section Line Plots and 3D Cross-Section Line Plots	Create lines through 2D and 3D geometries to visualize along the line. Also explains how to use the interactive cross-section toolbar buttons.	
*3D Cross-Section Surface Plot	Create planes through a 3D model in a 2D geometry to visualize on the plane. The cut plane corresponds to an orthogonal 2D coordinate system embedded in 3D. Also explains how to use the interactive cross-section toolbar buttons.	
* Cross-section plots are not selected from this menu. Instead, these are created in two steps using datasets and plot groups to generate the plot or use interactive cross-section toolbar buttons.		

TABLE 21-12: PLOT ATTRIBUTES.

PLOT ATTRIBUTE	DESCRIPTION	ADD TO THESE PLOT TYPES
Color Expression	To add coloring to the shapes defined by a plot.	Arrow (line, surface, and volume), contour, isosurface, particle tracing, particle trajectories, point trajectories, polarization, principal stress, ray, ray trajectories, streamline, streamline multislice, streamline surface, and spot diagram.
Comparison	To make a comparison of a graph plot and a table graph.	1D line graph, point graph, and global plots.

TABLE 21-12: PLOT ATTRIBUTES.

PLOT ATTRIBUTE	DESCRIPTION	ADD TO THESE PLOT TYPES
Deformation	Deform the plot according to a vector quantity, for example, the displacement field in structural mechanics.	All 2D and 3D plots except annotation data, arrow data, directivity, function, interference pattern, histogram, matrix histogram, optical aberration, pellets, phase portrait, Poincaré map, scatter, spot diagram, streamline, streamline multislice, streamline surface, table annotation, table graph, table histogram, table histogram, waterfall, and whirl plots.
Energy Decay	Energy decay for impulse response plots.	Impulse response plots.
Error Bars (Global, Point Graph, and Function)	Error bars for point graph and global plots.	1D point graph and global plots.
Error Bars (Table Graph)	Error bars for table graph plots.	1D table graph plots.
Export Expressions	Add expressions for exporting data.	Particle trajectories, point trajectories, radiation pattern, ray trajectories, streamline, streamline multislice, and streamline surface.
Filter, Filter for Particle Trajectories, Filter for Point Trajectories, Filter for Ray and Ray Trajectories, and Filter for Table Graph	Filter the element selection for a plot.	Admittance graph, arrow (line and surface), contour, coordinate system (line and surface), function (2D only), global, histogram. impedance graph, isosurface, line graph, line plot, matrix histogram, mesh, Nyquist, particle trajectories, point graph, point trajectories, principal stress, ray, ray trajectories, reflection graph, slice, streamline, streamline multislice, streamline surface, surface, table graph, and volume.
Graph Marker	Markers such as minimum and maximum markers for graph plots.	1D point graph, global, table graph, radiation pattern, and octave band plots.
Height Expression	Height attributes introduce a 3D height on a 2D surface plot.	2D histogram and matrix histogram, 2D line plot, optical aberration, 2D surface plot, 2D contour and table contour plots, 2D table surface plot, and 2D function plots.
Image (Plot Attribute)	To add an image to a surface or volume,	3D volume plots, and 2D and 3D surface plots.
Marker	Minimum and maximum markers.	3D volume, 2D and 3D surface and surface data, 2D and 3D line and line data, contour and contour series, isosurface and isosurface series, layered material slice, multislice, point data, slice, surface slit, and table contour, table point, table surface, and tube data plots.

TABLE 21-12: PLOT ATTRIBUTES.

PLOT ATTRIBUTE	DESCRIPTION	ADD TO THESE PLOT TYPES
Material Appearance	Use a material appearance in plots.	3D volume, 2D and 3D surface, 2D and 3D arrow, 2D and 3D contour and 2D table contour, image, isosurface, 2D and 3D layered material slice, 2D and 3D line, multislice, 2D and 3D particle trajectories, phase portrait, 2D and 3D principal stress, Poincaré map, 2D and 3D, 2D and 3D point trajectories, radiation pattern, 2D and 3D ray trajectories, scatter surface, scatter volume, slice, 2D and 3D streamline, streamline multislice, streamline surface, surface data, surface slit, table surface, waterfall, and whirl plots.
Selection (Plot Attribute)	Add a selection of geometric entities for which to show the plot.	Arrow, contour, coordinate system (line, surface, and volume), isosurface, line plot, mesh, multislice, principal stress, slice, streamline, streamline multislice, surface, and volume plots.
Transformation	Add a translation to 2D and 3D plots.	All 2D and 3D plots except annotation data, arrow data, directivity, function, interference pattern, histogram, matrix histogram, optical aberration, pellets, phase portrait, Poincaré map, scatter, spot diagram, streamline, streamline multislice, streamline surface, table graph, table histogram, table surface, waterfall, and whirl plots.
Transparency	Add transparency to 3D plots and 2D plots with a Height Expression.	Annotation, arrow, contour, coordinate system, image, isosurface, layered material slice, line, max/min, mesh, multislice, particle tracing, particle trajectories, particle trajectories with mass, pellets, Poincaré map, point, point trajectories, principal stress, radiation pattern, ray trajectories, scatter volume, slice, streamline, streamline multislice, streamline surface, surface, surface slit, table annotation, volume, waterfall, and whirl 3D plots. Also, for contour, contour series, table contour, function, histogram, line, matrix histogram, optical aberration, surface, table histogram, and table surface 2D plots that use a height expression.
Visual Effects	Add visual effects (ambient occlusion and direct shadows) to 3D plots and 2D plots with a Height Expression.	All 3D plots. Also, for contour, contour series, function, histogram, line, matrix histogram, optical aberration, surface, table contour, table histogram, and table surface 2D plots that use a height expression.

The Plot Windows

Plot windows are also graphics windows. COMSOL Multiphysics generates such plot windows for displaying convergence results and to monitor probe values while solving (if your model contains probes). To create a new plot window, choose **Plot In** > **New Window** from the context menu for a plot group.

- At any time during plot creation, click the **Plot** button ( ) to visualize a dataset or plot.
- When you are working with **Functions**, you can also click the **Create Plot** button ( ) to create a customized plot of the function under **Results**, including default plot groups and plots.
- You can close all plot windows (except the main **Graphics** window) by right-clicking the **Results** node ( ) and selecting **Close All Plot Windows** ( ).

This section explains how to add plot windows, specify the window to plot in, and lock plot windows.

ADDING PLOT WINDOWS

The COMSOL Desktop always includes The Graphics Window, which is the default window for all kinds of plots, but you can also add other plot windows for results plots by right-clicking a plot group node and choosing **Plot In** > **New Window** or by adding a plot window in the **Window Settings** section of the plot group nodes' **Settings** windows.

SPECIFYING THE WINDOW TO PLOT IN

The default for all plot groups is to plot in the **Graphics** window, but you can plot in any other plot window by right-clicking the plot group node and choosing another plot window from the **Plot In** submenu. The **Plot In** submenu also exists in the context menu for each plot type if you want to plot only an individual plot type in a plot group. You can also control where the plots appear and add new plot windows in the **Window Settings** section of the **Settings** windows for the plot group nodes.

To create and update all plots in all plot windows, right-click the **Results** node and select **Plot All** ( ). If more than one plot group use the same plot window, that plot window contains the plots from the last plot group. To update all plots under a **Group** node, right-click that node, and then select **Plot All in Group**.

LOCKING PLOT WINDOWS

If you want to prevent a plot in a plot window from being overwritten by other plots, you can lock the plot window. To prevent a plot displaying in this window from being overwritten by other plots, click the **Lock Plot Window** button ( ) in the plot window toolbar. Any attempt to create a plot in a locked plot window then results in a message such as **Window 'Plot 1' is locked** in the **Messages** window. Click the **Lock Plot Window** button ( ) again to clear the lock. It is not possible to lock the **Graphics** window, which COMSOL Multiphysics uses for general visualization.

- Getting Results While Solving
- Results Toolbar and Plot Group Contextual Toolbar
- The Graphics Window

Adding and Creating Result Templates

Open the **Result Templates** window to add plot groups, evaluation groups, and derived values that are predefined by the physics interfaces in the model but not added directly when you compute the solution. You can open the **Result Templates** window ( ) from the **Results** section in the **Home** toolbar, the **Definitions** section in the **Results** toolbar, and from the **Windows** menu. Click the button again in a toolbar to close the **Result Templates** window.

In the **Result Templates** window, the available result templates are organized in a tree structure. Select the result templates that you want to add. Then right-click and choose **Add Result Template**, or click the **Add Result Template** button at the top of the window. You can also type a filter text in the text field above the plot tree to only show result templates that match the filter text. Click **Reload** to reload the content of the **Result Templates** window.

The tree of predefined result templates appears when you have computed the solution, and its content depends on the physics interfaces and studies used in the model. If the physics interfaces in the model do not create any predefined result templates, the tree is empty.

Notes like the following contain information about predefined result templates as well as special results variables and other results considerations for many physics interfaces:

These notes contains information about result templates, results variables, and other results considerations that are specific to a physics interface.

USER-DEFINED RESULT TEMPLATES

You can add your own favorite plot groups as well as evaluation groups and derived values to the **Result Templates** window for reuse in other models. When you have made a plot that you would like to reuse, select **Add as Result Template** ( ) in the context menu for many result nodes. It is available for plot group nodes, **Evaluation Group** nodes and nodes under **Derived Values**. You can also choose **Add as Result Template** from group nodes, if you have added plots under a group node, for example. The plot then shows up in the **Result Templates** window under **User-Defined** ( ), using the same group structure, if applicable. You can sort the result templates using the **Move Up** and **Move Down** options on the user-defined result templates' context menus. You can also choose **Remove from Result Templates** to remove that plot or result evaluation from the result templates. When adding a result template to the model tree, the COMSOL software tries to find the same type of solution dataset that was used when the result template was created. For example, a plot made using a time-dependent solution tries to use a time-dependent solution dataset if there is one in the model. The software also tries to find a correct expression even if the physics in the model has another scope or other dependent variable names than the one in the original model.

Creating Cross-Section Plots and Combining Plots

Cross-section plots are created using a combination of datasets and plot groups. Cross-section plots show the values over time, along a parametric solution, or for several eigenvalues. Cross-section plots visualize a quantity as a family of plots on:

- An arbitrary set of points (in 1D, 2D, or 3D)

  A point cross-section plot makes it easy to view an expression at an arbitrary set of spatial coordinates and results in a line plot. See 1D, 2D, and 3D Cross-Section Point Plots.

Expressions and variables that include derivatives of the dependent variables (for example, stresses in a structural analysis) are not available at isolated geometry vertices (points).

- An arbitrary line (in 2D or 3D). See 2D Cross-Section Line Plots and 3D Cross-Section Line Plots.

  Use Cut Line datasets to create lines through 2D or 3D geometries to visualize along the line. All plots and results analysis nodes available in 1D are available for Cut Line datasets as well as 3D plots and results analysis nodes for edges.

- Arbitrary planes (in 3D) using a surface plot and cut plane dataset. See 3D Cross-Section Surface Plot.

  Use Cut Plane datasets to create planes through a 3D geometry in a 2D geometry to visualize on the plane. All plots and results analysis nodes available in 2D are available for Cut Plane datasets as well as for surfaces in 3D. The cut plane corresponds to an orthogonal (Cartesian) 2D coordinate system embedded in 3D.

A typical cross-section plot uses a Cut Line 2D dataset (which you add in the **Datasets** branch), which defines a straight line (or set of parallel lines) in a 2D geometry, and a Line Graph in a 1D Plot Group, which uses the Cut Line 2D dataset as its data input. You can use the same Cut Line dataset for multiple cross-section plots of various quantities along the line that the dataset defines, and you can create several Cut Line datasets to plot quantities along different lines of interest.

INTERACTIVE CROSS-SECTION LINE AND SURFACE PLOTS

You can also interactively create cross-section line and surface plots using a combination of cross-section toolbar buttons and clicking the geometry. When you use the cross-section toolbar, plot groups and datasets are automatically added and updated in the Model Builder whenever any line or plane is changed. See Creating Interactive 2D Cross-Section Line Plots, Creating Interactive 3D Cross-Section Line Plots, and Creating Interactive 3D Cross-Section Surface Plots.

The following sections give examples on how to create cross-section plots.

- Plot Groups and Plots
- Results Toolbar and Plot Group Contextual Toolbar
- See Table 21-11 for links to all the plots.

Plotting and Cross-Section Interactive Toolbar

On the **2D Plot Group** or **3D Plot Group** toolbars, interactive buttons are available based on the plot type in the **Graphics Interaction** section. Use these buttons during the creation of cross-section plots or in general while creating plots.

- Plot Group Contextual Toolbar
- Results Toolbar and Plot Group Contextual Toolbar
- See Table 21-11 for links to all the plots.

TABLE 21-13: PLOTTING AND CROSS-SECTION TOOLBAR: GRAPHICS INTERACTION.

ICON	NAME	USE AND RESULT
	Evaluate Along Normal	If you click in a point in the graphics window when a 3D view is shown, then the ray that begins in the point on the screen is intersected with the surfaces of the plot and the color in the first intersection is evaluated to a table with four columns: (x, y, z, color).
	Evaluate	In 2D, if you click on the plot, then the value of the expression that defines the color in that point is evaluated to a table. It contains three columns: (x, y, value).
	Marker Point	If you click on a Surface, Volume, or Line 2D or 3D plot, a marker is added at that location with the plotted quantity's value at that point, and a corresponding row with the marker coordinates is added to an existing Marker subnode set up to display point evaluations, or a new **Marker** subnode is added if needed.

TABLE 21-13: PLOTTING AND CROSS-SECTION TOOLBAR: GRAPHICS INTERACTION.

ICON	NAME	USE AND RESULT
	First Point for Cut Line	Available for 2D and 3D plot groups to create a cross-section line plot. Adds a **Cut Line** dataset and a **1D Plot Group** with a **Line Graph** that uses this dataset. Click these buttons to plot a cross-section of data between two points.
	Second Point for Cut Line	
	Cut Line Direction	Available with 3D plot groups to create a cross-section line plot. Adds a **Cut Line** dataset and a **1D Plot Group** with a **Line Graph** that uses this dataset. Click this button to plot a line perpendicular to a point selected in the Graphics window.
	Cut Line Surface Normal	Available with 3D plot groups to create a cross-section line plot. Adds a **Cut Line** dataset and a **1D Plot Group** with a **Line Graph** that uses this dataset. Click this button to plot a line in the same way as a domain point probe, with point and direction.
	First Point for Cut Plane Normal	Available with 3D plot groups to create a cross-section surface plot. Adds a **Cut Plane 3D** dataset and a **2D Plot Group** with a **Surface** plot that uses this dataset. Click these buttons to plot a cross-section of data between the two points along the plane.
	Second Point for Cut Plane Normal	
	Cut Plane Normal	Available with 3D plot groups to create a cross-section surface plot. Adds a **Cut Plane 3D** dataset and a **2D Plot Group** with a **Surface** plot that uses this dataset. Click this button to plot a plane perpendicular to a point selected in the Graphics window.
	Cut Plane Normal from Surface	Available with 3D plot groups to create a cross-section surface plot. Adds a **Cut Plane 3D** dataset and a **2D Plot Group** with a **Surface** plot that uses this dataset. Click this button to plot a plane.

In addition, various types of plots can be added from the **Add Plot** section.

NOTES ABOUT USING THE CROSS-SECTION INTERACTIVE TOOLBAR

The first time any button is clicked on the cross-section toolbar, a dataset and a plot group containing either a line graph or surface plot are added to the **Model Builder**. No new dataset or plot group is created unless the generated dataset or plot groups are deleted or disabled. See below for exceptions. The COMSOL software chooses the default coordinates for the cross section as a vertical line intersecting the data in the middle.

It is important to ensure the areas of the geometry selected contain data when defining the line or plane. When lines or planes are changed, the coordinates and calculations are automatically updated in the dataset and in the final plot.

Deleting and Disabling Datasets and Plot Groups

The following exceptions apply to the datasets and plot groups that are automatically added using the cross-section toolbar.

- If a plot group is *disabled*, no new dataset or plot group is created even if you click one of the interactive buttons. You need to enable the plot group to regenerate the cross-section plot.
- If a plot group is *deleted*, click one of the interactive buttons to regenerate the plot group using the cut plane or cut line dataset.

- If a dataset is *deleted*, and it is used with a plot group, the plot group is also deleted at the same time. However, if the plot group is using another dataset, it is not deleted.
- If a dataset is *disabled*, the associated plot group is not disabled. However, if you want to plot another cross section, click one of the interactive buttons to create a new dataset to use with the plot group.

1D, 2D, and 3D Cross-Section Point Plots

CREATING A 1D CROSS-SECTION PLOT USING A CUT POINT DATASET

A 1D cross-section point plot visualizes a quantity in one or several points in time, along a parameter range, or for several different eigenvalues.

1 Create a **Cut Point 1D** dataset.

Under **Point Data**, enter the **x**-coordinates for the plot. Enter one or several space-separated values or a vector of coordinates, for example, `range(0,10,100)`.

2 Add a **1D Plot Group** ( ). In the **Settings** window, select **Cut Point 1D** as the **Dataset**. If required, right-click and **Rename** the plot group, for example, **Cross-Section-1D Point**.

3 Add a **Point Graph** to this 1D plot group and select **Cut Point 1D** as the **Dataset** or **From parent** (the default) to use the same dataset as the plot group to which it belongs.

4 Continue to define the **Point Graph** as needed.

5 Click the **Plot** button ( ), right-click the node, and select **Plot**, or press F8.

CREATING A 2D CROSS-SECTION PLOT USING A CUT POINT DATASET

The 2D point cross-section plot visualizes a quantity in one or several points in time, along a parameter range, or for several eigenvalues. This example uses the *Stresses in a Pulley* model from the COMSOL Multiphysics Application Library.

1 Create a **Cut Point 2D** dataset. Under **Point Data**, enter the x- and y-coordinate values for the plot. Enter the same number of space-separated values in the **x** and **y** fields. Alternatively, enter a vector of coordinates; for example, `range(0,10,100)`.

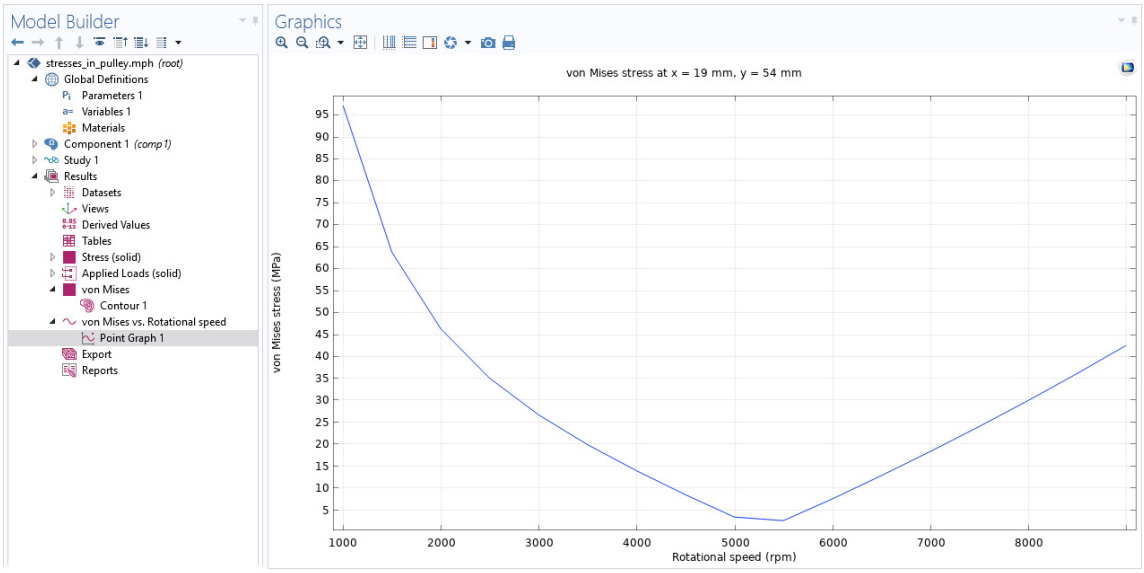
2 Add a **1D Plot Group** ( ). In the **Settings** window, select **Cut Point 2D** as the **Dataset**.

3 Add a **Point Graph** and select **Cut Point 2D** as the **Dataset** or **From parent** to use the same dataset as the plot group to which it belongs.

- The x-axis corresponds to time, parameter values, or the eigenvalue number.
- The settings in the **y-axis data** area determine the quantity on the y-axis. Select from predefined quantities or enter an expression that contains variables.

4 Continue to define the **Point Graph** as needed.

5 Click the **Plot** button ( ), right-click the node, and select **Plot**, or press F8.



CREATING A 3D CROSS-SECTION PLOT USING A CUT POINT DATASET

A 3D point cross-section plot visualizes a quantity in one or several points in time, along a parameter range, or for several eigenvalues. This example uses the *Star-Shaped Microchannel Chip* model from the Microfluidics Module Application Library.

1 Create a **Cut Point 3D** dataset. Under **Point Data**, enter the x-, y-, and z-coordinate values for the plot. Enter the same number of space-separated values in the **x**, **y**, and **z** fields. Alternatively, enter a vector of coordinates; for example, `range(0,10,100)`.

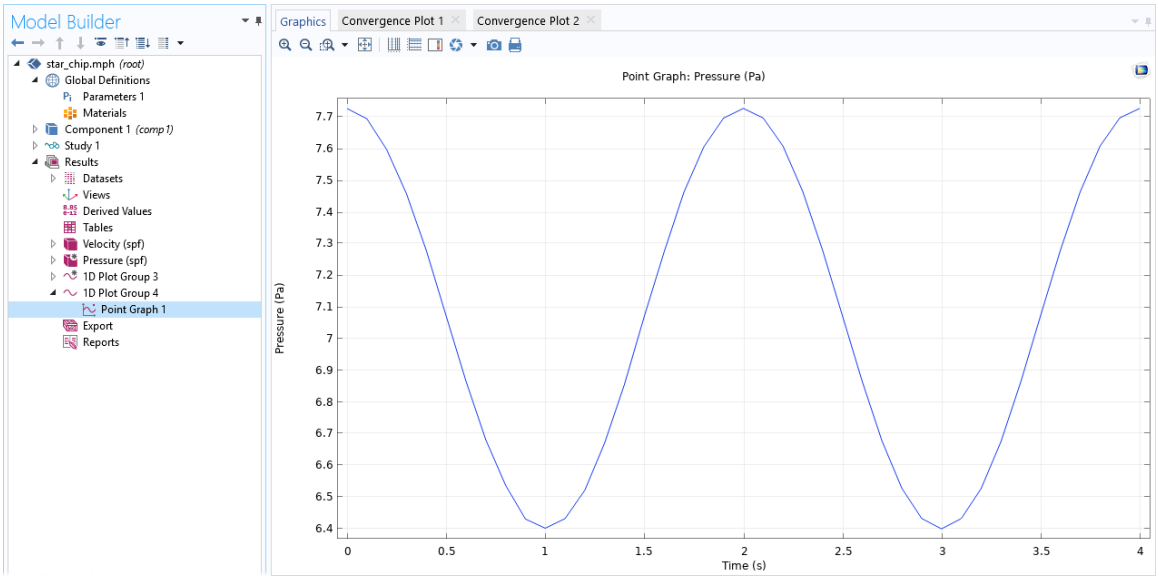
2 Add a **1D Plot Group** ( ). In the **Settings** window, select **Cut Point 3D** as the **Dataset**. Click the **Go to Source** button ( ) to move to the node to which the selection in the list next to the button refers.

3 Add a **Point Graph** and select **Cut Point 3D** as the **Dataset** or **From parent** to use the same dataset as the plot group to which it belongs. Click the **Go to Source** button ( ) to move to the node to which the selection in the list next to the button refers.

- The x-axis corresponds to time, parameter values, or the eigenvalue number.
- The settings in the **y-axis data** area determine the quantity on the y-axis. Select from predefined quantities or enter an expression that contains variables.

4 Continue to define the **Point Graph** as needed.

5 Click the **Plot** button ( ), right-click the node, and select **Plot**, or press F8.



- Plot Groups and Plots
- See Table 21-11 for links to all the plots.

2D Cross-Section Line Plots

The 2D line cross-section plot visualizes a quantity in one or several lines in time, along a parameter range, or for several eigenvalues.

CREATING A 2D CROSS-SECTION PLOT USING A CUT LINE DATASET

1 Create a **Cut Line 2D** dataset.

- Enter the 2D coordinates for the plot. Set the starting point and endpoint of the line under **x** and **y**, for Point 1 and Point 2.
- Select the **Additional parallel lines** checkbox to visualize on a set of parallel lines. Enter the **Distances** from the line as space-separated values.

2 Add a **1D Plot Group** ( ). In the **Settings** window, select **Cut Line 2D** as the **Dataset**.

3 Add a **Line Graph** and keep **From parent** to use the same dataset as the plot group to which it belongs. Settings under **y-Axis Data** and **x-Axis Data** determine the quantity on those axes.

4 Continue to define the **Line Graph** as needed.

5 Click the **Plot** button ( ), right-click the node, and select **Plot**, or press F8.

CREATING INTERACTIVE 2D CROSS-SECTION LINE PLOTS

1 In the **Model Builder**, click a **2D Plot Group** node to display the buttons available in the **Plot** toolbar.

2 On the **Plot Group** contextual toolbar, click the **First Point for Cut Line** button ( ). Click a starting point on the geometry. COMSOL Multiphysics chooses default coordinates as a vertical line intersecting the data in the middle.

3 Click the **Second Point for Cut Line** button ( ). Click an endpoint on the geometry.

A line connecting the two points is displayed in the **Graphics** window. The first time the cross-section toolbar buttons are clicked, a **Cut Line 2D** dataset and a **1D Plot Group** with a **Line Graph** are added to the **Model Builder**.

4 Adjust the cut line as needed by clicking the buttons, then click the geometry to change where the first and second point start and end (respectively). The coordinates are updated automatically in the dataset and plot group. Click the **1D Plot Group** node to view the updates to the line graph.

5 Continue adjusting the cut line until the line graph representing the points plots the data as needed.

- See Table 21-11 for links to all the plots.
- Results Toolbar and Plot Group Contextual Toolbar
- Plot Group Contextual Toolbar

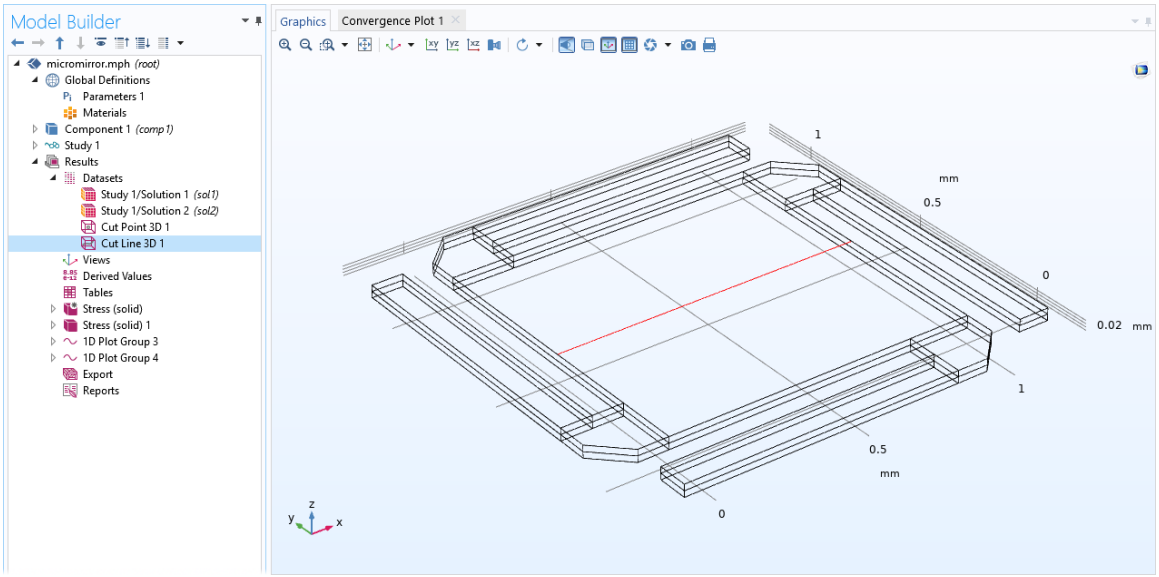
3D Cross-Section Line Plots

A 3D line/extrusion cross-section plot visualizes a quantity in one or several lines in time, along a parameter range, or for several eigenvalues. This example uses the *Prestressed Micromirror* model from the MEMS Module Application Library.

CREATING A 3D CROSS-SECTION PLOT USING A CUT LINE DATASET

1 Create a **Cut Line 3D** dataset. Enter the 3D coordinates for the plot. Set the starting point and endpoint of the line under **x**, **y**, and **z** for **Point 1** and **Point 2**.

2 Click the **Plot** button ( ).

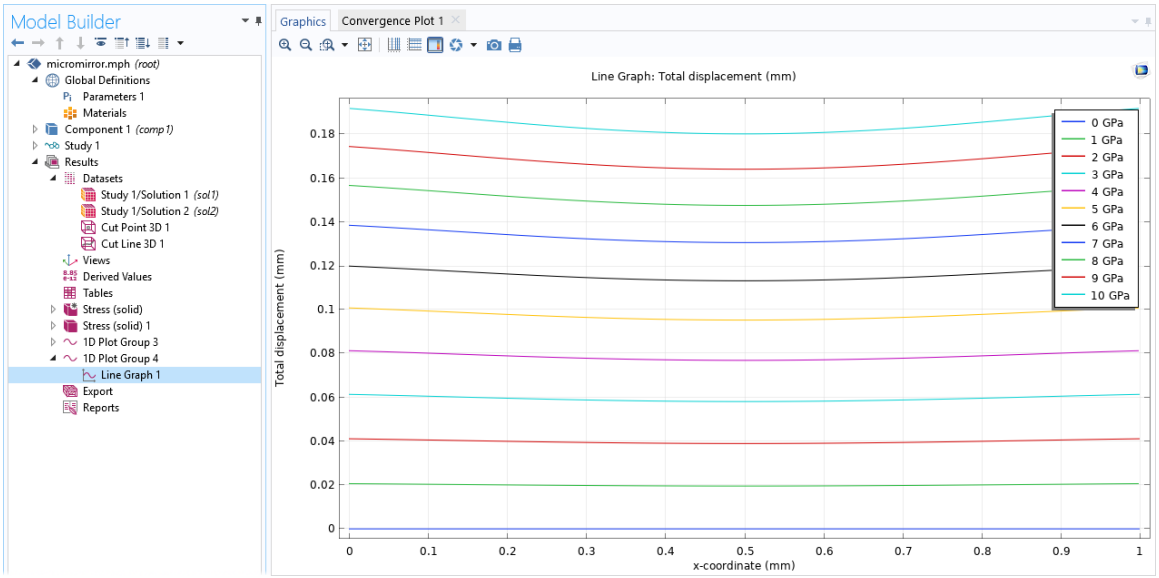


3 Add a **1D Plot Group** ( ). In the **Settings** window, select **Cut Line 3D** as the **Dataset**.

4 Add a **Line Graph**. For the dataset, **From parent** uses the same dataset as the plot group to which it belongs. Settings under **y-Axis Data** and **x-Axis Data** determine the quantity on those axes.

5 Continue to define the **Line Graph** as needed. See Line Graph.

6 Click the **Plot** button ( ), right-click the node, and select **Plot**, or press F8.



CREATING INTERACTIVE 3D CROSS-SECTION LINE PLOTS

1 In the **Model Builder**, click a **3D Plot Group** node to display the buttons available on the **Plot Group** contextual toolbar. In the main toolbar, click the cross-section buttons as needed.

The first time the cross-section toolbar buttons are clicked, a **Cut Line 3D** dataset and a **1D Plot Group** with a **Line Graph** are added to the **Model Builder**.

Define a Cut Line:

a On the **Plot Group** contextual toolbar, click the **First Point for Cut Line** button ( ). Click a starting point on the geometry. COMSOL Multiphysics chooses default coordinates as a vertical line intersecting the data in the middle.

b Click the **Second Point for Cut Line** button ( ). Click an endpoint on the geometry. A line connecting the two points is created in the **Graphics** window.

c Click either of the buttons, and then click on the geometry to change the starting point and endpoint, respectively.

d Click the **1D Plot Group** to view the **Line Graph** based on the selected points.

Define a Cut Line — Direction:

a On the **Plot Group** contextual toolbar, click the **Cut Line Direction** button ( ).

b Click on the geometry to add a line perpendicular to where you clicked. COMSOL Multiphysics chooses default coordinates as a vertical line intersecting the data in the middle.

c Click the **1D Plot Group** node to view the **Line Graph** based on the selected points.

Define a Cut Line — Surface Normal:

a On the **Plot Group** contextual toolbar, click the **Cut Line Surface Normal** button ( ).

b Click on the geometry to add a line with a point and direction. COMSOL Multiphysics chooses default coordinates as a vertical line intersecting the data in the middle.

c Click the **1D Plot Group** node to view the **Line Graph** based on the selected points.

2 Adjust the cut line as needed by clicking the buttons, then clicking the geometry to change its coordinates. The dataset and plot group are updated automatically with the cut line data. Click the **1D Plot Group** node to view the updates to the line graph.

3 Continue adjusting the cut line until the line graph representing the points plots the data as needed.

- See Table 21-11 for links to all the plots.
- Results Toolbar and Plot Group Contextual Toolbar
- Plot Group Contextual Toolbar

3D Cross-Section Surface Plot

3D CROSS-SECTION SURFACE PLOT USING A CUT PLANE DATASET

A 3D surface cross-section plot visualizes a quantity in one or several planes in time, along a parameter range, or for several eigenvalues. This example uses the *Airflow Over an Ahmed Body* model from the CFD Module Application Library.

1 Create a **Cut Plane 3D** dataset.

2 Add a **2D Plot Group** ( ). In the **Settings** window, select **Cut Plane 3D** as the **Dataset**.

3 Add a **Surface** plot and keep **From parent** to use the same dataset as the plot group to which it belongs.

4 Continue to define the **Surface** plot as needed.

5 Click the **Plot** button ( ), or right-click the node and select **Plot**.

The plot displays in the window selected in the **Plot window** list. To plot results in another window, right-click the plot group node or the plot node and select a plot window from the **Plot In** submenu.

CREATING INTERACTIVE 3D CROSS-SECTION SURFACE PLOTS

1 In the **Model Builder**, click a **3D Plot Group** node to display the buttons available on the **Plot Group** contextual toolbar. In the main toolbar, click the cross-section buttons as needed.

The first time the cross-section toolbar buttons are clicked, a **Cut Plane 3D** dataset and a **2D Plot Group** with a **Surface** plot are added to the **Model Builder**.

To define a Cut Plane:

a Click the **First Point for Cut Plane Normal** button ( ). Click a starting point on the geometry. The COMSOL software chooses default coordinates as a vertical line intersecting the data in the middle. The green highlighted areas show you what the cut plane looks like if this first click point is selected for the surface plot.

b Click the **Second Point for Cut Plane Normal** button ( ). Click an endpoint on the geometry. The green highlighted areas show you what the cut plane looks like if this second click point is selected for the surface plot.

c Click either of the buttons and then on the geometry to change the starting point and endpoint, respectively.

d Click the **2D Plot Group** to view the **Surface** plot based on the selected points.

To define a Normal Cut Plane:

a Click the **Cut Plane Normal** button ( ).

b Click the geometry to add a plane perpendicular to the click location. COMSOL Multiphysics chooses default coordinates as a vertical line intersecting the data in the middle. The green highlighted areas show you what the plot looks like if this normal cut plane is selected for the surface plot.

c Click the **2D Plot Group** to view the **Surface** plot based on the selected points.

To Define a Normal Cut Plane from Surface:

a Click the **Cut Plane Normal from Surface** button ( ).

b Click the geometry to add a line with a point and direction starting at the click location. COMSOL Multiphysics chooses default coordinates as a vertical line intersecting the data in the middle. The green highlighted areas show you what the plot looks like if this normal from surface cut plane is selected for the surface plot.

c Click the **2D Plot Group** to view the **Surface** plot based on the selected points.

2 Adjust the cut plane as needed by clicking the buttons, then clicking the geometry to change the coordinates. The dataset and plot group are updated automatically with the cut plane data. Click the **2D Plot Group** node to view the updates to the surface plot.

3 Continue adjusting the cut plane until the surface plot representing the points plots the data as needed.

- See Table 21-11 for links to all the plots.
- Results Toolbar and Plot Group Contextual Toolbar
- Plot Group Contextual Toolbar

1D Plot Group and Polar Plot Group

1D PLOT GROUPS

Use a **1D Plot Group** ( ) to plot graphs of, for example, a value that varies with time or a frequency spectrum, using options to use FFT with a time-dependent solution. You can also use 1D plot groups to create cross-section plots for solutions in 2D and 3D models. Normally the plot axes (x-axis and y-axis) use linear scaling but, depending on the plotted data, it might be beneficial to display the graphs using a log scale on the x-axis or y-axis. From the **Graphics** window's toolbar, click the **x-Axis Log Scale** ( ) and **y-Axis Log Scale** ( ) buttons to use a log

scale on the x-axis and y-axis, respectively. If you use two y-axes, there is also a **Secondary y-Axis Log Scale** ( ) button. Click again to return to a linear scale. For a log scale on an axis, COMSOL Multiphysics tries to show values like $10^{\{integer\}}$ (for example, 10^{1} or 10^{-2}); if it is not possible to show more than three ticks like $10^{\{integer\}}$, the software instead shows regular numerical values on the axis such as 1, 2, 5,10, 20, 50, 100; and finally, if these regular values are not possible to display, the axes show uniformly distributed regular values. For information about panning and zooming of graph plots in 1D Plot Groups, see Panning and Zooming in 1D Graph Plots.

You can step through time, eigenvalues or eigenfrequencies, or parameter values using the **Plot Previous** (←) and **Plot Next** (→) buttons at the top of the plot group nodes and their plot nodes. You can also use the F6 and F7 keyboard shortcuts to step to the previous or next solution, respectively. For a parametric sweep with multiple parameters, the buttons step through the innermost parameter only. To move to the solution associated with the first or last time, eigenvalue, or parameter value, click the **Plot First** (|←) or **Plot Last** (→|) button. For models with multiple levels of parameters and time, for example, use the list to the right of the **Plot Last** button to choose the level for which you want to step through the solutions (see Figure 21-5).

1D plot groups do not correspond to any Cartesian space, so, for example, whereas annotations in 2D and 3D show the length unit after the **Position** fields, in 1D annotations, no unit is shown.

POLAR PLOT GROUPS

The **Polar Plot Group** node ( ) creates a graph for *polar plots*: plots of a function in polar coordinates: the radius r and the angle θ. This is useful for visualizing, for example, a radar cross section or other similar polar plots for electromagnetic or acoustic wave models. The available plot types and settings for the **Polar Plot Group** node are similar to those for the 1D Plot Group.

DATA

Select a **Dataset**. Depending on the type of data, also specify, for example, the time, frequency, or eigenvalue selection. You can also select parameters from parametric sweeps.

Parametric Sweep Studies

For **Parametric Sweep** studies, also select an option from the **Select via** list: **Stored output times** or **Interpolated times**.

- If **Stored output times** is selected, the **Times** section is auto-filled with information from the selected **Dataset**.
- If **Interpolated times** is selected, enter **Times**.

Load Cases

For some solution **Datasets,** you can select the **Load case** to use in the plot group (if any load cases exist).

Solution Datasets

For some Solution datasets, select a **Parameter selection (freq)**: **All**, **First**, **Last**, **From list**, or **Manual**.

- If **From list** is selected, select the **Parameter values** from the box that displays.
- If **Manual** is selected, enter **Parameter indices (1-91)** (the actual indices depend on the number of solutions). Or click the **Range** button ( ) to define an **Integer Range**.

If you have defined a compatible configuration (see Configurations), which is typically a Multiselect Solution, the you can choose **From configuration** from the **Solution parameters** list (the default is **Manual**). With **From configuration**, choose a compatible configuration from the **Configuration** list to use its settings for the solution parameters such as the time, eigenvalue, or parameter values to use.

PHASE

This section is only available if at least one physics or multiphysics interface in the model includes a phase. See Phase Settings in Plots.

SAVE DATA IN THE MODEL

Select **Save plot data** to save the plot data in the model. This section only appears for the manual setting of the option for saving plot data. See Saving Plot Data in the Model.

TITLE

The **Title type** is automatically generated by default (the **Automatic** option). Select **Custom**, **Manual**, **Label**, or **None** as needed. See Plot Titles for Plot Groups and Plots for more information.

From the **Color** list, choose **Custom** to define a custom color for the title, or choose one of the predefined colors (the default is **Black**).

PLOT SETTINGS

Manually enter axis labels by selecting the **x-axis label** and **y-axis label** checkboxes for 1D plot groups.

If you have more than one plot in the plot group, you can use two y-axes. Select the **Two y-axes** checkbox to add a secondary y-axis to the right of the plot. Then you can also select the **Secondary y-axis label** checkbox to add a label for that y-axis in the associated text field. At the bottom of this section, a list of all graph plot and annotation nodes under this plot group that can use the secondary y-axis appears. In the **Plot on secondary y-axis** column, select the checkboxes for the plots and annotations that you want to plot on the secondary y-axis. You can also specify that a plot should use the secondary y-axis in each plot's **Settings** window's **y-Axis** section, where you can select or clear the **Plot on secondary y-axis** checkbox.

If the plot data for two plots have the same x-axis data range and the same slope of the y data, the plots will overlap when plotting them on two y-axes. The following workarounds are available to avoid that one plot hides the other:

- Use another line style for one or both of the overlapping plots. For example, use different line styles (dotted, dashed, or dash-dot) or different line markers.
- Change the axis limits in the 1D Plot Group setting for one of the axis to shift it a bit in the y direction.

Select the **Flip the x- and y-axes** checkbox in cases where flipping the data for the axes may provide a better visualization. Switching the data also switches the axis labels if they are not specified manually.

AXIS

Select the **Manual axis limits** checkbox to edit the limits already assigned based on the dataset. For 1D plot groups, this is for the **x minimum**, **x maximum**, **y minimum**, and **y maximum**. If the plot uses two y-axes, you can also specify the **Secondary y minimum** and **Secondary y maximum**. For Polar Plot Groups, this is for the **r minimum** and **r maximum**. Additionally, for Polar Plot Groups, the following settings are available:

- Select the **Symmetric angle range** checkbox if you want the plot to display angles as +/–180 degrees around zero instead as a full 360 degree revolution.
- From the **Zero angle** list, choose **Right** (the default), **Up**, **Left**, or **Down** to specify the direction of the zero angle.
- From the **Angular unit** list, choose **Degrees** (the default) or **Radians**.
- From the **Rotation direction** list, choose **Counterclockwise** (the default) or **Clockwise** to specify the direction in which the angle increases.

For the 1D Plot Group, and as needed, select the following checkboxes: **Preserve aspect ratio**, **x-axis log scale**, and **y-axis log scale**. If the plot uses two y-axes, you can also select the **Secondary y-axis log scale** checkbox. Select the **Preserve aspect ratio** checkbox to preserve aspect ratio and keep the distances on the x-axis and y-axis equal. The

second part is not possible to achieve if one of the *y*-axes uses a log scale. However, the first part stays active; that is, if you zoom on one of the axes, all of the axes will be equally transformed (scaled).

GRID

Clear the **Show grid** checkbox if you do not want to include a grid in the plot.

Select the **Manual spacing** checkbox to edit the following fields: For 1D plot groups, this is for the **x spacing** and **y spacing** fields. For Polar Plot Groups, this is for the **r spacing** and θ **spacing** (SI unit: degrees) fields.

For 1D plot groups, also specify extra grid points on the *x*-axis and *y*-axis in the **Extra x** and **Extra y** fields. If the plot uses two *y*-axes, you can also add extra grid points for the secondary *y*-axis in the **Secondary extra y** field. For Polar plot groups, this is for the **Extra** θ and **Extra r** fields.

STYLE CONFIGURATION

If you have added **Graph Plot Style** configuration nodes (see Configurations), you can choose to use one for the plot style settings in the graph plot nodes under this plot group. To do so, choose it from the **Configuration** list. The plot style settings that are then takes from the configuration will be grayed out in the settings for the graph plot nodes in this plot group.

LEGEND

Select the **Show legends** checkbox to display legends for the quantities in the graph and, if using a **Color Expression** subnode, color legends.

Specify the position of the graph legends for the plots in the plot group. From the **Layout** list, choose **Inside graph axis area** (the default) to show the legends within the graph plot limits, or choose **Outside graph axis area** to show them outside of the graph plot limits. From the **Position** list, when **Inside graph axis area** has been selected, select **Upper right** ( ) (the default), **Upper middle** ( ), **Upper left** ( ), **Middle right** ( ), **Center** ( ), **Middle left** ( ), **Lower right** ( ), **Lower middle** ( ), **Lower left** ( ), or **Manual**. If you choose **Manual**, define the relative position (0–1) in the **x-position** and **y-position** fields. If **Outside graph axis area** was selected, choose **Bottom** ( ), **Left** ( ), **Right** ( ) (the default), or **Top** ( ).

Also, if the desired, you can specify to display the legends using a number of columns or rows (depending on the position) in the **Number of columns** or **Number of rows** (only for **Bottom** and **Top** when **Outside graph axis area** was selected) field (default: 1).

If **Inside graph axis area** has been selected, you can also change the value in the **Maximum relative width** field from the default value of 0.5 to some other values between 0 and 1. Doing so can be useful if a legend text is too wide for the default width, for example.

Legends in all plots in the plot group use the selected layout and position.

COLOR LEGEND

This subnode is only available if you have added a **Color Expression** subnode to plot some quantity using colors.

For color legends, select or clear the **Show maximum and minimum values** checkbox to show or hide those values from the top and bottom of the color legends. Also select the **Show units** checkbox to display a unit above the color legend, if desired.

Specify the location of the color legends (color scales) for the plots for this plot group. The **Position** list contains the following positions for the color legends:

- Select **Alternating** ( ) to position the first color legend to the right of the plot, the second color legend to the left of the plot, and so on.
- Select **Bottom** ( ) to position the color legends horizontally at the bottom of the plot window.
- Select **Left** ( ) to position the color legends to the left of the plot.
- Select **Left double** ( ) to position the color legends to the left of the plot with two color legends positioned on top of each other (tiled vertically).
- Select **Right** ( ) to position the color legends to the right of the plot. This is the default position.
- Select **Right double** ( ) to position the color legends to the right of the plot with two color legends positioned on top of each other (tiled vertically).

NUMBER FORMAT

In this section you can override the automatic formatting of the numbers used on the axes of the grid:

Axis Formats

To override the automatic formatting of the numbers on the axes, select the **Manual axis settings** checkbox. Then adjust the formatting using the following settings:

From the **Notation** list, choose **Automatic** to let the program choose decimal notation or scientific notation (E-notation) depending on the values of the displayed numbers. Choose **Scientific** to only use scientific notation.

Select the **Use common exponent** checkbox (selected by default) to use a common exponent at the end of each axis. Clear this checkbox to instead display the full numbers, including the exponents, next to the corresponding axis tick. One of these formats may be better suited to display the axes if the plot window is small, for example.

Select the **Show trailing exponent** checkbox to display all numbers based on the precision used, including trailing zeros (for example, 5 is then displayed as 5.000 when the precision is set to 4).

In the **Precision** field, enter a positive integer (default: 5) for the numerical precision (number of digits displayed).

If the plot group includes any plot that has a color expression, you can also control the number formatting for the color legend (the settings below are then added above the manual axis settings).

Color Legend Formats

To override the automatic formatting of the numbers in the color legend, select the **Manual color legend settings** checkbox. Then adjust the formatting using the following settings:

From the **Notation** list, choose **Automatic** to let the program choose decimal notation or scientific notation (E-notation) depending on the values of the displayed numbers. Choose **Engineering** to use engineering notation, or choose **Scientific** to only use scientific notation.

Select the **Use common exponent** checkbox (selected by default) to use a common exponent above the color legend. Clear this checkbox to instead display the full numbers, including the exponents, next to the corresponding levels in the color legend. One of these formats may be better suited to display the color legend if the plot window is small, for example.

Select the **Show trailing exponent** checkbox to display all numbers based on the precision used, including trailing zeros (for example, 5 is then displayed as 5.00 when the precision is set to 3).

In the **Precision** field, enter a positive integer (default: 3) for the numerical precision (number of digits displayed).

WINDOW SETTINGS

Select a **Plot window**. The **Graphics** window is the default, but any other plot window can be selected, or select **New window** to plot in a new window. Select the **Window title** checkbox to enter a custom title (except for the **Graphics** window), which is then available in the **Plot window** list for all models. Click the **Add Plot Window** button (+) to add a plot window to the list of available windows.

INTERACTIVE (1D PLOT GROUP)

Use a combination of datasets and plots to create a cross-section point plot and cross-section line plot. To add plots to a group, right-click the **1D Plot Group** node to select as many as needed. Each plot group can have several plots combined to create a meaningful representation of the data.

You can adjust the default precision settings for the axis labels if required. Open The Preferences Window and open the **Graphics** > **Display Format** page. Under **Display format (Maximum Number of Digits)**, in the **Graphs** field, enter an integer between 1 and 15 for the number of digits for the values on the axes in 1D plots and graphs. The default setting is 5 digits.

- Plot Groups and Plots
- Results Toolbar and Plot Group Contextual Toolbar
- See Table 21-11 for a summary of all the available plot types, including links to each plot described in this guide.

Smith Plot Group

The **Smith Plot Group** node ( ) creates a graph for *Smith plots*, where electromagnetic properties are plotted on the complex reflection coefficient plane. Typically, the plotted values are the normalized reflection, impedance, or admittance. The complex-valued reflection coefficient Γ for an impedance Z_L attached to a transmission line is defined as

$$\Gamma = \frac{Z_L - Z_0}{Z_L + Z_0}$$

where Z_0 is the characteristic impedance. Physically, Γ must have an absolute value of at most 1, and it can therefore be plotted in the complex unit circle. The normalized input impedance z_L is defined as

$$z_L = \frac{1 + \Gamma}{1 - \Gamma}$$

For a passive circuit (no gain), it holds that $|\Gamma| \leq 1$ and that $\mathrm{Re}(z_L) \geq 0$. Thus the relation between Γ and z_L defines a conformal mapping between the unit circle and the right half of the complex plane. An impedance Smith plot is the unit circle with grid lines for $\mathrm{Re}(z_L)$ = constant and $\mathrm{Im}(z_L)$ = constant for impedance coordinates. The admittance is defined as $Y = 1/Z$, and similarly you then have $Y_0 = 1/Z_0$ and $y_L = Y/Y_0$. Consequently,

$$z_L = \frac{1 - \Gamma}{1 + \Gamma}$$

is useful to display as an admittance Smith plot with grid lines for $\mathrm{Re}(z_L)$ = constant and $\mathrm{Im}(z_L)$ = constant for admittance coordinates.

You can click anywhere inside the perimeter of the Smith plot's coordinates to get the numerical values for the reflection, impedance, or admittance in a **Smith evaluation** table window.

It is not possible to zoom or pan in a plot window that displays a Smith plot. In most respects, it otherwise behaves and have settings similar to a 1D Plot Group, with some differences according to the descriptions below for the available sections of the **Settings** window for a **Smith Plot Group**.

The available plot types for the Smith Plot Group are Reflection Graph, Impedance Graph, Admittance Graph, and Table Graph.

	The Smith Plot Group requires a license for the AC/DC Module, MEMS Module, RF Module, or Plasma Module.

	The time-related settings only display for time-dependent models.

DATA

Select a **Dataset**. Depending on the type of data, also specify, for example, the time, frequency, or eigenvalue selection.

Parametric Sweep Studies

For **Parametric Sweep** studies, also select an option from the **Select via** list: **Stored output times** or **Interpolated times**.

- If **Stored output times** is selected, the **Times** section is auto-filled with information from the selected **Dataset**.
- If **Interpolated times** is selected, enter **Times**.

Load Cases

For some Solution datasets, you can select the **Load case** to use in the plot group (if any load cases exist).

Solution Datasets

For some Solution datasets, select a **Parameter selection (freq)**: **All**, **First**, **Last**, **From list**, or **Manual**.

- If **From list** is selected, select the **Parameter values** from the box that displays.
- If **Manual** is selected, enter **Parameter indices (1-91)** (the actual indices depend on the number of solutions). Or click the **Range** button ( ) to define an **Integer Range**.

If you have defined a compatible configuration (see Configurations), which is typically a Multiselect Solution, the you can choose **From configuration** from the **Solution parameters** list (the default is **Manual**). With **From configuration**, choose a compatible configuration from the **Configuration** list to use its settings for the solution parameters such as the time, eigenvalue, or parameter values to use.

PHASE

This section is only available if at least one physics or multiphysics interface in the model includes a phase. See Phase Settings in Plots.

SAVE DATA IN THE MODEL

Select **Save plot data** to save the plot data in the model. This section only appears for the manual setting of the option for saving plot data. See Saving Plot Data in the Model.

TITLE

The **Title type** is automatically generated by default (the **Automatic** option). Select **Custom**, **Manual**, **Label**, or **None** as needed. See Plot Titles for Plot Groups and Plots for more information.

From the **Color** list, choose **Custom** to define a custom color for the title, or choose one of the predefined colors (the default is **Black**).

GRID

- Select the **Impedance coordinates** checkbox to create a grid for an impedance Smith plot.
- Select the **Admittance coordinates** checkbox to create a grid for an admittance Smith plot.

Although it is possible to use both sets of coordinates for the grid, you typically only select on the checkboxes for either an impedance or an admittance Smith plot.

From the **Resolution** list, select a resolution for the grid: **Fine**, **Normal** (the default), or **Coarse**.

STYLE CONFIGURATION

If you have added **Graph Plot Style** configuration nodes (see Configurations), you can choose to use one for the plot style settings in the graph plot nodes under this plot group. To do so, choose it from the **Configuration** list. The plot style settings that are then taken from the configuration will be grayed out in the settings for the graph plot nodes in this plot group.

LEGEND

Select the **Show legends** checkbox to display legends for the quantities in the graph and, if using a **Color Expression** subnode, color legends. For color legends, select or clear the **Show maximum and minimum values** checkbox to show or hide those values from the top and bottom of the color legends. Specify the position of the graph legends for the plots in the plot group. From the **Position** list, select **Upper right** (the default), **Upper middle**, **Upper left**, **Middle right**, **Center**, **Middle left**, **Lower right**, **Lower middle**, or **Lower left**. Legends in all plots in the plot group use this position.

NUMBER FORMAT

In this section you can override the automatic formatting of the numbers used on the axes of the grid:

Axis Formats

To override the automatic formatting of the numbers on the axes, select the **Manual axis settings** checkbox. Then adjust the formatting using the following settings:

From the **Notation** list, choose **Automatic** to let the program choose decimal notation or scientific notation (E-notation) depending on the values of the displayed numbers. Choose **Scientific** to only use scientific notation.

Select the **Use common exponent** checkbox (selected by default) to use a common exponent at the end of each axis. Clear this checkbox to instead display the full numbers, including the exponents, next to the corresponding axis tick. One of these formats may be better suited to display the axes if the plot window is small, for example.

Select the **Show trailing exponent** checkbox to display all numbers based on the precision used, including trailing zeros (for example, 5 is then displayed as 5.000 when the precision is set to 4).

In the **Precision** field, enter a positive integer (default: 5) for the numerical precision (number of digits displayed).

WINDOW SETTINGS

Select a **Plot window**. The **Graphics** window is the default, but any other plot window can be selected, or select **New window** to plot in a new window. Select the **Window title** checkbox to enter a custom title (except for the **Graphics** window), which is then available in the **Plot window** list for all models. Click the **Add Plot Window** button (+) to add a plot window to the list of available windows.

2D Plot Group and 3D Plot Group

Use a **2D Plot Group** ( ) to combine one or more 2D plots, such as surface plots and contour plots, and visualize the plots simultaneously. Use a **3D Plot Group** ( ) to combine one of more 3D plots, such as volume plots and slice plots, into one to visualize the plots simultaneously. The datasets that you can use are solution datasets for 2D

and 3D solutions, respectively, but also, for example, cut planes from a 3D model in a 2D plot group or a revolved 2D axisymmetric solution in a 3D plot group.

The time-related settings only display for time-dependent models.

DATA

Select a **Dataset**. From the lists below select the solution to use. For **Parametric Sweep** studies, select, for example, a **Parameter value** as needed. For time-dependent problems, select a **Time**. For eigenvalue and eigenfrequency analyses, select an **Eigenvalue** or **Eigenfrequency**. For solutions that contain multiple eigenvalues, the list includes entries such as **3241 (1)** and **3241 (2)** for selecting either of the two eigenmodes associated with the same eigenvalue. You can step through time, eigenvalues or eigenfrequencies, or parameter values using the **Plot Previous** (←) and **Plot Next** (→) buttons at the top of the plot group nodes and their plot nodes. You can also use the F6 and F7 keyboard shortcuts to step to the previous or next solution, respectively. To move to the solution associated with the first or last time, eigenvalue, or parameter value, click the **Plot First** (⇤) or **Plot Last** (⇥) button (the **Plot Last** button changes the value of the list of times, eigenvalues or eigenfrequencies, or parameters to **Last**). For models with multiple levels of parameters and time, for example, use the list to the right of the **Plot Last** button to choose the level for which you want to step through the solutions (see the figure below).

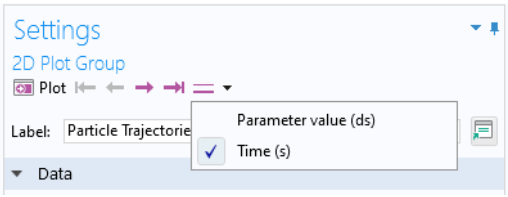


Figure 21-5: Choose between stepping through parameter values or time for a model with multiple solution levels.

If you have defined a compatible configuration (see Configurations), which is typically a Single-Select Solution, the you can choose **From configuration** from the **Solution parameters** list (the default is **Manual**). With **From configuration**, choose a compatible configuration from the **Configuration** list to use its settings for the solution parameters such as the time, eigenvalue, or parameter value to use.

SELECTION

By default, the plots in the plot group are active in the entire geometry. Using a selection defined in this section, you can limit the plots to some geometric entities (parts of the geometry). From the **Geometric entity level** list, choose **Entire geometry** (the default), **Domain**, **Boundary**, **Edge** (3D only), or **Point**.

For all levels except **Entire geometry**, you can choose a selection of entities at that level from the **Selection** list:

- **Manual**, to select entities manually from the **Graphics** window or using the selection tools below.
- **All domains** (for example), to select all entities at the selected entity level.
- Any user-defined selections that are available for the selected entity level.

The following settings are also available for all levels except **Entire geometry**:

By default, the **Propagate to lower dimensions** checkbox is selected. If you clear it, only plots defined on the selected entity level will appear (for domains, a surface plot would then not appear, for example).

Select the **Apply to dataset edges** checkbox to only display dataset edges for the chosen selection of entities instead of for the entire geometry.

The selection made in the **Settings** window for the plot group can be overridden by **Selection** subnodes for the individual plot nodes in that plot group.

PHASE

This section is only available if at least one physics or multiphysics interface in the model includes a phase. See Phase Settings in Plots.

SAVE DATA IN THE MODEL

Select **Save plot data** to save the plot data in the model. This section only appears for the manual setting of the option for saving plot data. See Saving Plot Data in the Model.

TITLE

The **Title type** is automatically generated by default. Select **Custom**, **Manual**, **Label**, or **None** as needed. See Plot Titles for Plot Groups and Plots for more information.

From the **Color** list, choose **Custom** to define a custom color for the title, or choose one of the predefined colors (the default is **Black**).

PLOT SETTINGS

- Select a **View**. The default is **Automatic**, which picks a view automatically. You can also choose any applicable view that is defined under **Definitions** or under **Results** > **Views**. It is also possible to choose **New view**. The plot then uses that new view, which appears as a **View 2D** ( ) or **View 3D** ( ) node under **Views**.
- (2D only) The **x-axis label** and **y-axis label** checkboxes are cleared by default, indicating that empty axis labels are used by default. Select the checkboxes to enter labels for the x-axis and the y-axis. This can be useful for scatter plots, for example, where the axes represent quantities other than the x and y directions.
- By default, the plot does not include hidden entities (geometric entities that are hidden in the selected **View**). To include such hidden geometric entities in the plot, select the **Show hidden entities** checkbox. To make the hiding also apply to lower dimensions (for example, when hidden 3D domains affect faces where all adjacent domains are hidden), select the **Propagate hiding to lower dimensions** checkbox.
- For 2D axisymmetric plots, select the **Show symmetry axis** checkbox to display the symmetry axis at $r = 0$.
- The **Plot dataset edges** checkbox is selected by default. Click to clear if required. Otherwise, select a **Color** (**Black** is the default) or select **Custom** to click the **Color** button and choose a different color from a color palette. Select a **Frame**: **Material** (the default), **Mesh**, **Geometry frame**, **Spatial**, or **From dataset**.

COLOR LEGEND

You can control the appearance of the color legends (color scales) for the plots for this plot group using the following settings:

To turn off the display of the color legends, clear the **Show legends** checkbox. If the **Show legends** checkbox is selected, you can control the look and feel and position of the color legend using the settings below.

You can show or hide the maximum and minimum values for the plotted quantity that appear above and below the color legend using the **Show maximum and minimum values** checkbox. Turning off the maximum and minimum values can save screen space in the vertical direction.

To display a title, including optional LaTeX characters, for the color legends in the plot group, select the **Show titles** checkbox. A **Color legend title** field then appears in the **Coloring and Style** section for the plot nodes in this plot group.

To display a unit for the values of the color legend, select the **Show units** checkbox. The unit appears above the color legend.

Specify the location of the color legends (color scales) for the plots for this plot group. The **Position** list contains the following positions for the color legends:

- Select **Alternating** ( ) to position the first color legend to the right of the plot, the second color legend to the left of the plot, and so on.
- Select **Bottom** ( ) to position the color legends horizontally at the bottom of the plot window.
- Select **Left** ( ) to position the color legends to the left of the plot.
- Select **Left double** ( ) to position the color legends to the left of the plot with two color legends positioned on top of each other (tiled vertically).
- Select **Right** ( ) to position the color legends to the right of the plot. This is the default position.
- Select **Right double** ( ) to position the color legends to the right of the plot with two color legends positioned on top of each other (tiled vertically).

From the **Text color** list, choose **Custom** to define a custom color for the text in the color legend, or choose one of the predefined colors (the default is **Black**).

The default precision for the color legend labels is 5 digits. You can change the precision in the **Preferences** window, using the **Color legend** field on the **Display Format** page under **Graphics**.

NUMBER FORMAT

In this section you can override the automatic formatting of the numbers used in the color legend and the axes of the grid:

Color Legend Formats

To override the automatic formatting of the numbers in the color legend, select the **Manual color legend settings** checkbox. Then adjust the formatting using the following settings:

From the **Notation** list, choose **Automatic** to let the program choose decimal notation or scientific notation (E-notation) depending on the values of the displayed numbers. Choose **Engineering** to use engineering notation, or choose **Scientific** to only use scientific notation.

Select the **Use common exponent** checkbox (selected by default) to use a common exponent above the color legend. Clear this checkbox to instead display the full numbers, including the exponents, next to the corresponding levels in the color legend. One of these formats may be better suited to display the color legend if the plot window is small, for example.

Select the **Show trailing exponent** checkbox to display all numbers based on the precision used, including trailing zeros (for example, 5 is then displayed as 5.00 when the precision is set to 3).

In the **Precision** field, enter a positive integer (default: 3) for the numerical precision (number of digits displayed).

Grid and Axis Formats

To override the automatic formatting of the numbers on the grid axes, select the **Manual axis settings** checkbox (2D) or **Manual grid settings** (3D). Then adjust the formatting using the following settings:

From the **Notation** list, choose **Automatic** to let the program choose decimal notation or scientific notation (E-notation) depending on the values of the displayed numbers. Choose **Engineering** to use engineering notation, or choose **Scientific** to only use scientific notation.

Select the **Use common exponent** checkbox (selected by default) to use a common exponent at the end of each axis. Clear this checkbox to instead display the full numbers, including the exponents, next to the corresponding axis tick. One of these formats may be better suited to display the grid if the plot window is small, for example.

Select the **Show trailing exponent** checkbox to display all numbers based on the precision used, including trailing zeros (for example, 5 is then displayed as 5.000 when the precision is set to 4).

In the **Precision** field, enter a positive integer (default: 3) for the numerical precision (number of digits displayed).

PLOT ARRAY

Use the settings in this section to create an array of plots for comparing or showing multiple solutions or quantities and for presentation purposes, for example.

Select the **Enable** checkbox to activate the plot array functionality. All plot subnodes under the plot group node then get a **Plot Array** section (see Plot Array Settings for Plot Nodes), and by default its **Belongs to array** checkbox is selected, so that all plots in the plot group are included in the plot array.

From the **Array shape** list, choose **Linear** (the default) or **Square**. By default, the size of the square array is the smallest square that the number of plots (which belong to the array) in the plot group would fit into. For example, with four plot subnodes, selecting **Square** yields a 2-by-2 array. With five plot subnodes, selecting **Square** yields a 3-by-3 array. For a linear plot array, choose an array axis (such as **x**, **y**, or **z** in 3D) from the **Array axis** list. For a square plot array, instead choose an array plane (3D only), such as **xy**, from the **Array plane** list. You can also choose, from the **Order** list, if the ordering of the plots in a square plot array should be a row-major (the default) or column-major order. Choose **Row-major** (the default) to first fill the available rows, or choose **Column-major** to first fill the available columns. The order of the plots reflects the order of the plot nodes in the plot group, unless you have used a manual indexing for any of the plots. If you change the order, the plot array will reflect the new order when it is replotted.

From the **Displacement** list, choose **Relative** (the default) to use a relative padding (see below)), or choose **Absolute** to enter absolute displacements in the **Cell displacement** field (SI unit: m), if the **Array shape** is set to **Linear**, or the Row displacement and Column displacement fields (SI unit: m), if the **Array shape** is set to **Square**. The **Absolute** option can be useful with animations, to make sure that a position change between the frames does not occur.

If you have set **Displacement** list to **Relative**, then from the **Padding** list, choose **Relative** (the default) or **Absolute** to control the padding between the plots in the plot array. The default relative padding length is 0.3 (that is, 30% of the plot size). For a linear array, enter the value in the **Relative padding** field; for a square array, enter padding values in the **Relative row padding** and **Relative column padding** fields. The absolute padding length (SI unit: m) makes it possible to set a padding suitable to the overall absolute size of the plot array. For a linear array, enter the value in the **Padding length** field; for a square array, enter padding values in the **Row padding length** and **Column padding length** fields.

WINDOW SETTINGS

- Select a **Plot window**. The **Graphics** window is the default setting, but any other plot window can be selected, or select **New window** to plot in a new window.
- Select the **Window title** checkbox to enter a custom title (except for the **Graphics** window), which is then available in the **Plot window** list for all models. Click the **Add plot window** button (+) to add a plot window to the list of available windows.

INTERACTIVE

Use a combination of datasets and plots to create a cross-section point plot, cross-section line plot, or cross-section surface plot.

To add plots to a group, right-click the **3D Plot Group** or the **2D Plot Group** node to select as many as needed. Each plot group can have several plots combined to create a meaningful representation of the data.

You can adjust the default precision settings for the axis labels if required. Open The Preferences Window and open the **Graphics** > **Display Format** page. Under **Display format (Maximum Number of Digits)**:

- In the **2D axis** field, enter an integer between 1 and 15 for the number of digits for the values on the axes in 2D plots. The default setting is 4 digits.
- In the **3D grid** field, enter an integer between 1 and 15 for the number of digits for the values on the axes of the grid in 3D plots. The default setting is 3 digits.

- Plot Groups and Plots
- Results Toolbar and Plot Group Contextual Toolbar

See Table 21-11 for a summary of all the available plot types, including links to each plot described in this guide.

Admittance Graph

Add an **Admittance Graph** subnode ( ) to a **Smith Plot Group** node to create an admittance Smith plot. After defining the expression to plot (an S-parameter, for example), click **Plot** ( ) to create the admittance Smith plot. If you want to add color to the plotted curve (to represent the frequency, for example) or a filter, add Color Expression or Filter subnodes.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**.

EXPRESSIONS

For an Admittance Graph, you can plot multiple curves in the same graph (Smith plot) using varying line styles and colors. In the table in this section, add one or more expressions to the rows under **Expression** to define the quantity for each curve, and optionally add descriptions under **Description**. The descriptions appear in the legends.

For this table of expressions, the **Replace Expression** and **Add Expression** buttons have the following effect:

- Click the **Replace Expression** ( ) button to select a predefined quantity and replace the entire contents of the **Expression** table with the corresponding variable as the only expression.
- Click the **Add Expression** (+) button to insert the corresponding variable on a new row in the **Expression** table.

Enter a reference admittance (SI unit: S) in the **Reference admittance** field.

LEGENDS

The **Show legends** checkbox is selected by default to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes to control what to include in the automatic legends (by default it includes the

description only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Annotation

Use an **Annotation** plot ( ) to add an annotation anywhere in a plot. You can add **Annotation** subnodes to any plot group by right-clicking the plot group node and selecting **Annotation**. Add Deformation, Transformation, Transformation (3D only), or Visual Effects (3D only) subnodes as desired. If you want to use a Deformation subnode to move the annotation in accordance with some other deformed plot, typically, use expressions to define the deformation vector and select the other plot in the **Inherit Style** section to inherit the plot style from the plot that you want the annotation to move in accordance with.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Inherit Style**.

Y-AXIS

This section is only available for an **Annotation** node under a **1D Plot Group** that use two *y*-axes. In that case, select the **Plot on secondary y-axis** checkbox to plot the annotation using the coordinates for the secondary *y*-axis. You can also specify the axis to use in the **Plot Settings** section in the settings for the **1D Plot Group** node.

ANNOTATION

In the **Text** field, type the text that you want to display as an annotation. If you want the annotation to also contain the position (displayed before the annotation text), select the **Prepend the position** checkbox.

Select the **LaTeX markup** checkbox if you want to include mathematical symbols and Greek letters, for example, in the annotation. To include such symbols, surround the LaTeX syntax with $ (so-called math mode) to indicate that the text inside of the $ signs is LaTeX. For example, `$\alpha = \beta/\pi$` appears as $\alpha = \beta/\pi$. If the **LaTeX markup** checkbox is selected, you can also add line breaks as `\\`. See Mathematical Symbols and Special Characters for more information about available LaTeX symbols and characters (of which most but not all are applicable in this context).

You can include the value of some variable in the annotation. For example, type `eval(T)` to evaluate the temperature T in the annotation position, or `eval(t,min)` to evaluate the time t (in minutes). Use an optional third argument to eval to control the precision as an integer. For example, `eval(t,min,3)`. If there is no unit, you can leave the second argument empty.

You can also use `printf`-style number format specifiers of the form `%[`*`flags`*`][`*`width`*`][.`*`precision`*`]`*`type* as the last argument using the syntax `eval(`*`expr`*`,`*`unit`*`,`*`precision`*`)`, where the unit is optional. Allowed types are {`d`, `f`, `e`, `E`, `g`, `G`}. Two examples are `eval(pi,,%05d)`, which appears as `00003`, showing the number as a rounded integer with the width of 5 and zero padding, and `eval(pi*1e10,,%+.3e)`, which appears as `+3.142e+10`, a number with scientific format with 3 decimal values and with the sign of the number shown.

From the **Geometry level** list, you can select the geometry level for the evaluation: **From dataset** (the default), **Volume** (3D only), **Surface**, **Line**, **Point**, or **Global**. Click the **Replace Expression** ( ) or **Insert Expression** ( ) button to select predefined expressions to use inside of the `eval` statement.

POSITION

In the **x**, **y**, and **z** fields (for a 3D model with Cartesian coordinates; coordinate names can vary), enter the positions of the annotation as space-separated coordinate values. If you want to evaluate an expression that is defined in the

geometry, the positions must be within the geometry. Click the **Range** ( ) button to define a range of values for a coordinate. Click the **Replace Expression** ( ) button to select predefined expressions to use as positions of the annotation. For example, if you have added a **Mass Properties** node and created variables for the center of mass, you can choose them to place the annotation at the center of mass.

If the selected dataset is a Cut Point dataset, the coordinates are taken as the cut point coordinates, and the **Position** section is not available.

ADVANCED

From the **Expression number format** list, choose one of the following formats:

- **Default**: Numerical values that come from the solvers are presented as-is. Numbers formatted during postprocessing use the **Output display precision** preference setting.
- **Automatic**: All numbers are formatted using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Engineering**: All numbers are formatted using engineering notation (such as `31.416E-6`; it is similar to scientific notation but with the powers of ten as multiples of three) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Scientific**: All numbers are formatted using scientific notation (such as `3.1416E-5`) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Stopwatch**: All numbers are formatted in decimal notation with a specified number of integer digits and decimals, which you enter in the **Number of integer digits** field (default: 3) and **Number of decimals** field (default: 2), respectively. Unnecessary zeros are always shown. For example, with the default settings, 17.1 would be formatted as `017.10`. The specified number of integer digits is not respected if the number is too large or if it is NaN or Inf. Select the **Always show the sign** checkbox to keep the width from changing for a sequence that includes both positive and negative values. Select the **Always show the imaginary part** checkbox to keep the width from changing for a sequence that includes both real numbers and numbers with a nonzero imaginary part.
- **Scientific stopwatch**: All numbers are formatted in scientific notation with one integer digit and a specified number of decimals and exponent digits. For example, with the default settings, 17.1 would be formatted as `1.71E1`. The settings are the same as for the **Stopwatch** format, with the addition of an **Always show the sign of the exponent** checkbox. Select it to keep the width from changing for a sequence that includes both positive and negative exponents.

The **Recover** default is **Off** because recovery takes processing time. To use polynomial-preserving recovery and recover fields with derivatives such as stresses or fluxes with a higher theoretical convergence than smoothing, from the **Recover** list, select **Within domains** to perform recovery inside domains or **Everywhere** to apply recovery to all domain boundaries.

COLORING AND STYLE

Clear the **Show point** checkbox if you do not want to include a point in the plot at the location of the annotation. If desired, and if the **Show point** checkbox is selected, change the value in the **Point radius** field (default: 2) to a value between 0 and 1 to adjust the point size.

From the **Color** list, choose the color to use for the annotation text. Choose **From theme** (the default) to use the color from the current color theme, or choose **Custom** to choose a custom color from a color palette. Select the frame background color from the **Background color** list. Choose **From theme** to use a background color that changes with the selected color theme.

From the **Anchor point** list, choose the position of the anchor point relative to the annotation text: **Upper right**, **Upper middle**, **Upper left** (the default), **Middle right**, **Center**, **Middle left**, **Lower right**, **Lower middle**, or **Lower left**.

From the **Orientation** list, choose **Horizontal** (the default) or **Vertical**, if you want the annotation text to be displayed vertically instead of horizontally.

Select the **Show frame** checkbox to display the annotation in a rectangular frame.

Annotation Data

An **Annotation Data** plot node appears in 2D and 3D ( ) plot groups if you run a method that creates an `AnnotationData` plot. Add a Transparency or Visual Effects subnode as needed (3D only).

	It is not possible to add an **Annotation Data** node from the model tree or toolbars in the COMSOL Desktop. It is only available from the COMSOL Multiphysics API and if you run a method from the **Developer** toolbar. See AnnotationData in the *COMSOL Multiphysics Programming Reference Manual*.

ANNOTATION

The annotation to be displayed appears in the **Text** field.

Select the **LaTeX markup** checkbox if you want to include mathematical symbols and Greek letters, for example.

POSITION

The position of the annotation text appears in the coordinate fields.

	Go to Common Results Node Settings for a link to information about the **Title** and **Coloring and Style** section.

Arrow Data

An **Arrow Data** plot node appears in 2D ( ) and 3D ( ) plot groups if you run a method that creates an `ArrowData` plot. You can add Material Appearance, Transparency (3D only), and Visual Effects (3D only) subnodes as needed

	It is not possible to add an **Arrow Data** node from the model tree or toolbars in the COMSOL Desktop. It is only available from the COMSOL Multiphysics API and if you run a method from the **Developer** toolbar. See ArrowData in the *COMSOL Multiphysics Programming Reference Manual*.

DATA

In the **Data** section, the number of points in the data is listed.

	Go to Common Results Node Settings for a link to information about the **Title**, **Range**, and **Coloring and Style** sections.

Arrow Line

Use an **Arrow Line** plot to visualize a vector quantity as arrows on lines using a 2D **Arrow Line** ( ) plot, or lines and edges using a 3D **Arrow Line** ( ) plot. Add Color Expression, Deformation, Filter, Material Appearance, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes as needed. For example, add a **Color Expression** node to color the arrows with the magnitude of the vector quantity that the arrows represent. Right-click a **2D Plot Group** or **3D Plot Group** to add these plots.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Arrow Positioning**, **Coloring and Style**, and **Inherit Style**.

Arrow Point

Use an **Arrow Point** plot to visualize a vector quantity as arrows at points using a 2D or 3D **Arrow Point** plot (or). Add Color Expression, Deformation, Filter, Material Appearance, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes as needed. For example, add a **Color Expression** node to color the arrows with the magnitude of the vector quantity that the arrows represent. Right-click a **2D Plot Group** or **3D Plot Group** to add these plots from the **More Point Plots** submenu.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Coloring and Style**, and **Inherit Style**.

Arrow Surface

Use an **Arrow Surface** plot to visualize a vector quantity as arrows on a surface using a 2D **Arrow Surface** ( ) or 3D **Arrow Surface** ( ) plot. Add Color Expression, Deformation, Filter, Material Appearance, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes as needed. For example, add a **Color Expression** node to color the arrows with the magnitude of the vector quantity that the arrows represent. Right-click a **2D Plot Group** or **3D Plot Group** to add these plots.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Arrow Positioning**, **Coloring and Style**, and **Inherit Style**. For a settings specific to Arrow Surface plots in the **Expression** section, see below.

EXPRESSION

In addition to the expressions for the components of the vector to plot using arrows, and a description for that vector, this section contains an additional setting:

From the **Components to plot** list, choose **All** (the default), **Normal**, or **Tangential** to plot the full vector or only its normal or tangential components relative to the selected surfaces.

Arrow Volume

Use an **Arrow Volume** ( ) plot visualize a vector quantity as arrows in a 3D volume. Add Color Expression, Deformation, Filter, Material Appearance, Selection (Plot Attribute), Transformation, Transparency, or Visual

Effects subnodes as needed. For example, add a **Color Expression** node to color the arrows with the magnitude of the vector quantity that the arrows represent. Right-click a **3D Plot Group** to add this plot.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Arrow Positioning**, **Coloring and Style**, and **Inherit Style**.

Contour (Plot)

Use a **Contour** plot to visualize a scalar quantity as a contour in 2D ( ) or 3D ( ) and display the quantity as a set of colored lines. You can also use filled contours to create a kind of a surface plot with color banding. The selected quantity has a constant value on these contour lines, optionally with a 3D height for 2D contours. Add Color Expression, Deformation, Filter, Marker, Material Appearance, Selection (Plot Attribute), Transformation, Height Expression (2D only), Transparency (3D and 2D with Height Expression), or Visual Effects (3D and 2D with Height Expression) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add these plots.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Levels**, **Quality**, **Inherit Style**, and, except for some details below, **Coloring and Style**.

COLORING AND STYLE

Select a **Contour type**: **Line** (the default), **Filled**, or **Tube**. Using filled contours creates a plot with color banding rather than isolated contour lines or tubes when using the other contour types.

- If **Line** is selected, you can also select the **Level labels** checkbox to display line labels on the graph.
- If **Filled** is selected, you can also clear the **Fill surfaces outside of contour levels** checkbox (selected by default) to not fill the areas of the geometry's surface that are above the highest and below the lowest contour.
- If **Tube** is selected, you can enter an expression that defines the radius in the **Tube radius expression** field (default: 1). Click the **Replace Expression** button ( ) to choose a predefined expression to use for the tube radius. Click the **Radius scale factor** checkbox to change the default radius scale factor if you want to make the tubes thicker or thinner.

If you select to display level labels (not available for filled contours), select the **Level labels** checkbox and specify the precision (number of significant digits) as a positive integer in the **Precision** field (default: 4). You can also choose a color for the labels from the **Label color** list: Choose **From theme** to use the color from the color theme, choose **Custom** to define a custom color, or choose any of the predefined colors.

For coloring the contours, select one of the following options from the **Coloring** list:

- Select **Color table** (the default) to color the contours using a color table that you choose from the **Color table** list below.
- Select **Uniform** to use a predefined uniform color, or select **Custom** to define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette.
- Select **Gradient** to specify the coloring as a gradient between two colors, which you specify using the **Top color** and **Bottom color** lists.

The **Color legend** checkbox is selected by default. Clear it to remove the color legend. Select the **Reverse color table** or **Reverse color gradient** and **Symmetrize color range** checkboxes as required.

For information about the **Legend type** list, see Legend Type.

Contour Series

Use a **Contour Series** plot to visualize a scalar quantity as a contour in 2D ( ) or 3D ( ) and display the quantity as a set of colored lines. You can also use filled contours to create a kind of a surface plot with color banding. The selected quantity has a constant value on these contour lines, optionally with a 3D height for 2D contours. Add Color Expression, Deformation, Filter, Marker, Selection (Plot Attribute), Transformation, Height Expression (2D only), Transparency (3D and 2D with Height Expression), or Visual Effects (3D and 2D with Height Expression) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add these plots from the **More Surface Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Quality**, **Inherit Style**, and, except for some details below, **Coloring and Style**.

COLORING AND STYLE

Select a **Contour type**: **Line** (the default), **Filled**, or **Tube**. Using filled contours creates a plot with color banding rather than isolated contour lines or tubes when using the other contour types.

- If **Line** is selected, you can also select the **Level labels** checkbox to display line labels on the graph.
- If **Filled** is selected, you can also clear the **Fill surfaces outside of contour levels** checkbox (selected by default) to not fill the areas of the geometry's surface that are above the highest and below the lowest contour.
- If **Tube** is selected, you can enter an expression that defines the radius in the **Tube radius expression** field (default: 1). Click the **Replace Expression** button ( ) to choose a predefined expression to use for the tube radius. Click the **Radius scale factor** checkbox to change the default radius scale factor if you want to make the tubes thicker or thinner.

If you select to display level labels (not available for filled contours), select the **Level labels** checkbox and specify the precision (number of significant digits) as a positive integer in the **Precision** field (default: 4). You can also choose a color for the labels from the **Label color** list: Choose **From theme** to use the color from the color theme, choose **Custom** to define a custom color, or choose any of the predefined colors.

For coloring the contours, select one of the following options from the **Coloring** list:

- Select **Color table** (the default) to color the contours using a color table that you choose from the **Color table** list below.
- Select **Uniform** to use a predefined uniform color, or select **Custom** to define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette.
- Select **Gradient** to specify the coloring as a gradient between two colors, which you specify using the **Top color** and **Bottom color** lists.

The **Color legend** checkbox is selected by default. Clear it to remove the color legend. Select the **Reverse color table** or **Reverse color gradient** and **Symmetrize color range** checkboxes as required.

For information about the **Legend type** list, see Legend Type.

Coordinate System Volume, Coordinate System Surface, Coordinate System Line, and Coordinate System Point

Use the **Coordinate System Volume** (3D), **Coordinate System Surface** (2D and 3D), **Coordinate System Line** (2D and 3D), and **Coordinate System Point** (2D and 3D) plots to visualize the coordinate systems used in, for example, models of piezoelectric devices, where there can be multiple domains, each using its

own set of coordinate systems. Right-click to add Deformation, Filter, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** node to add these plots from the **More Volume Plots** (3D only), **More Surface Plots**, **More Line Plots**, and **More Point Plots** submenus.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Coloring and Style**, and **Inherit Style**.

COORDINATE SYSTEM

Choose to plot a **Coordinate system** (the default) or a **Matrix variable**:

- For **Coordinate system**, choose one of the available coordinate systems from the **Coordinate system** list. The default is **None** (no coordinate system). The coordinate system directions arrows are red for the first coordinate direction's basis vector, green for the second coordinate direction's basis vector, and blue for the third coordinate direction's basis vector.
- For **Matrix variable**, click the **Replace Expression** button ( ) to select an available matrix variable from the list, which includes transformation matrices to and from the added coordinate systems and physical quantities that are tensors, such as the thermal conductivity. Only 2-by-2- and 3-by3-matrices are supported. The selected variable (for example, `ht.k`) then appears next to the **Matrix variable**. Each row of the matrix is plotted as a vector. The first row is plotted in red, the second row in green, and the third row, if any, in blue. Click the **Description** checkbox if you want to add a description for the matrix variable. From the **Vector to plot** list, choose **Rows** (the default) or **Columns**. Plotting the vectors as columns can be useful, for example, when plotting the deformation gradient variables in a structural mechanics interfaces. Plotting the deformation gradient's columns as a triplet of arrows gives a good picture of the local deformation and rotation of the material.

POSITIONING

For **Coordinate System Surface** in 3D plot groups and **Coordinate System Line** in 3D and 2D plot groups:

Under **Positioning**, first select a **Placement**: **Gauss points**, **Mesh vertices**, **Uniform**, or **Uniform anisotropic**.

- Select **Gauss points** to position the coordinate system symbols in the elements' Gauss points when a solution is available. Also specify the order of the Gauss points in the **Gauss-point order** field (default: 1). A higher order increases the coordinate system symbol density in each element. This option is not available for **Coordinate System Line** plots in 2D plot groups.
- Select **Mesh vertices** for coordinate system symbols positioned in the mesh vertices (that is, more densely placed symbols where the mesh density is high).
- Select **Uniform** (the default) for coordinate system symbols positioned uniformly on the surface. Then enter the number of symbols to plot in the **Number of points** field (default: 200).
- Select **Uniform anisotropic** to position the coordinate system symbols using an anisotropic density (that is, more symbols in some directions than in others). In addition to entering the number of coordinate system symbols to plot in the **Number of points** field (default: 200), use the **x weight**, **y weight**, and (in 3D) **z weight** fields to give weights for the symbol density in the different directions (using positive scalar weights). The default weights are 1 in all directions. A higher value increases the symbol density in the corresponding direction.

For **Coordinate System Volume** in 3D plot groups and **Coordinate System Surface** in 2D plot groups:

Under **Positioning**, first select a **Placement**: **Element centers**, **Mesh vertices**, or **Grid** (the default).

- Choose **Element centers** to position the principal stress symbols in the element centers; if desired, change the value in the **Maximum number of points** field (default: 100,000).
- For **Mesh vertices**, see above.

- For **Grid**, in the **x grid points**, **y grid points**, and **z grid points** fields, select an **Entry method**: **Number of points** or **Coordinates**:
  - If **Number of points** is selected, enter the number of **Points** in each direction (the default is 7 for Coordinate System Volume plots and 15 for Coordinate System Surface plots).
  - If **Coordinates** is selected, enter **Coordinates** (SI unit: m) or click the **Range** button ( ) to define a range of values.

Directivity

The **Directivity** plot ( ) is an extension of the far-field plots and is a common acoustic plot for speakers, for example. The plot collects spatial information across frequencies and shows this information in a contour plot.

You can add **Directivity** plot nodes to 1D and 2D plot groups from the **More Plots** (1D) and **More Surface Plots** (2D) submenus.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Levels**, **Range**, **Inherit Style**, and **Coloring and Style**. See below for some specific settings in the **Coloring and Style** section.

	The Directivity plot is only available with the Acoustics Module.

EXPRESSION

For the standard settings, see Expressions and Predefined Quantities. You can also choose a normalization of the data from the **Normalization** list:

- Choose **With respect to angle** (the default) to compute an expression with the level normalized with respect to the value at a specific angle. You specify the angle (in degrees) in the **Angle** field (unit: deg).
- Choose **With respect to maximum** to compute the expression normalized with respect to its maximum level value for each frequency.
- Choose **None** to not use any normalization.

EVALUATION

Under **Angles**, enter the **Number of angles**. The default is 50.

Select a **Restriction**: **None** (the default) or **Manual**.

If **Manual** is selected, enter values (SI unit: deg) for:

- φ **start** (the default is 0 degrees).
- φ **range** (the default is 360 degrees). Typically the range will be 180 degrees to evaluate the directivity in the half space in front of a speaker.

The following settings only appear if there is a physics interface in the model that makes use of them. Under **Center**, enter values for the coordinates at the center of the evaluation circle. Under **Normal vector**, enter the components of the normal vector defining the evaluation plane in the **x**, **y**, and **z** fields. Under **Evaluation distance** (only available when applicable), enter a **Radius** for the evaluation; the default is 1 m as usually used for these plots. Under **Reference direction**, specify the coordinates of the vector that specifics the direction representing 0 degrees in the plot. The

entered vector is projected onto the evaluation plane. A schematic of the evaluation circle is given in Figure 21-6 below.

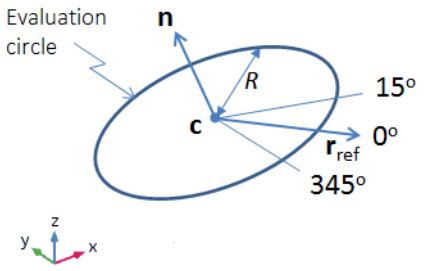

Figure 21-6: Schematic of the evaluation circle used in the Directivity and Radiation Pattern plots, showing the circle center $\mathbf{c}$*, evaluation plane normal* $\mathbf{n}$*, evaluation radius* R*, and reference direction* $\mathbf{r}_{\text{ref}}$.

In 3D and 2D axisymmetric models, you can preview the evaluation plane, including circle, normal, and reference direction, in the geometry by clicking the **Preview Evaluation Plane** button at the bottom of the **Evaluation** section. An example of the resulting plot is depicted in Figure 21-7 below.

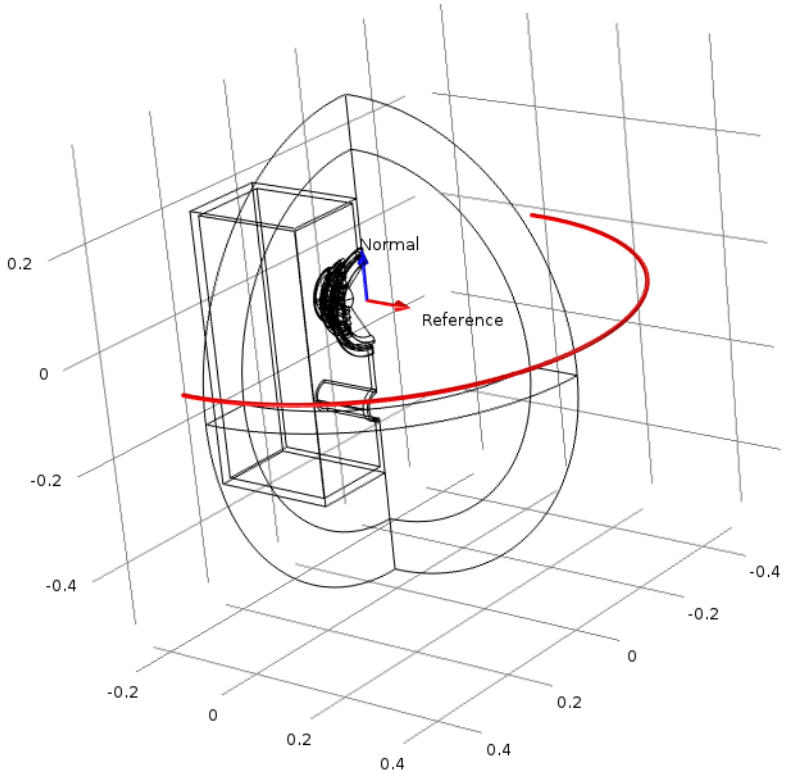

Figure 21-7: Preview plot of the evaluation circle used in the directivity plot for the Vented Loudspeaker Enclosure model from the Acoustics Module Application Gallery.

COLORING AND STYLE

In addition to common coloring and style settings, you can specify the axis and scale for the frequency and the contour type.

From the **Layout** list, choose:

- **Frequency on x-axis** to plot with the frequency on the *x*-axis.
- **Frequency on y-axis** to plot with the frequency on the *y*-axis.

From the **Frequency scale** list (2D only), choose:

- **Logarithmic** (the default) to plot the frequency using a logarithmic scale.
- **Linear** to plot the frequency using a linear scale.

Select a **Contour type**: **Line** or **Filled** (the default). Using filled contours creates a plot with color banding rather than isolated contour lines.

- If **Line** is selected, you can also select the **Level labels** checkbox to display line labels on the graph. When that checkbox is selected, you can specify a numerical precision in the **Precision** field (default: 4). In 1D, you can also specify a line width in the **Width** field (default: **Default from preferences**) in 1D.
- If **Filled** is selected, you can also clear the **Fill surfaces outside of contour levels** checkbox (selected by default) to not fill the areas of the geometry's surface that are above the highest and below the lowest contour.

Function

A **Function** plot is created under a **1D Plot Group** (f(x)), **2D Plot Group** (f(x)), or **3D Plot Group** (f(x)) node when you click **Create Plot** ( ) in a function node, depending on if the function depends on 1 or 2 variables. For 2D and 3D Function plots, add Height Expression (2D only), Filter, and Transparency or Visual Effects (3D and 2D if a **Height Expression** node is used) subnodes if desired. For 1D Function plots, add an **Error Bars** subnode if desired. Right-click a **1D Plot Group**, **2D Plot Group**, or **3D Plot Group** to add this plot type from the **More Volume Plots**, **More Surface Plots**, or **More Plots** submenu, respectively.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Range** (2D only), and **Coloring and Style**. Also see the section Expressions and Predefined Quantities.

	Note that a Function plot should use its associated Grid dataset; using some other dataset results in an error.

The following sections are only available for 1D **Function** plots:

Y-AXIS

	This section is only available if the **Two y-axes** checkbox is selected in the **Plot Settings** section of the parent **1D Plot Group** node's **Settings** window.

Select the **Plot on secondary y-axis** checkbox to plot the *y*-axis data on the secondary *y*-axis to the right of the plot instead of the primary *y*-axis to the left of the plot.

Y-AXIS DATA

Enter the expression to plot in the **Expression** field. For a **Function** plot created from a function definition node, the expression is already present, such as `an1(x)` for an analytic function with the function name `an1`. Click the **Replace Expression** ( ) button or the **Add Expression** (+) button to replace or add to the expression using some predefined expression. Also add a **Unit** and **Description** if desired.

X-AXIS DATA

Enter the expression for the *x*-axis in the **Expression** field. For a **Function** plot created from a function definition node, the expression is already present, such as `x` for an analytic function with the argument `x`. Click the **Replace**

Expression ( ) button or the **Add Expression** (+) button to replace or add to the expression using some predefined expression. Also add a **Unit** and **Description** if desired. Enter values in the **Lower bound** and **Upper bound** fields to define the range of the argument for the function.

OUTPUT

In this section, you can control what to display for the function plot. From the **Display** list, choose one of the following display types:

- **Line** (the default), to display the function using a line plot.
- **Line and points**, to display the function using a line plot and points defined using the **Point definition** list. The points can, for example, come from a **Cut Point 1D** dataset that points to a **Grid 1D** dataset.
- **Points**, to display the function using a points defined using the **Point definition** list. The points can, for example, come from a **Cut Point 1D** dataset that points to a **Grid 1D** dataset.
- **Discrete Fourier transform**, to display a discrete Fourier transform (DFT) of the function. If you select to display a DFT, choose one of the following options from the **Show** list:
  - **Real part**, to show the real part of the output only.
  - **Imaginary part**, to show the imaginary part of the output only.
  - **Amplitude**, to show the amplitude of the output (the default).
  - **Phase**, to show the phase of the output.
  - **Frequency spectrum**, to display the function's frequency spectrum by computing the number of frequencies and the frequency range based on the FFT (fast Fourier transform) of the function. The transform is valid for all functions, but what you get corresponds to a periodic continuation of the function outside the chosen bounds. To specify these values manually, select the **Number of frequencies** checkbox and enter a value in the associated field (the default is based on the number of time samples). From the **Scale** list, choose **None** (the default), **Multiply by sampling point**, or **Divide by number of frequencies**. You can choose to scale with the sampling period to show Fourier transform values instead of a pure DFT transform. Select the **Scale** checkbox to scale the values on the y-axis so that their magnitude reflects the magnitude of the original signal. The values then have the same unit as the input data for the FFT. For a pure sinusoid, the scaled value is the peak magnitude divided by the square root of 2 ($u_{\max}/\sqrt{2}$). Select the **Frequency range** checkbox and then enter the bounds of the frequency range in the **Minimum** and **Maximum** fields (in Hz). The FFT algorithm uses resampling based on linear interpolation. The x-axis shows the frequency (in Hz). By default, the y-axis shows the unscaled Fourier coefficients.

    If you have selected **Amplitude** or **Frequency spectrum**, you can select the **In dB** checkbox to present the values in dB. From the **dB type** list, choose **10log** (the default) or **20log**. The display in dB requires a reference value. From the dB reference list, choose **Maximum** (the default) to use the maximum value as the reference, or choose **Manual** to enter a suitable reference value in the **Reference value** field.

    If you have selected **Real part**, **Imaginary part**, **Amplitude**, or **Phase**, the following additional settings are available: To specify this value manually, select the **Number of uniform samples** checkbox and enter a value in the associated field. If desired, select the **Inverse transform** checkbox to use an inverse DFT. Select the **Mask DC** checkbox to set the DC value (zero frequency component) to zero (not available if **Inverse transform** is selected). The **Ignore last sample** checkbox is selected by default to not include the last sample in the transform (not available if **Inverse transform** is selected). The **Shift zero frequency** and **Scale with sampling period** checkboxes are selected by default. Clear one or more of these checkboxes if you want to exclude those steps.

If you have selected **Line** or **Line and Points**, also select an extrapolation of the function from the **Extrapolation** list:

- **None** for no extrapolation (the default).
- **Left** to extrapolate to the left of the function's bounds.

- **Right** to extrapolate to the right of the function's bounds.
- **Left and right** to extrapolate to the left and right of the function's bounds.

COLORING AND STYLE

In addition to the standard settings for the line style and color under **Line style**, these additional settings are available:

- Choose an **Extrapolation color** if desired. It is the color of the extrapolation zones (if any).
- Choose a **Point color** to specify the color of the points.

LEGENDS

Select the **Show legends** checkbox to display the plotted expression to the right of the plot.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes under **Include** to control what to include in the automatic legends (by default, it includes the description only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table.

The following sections are only available for 2D and 3D **Function** plots:

AXES

In this section, you can specify the units for the plot axis in the **x unit**, **y unit**, and (3D only) **z unit** fields.

COLORING AND STYLE

In 2D, this section contains the same settings as those for a **Surface** plot, except that the **Wireframe** setting is not available. In 3D, this section contains the same settings as those for a **Slice** plot.

The following section is only available for 3D **Function** plots:

PLANE DATA

Under **Plane Data**, select a **Plane Type**: **Quick** (the default) to specify planes orthogonal to the coordinate axes or **General** to specify general planes.

If **Quick** is selected:

- From the **Plane** list, select **xy-planes**, **yz-planes**, or **zx-planes** as the set of planes orthogonal to the coordinate axes applicable for the model geometry.
- Select an **Entry method**: **Number of planes** or **Coordinates**.
  - If **Number of planes** is selected, enter **Planes**.
  - If **Coordinates** is selected, enter the applicable (x, y, or z) grid **Coordinates**. Choose a set of cut plane slices to a coordinate axis, specify the transverse coordinate by entering the location along the transverse coordinate axis in the **Coordinates** field.

If **General** is selected:

- Select an option from the **Plane entry method** list: **Three points** or **Point and normal**.
  - If **Three points** is selected, enter **x**, **y**, or **z** coordinates in the **Point 1**, **Point 2**, and **Point 3** fields.
  - If **Point and normal** is selected, enter **x**, **y**, or **z** coordinates in both the **Point** and **Normal** sections.
- If required, select the **Additional parallel planes** checkbox and select an **Entry method**: **Number of planes** or **Distances**.
  - If **Number of planes** is selected, enter the number of grid **Planes** (the default is 4).
  - If **Distances** is selected, enter the **Distances** (SI unit: m).

Global

Use a **Global** ( ) plot to graph a scalar quantity as a function of time or a parameter. Add Color Expression, Filter, Graph Marker, or Error Bars (Global, Point Graph, and Function) subnodes as needed. Right-click a **1D Plot Group** or **Polar Plot Group** to add this plot type.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**. Also see the section Expressions and Predefined Quantities.

Y-AXIS

This section is only available if the **Two y-axes** checkbox is selected in the **Plot Settings** section of the parent **1D Plot Group** node's **Settings** window.

Select the **Plot on secondary y-axis** checkbox to plot the y-axis data on the secondary y-axis to the right of the plot instead of the primary y-axis to the left of the plot.

Y-AXIS DATA (1D PLOTS) OR R-AXIS DATA (POLAR PLOTS)

For a Global plot, you can plot multiple curves in the same graph using varying line styles and colors. In the table in this section, add one or more expressions to the rows under **Expression** to define the quantity on the y-axis for each curve, and optionally add descriptions under **Description**. The descriptions appear in the legends.

For this table of expressions, the **Replace Expression** and **Add Expression** buttons have the following effect:

- Click the **Replace Expression** ( ) button to select a predefined quantity and replace the entire contents of the **Expression** table with the corresponding variable as the only expression.
- Click the **Add Expression** (+) button to insert the corresponding variable on a new row in the **Expression** table.

If the expression for the y-axis data has the unit of an angle, an **Unwrap phase** checkbox appears. Select it to unwrap the phase data. Unwrapping the phase means to let the phase angle grow outside the range $[-\pi, \pi]$.

The phase unwrapping only works correctly if there is less than a π difference in phase between points.

X-AXIS DATA (1D PLOTS) OR θ ANGLE DATA (POLAR PLOTS)

From the **Parameter** list, select an option for what the x-axis represents: **Solution number**, **Frequency spectrum**, **Phase**, or **Expression**. For **Parametric Sweep** studies, and when there are multiple inner solutions, **Parameter value** and **Time** are available instead of **Solution number**. Select:

- **Solution number**, to use the solution numbers as the x-axis data (or θ angle data for polar plots) for an eigenvalue solution or for a parametric solution with more than one parameter.

- **Discrete Fourier transform**, to display a discrete Fourier transform (DFT) of the data. If you select to display a DFT, choose one of the following options from the **Show** list:
  - **Real part**, to show the real part of the output only.
  - **Imaginary part**, to show the imaginary part of the output only.
  - **Amplitude**, to show the amplitude of the output (the default).
  - **Phase**, to show the phase of the output.
  - **Frequency spectrum**, to display the function's frequency spectrum by computing the number of frequencies and the frequency range based on the FFT (fast Fourier transform) of the function. The transform is valid for all functions, but what you get corresponds to a periodic continuation of the function outside the chosen bounds. To specify these values manually, select the **Number of frequencies** checkbox and enter a value in the associated field (the default is based on the number of time samples). From the **Scale** list, choose **None** (the default), **Multiply by sampling point**, or **Divide by number of frequencies**. You can choose to scale with the sampling period to show Fourier transform values instead of a pure DFT transform. Select the **Scale** checkbox to scale the values on the y-axis so that their magnitude reflects the magnitude of the original signal. The values then have the same unit as the input data for the FFT. For a pure sinusoid, the scaled value is the peak magnitude divided by the square root of 2 ($u_{\max}/\sqrt{2}$). Select the **Frequency range** checkbox and then enter the bounds of the frequency range in the **Minimum** and **Maximum** fields (in Hz). The FFT algorithm uses resampling based on linear interpolation. The x-axis shows the frequency (in Hz). By default, the y-axis shows the unscaled Fourier coefficients.

    If you have selected **Amplitude** or **Frequency spectrum**, you can select the **In dB** checkbox to present the values in dB. From the **dB type** list, choose **10log** (the default) or **20log**. The display in dB requires a reference value. From the dB reference list, choose **Maximum** (the default) to use the maximum value as the reference, or choose **Manual** to enter a suitable reference value in the **Reference value** field.

    If you have selected **Real part**, **Imaginary part**, **Amplitude**, or **Phase**, the following additional settings are available: To specify this value manually, select the **Number of uniform samples** checkbox and enter a value in the associated field. If desired, select the **Inverse transform** checkbox to use an inverse DFT. Select the **Mask DC** checkbox to set the DC value (zero frequency component) to zero (not available if **Inverse transform** is selected). The **Ignore last sample** checkbox is selected by default to not include the last sample in the transform (not available if **Inverse transform** is selected). The **Shift zero frequency** and **Scale with sampling period** checkboxes are selected by default. Clear one or more of these checkboxes if you want to exclude those steps.
- **Expression**, to specify an expression to use for the x-axis data in the **Expression** field.
- **Phase**, to specify a range of phase angles for the x-axis data. The default for the **Phase** is `(pi/10)*range(0,1,20)` (0–360 degrees in steps of $\pi/10$ rad). Select a **Unit** for the phase angle.
- **Parameter value**, to use the x-axis data (or θ angle data for polar plots) stored in the solution for a parametric solution with a single parameter.
- **Time**, to use time as the x-axis data (or θ angle data for polar plots) for a time-dependent solution.

Parametric Sweep Studies

Under **x-Axis Data** (θ **Angle Data** for polar plots), for **Parametric Sweep** studies, and when there are multiple inner solutions, select an option from the **Solutions** list: **Inner** or **Outer**.

- If **Inner** is selected, and for time-dependent studies, the **Times** steps are plotted on the x-axis and one line per parameter is included in the graph (as listed in the **Data** > **Parameter values** section on this page).
- If **Outer** is selected, one line in the graph is plotted for each inner solution and the **Parameter values** are plotted on the *x*-axis.

One example is a time-dependent problem with a geometric parametric sweep. The time steps are the inner solutions and the swept parameters are the outer solutions.

QUALITY

This section is only available when the dataset refers to a solution using a time-dependent study. You can then increase the time resolution if needed for a smooth graph plot. In the **Refinement** list, enter an integer between 1 (the default value) and 1000. For an increased time resolution, enter a higher refinement value.

LEGENDS

The **Show legends** checkbox is selected by default to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes under **Include** to control what to include in the automatic legends (by default, it includes the solution and description only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Small-Signal Analysis, Prestressed Analysis, and Harmonic Perturbation Plot Settings

Histogram

Use a **Histogram** node in 1D ( ) or 2D ( ) to plot a histogram that shows how a quantity is distributed over the geometry (mesh volume). In 1D histograms, the *x*-axis in the histogram represents the values of the quantity (as a number of bins or a range of values), and the *y*-axis represents the count of the total element volume in each interval. You can also view the histogram as a plot showing the area between contours or isosurfaces. In 2D histograms, the *x*-axis and *y*-axis represent the values of two quantities (as a number of bins or a range of values), and the color surface represents the count of the total element volume in each "bin". The histogram can be normalized and also displayed as a cumulative plot, and it can appear as a discrete or a continuous function. You can use a histogram with settings that provide a bar chart of, for example, the distribution of values in different ranges. Right-click a **1D Plot Group** or **2D Plot Group** to add this plot. For the 2D Plot Group, select this from the

More Surface Plots submenu. Add a Filter, Height Expression (2D only), and Transparency or Visual Effects (2D with Height Expression only) subnodes if required.

- Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Range**, **Coloring and Style**, and **Quality**.
- For a 2D histogram based on a precomputed matrix of data, see Matrix Histogram.

Y-AXIS

This section is only available for 1D **Histogram** plots and if the **Two y-axes** checkbox is selected in the **Plot Settings** section of the parent **1D Plot Group** node's **Settings** window.

Select the **Plot on secondary y-axis** checkbox to plot the *y*-axis data on the secondary *y*-axis to the right of the plot instead of the primary *y*-axis to the left of the plot.

BINS

Select an **Entry method** — **Number of bins** or **Limits** — to define the bins for the histogram's *x*-axis. Select **Number of bins** (the default) to specify the number of bins (default is 10), or select **Limits** to specify a range of limits (`1 2 3 4`, for example) for the histogram bins.

For 2D Histogram nodes, these settings are available for the *x* direction and *y* direction under **x bins** and **y bins**.

OUTPUT

Under **Output**, specify some properties for the appearance of the histogram. Specify whether to use a continuous or discrete function for the histogram, the normalization, and whether to use a standard or a cumulative histogram.

From the **Function** list, select **Continuous** (the default) to plot the histogram as a continuous function or **Discrete** to plot it as a discrete function (that is, using a constant level in each bin). The discrete version is useful to display the histogram as a bar chart, perhaps with the **Integral** normalization setting so that each bin (bar) shows its relative size and the **Type** set to **Solid** under **Coloring and Style** for filled histogram bins.

From the **Normalization** list, select:

- **Sum of values** to normalize the histogram so that the integral is equal to 1 by dividing the absolute count of each bin by the sum of the counts over all bins. Use this normalization to get the relative size (percentage) of values in each bin.
- **Integral** to normalize the histogram by dividing the absolute count of each bin by the sum of the counts over all bins, each multiplied by the width of the bin.
- **None** (the default) to show the actual element volume without any normalization.
- **Peak** to normalize the histogram so that the peak value is equal to 1.

Select the **Cumulative** checkbox to make the histogram cumulative (that is, the value in each bin is the sum of the values for all bins up to the current one).

EVALUATION

From the **Measure** list, choose **Auto** (the default); **Integral**, for volume-based data; or **Count**, for element-based data. The **Auto** option uses a measure that depends on the dataset that is used. For Mesh datasets, the element-based measure (**Count**) is used: otherwise, the volume-based measure (**Integral**) is used.

Specify the **Space dimension** and the **Geometry level** for the evaluation. By default, the settings are taken from the dataset. For a specific model, some space dimensions and geometry levels might not be applicable.

From the **Space dimension** list, select **From dataset** (the default) or one of the space dimensions **0**, **1**, **2**, or **3**. The default is sufficient except when the dataset is, for example, a cut plane, which can be evaluated for space dimensions 2 or 3.

From the **Geometry level** list, select **From dataset** (the default), **Volume**, **Surface**, **Line**, or **Point**. Using a geometry level other than the dataset can be useful, for example, for evaluating over the surfaces of a 3D geometry. For solution datasets, **From dataset** defaults to the highest dimension where there are any mesh elements.

LEGENDS

This section is available in 1D plot groups only. Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes under **Include** to control what to include in the automatic legends (by default, it includes the solution only). If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Image

Use an **Image** plot ( ) to add an image as a plot. You can add it to 3D and 2D plot groups as an image on the surfaces of the plot. You can also add Image (Plot Attribute) subnodes directly to a 2D or 3D plot group. Right-click the Image node to add Deformation, Material Appearance, Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes if desired.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Selection**, **Title**, **Quality**, and **Inherit Style**.

FILE

Click the **Browse** button ( ) to browse to and select an image to add. Select it in the **Image** file browser window and then click **Open**. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ). Click the **Plot** button ( ) to add the image to the plot. Click the **Refresh** button ( ) to update the image plot with the latest version of the image file. Click the **Import** button ( ) to store the image in the model. You then get information about the imported image file (the filename and its width and height). Click **Export** ( ) or press F8 to export the image to a file, and click the **Discard** button to remove the imported image file and return to the original settings in this section. You can also click the downward arrow beside the **Export** button and choose **Export To** ( ) to open the fullscreen **Export** window for exporting to a database.

MAPPING

This section controls how the image is mapped to the 2D and 3D surfaces; you can choose an automatic or manual mapping as well as predefined planar, cylindrical, and spherical mappings for 3D surfaces and a rectangular mapping for 2D surface.

- When the **Mapping** list is set to **Auto**, an automatic planar projection algorithm is used to map the image to the surfaces. The **Auto** setting always finds the best fitting plane and projects on it while choosing a suitable projection size. If the **Preserve aspect ratio** checkbox is selected (the default), then the image's aspect ratio is

preserved by the automatic mapping algorithm. If the image and the data have aspect ratios, then some padding must be added. The images are centered in the dimension where padding is needed.

- When you select **Manual** from the **Mapping** list, you get access to more detailed control over the mapping. Each point on the surface is mapped to a pixel in the image. This functionality can be used for more advanced mappings. The following example provides a mapping that embeds a world map that uses an equirectangular projection on a sphere of radius *r* centered at the origin (when using a relative coordinate interpretation):
  - For the **u-coordinate** field, enter `0.5+atan2(y,x)/(2*pi)`.
  - For the **v-coordinate** field, enter `1-acos(z/r)/pi`.

  The default setting for the **Coordinate interpretation** list is **Relative** (a value in the range of 0–1). Choose **Pixels** to instead enter the coordinates using absolute pixels coordinates.

  The following mapping types are available in 3D:

- When you select **Planar** from the **Mapping** list, you can define a plane for the image to be mapped to. From the **Plane type** list, choose one of the following planes: **xy-plane**, **yz-plane**, **zx-plane**, **yx-plane**, **zy-plane**, **xz-plane**, **Auto** (the default), or **General**. For **Auto**, the software chooses the plane type that best suits the selected surfaces.

  Enter a **Width** under **Size**, which is the side length that the image will have, interpreted in the length unit of the geometry that the solution dataset refers to. The **Height** will be computed based on the image's size. Also, provide the coordinates for an anchor point in the **x**, **y**, and **z** fields under **Anchor point**. For **General**, specify a normal vector in the **x**, **y**, and **z** fields under **Normal**. The default is (0, 0, 1); that is, the positive *z* direction). Also specify a rotation angle, in degrees, if desired, in the **Rotation** field.
- When you select **Cylindrical** from the **Mapping** list, you get a cylindrical mapping of the image. Specify the position of the cylinder (center of the bottom circle) in the **x**, **y**, and **z** fields under **Position**, and from the **Axis type** list under **Axis**, choose **X-axis**, **Y-axis**, **Z-axis** (the default), **Cartesian**, or **Spherical**. For **Cartesian**, specify the axis direction in the **x**, **y**, and **z** fields. For **Spherical**, specify the axis direction in the **theta** and **phi** fields as θ and φ angles in degrees. Under **Angle**, specify a rotation angle, in degrees, if desired, in the **Rotation** field and an angle range, in degrees. for which you want to apply the mapping (default: 360 degrees). Under Height, choose one of the following options from the Mode list: **Auto** (the default), **Fit to object**, or **Manual**. If you choose **Manual**, enter a height and a displacement in the **Height** and **Displacement** fields, both in coordinates in the geometry's coordinate system and its length unit. The displacement is the shift along the axis measured from the middle.
- When you select **Spherical** from the **Mapping** list, you get a spherical mapping of the image. Specify the position of the sphere's center in the **x**, **y**, and **z** fields under **Position**, and from the **Axis type** list under **Axis**, choose **X-axis**, **Y-axis**, **Z-axis** (the default), **Cartesian**, or **Spherical**. For **Cartesian**, specify the axis direction in the **x**, **y**, and **z** fields. For **Spherical**, specify the axis direction in the **theta** and **phi** fields as θ and φ angles in degrees. Also specify a rotation angle, in degrees, if desired, in the **Rotation** field.

  The following mapping type is available in 2D:

- When you select **Rectangular** from the **Mapping** list, you define a rectangle for the image to be mapped to. Enter a **Width** under **Size**, which is the side length that the image will have, interpreted in the length unit of the geometry that the solution dataset refers to. The **Height** will be computed based on the image's size.

From the **Extrapolation** list under **Tiling**, choose **Repeat** (the default), **Repeat mirrored**, or **Clamp to edge** to control the type of extrapolation to use. The effect of the **Clamp to edge** option is that each coordinate is mapped to the closest valid value at an edge of the image. The **Extrapolation** list is not available when you have selected the **Cylindrical** or **Spherical** mapping from the **Mapping** list.

The coordinate names above are the default names: **x**, **y**, and **z**, but they can vary depending on the physics and setup of the current model.

Impedance Graph

Add an **Impedance Graph** subnode ( ) to a **Smith Plot Group** node to create an impedance Smith plot. After defining the expression to plot (an S-parameter, for example), click **Plot** ( ) to create the impedance Smith plot. If you want to add color to the plotted curve (to represent the frequency, for example) or a filter, add Color Expression or Filter subnodes.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**.

EXPRESSIONS

For an Impedance Graph, you can plot multiple curves in the same graph (Smith plot) using varying line styles and colors. In the table in this section, add one or more expressions to the rows under **Expression** to define the quantity for each curve, and optionally add descriptions under **Description**. The descriptions appear in the legends.

For this table of expressions, the **Replace Expression** and **Add Expression** buttons have the following effect:

- Click the **Replace Expression** ( ) button to select a predefined quantity and replace the entire contents of the **Expression** table with the corresponding variable as the only expression.
- Click the **Add Expression** (+) button to insert the corresponding variable on a new row in the **Expression** table.

Enter a reference impedance (SI unit: Ω), if using, in the **Reference impedance** field.

LEGENDS

The **Show legends** checkbox is selected by default to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label, Solution**, **Description**, **Expression**, and **Unit** checkboxes to control what to include in the automatic legends (by default it includes the solution and description only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Impulse Response

Add an **Impulse Response** subnode ( ) to a 1D plot group to create an impulse response plot. After defining the characteristics of the impulse response, click **Plot** ( ) to create the impulse response plot. Add a Color Expression or Energy Decay subnode as needed. The impulse response plot reconstructs the impulse response based on a Ray Acoustics simulation.

For details on setting up a Ray Acoustics model and postprocess the impulse response, see *Impulse Response and Receiver* in the *Acoustics Module User's Guide*.

Go to Common Results Node Settings for links to information about these sections: **Title** and **Coloring and Style**.

SOURCE

From the **Source** list, choose **Dataset** (the default) or **Function**.

If you chose **Dataset**, from the **Dataset** list, choose an applicable dataset or **None**. The default option, **From parent**, uses the dataset from the parent plot group node. Only the Receiver 2D and Receiver 3D datasets are valid for this specialized plot.

If you chose **Function**, choose an applicable functions or **None** from the **Function** list. Click the **Refresh** button to update the list of functions.

From the **Frequency interpretation** list, choose an interpretation of the frequency: **Octave** (the default), **1/3 octave**, or **1/6 octave**. This selections should coincide with the frequency interpretation used in boundary conditions and sources in the underlying Ray Acoustics simulation. The frequency content and resolution of the impulse response are based on this selection.

EXPRESSION

Set up the variables that are necessary for reconstructing the impulse response. In practice these variables are used to define and add the contribution of each ray that intersects the receiver dataset to the impulse response.

- Define the frequency variable for the rays (SI unit: Hz) in the **Frequency** field. The default is `rac.f`.
- Define the power variable for the rays (SI unit: $\mathrm{kg{\cdot}m^2/s^2}$) in the **Power** field. The default is `rac.Q`.
- Define the density (SI unit: $\mathrm{kg/m^3}$) in the **Density** field. The default is `rac.rho`.
- Define the speed of sound (SI unit: m/s) in the **Speed of sound** field. The default is `rac.c`
- Define the number of reflections (SI unit: 1) in the **Number of reflections** field. The default is `rac.Nrefl`.

For all text fields, click the **Replace Expression** ( ) button to select a predefined quantity and replace the entire contents of the field.

X-AXIS DATA

From the **Transformation** list, choose a transformation of the data on the x-axis: **None** (the default) for no transformation, or **Discrete Fourier transform**. If you select to display a discrete Fourier transform (DFT), choose one of the following options from the **Show** list:

- **Real part**, to show the real part of the output only.
- **Imaginary part**, to show the imaginary part of the output only.
- **Amplitude**, to show the amplitude of the output (the default).
- **Phase**, to show the phase of the output.
- **Frequency spectrum**, to display the function's frequency spectrum by computing the number of frequencies and the frequency range based on the FFT (fast Fourier transform) of the function. The transform is valid for all functions, but what you get corresponds to a periodic continuation of the function outside the chosen bounds. To specify these values manually, select the **Number of frequencies** checkbox and enter a value in the associated field (the default is based on the number of time samples). From the **Scale** list, choose **None** (the default), **Multiply by sampling point**, or **Divide by number of frequencies**. You can choose to scale with the sampling period to show Fourier transform values instead of a pure DFT transform. Select the **Scale** checkbox to scale the values on the y-axis so that their magnitude reflects the magnitude of the original signal. The values then have the same unit as the input data for the FFT. For a pure sinusoid, the scaled value is the peak magnitude divided by the square root of 2 ($u_{\max}/\sqrt{2}$). Select the **Frequency range** checkbox and then enter the bounds of the frequency range in the **Minimum** and **Maximum** fields (in Hz). The FFT algorithm uses resampling based on linear interpolation. The x-axis shows the frequency (in Hz). By default, the y-axis shows the unscaled Fourier coefficients.

If you have selected **Amplitude** or **Frequency spectrum**, you can select the **In dB** checkbox to present the values in dB. From the **dB type** list, choose **10log** (the default) or **20log**. The display in dB requires a reference value. From the

dB reference list, choose **Maximum** (the default) to use the maximum value as the reference, or choose **Manual** to enter a suitable reference value in the **Reference value** field.

If you have selected **Real part**, **Imaginary part**, **Amplitude**, or **Phase**, the following additional settings are available: To specify this value manually, select the **Number of uniform samples** checkbox and enter a value in the associated field. If desired, select the **Inverse transform** checkbox to use an inverse DFT. Select the **Mask DC** checkbox to set the DC value (zero frequency component) to zero (not available if **Inverse transform** is selected). The **Ignore last sample** checkbox is selected by default to not include the last sample in the transform (not available if **Inverse transform** is selected). The **Shift zero frequency** and **Scale with sampling period** checkboxes are selected by default. Clear one or more of these checkboxes if you want to exclude those steps.

SMOOTHING

In this section, only available if you have selected **Discrete Fourier transform** from the **Transformation** list above, you can add a moving average when analyzing an impulse response plot in ray acoustics. To do so, select the **Moving average** checkbox. You can then choose **Linear** (the default) or **1/n octave** from the **Type** list to choose the type of moving average. For the latter option, also specify **n** as a positive integer (default value: 1).

ADVANCED

The following settings are available to control the filter kernel used when reconstructing the impulse response. Each ray contributes with a power, arrival time, and frequency content to the time-domain signal.

- Define a sampling frequency f_s (SI unit: Hz). The default is 44100.
- Define a zero padding length N_p (SI unit: 1). The default is 11025.

If you have selected a dataset, use the following settings:

Select to **Remove noncausal signal** (not selected per default). This options removes the unphysical parts of the impulse response signal that appear before the arrival time of the first ray. This part is generated due to the nature of the window functions used for the signal reconstruction.

Select **Use fully randomized phase** (not selected per default) to switch the impulse response generation to the legacy method where a random phase is applied to all rays. In contrast, the default method bases the phase on the number of reflections. The default method leads to consistent values for the direct sound.

The following settings are available with all sources:

From the **Display** list, choose what to show: **Broadband** (the default), **Individual bands,** or **Filters**. Choose **Individual bands** to see the signal of each band separately and how they are separated in frequency.

Select the **Filter kernel** as either the **Brick-wall with Kaiser window** (the default) or **User defined**.

For the first option, enter the ripple factor δ (SI unit: Hz). The default is 0.05.

For **User defined**, if desired, enter an expression of the kernel itself in the time domain in the $h_{f_c}(t)$ field. For an FIR filter it is usually a filter (by default, **hB**) multiplied by a window function (by default, **wK**). These default factors are defined in the **Parameters** table below. Also, if desired, enter expressions for the kernel expression using the definitions in the **Parameters** table. The default parameters set up the Brick-wall with Kaiser window filter.

LEGENDS

The **Show legends** checkbox is selected by default to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label** and **Solution** checkboxes to control what to include in the automatic legends (by default it includes the solution only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated

legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Interference Pattern

The **Interference Pattern** ( ) plot shows the intensity on a cut plane resulting from the interference of multiple rays passing through the cut plane. It is available with a **2D Plot Group**, and you select it from the **More Ray Optics Plots** submenu. A Cut Plane dataset pointing to a Ray (Dataset) dataset must be used. The dataset must point to an instance of the Geometrical Optics interface in which the ray intensity and phase are computed.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Range**, **Coloring and Style**, and **Inherit Style**. For **Interference Patterns** plots, only Cut Plane datasets are allowed as inputs.

The **Interference Pattern** plot is available with the Ray Optics Module.

COORDINATE RANGE

Specify the origin of the coordinate system in which the interference pattern is plotted. From the **Origin location specification** list, select **Manual** (the default), **By ray index**, or **At ray of greatest intensity**. If **Manual** is selected, enter the **Origin location, x-component**; **Origin location, y-component**; and **Origin location, z-component**. If the specified point does not coincide with the cut plane, the closest point on the cut plane is used as the origin. If **By ray index** is selected, enter the **Ray index**. The origin is then defined at the point where the ray of specified index intersects the cut plane. If **At ray of greatest intensity** is selected, the origin is located where the ray of greatest intensity intersects the cut plane. Select the **Manual x range** and **Manual y range** checkboxes to adjust the size of the region in which the interference fringes are plotted. Enter a **Resolution** to determine the number of grid points in each direction that are used to render the interference pattern. The **Resolution** must be an integer from 0 to 1000.

Isosurface (Plot)

Plot a scalar quantity as an **Isosurface** ( ) plot in 3D. An isosurface plot displays a quantity as a colored set of isosurfaces on which the result has a constant value. The plot can also color isosurfaces based on an independent quantity. You can move the isosurfaces interactively. Add Color Expression, Deformation, Filter, Marker, Selection (Plot Attribute), Transformation, Transparency, or Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add this plot type.

Before plotting, select the **Interactive** checkbox to move the isosurfaces defined in this **Isosurface** node interactively using the slider or by entering a shift in the **Shift** field. A zero shift represents the original position of the isosurfaces.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Levels**, **Quality**, and **Inherit Style**.

COLORING AND STYLE

From the **Isosurface type** list, choose **Surface** (the default), to plot isosurface as surfaces, or **Filled**, to plot isosurfaces as filled volumes. For the filled isosurfaces, it is recommended to use transparency for the plot.

If you chose **Surface**, select the **Level labels** checkbox to add labels for the isosurface levels.

If you chose **Filled**, the **Fill volume outside of isosurface levels** checkbox is selected by default. Clear this checkbox if you do not want filled volumes for levels above and below the isosurface levels. Also, select the **Include interior boundaries** checkbox if you want to include any interior boundaries in the filled isosurface plot.

For coloring the isosurfaces, select one of the following options from the **Coloring** list:

- Select **Color table** (the default) to color the contours using a color table that you choose from the **Color table** list below.
- Select **Uniform** to use a predefined uniform color, or select **Custom** to define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette.
- Select **Gradient** to specify the coloring as a gradient between two colors, which you specify using the **Top color** and **Bottom color** lists.

Choose a color table for the isosurfaces from the **Color table** list.

The **Color legend** checkbox is selected by default. Clear it to remove the color legend. Select the **Reverse color table** or **Reverse color gradient** checkboxes as required.

For information about the **Color table transformation** list, see Color Table Transformation.

From the **Scale** list, choose **Linear** (the default), **Linear symmetric**, or **Logarithmic**.

For information about the **Legend type** list, see Legend Type.

Isosurface Series

Plot a scalar quantity as an **Isosurface Series** ( ) plot in 3D. An isosurface series plot displays quantity at different times, for example, as a set of isosurfaces on which the result has a constant, specified value. The plot can also color isosurfaces based on an independent quantity. Add Color Expression, Deformation, Filter, Marker, Selection (Plot Attribute), Transformation, Transparency, or Visual Effects subnodes as needed. Right-click a **3D Plot Group** and add this plot type from the **More Volume Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Quality**, and **Inherit Style**.

COLORING AND STYLE

From the **Isosurface type** list, choose **Surface** (the default), to plot isosurface as surfaces, or **Filled**, to plot isosurfaces as filled volumes. For the filled isosurfaces, it is recommended to use transparency for the plot.

If you chose **Surface**, select the **Level labels** checkbox to add labels for the isosurface levels.

If you chose **Filled**, the **Fill volume outside of isosurface levels** checkbox is selected by default. Clear this checkbox if you do not want filled volumes for levels above and below the isosurface levels. Also, select the **Include interior boundaries** checkbox if you want to include any interior boundaries in the filled isosurface plot.

For coloring the isosurfaces, select one of the following options from the **Coloring** list:

- Select **Color table** (the default) to color the contours using a color table that you choose from the **Color table** list below.

- Select **Uniform** to use a predefined uniform color, or select **Custom** to define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette.
- Select **Gradient** to specify the coloring as a gradient between two colors, which you specify using the **Top color** and **Bottom color** lists.

Choose a color table for the isosurfaces from the **Color table** list.

The **Color legend** checkbox is selected by default. Clear it to remove the color legend. Select the **Reverse color table** or **Reverse color gradient** checkboxes as required.

For information about the **Color table transformation** list, see Color Table Transformation.

From the **Scale** list, choose **Linear** (the default), **Linear symmetric**, or **Logarithmic**.

For information about the **Legend type** list, see Legend Type.

Joint Probability Distribution

Use a **Joint Probability Distribution** plot ( ) in 2D plot groups to plot joint probability distributions as a postprocessing step for models using uncertainty quantification. Right-click a **2D Plot Group** to add a **Joint Probability Distribution** plot from the **More Point Plots** submenu

The Joint Probability Distribution plot requires the Uncertainty Quantification Module.

Go to Common Results Node Settings for links to information about the **Title** section.

DATA

From the **Table** list, choose a table to use as the data for the joint probability distribution plot.

From the **Mode** list, choose **Overview** (the default) to show the scatter plot for each parameter pair in the lower diagonal subplots and the kernel density estimation plot for each parameter in the diagonal subplots, or choose **Parameter pair** to show the enlarged view of the scatter plot of the selected parameter pair. In the latter case, choose what parameters to use for the x-axis and y-axis columns from the **x-axis column** and **y-axis column** lists. In the **Parameter pair** mode, when the x-axis and y-axis columns are equal, what is plotted corresponds to the diagonal elements of what is plotted in **Overview** mode.

COLORING AND STYLE

If you have chosen **Overview** from the **Mode** list in the **Data** section, then choose from the following settings:

Select the **Include parameter pairs above the diagonal** checkbox to also show the scatter plot for each parameter pair in the upper diagonal subplots.

Under **Parameter distributions**, the **Plot estimated distribution** and **Plot histogram** checkboxes are selected by default to include those plots for the parameter distributions. From the **Color** lists underneath each checkbox, choose a color for the plot (choose **Custom** to pick a custom color from a color palette).

The remaining settings are available, regardless of what has been chosen from the **Mode** list:

Under **Joint distributions**, the **Plot contours** and **Plot points** checkboxes are selected by default to include those plots for the joint distributions. For the contours, under the Plot contours checkbox, specify the number of contour

levels in the **Number of levels** field (default: 10) and choose a color table from the **Color table** list (default: **Rainbow**). From the **Color** list underneath the **Plot points** checkbox, choose a color for the point plot (choose **Custom** to pick a custom color from a color palette).

Under **Spacing**, specify the **Padding of parameter ranges** as a relative padding (default: 0.02). Also, when you have selected **Overview** from the **Mode** list, specify the **Horizontal spacing between plots** and **Vertical spacing between plots** as relative spacings (default: 0.05).

Layered Material Slice

Use a **Layered Material Slice** (in 2D; in 3D) plot to display a layered material quantity on a slice created at a specified through-thickness location in 2D (plane or axisymmetric) or 3D. Add Deformation, Filter, Marker, Material Appearance, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add a **Layered Material Slice** plot from the **More Line Plots** or **More Surface Plots** submenu, respectively.

The Layered Material Slice plot requires the AC/DC Module, Composite Materials Module, Heat Transfer Module, or Structural Mechanics Module.

THROUGH-THICKNESS LOCATION

In order to create a slice within a layered material, a through-thickness location is required.

Select a **Location definition**: **Reference surface** (the default), **Physical**, **Relative**, **Interfaces**, or **Layer midplanes**.

Once **Reference surface** is selected, the through-thickness location is taken from a layered material definition specified in a **Layered Material Link**, **Layered Material Stack**, or **Material** node (defined as a single-layer material) under **Materials**.

Enter one or more values for a **Local z-coordinate** for the **Physical** option or **Local z-coordinate [-1,1]** for the **Relative** option. The bottom, middle, and top through-thickness location of a layered material, having a total thickness d, can be defined as follows:

- Bottom: 0 (Physical) or −1 (Relative)
- Middle: $d/2$ (Physical) or 0 (Relative)
- Top: d (Physical) or 1(Relative)

Click the **Range** button ( ) to define a range of local z-coordinates using the **Range** dialog.

LAYOUT

Use the settings in this section to control the layout of the slices. From the **Displacement** list, choose **None** (the default), **Linear**, or **Rectangular**.

If you chose **Linear**, then choose a linear displacement orientation from the **Orientation** list: **x**, **y** (2D); **x**, **y**, **z**, or **Diagonal** (3D). For the first three options, also specify a relative separation distance in the **Relative x-separation** field, for example. The **Diagonal** option uses suitable displacements in the x and y directions; you can specify a relative separation in the z direction in the **Relative z-separation** field.

If you chose **Rectangular**, then choose a rectangular displacement orientation from the **Orientation** list: **xy**, **yx** (2D); **xy**, **yz**, **zx**, **yx**, **zy**, or **xz** (3D). Also specify relative separation distances in the **Relative x-separation** and **Relative y-separation** fields, for example. The first letter indicates the index that increases the fastest (for example, for the **xy** option, the x values increase before the y values).

Select the **Show descriptions** checkbox to add a description (annotation) for each of the slices. The description depends on the selected **Location definition**:

- For **Reference surface**: The reference surface's local z-coordinate.
- For **Physical** and **Relative**: The evaluated z-coordinate.
- For **Interfaces**: The interface descriptions.
- For **Layer midplanes**: The layer names.

You can also specify a separation of the descriptions as a relative number in the **Relative separation** field.

Go to Surface (Plot) for the information about other sections present in this plot.

Line

Use a **Line** plot to display a quantity on lines — that is, boundaries in 2D ( ) or edges in 3D ( ). Add Deformation, Filter, Marker, Material Appearance, Selection (Plot Attribute), Transformation, Transparency (3D and 2D with Height Expression), Visual Effects (3D and 2D with Height Expression) or Height Expression (2D only) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add these plot types. It is possible to use 1D data in 2D and 3D line plots; the 1D data is then embedded into 2D or 3D, respectively.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Range**, **Coloring and Style**, **Quality**, and **Inherit Style**.

Line Data

A **Line Data** plot node appears in 2D ( ) and 3D ( ) plot groups if you run a method that creates a `LineData` plot. Add Marker, Material Appearance, Transparency (3D only), and Visual Effects (3D only) subnodes as needed.

It is not possible to add a **Line Data** node from the model tree or toolbars in the COMSOL Desktop. It is only available from the COMSOL Multiphysics API and if you run a method from the **Developer** toolbar. See LineData in the *COMSOL Multiphysics Programming Reference Manual*.

DATA

In the **Data** section, the number of points in the data and the number of line segments in the plot are listed.

Go to Common Results Node Settings for a link to information about the **Title**, **Range**, and **Coloring and Style** sections.

Line Graph

Use a **Line Graph** ( ) to plot a scalar quantity along a geometric line. The line can be an edge in the geometry, a parametric curve, or a cut line. Make a graph plot of a quantity versus another quantity (for example, time). Add a

Color Expression, Graph Marker, or Filter subnode as needed. Right-click a **1D Plot Group** or **Polar Plot Group** to add this plot type.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Through-Thickness Location**, **y-Axis Data** (or **r-Axis Data**), **Title**, **Coloring and Style**, and **Quality**.

SELECTION (SOLUTION DATASETS ONLY)

When **Solution** is selected as a **Dataset**, this section displays. Select **Manual** from the **Selection** list to choose geometry directly from the **Graphics** window. Select **All** to add the applicable geometry or any other predefined grouping.

Y-AXIS

This section is only available if the **Two y-axes** checkbox is selected in the **Plot Settings** section of the parent **1D Plot Group** node's **Settings** window.

Select the **Plot on secondary y-axis** checkbox to plot the y-axis data on the secondary y-axis to the right of the plot instead of the primary y-axis to the left of the plot.

X-AXIS DATA OR θANGLE DATA

For **Parametric Sweep** studies, for each pair of outer solutions or inner solutions, one line is plotted on the graph. For example, if there are 10 outer solutions and each outer solution has five inner solutions, then 50 lines are drawn. The number of inner solutions can vary between outer solutions.

Select **Arc length** or **Reversed arc length** from the **Parameter** list to visualize along an arc length in the direction of the arc or the reversed direction of the arc, respectively; select **Dataset space variable** to use the space variable in the chosen dataset as the data on the horizontal axis; or select **Expression** to visualize along, for example, a coordinate expression. If **Expression** is selected, go to Expressions and Predefined Quantities.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes to control what to include in the automatic legends (by default, it includes the solution only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default value: 3).

Line Segments

Use a **Line Segments** ( ) node to plot line segments in a 1D plot. The lines can be used to indicate some level, for example. Right-click a **1D Plot Group** or **Polar Plot Group** to add this plot type.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**. The default for the line colors is to cycle the colors.

X-COORDINATES

Enter two or more values or expressions for the x-coordinates in the table. You must use an equal number of x- and y-coordinates. For general information about adding expressions, see Expressions and Predefined Quantities.

Y-COORDINATES

This section is similar to the **x-Coordinates** section but for the corresponding y-coordinates.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label** and **Solution** checkboxes to control what to include in the automatic legends (by default it includes the solution only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table.

Matrix Histogram

Use the **Matrix Histogram** plot in 2D ( ) when you have a precomputed matrix that you want to visualize as a 2D histogram. For example, in a fatigue analysis, you can use it for rainflow counting to be able to visualize how the stress amplitudes and mean stresses are distributed. Using this plot can then help to see how the actual damage is distributed between the different stress levels. If a large fraction of the total damage is caused by loads that occur only a few times, the statistical sample of the loads can be too small to reach any good conclusions. Add Filter, Height Expression, and Transparency or Visual Effects (only when Height Expression is used) subnodes if required.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**.

	This plot is available with the Fatigue Module.

EXPRESSION

Click the **Replace Expression** button ( ) to select the matrix variable to use as input for the matrix histogram. The matrix histogram plot uses precomputed matrix variables only.

From the **Unit** list, select any applicable unit for the histogram plot. Select the **Description** checkbox to customize or enter a description of the plot.

AXES

From the **Unit** list, select an applicable unit for the x- and y-axis of the histogram. The matrix contains data points in the xy-plane, where the x- and y-values are stresses. This means that the x- and y-values can have any pressure unit (pascal, for example). By changing the axis' unit, you choose how to interpret the x- and y-axis in the plot.

Max/Min Volume, Max/Min Surface, Max/Min Line, Max/Min Point

Use the **Max/Min Volume** ( ), **Max/Min Surface** (2D:); 3D:), **Max/Min Line** (2D:); 3D:), and **Max/Min Point** (2D: ; 3D:) plots to plot the maximum and minimum values of an expression and the points there they are attained within the geometry.

When plotting the maximum and minimum value, an associated table appears in the **Table** window (underneath the **Graphics** window if using the default COMSOL Desktop layout). The table contains the maximum and minimum

values along with the coordinates for the corresponding locations. The coordinate columns' titles contain the space variable names from the dataset, if you use a **Cut Plane** dataset, for example. Add Deformation, Filter, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes as needed (note that, for a **Max/Min Point** plot, the **At least one but not all** option in the **Filter** subnode is not applicable). Right-click a **2D Plot Group** or **3D Plot Group** to add these plots from the **More Volume Plots** (3D only), **More Surface Plots**, **More Line Plots**, and **More Point Plots**, submenus.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, and **Inherit Style**.

DISPLAY

Select an option from the **Display** list to determine what to display: **Min and max** (the default), **Min**, or **Max**.

TEXT FORMAT

In this section, you can control the text format for the markers using the following settings:

- Select the **Prepend the position** checkbox to include the position of the marker (its space coordinates) before the maximum and minimum values.
- Select the **Include unit** checkbox to add the unit of the expression for which the plot shows the maximum or minimum value.
- If you want to add a prefix or a suffix to the labels for the minimum and maximum values, add them in the **Prefix** and **Suffix** fields. The same prefix and suffix are used for the minimum and maximum labels.

From the **Number format** list, choose one of the following formats:

- **Default**: Numerical values that come from the solvers are presented as-is. Numbers formatted during postprocessing use the **Output display precision** preference setting.
- **Automatic**: All numbers are formatted using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Engineering**: All numbers are formatted using engineering notation (such as `31.416E-6`; it is similar to scientific notation but with the powers of ten as multiples of three) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Scientific**: All numbers are formatted using scientific notation (such as `3.1416E-5`) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Stopwatch**: All numbers are formatted in decimal notation with a specified number of integer digits and decimals, which you enter in the **Number of integer digits** field (default: 3) and **Number of decimals** field (default: 2), respectively. Unnecessary zeros are always shown. For example, with the default settings, 17.1 would be formatted as `017.10`. The specified number of integer digits is not respected if the number is too large or if it is NaN or Inf. Select the **Always show the sign** checkbox to keep the width from changing for a sequence that includes both positive and negative values.
- **Scientific stopwatch**: All numbers are formatted in scientific notation with one integer digit and a specified number of decimals and exponent digits. For example, with the default settings, 17.1 would be formatted as `1.71E1`. The settings are the same as for the **Stopwatch** format, with the addition of an **Always show the sign of the exponent** checkbox. Select it to keep the width from changing for a sequence that includes both positive and negative exponents.

ADVANCED

Under **Advanced**, select the evaluation point type from the **Point type** list:

- **Lagrange points** (the default) to evaluate the maximum or minimum value in the Lagrange points. Select a **Lagrange order** (default: 5; the Lagrange order is the number of partitions of an element edge) to adjust the accuracy of the minimum or maximum values.
- **Mesh vertices** to evaluate the maximum or minimum value in the mesh vertices of the extended mesh.
- **Integration points** to evaluate the maximum or minimum value in the integration points. Select an **Integration order** (default: 4) to adjust the accuracy of the minimum or maximum values.

If such solution data is not available, instead enter a refinement as an integer, 1 or higher, in the **Element refinement** field (default: 2).

The **Recover** default is **Off** because recovery takes processing time. To edit the default and use polynomial-preserving recovery and recover fields with derivatives such as stresses or fluxes with a higher theoretical convergence than smoothing, from the **Recover** list, select **Within domains** to perform recovery inside domains or **Everywhere** to apply recovery to all domain boundaries.

COLORING AND STYLE

The **Show point** check point is selected by default to show the points for the minimum and maximum values. If desired, and if the **Show point** checkbox is selected, change the value in the **Point radius** field (default: 2) to a value between 0 and 1 to adjust the point size.

From the **Color** list, choose the color to use for the maximum and minimum values; choose **Custom** to choose a custom color from a color palette; choose **From theme** (the default) to use the color from the current color theme; or choose **Custom** to choose a custom color from a color palette. Select the frame background color from the **Background color** list.

From the **Background color** list, choose a background color for a rectangular area around the displayed maximum and minimum values; the default is **None**, which means that there is no background color. Choose **From theme** to use a background color that changes with the selected color theme.

From the **Anchor point** list, choose the position of the anchor point relative to the displayed values: **Upper right**, **Upper middle**, **Upper left** (the default), **Middle right**, **Center**, **Middle left**, **Lower right**, **Lower middle**, or **Lower left**.

From the **Orientation** list, choose **Horizontal** (the default) or **Vertical**, if you want the values to be displayed vertically instead of horizontally.

Select the **Show frame** checkbox to display the maximum and minimum values in a rectangular frame. Select the frame background color from the **Background color** list.

Mesh (Plot)

Use a **Mesh** plot ( ) to display a mesh. It is possible to plot the mesh without solving a model using a Mesh dataset. The plot can display the mesh quality (2D or 3D) or the mesh size. For 2D and 3D meshes, add Deformation, Filter, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnodes as needed. Right-click a plot group to add this plot type.

Go to Common Results Node Settings for links to information about these sections: **Data**, for all meshes, and **Title**, **Element Filter**, **Shrink Elements**, and **Inherit Style** for 2D and 3D meshes.

You can also create a Mesh plot by right-clicking the **Mesh** node and selecting **Plot** ( ).

The following two sections describe the **Settings** window for 1D meshes.

Y-AXIS

This section is only available for 1D **Mesh** plots and if the **Two y-axes** checkbox is selected in the **Plot Settings** section of the parent **1D Plot Group** node's **Settings** window.

Select the **Plot on secondary y-axis** checkbox to plot the y-axis data on the secondary y-axis to the right of the plot instead of the primary y-axis to the left of the plot.

COLORING AND STYLE

From the **Color** list, choose a color for the 1D mesh plot (default: **Black**). Choose **Custom** to pick a custom color from the color palette that appears.

The following two sections describe the **Settings** window for 2D and 3D meshes.

LEVEL

This section is available for 2D and 3D **Mesh** plot nodes. Select a **Level** to display the mesh: **All**, **Volume** (3D only), **Surface**, **Line**, or **Point**. If **Surface** is selected, select the base **Element type** to visualize: **All**, **Triangle**, or **Quad**.

For 3D models and if **Volume** is selected, select the base **Element type** to visualize: **All**, **Tetrahedron**, **Pyramid**, **Prism**, or **Hexahedron**.

COLORING AND STYLE

This section is available for 2D and 3D **Mesh** plot nodes and when **Level** is not set to **Point**. Under **Coloring and Style**, use the following settings to control the coloring of the mesh plot:

- Select an **Element color**: Any basic color, **Quality** (the default) to get a mesh element quality plot, **Size** to get a plot of the local mesh size, **Type** to plot colors representing the mesh element types, **Custom** to select a different color from the color palette, or **None** to plot with no color.

  If you have selected **Type**, the mesh element types are colored according to the following table:

TABLE 21-1: DEFAULT MESH ELEMENT TYPE COLORS.

MESH ELEMENT TYPE	COLOR
Edge	Red
Triangle	Orange
Quad	Blue
Tetrahedron	Green
Pyramid	Magenta
Prism	Yellow
Hexahedron	Cyan

If you have selected **Quality** from the **Element color** list, you can select a quality measure:

- Select a **Quality measure**:
  - **Skewness**, which is the default quality measure, is a measure of the equiangular skew.
  - **Maximum angle**, which is based on the cosine of the largest angle in the element.
  - **Volume versus circumradius** is the default quality measure, which is based on a quotient of the element volume and the radius of the circumscribed sphere (or circle) of the element.
  - **Volume versus length**, which is based on a quotient of element edge lengths and element volume.
  - **Condition number**, which is based on the element dimension divided by the condition number of the matrix transforming the element to a reference element.
  - **Growth rate**, which is a measure of the local (anisotropic) mesh growth rate.
  - **Curved skewness**, which is a measure that can be used to find badly shaped mesh elements when higher-order elements are used for solving. It is defined as the elementwise product of skewness and `reldetjacmin`, a measure of the deformation when mapping from the linear to the higher-order element.
  - **Custom expression** provides a **Quality expression** field where you can enter a custom expression for the mesh quality. The expression should provide scalar values between 0 and 1, where 1 is an element of the highest possible value. You can use it, for example, to combine some of the existing mesh quality measures. Click the **Replace Expression** ( ) button to choose and insert a predefined expression to replace the contents of the **Quality expression** field.

  For more information about mesh quality, see Mesh Element Quality.
- The **Color range [0, 1]** checkbox is selected by default to span the largest possible span of mesh quality values. Clear it to use a range that spans the actual range of mesh quality values for the plotted mesh. Such a plot can make it easier to see a difference between mesh elements in some cases.
- Choose a **Color table** for the element quality or element size. By default, the **TrafficFlow** color table is used with the **Reverse color table** checkbox selected, so that a high element quality is indicated with a light green color and elements with a poor element quality are red. If the default is not suitable for the plot, try other options.
- Also, if the element color displays the element quality or element size, select the **Color legend** checkbox (selected by default) to display a color legend next to the plot.
- The default **Color table transformation** setting is **Nonlinear**. For descriptions of the available options and their associated settings, see Color Table Transformation in the Common Results Node Settings section.
- By default, if the element color displays the element quality or element size, the **Reverse color table** checkbox is selected. Clear this checkbox, if needed, to reverse the colors in the color table so that the color for the minimum value instead indicates the maximum value, and vice versa.
- Choose a **Color table type** — **Continuous** (the default) or **Discrete**. If you chose **Discrete**, specify the number of discrete color bands in the **Number of bands** field (default: 10).
- Choose a **Wireframe color** — any basic color (default **Black**), **Custom** to select a different color, or **None** to plot with no color indicating the mesh element boundaries. This setting is not available when **Level** is set to **Line**.
- Choose a **Resolution** for the elements in mesh plots where the geometry order is greater than one: **Extra fine**, **Finer**, **Fine**, **Normal** (the default), **Coarse**, **No refinement**, or **Custom**. If you chose **Custom**, enter a positive integer (default: 1) in the **Element refinement** field.

- When you plot a mesh plot using a Solution dataset, you can choose an option from the **Node points** list (default: **None**) to show the node points, including those of interior nodes in higher-order elements:
  - Choose **Geometry shape function** to plot the node points from the geometry shape discretization.
  - Choose any physics field included in the Solution dataset, such as **Solid mechanics: Field name: u** to plot the node points for that field's discretization.

  The points are often similar for the geometry shape function and the physics field's discretization when the geometry shape function is set to automatic (which is the default setting).

  You can control the radius of the node points using the **Point radius** field when the **Node points** lists is not set to **None**. Enter a radius between 0 and 10 (default: 1.5).

The following section is only available in the **Settings** window for 1D meshes.

EXPRESSION

This section is available for 1D **Mesh** plot nodes. From the **Expression** list, choose **None** to display the 1D mesh as a straight line. Choose **Size** to plot the mesh so that the value on the y-axis is the local mesh size.

See also Mesh Plots in the Meshing chapter.

Multislice

Use a **Multislice** ( ) plot to display a scalar quantity on slices in multiple directions inside a 3D domain. Add Deformation, Filter, Marker, Material Appearance, Selection (Plot Attribute), Transformation, Transparency, or Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add this plot from the **More Surface Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Range**, **Coloring and Style**, **Quality**, and **Inherit Style**.

MULTIPLANE DATA

Under **Multiplane Data**, select an **Entry method** — **Number of planes** or **Coordinates** — for the **x-planes**, **y-planes**, and **z-planes**.

For **Number of planes**, enter the number of planes in the **Planes** field. For **Coordinates**, enter a range of coordinates in the **Coordinates** field.

Nyquist

Use a **Nyquist** ( ) plot to plot a Nyquist plot that shows the magnitude and phase of a frequency response. The plot shows the magnitude as the distance from the origin and the phase as the angle using a curve with the frequency as the parameter. Typical data to use for a Nyquist plot includes complex-valued impedance data from a frequency domain study. Add Color Expression and Filter subnodes as needed. To add this plot type, right-click a **1D Plot Group** or **Polar Plot Group** node and choose **Nyquist** from the **More Plots** submenu.

Except where noted below, see Global for all of the settings. For Global Plots, the **Expressions** section is called **y-Axis Data** (or **r-Axis Data** for polar plots), but the instructions are the same.

Under **Coloring and Style**, select the **Show unit circle** checkbox to include a unit circle in the Nyquist plot.

	1D Plot Group and Polar Plot Group

Octave Band

Use an **Octave Band** ( ) plot to represent and plot a frequency response in frequency bands. An octave band plot corresponds to plotting the average or integrated value of, for example, the squared pressure over a given frequency band defined by the center frequency or midfrequency and the bandwidth. What the plot shows is a "white noise transfer function" of the system; that is, it assumes that the input is of the same nature as the output. The data input to an octave band plot is a frequency-domain solution; for example, it can be the acoustic pressure resulting from a Frequency Domain study or a parametric frequency sweep. To add this plot type, right-click a **1D Plot Group** node and choose **Octave Band** from the **More Plots** submenu. Right-click an **Octave Band** node to add a Graph Marker subnode if desired.

	Go to Common Results Node Settings for links to information about these sections: **Data** and **Title**.

	This plot type is available with the Acoustics Module, MEMS Module, and Structural Mechanics Module.

	For examples that use an Octave Band plot, see *Absorptive Muffler*: Application Library path **Acoustics_Module/Automotive/absorptive_muffler** and *The Brüel & Kjær 4134 Condenser Microphone*: Application Library path **Acoustics_Module/Electroacoustic_Transducers/bk_4134_microphone**.

SELECTION

From the **Geometric entity list**, select the entity level (default: **Point**) for the evaluation of the octave band plot. Choose **Global** for a global evaluation. If you select line, boundary, or domain, the quantity will be averaged. You can use those entity levels to plot the response as the average over the outlet of a system, for example. Then, except for **Global**, use the selection tools to select geometric entities on that level for the evaluation.

Y-AXIS DATA

In the **Expression** field, enter an expression for the input to the octave band plot. Press Ctrl+space to select predefined expressions based on the physics of the model. If you want to add a description of the expression for the plot title, select the **Description** checkbox and enter a description in the text field below.

If available, for information about the settings in the **Expression evaluated for** list, see Expression Evaluated For.

From the **Domain** list, choose **Frequency** (the default) for frequency-domain expressions, or choose **Time** for time-domain expressions. For **Time**, the **Expression type** (see below) can only be **Pressure** and **Amplitude**. The spectrum of the time-domain signal is calculated through FFT, and those values are used. The `freq` variable is defined to be the corresponding frequencies to be used in weighting.

From the **Expression type** list, choose one of the following types:

- **Pressure** (the default), to compute the octave plot treating the expression as an pressure p_{rms}. The input is the value p (it is generally a complex-valued variable). It is in turn used to calculate the rms pressure p_{rms}, which defines the level L:

$$L = 10\log_{10}\left(\frac{p_{\mathrm{rms}}^2}{p_{\mathrm{ref}}^2}\right), p_{\mathrm{rms}}^2 = 0.5|p|^2$$

  In the **Pressure reference** field, enter a value of expression for a pressure reference p_{ref}. Click the **Replace Expression** ( ) to pick a pressure reference from a list of predefined expressions.

- **Amplitude** (the default), to compute the octave plot treating the expression as an amplitude A. The input is the value A. It is in turn used to calculate the level L as $L = A/A_{\mathrm{ref}}$. In the **Amplitude reference** field, enter a value of expression for an amplitude reference A_{ref}. Click the **Replace Expression** ( ) to pick an amplitude reference from a list of predefined expressions.

- **Power**, to compute the octave plot treating the expression as a power P, which defines the level L:

$$L = 10\log_{10}\left(\frac{P}{P_{\mathrm{ref}}}\right)$$

  In the **Power reference** field, enter a value of expression for a power reference P_{ref}. Click **Replace Expression** ( ) to pick a power reference from a list of predefined expressions.

- **Transfer function**, to compute the octave plot treating the expression as a transfer function H (generally, a complex-valued variable), which defines the level L:

$$L = 10\log_{10}|H| + L_{\mathrm{ref}}$$

  In the **Level reference** field, enter a value of expression for a level reference L_{ref}. Click **Replace Expression** ( ) to pick a level reference from a list of predefined expressions.

Underneath those settings, the mathematical formula used for each expression type is displayed.

Outside the frequency range, the signal is assumed to be zero and no extrapolation is done.

PLOT

You can choose one of the following quantities of the octave band from the **Quantity** list:

- **Continuous power spectral density**, to plot a continuous response
- **Band power** (the default), to plot the response using bands.
- **Band average power spectral density**, to plot a bar plot with band averages.

If the **Expression type** is set to **Amplitude**, you can instead choose one of the following quantities of the octave band from the **Quantity** list:

- **Continuous spectrum**, to plot a continuous response spectrum
- **Band integral** (the default), to plot the response using bands.
- **Band average**, to plot a bar plot with band averages.

For the two last options (regardless of the expression type), using bands or band average, you can also specify a band type from the **Band type** list:

- **Octave**, to plot the response using octave bands.
- **1/3 octave bands**, to plot the response using 1/3 octave bands.
- **1/6 octave bands**, to plot the response using 1/6 octave bands.

Also, the **Use in-band data only** checkbox is selected by default to use an integral that is evaluated as an average only based on data points inside the different octave bands.

You can use some predefined weighting or a user-defined weighting of the frequency data. The frequency weighting is used in acoustics to shape the response to match the characteristics of the human ear.

The predefined weightings are defined in IEC 61672-1. See *IEC 61672-1 Electroacoustics - Sound level meters - Part 1: Specifications* for details.

From the **Weighting** list, select:

- **Z-weighted (flat)** (the default), to use a zero weighting; that is, a flat weighting.
- **A-weighted**, to use a weighting that mimics the loudness perceived by the human ear.
- **C-weighted**, to use a C-weighting, which is an alternative standardized weighting that is in use within the acoustics community.
- **Expression**, to enter a user-defined value or expression for the weighting in the **Expression** field. The expression defines the gain as a function of the frequency. The gain given in dB is then given as 20·`log10`(*expression*). Use the frequency variable `freq` for user-defined expressions.

The following COMSOL Multiphysics plot shows the different weighting types as gain (dB) versus frequency (Hz):

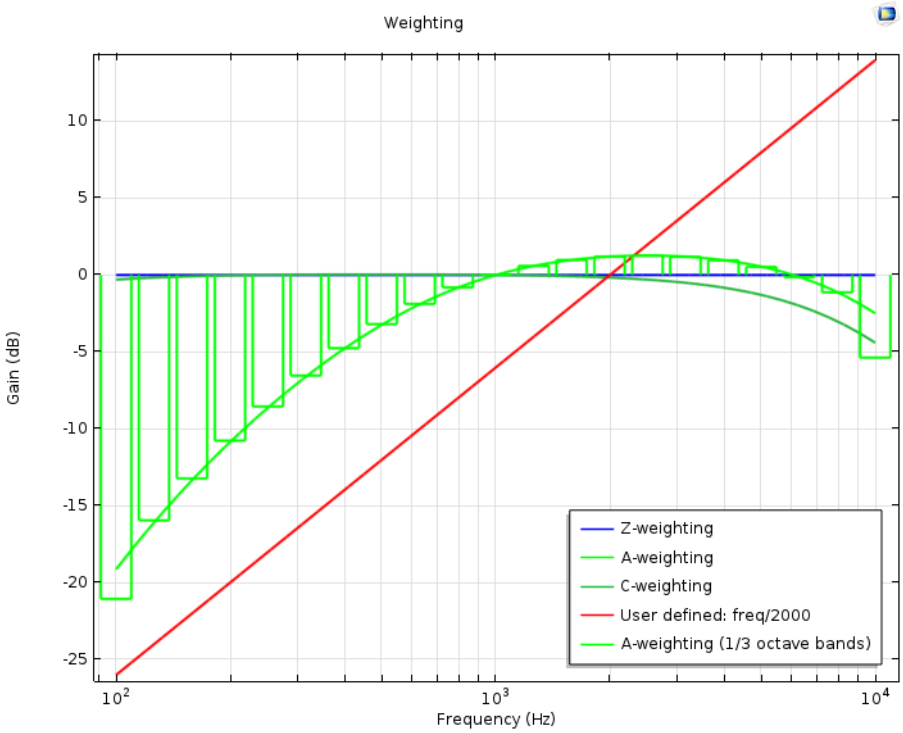

Figure 21-8: The plot shows Z-weighting (blue), A-weighting (light green), C-weighting (dark green), and a user-defined weighting (red). The 1/3 octave bands (light green) also show A-weighting.

COLORING AND STYLE

When the plot style is set to continuous, you can specify settings for the line style and line markers. When the plot style is to show octave bands, select the type of visualization from the **Type** list:

- Select **Bar** (the default) to display filled bars. Then select the color for the bars from the **Color** list. Choose **Custom** to select a custom color from the color palette that appears.

- Select **Outline** to display outlines of the bars. You can then specify settings for the line style and line markers for the outlines.
- Select **Line** to display a graph connecting the centerpoints of the bands. You can then specify settings for the line style and line markers for the graph.

For the **Color** and **Line style** options, see Common Results Node Settings.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, and **Expression** checkboxes to control what to include in the automatic legends (by default it includes the solution and description only). If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Optical Aberration

The **Optical Aberration** ( ) plot shows various types of monochromatic aberration that arise when electromagnetic rays are focused by a system of lenses and mirrors. It is available with a **2D Plot Group**, and you select it from the **More Ray Optics Plots** submenu. Add Height Expression and Transparency or Visual Effects (only if Height Expression is used) subnodes if required.

An Intersection Point 3D dataset (see Intersection Point 2D and Intersection Point 3D) pointing to a Ray (Dataset) dataset must be used. The dataset must point to an instance of the Geometrical Optics interface in which the optical path length is computed.

In addition, in the **Settings** window for the Intersection Point 3D dataset, **Hemisphere** must be selected from the **Surface type** list. The **Center** of the hemisphere corresponds to the focus, and the **Axis direction** points from the focus toward the center of the exit pupil in the focusing system. Some of these details can be set up automatically using the settings and buttons available in the **Focal Plane Orientation** section.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Range**, **Coloring and Style**, and **Inherit Style**. For **Optical Aberration** plots, only Intersection Point 3D datasets are allowed as inputs.

	The **Optical Aberration** plot is available with the Ray Optics Module.

FILTERS

Use the options in the **Filters** section to exclude some rays from the calculation of the Zernike coefficients.

- Select the **Filter by wavelength** checkbox to exclude all rays except those of a specified vacuum wavelength. If this checkbox is selected, enter a **Wavelength** (default: 632.8 nm) and a **Tolerance** (default: 1 nm). If the difference between the specified wavelength and the vacuum wavelength of a ray exceeds this tolerance, then the ray will be ignored.
- Select the **Filter by release feature index** checkbox to exclude all rays except those released by a specific physics feature. Then enter an integer value for the index; the default is 1. This field is 1-indexed, meaning that 1 corresponds to the first ray release feature, 2 is the second ray release feature, and so on.

- Select the **Filter by number of reflections** checkbox to include rays only if they have reflected a specified number of times. Then enter an integer for the number of reflections; the default is 0. For this option to work correctly, it is necessary to select the **Count reflections** checkbox in the settings for the Geometrical Optics interface, before running the study.
- Select the **Filter by additional logical expression** checkbox to include rays if they satisfy another user-defined expression. The expression is considered to be true if it returns a nonzero value. The default expression is 1, which would cause all rays to be included.

FOCAL PLANE ORIENTATION

The settings in the **Focal Plane Orientation** section are used to define the position of the focus and the direction of the nominal optical axis that intersects this focus.

Select an option from the **Normal to focal plane** list: **Direction based** (the default), **Position based**, or **User defined**.

- For **Direction based**, the normal to the focal plane is the average ray direction. This average is taken over all rays that satisfy the filter criteria given by the **Filters** section above.
- For **Position based**, the normal to the focal plane is determined such that the ray positions are as close to the plane as possible. If the rays are stopped at a curved surface, the normal computed in this way may differ significantly from the surface normal.
- For **User defined**, enter values or expressions for the normal vector components directly. By default, the z-axis is used.

Enter a value or expression for the **Reference hemisphere radius** (SI unit: m). The default is 50 mm. When automatically generating an **Intersection Point 3D** dataset for the Gaussian reference hemisphere, this value is copied to the dataset settings. As a general rule, this value should be much larger than the RMS spot size but must be smaller than the back focal length of the optical system.

The **Create Reference Hemisphere Dataset** and **Recompute Reference Hemisphere Dataset** buttons can be used to automatically generate or update an **Intersection Point 3D** ( ) dataset from which the Gaussian reference hemisphere is defined. The hemisphere is centered at a location where the rms spot size is minimized. The hemisphere axis should point backward along the nominal optical axis through the focal point.

Before clicking **Create Focal Plane Dataset**, make sure that the **Dataset** is either a **Ray** dataset ( ) or **From parent** (if the parent is a **Ray** dataset). If rays are released at multiple field angles and you want to compute the Zernike coefficients associated with one of these fields, first select the **Filter** by release feature index checkbox in the **Filters** section.

Before clicking **Recompute Reference Hemisphere Dataset**, make sure that the **Dataset** is already an **Intersection Point 3D** dataset.

When clicking either button, the **Intersection Point 3D** dataset is then created (or updated) to define the intersection points with a hemisphere. The center of the hemisphere is positioned as close as possible to the RMS focus.

The button commands to create or update an **Intersection Point 3D** dataset indicating the reference hemisphere can also be accessed from the physics API. In a model method or in a model Java® file, you can use commands such as

```
ResultFeature plot = model.result("pg1").feature("oab1");
plot.runCommand("createReferenceHemisphereDataset");
plot.runCommand("recomputeReferenceHemisphereDataset");
```

ZERNIKE POLYNOMIALS

Select the **Length unit** in which the weighted Zernike polynomials will be plotted. The default is the micron (µm). This input is disabled if the model is dimensionless.

The optical path difference among all rays that pass through the exit pupil is computed. Then a linear least-squares fit is used to express the optical path difference as a linear combination of a standard set of orthogonal polynomials on the unit circle, called *Zernike polynomials*. The polynomials are scaled by the coefficients that are computed by the least-squares fit, called the *Zernike coefficients*.

Select a **Maximum polynomial order**: **2**, **3**, **4**, or **5** (the default).

Select an option from the **Terms to include** list: **All**, **All higher-order terms**, or **Select individual terms**:

- If **All** is selected, all Zernike polynomials up to the specified **Maximum polynomial order** are included in the plot.
- If **All higher-order terms** is selected, all Zernike polynomials up to the specified **Maximum polynomial order** are included in the plot, except for the terms of order 0 and 1. These terms indicate misalignment or misplacement of lenses within an optical system and are less useful for measuring lens quality.
- If **Select individual terms** is selected, checkboxes appear for all Zernike polynomials. The common names of the polynomials are included where applicable. Select or clear the checkboxes to determine which terms should be included in the plot. You can also use the **Select All** and **Clear All** buttons to quickly select or clear all of these checkboxes at the same time.

Enter a **Number of grid points**, which must be an integer between 100 and 1,000,000. Increasing the number of grid points increases the number of evaluations of the Zernike polynomials on the unit circle; this improves the quality of the plot but does not affect the calculation of the Zernike coefficients.

A list of Zernike polynomials and their derivation, properties, and references are included in the Ray Optics Modeling chapter of the *Ray Optics Module User's Guide*.

POSITION

Specify the position of the center of the unit circle. The default center location is the origin, (0,0). By assigning nonzero components to the center location it is possible to view multiple types of optical aberration in the Graphics window side-by-side.

For an example of the use of Optical Aberration plots: *Double Gauss Lens*: Application Library path **Ray_Optics_Module/Lenses_Cameras_and_Telescopes/double_gauss_lens**.

Particle (Plot)

Use the **Particle** ( ) plot in 1D to plot a particle variable versus time for all particles, or to plot one particle property versus another at a set of time steps. When plotting particle properties versus time, it is also possible to perform data series operations on the particle data. Add Color Expression and Filter subnodes as needed. To add a particle plot, right-click a **1D Plot Group** node and choose **Particle** from the **More Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**. For **Particle** plots, only Particle datasets are allowed as inputs.

Y-AXIS DATA

The **y-Axis Data** section allows you to define an expression, which may be dependent on both particle and field variables.

X-AXIS DATA

Select a **Parameter**: **Solution number** or **Expression**.

For **Solution number**, a distinct line is plotted for every particle, with the y-axis being the user-defined expression from the y-Axis data section and the x-axis being time. The total number of lines equals the total number of particles (after taking the Filter subnode and the selection of the Particle (Dataset), if any, into account) multiplied by the total number of selected outer solutions if applicable.

For **Expression**, the expressions entered in the **y-Axis Data** and **x-Axis Data** sections are plotted against each other for all particles at each specified time – that is, the total number of lines equals the total number of selected times multiplied by the total number of selected outer solutions.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes to control what to include in the automatic legends (by default it includes the solution and description only). If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

DATA SERIES OPERATION

Choose an **Operation**: **Sum** (the default), **None**, **Average**, **Maximum**, **Minimum**, **RMS**, **Standard deviation**, or **Variance**. The **Operation** is applied to the particles only if the *x*-axis is **Time**. If **None** is selected, a distinct line is plotted for each particle; otherwise, the selected data series operation is used to compute a single data point for all particles at each time step. The default operation prevents an extremely large number of lines from being plotted when a new Particle plot is created.

Particle Tracing

Use a **Particle Tracing** plot to visualize the trajectory of a massless particle subject to a flow field in 2D ( ) or 3D ( ). Visualize *pathlines* (that is, trajectories of particles released in a flow field), which can be time-dependent or static. For time-dependent flows, also use a snapshot in time of the flow field as a static field. The motion of the particles does not affect the flow field. Add a Color Expression, Deformation, Transformation, Transparency (3D only), or Visual Effects (3D only) subnode as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add these plot types from the **More Point Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Coloring and Style**, **Quality** (Resolution and Recover only), and **Inherit Style**. See below for sections specific to this plot: **Particle Positioning**, **Release**, **Quality** (ODE solver settings), and **Advanced**. For **Particle Tracing** plots, only Solution datasets are allowed as inputs.

There is an additional setting under **Coloring and Style** for this plot. The **Type** of **Point Style** available includes **Comet tail**. Comet tail plots provide a convenient way to indicate the direction of travel of particles at a given point in time. The tail of the comet typically points in the opposite direction to the particle velocity — so visually, it is the same as the tail of a comet approaching the sun. See Defining the Coloring and Style for the **Comet tail** settings.

To use the Particle Tracing plot type, first select the **All Plot Types** checkbox in the **Show More Options** dialog. This plot type is intended for visualizing a small number of particles on simple geometries. The Particle Tracing Module has vastly superior particle tracing capabilities and should be used for all but the simplest of models.

PARTICLE POSITIONING

For 3D models, enter the initial position of particles in the **x**, **y**, and **z** fields. For 2D models, enter the **Positioning** details as described below.

Select a **Positioning**: **Starting-point controlled** or **Boundary coordinates**. Boundary coordinates are useful, for example, for flow models with one or more inflow boundaries.

- If **Starting-point controlled** is selected, enter the initial position of particles in the **x** and **y** fields. The initial position can be defined as numbers but can also include parameters and variables.
- If **Boundary coordinates** is selected, select an item from the **Named selection** list and select an **Entry method**: **Number of points** or **Boundary parameters**.
  - If **Number of points** is selected, enter the number of grid **Points** (the default is 10).
  - If **Boundary parameters** is selected, enter the **Relative coordinates**.

RELEASE

Under **Release**, specify when to **Release particles**: **Once** (the default), **At intervals**, or **At times**. Select:

- **Once** to release particles once at the first available time, typically at time 0 (zero). To delay the release, select the **Start time** checkbox and enter a time.
- **At intervals** to release particles at regular intervals starting at the first available time, typically at time 0 (zero). To delay the release, select the **Start time** checkbox and enter a time. Enter a **Time between releases**. The default is 1.
- **At times** to release particles at an arbitrary time point; enter multiple **Times** to release particles.

QUALITY (ODE SOLVER SETTINGS)

Under **Quality**, also define the **ODE solver settings** as needed. Go to ODE Solver Settings — Relative Tolerance, ODE Solver Settings — Absolute Tolerance, and ODE Solver Settings — Step Size for details.

ADVANCED

The **Advanced** section contains settings that do not normally need to be adjusted.

Under **Advanced**, also define these settings as needed. Go to Advanced — Termination and Advanced — Instantaneous Flow Field for details.

In the **Termination** section, edit the **Maximum number of steps** and **Edge tolerance**. In the **Instantaneous flow field** section, edit the **Plot static flow field even when time dependent** checkbox, the **Time variable** default, and the **End time active**.

ODE Solver Settings — Relative Tolerance

Follow these supplementary instructions for the **ODE solver settings** section found under the **Quality** section.

Enter a **Relative tolerance** for the ODE solver. The default is 0.001.

- When solving the second-order ODE $m\ddot{x} = F(t, x, \dot{x})$ for x, the solver first rewrites it as two coupled first-order ODEs: one for the position x and one for the velocity $\dot{x}$, each with two components in 2D and three components in 3D.
- The **Relative tolerance** value is the relative error tolerance that the ODE solver uses. It applies to all components of the particle's position and velocity. The solver controls the step size so that the estimated error e in each integration step satisfies

$$\begin{cases} e < \max(\text{atolpos}, \text{rtol} \cdot |x_i|) & \text{(for all components } x_i \text{ of } x) \\ e < \max(\text{atolvel}, \text{rtol} \cdot |\dot{x}_i|) & \text{(for all components } \dot{x}_i \text{ of } \dot{x}) \end{cases}$$

  where rtol is the relative tolerance specified, atolpos is the absolute tolerance for the particle's position components, and atolvel equals the absolute tolerance for the particle's velocity components.

ODE Solver Settings — Absolute Tolerance

Follow these supplementary instructions for the **ODE solver settings** section found under the **Quality** section. Specify the solver's absolute tolerance. The default is **Automatic**. To enter different values, select **Manual** from the **Absolute tolerance** list and enter a **Position**. The **Position** field can contain a single value — it applies to all components of the position and is the absolute tolerance.

ODE Solver Settings — Step Size

Follow these supplementary instructions for the **ODE solver settings** section found under the **Quality** section. Specify the solver **Step size.** The default is **Automatic** — the COMSOL Multiphysics software uses the initial value of the acceleration (force divided by mass) and the relative and absolute tolerances to determine the initial time step.

- The automatic maximum step size is 10% of the total simulation time for time-dependent flows as well as for static flow fields where the end time is manually specified in the **Advanced** section (in the **Plot static flow field even when time dependent** > **End Time** field). For static flow fields where the end time is not set manually, there is no upper limit of the step size. However, in this case, the initial time step is less than or equal to 0.1.

To edit the settings, select **Manual** from the **Step size** list and enter values in the **Initial time step** and **Maximum time step** fields.

- The **Maximum time step** is the longest time step the solver takes. It has higher priority than the **Initial time step**; that is, if an initial step size is set larger than the maximum step size, the solver lowers the initial step size to the maximum step size.

The initial step size, whether entered manually or computed automatically, is not necessarily the first step the solver takes but is a first try. If this step leads to an error such that the tolerances are not met, the COMSOL software lowers it.

Advanced — Termination

Follow these supplementary instructions for the section found under the **Advanced** section. The **Termination** section contains settings that determine when to end the particle tracing simulation.

- To specify an upper limit of the number of time steps, click to select the **Maximum number of steps** checkbox and edit the default (1000). The particle simulation ends after this number of steps.
- To specify how close to the geometry boundary the pathlines are cut when they exit the geometry, edit the **Edge tolerance** default (0.001). This is a relative tolerance controlling how close to the geometry boundary the pathlines are cut when they exit the geometry. A lower value cuts the line closer to the geometry boundary.

Advanced — Instantaneous Flow Field

Follow these supplementary instructions for the section found under the **Advanced** section. To specify if you want to plot an instantaneous flow field, even if the solution is time dependent, select the **Plot static flow field even when time dependent** checkbox. This freezes the time selected previously — for example, from a **Plot Group** page in the **Data** > **Time** list — to the value specified and considers this a static flow field.

- Edit the **Time variable** default (`partt`) if required. Normally it is not necessary to change the default name but the name can be used in expressions as well as for the color when coloring the pathlines according to an expression.
- If required, select the **End time active** checkbox and enter a value.

Particle Tracing with Mass

Use a **Particle Tracing with Mass** plot in 2D ( ) or 3D ( ) to visualize the trajectory of a particle with mass and subject to a flow field. Add a Color Expression, Deformation, Transformation, Transparency (3D only), or Visual Effects (3D only) as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add these plot types from the **More Points Plots** submenu.

For particles with mass, COMSOL Multiphysics generates the pathlines by solving the fundamental equation of motion:

$$m\ddot{x} = F(t, x, \dot{x})$$

for the pathline $x(t)$. Here, m is the particle's mass, F equals the force acting on the particle, and t is time. This is a system of ODEs for x, which COMSOL Multiphysics solves using a pair of Runge-Kutta methods of orders four and five. The solver advances the algorithm with the solution of order five and uses the difference between the order-five and order-four solutions to obtain the local error estimate.

For massless particles, the equation of motion is:

$$\dot{x} = v(t, x)$$

The true formulation of Newton's second law of motion is

$$\frac{d}{dt}(m\dot{x}) = F(t, x, \dot{x})$$

That is, the time derivative of the mass must be considered. The particle-tracing algorithm does not solve this equation. Thus, if an expression is specified for the particle mass that depends on time, the result are incorrect.

In 2D axisymmetry, three components for the force are available for particles with mass.

When specifying all three, the algorithm solves for a line in 3D in cylindrical coordinates, but the plot only shows the projection on the axisymmetry plane. In this case, the centripetal force is considered; that is, the algorithm solves the equation

$$\ddot{r} = \frac{F_r}{m} + r\dot{\varphi}^2 \qquad \ddot{\varphi} = \frac{F_\varphi}{rm} - \frac{2\dot{r}\dot{\varphi}}{r} \qquad \ddot{z} = \frac{F_z}{m}$$

where m is the particle mass and (r, φ, z) are the cylindrical coordinates. The variable corresponding to the velocity component in the φ direction (the default name is `partv`) has the dimension length/time, and equals $r\dot{\varphi}$ as $\dot{\varphi}$ has the dimension radians/time.

- Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Coloring and Style**, **Quality** (Resolution and Recover only), and **Inherit Style**. For **Particle Tracing with Mass** plots, only Solution datasets are allowed as inputs.
- See Particle Tracing for **Particle Positioning**, **Release**, **Quality** (ODE solver settings), and **Advanced** settings.

See Particle Tracing in Fluid Flow for more information about predefined expressions for drag-driven particle movement that are available for these models.

There is an additional setting under **Coloring and Style** for this plot.

The **Type** of **Point Style** available includes **Comet tail**. Comet tail plots provide a convenient way to indicate the direction of travel of particles at a given point in time. The tail of the comet typically points in the opposite direction to the particle velocity — so visually, it is the same as the tail of a comet approaching the sun. Go to Common Results Node Settings for the **Comet tail** settings links.

To use the Particle Tracing with Mass plot type, first select the **All Plot Types** checkbox in the **Show More Options** dialog. This plot type is intended for visualizing a small number of particles on simple geometries. The Particle Tracing Module has superior particle tracing capabilities and should be used for all but the simplest of models.

TOTAL FORCE

Specify the total force acting on the particles. Click the **Replace Expression** ( ) or **Insert Expression** ( ) button to select predefined expressions based on the physics of the model. Or enter an **Expression** — for 2D, enter or select **Fx** and **Fy** components of the force; for 3D, enter or select **Fx**, **Fy**, and **Fz** components of the force. Enter a **Description** (or edit the default). When some predefined forces are added, there are additional **Parameters** with a **Value** to enter into a table.

MASS AND VELOCITY

Enter the particle **Mass**. Enter the **Initial velocity** — for 2D enter values for the **x-component** and **y-component**; for 3D enter values for **x-component**, **y-component**, and **z-component**.

QUALITY (ODE SOLVER SETTINGS)

Under **Quality**, also define the **ODE solver settings** as needed and described for Particle Tracing. Go to ODE Solver Settings — Relative Tolerance, ODE Solver Settings — Absolute Tolerance, and ODE Solver Settings — Step Size for details.

ADVANCED

Under **Advanced**, define the **Particle velocity variables**. Edit the default variable component names for each particle's velocity. The default names are `partu` (**x component**), `partv` (**y component**), and `partw` (**z component**).

Under **Advanced**, also define these settings as needed and described for Particle Tracing. Go to Advanced — Termination and Advanced — Instantaneous Flow Field for details.

Particle Trajectories

Use a **Particle Trajectories** ( ) plot to visualize the particle trajectories computed using one of the Particle Tracing physics interfaces. This plot must point to a Particle (Dataset). Add a Color Expression, Deformation, Export Expressions, Material Appearance, **Filter**, Transformation, Transparency (3D only), or Visual Effects (3D only) subnode as needed. For the settings in the **Filter** subnode, see Filter for Particle Trajectories. Right-click a **2D Plot Group** or **3D Plot Group** to add this plot.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Coloring and Style**, **Extra Time Steps**, and **Inherit Style**. For **Particle Trajectories** plots, Particle, Ray, Particle Bin, Ray Bin, Intersection Point 2D and 3D, Receiver 2D and 3D, and Transformation 2D and 3D datasets are allowed as inputs.

	The Particle Trajectories plot creates trajectories not for the actually selected time, parameter, or frequency value but for all values lower or equal to the selected value.

	This **Particle Trajectories** plot is available with the Particle Tracing Module. However, the plot does not compute the particle trajectories during results processing — the trajectories are computed by one of the physics interfaces in the Particle Tracing Module. The plot can thereby render tens of thousands of particles quickly because the trajectories have already been computed.

Filter for Particle Trajectories

You can right-click a Particle Trajectories plot node to add a **Filter** subnode ( ), which controls the particle types to include and whether to render all particles or a subset of the particles. The Filter node has the following section:

PARTICLE SELECTION

From the **Particles to include** list, select the particle types or subset to include in the particle trajectories plot:

- **All** (the default) to include all particles.
- **Primary** to include primary particles only.
- **Secondary** to include secondary particles only.
- **Logical expression** to include a subset of particles that fulfill the logical expression that you enter in the **Logical expression for inclusion** field. For example, `pt.V>1` only includes particles with a velocity larger than 1, and `x>0` only includes particles in areas where the x coordinate is positive. Click the **Replace Expression** ( ) button to select predefined expressions for the logical expression.

From the **Particles to render** list, select an option for controlling how many particles to render:

- **All** (the default) to render all particles in the particle tracing simulation.
- **Fraction** to only render a fraction of the particles. You specify the fraction as a number between 0 and 1 in the **Fraction of particles** field. The default fraction is 1; that is, to render all particles.
- **Number** to only render a certain number of particles, which you specify in the **Number of particles** field. The default is to render 100 particles.

Pellets

Use a **Pellets** plot in 2D ( ) and 3D ( ) plot groups to visualize a flow of pellets or similar objects as spheres or as three orthogonal filled circles (slices). Add Deformation, Transformation, Transparency (3D only), and Visual Effects (3D only) subnodes as needed. Right-click a **3D Plot Group** to add this plot from the **More Point Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Selection**, **Expression**, **Title**, **Range**, **Quality**. and **Inherit Style**.

COLORING AND STYLE

Select the **Radius scale factor** checkbox to enter a scalar number for the scale factor.

Select the **Shrinking core** checkbox if you want to a space-dependent radius scale factor. You can use this functionality to study shrinking core phenomena. If selected, enter a radius in the **Core radius** field (default: 0), or click the **Replace Expression** button ( ) to use a predefined expression. Also, choose a color from the **Core color** list (default: black). Select **Custom** to define a custom color using a color palette.

From the **Pellet shape** list, choose **Sphere** (the default) to visualize the pellets as spheres, or choose **Slice** to visualize the pellets as three orthogonal filled circles (slices). If you chose **Sphere**, you can also specify the following properties:

- From the **Axis** list, select a main axis for the spheres that represent pellets: **X-axis**, **Y-axis** (the default), or **Z-axis**.
- In the **Start angle** field, specify a start angle (default: 210 deg) for the sphere.
- In the **Revolution angle** field, specify a revolution angle (default: 240 deg) for the spherical sector. Use 360 degrees for a full sphere. If the angle is less than 360 degrees, a corresponding spherical wedge is removed from the sphere.

For the **Coloring**, **Color table**, **Color legend**, **Color table transformation**, and **Scale** settings, see Common Results Node Settings.

If you have the Chemical Reaction Engineering Module, see *A Multiscale 3D Packed Bed Reactor*: Application Library path **Chemical_Reaction_Engineering_Module/Reactors_with_Porous_Catalysts/packed_bed_reactor_3d**.

Phase Portrait

Use a **Phase Portrait** plot ( ) for 2D and 2D axisymmetric models to visualize large datasets of particle trajectories. The traditional use of a phase portrait is to plot the particle position on the x-axis and the particle velocity on the y-axis. Each dot in the xy-plane represents a particle. By default, the position is taken as the distance from the origin

(0, 0, 0) for 3D models. Add Color Expression and Material Appearance subnodes as needed. Right-click a **2D Plot Group** to add this plot from the **More Surface Plots** submenu.

This plot is available with the Particle Tracing Module.

EXPRESSION

Select an option from the **x-axis** list: **Position** or **Manual**. If **Manual** is selected, enter an **Expression** (SI unit: m). Select an option from the **y-axis** list: **Speed** or **Manual**. If **Manual** is selected, enter an **Expression** (SI unit: m/s).

The plot is best represented if the magnitude of the x-axis data and y-axis data are equal. Therefore, it can be useful to normalize the data by selecting **Manual** from the **x-axis** and **y-axis** lists under **Expression** and applying a suitable scaling factor.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Coloring and Style**, and **Inherit Style**.

Poincaré Map

Use a **Poincaré Map** plot ( ) to visualize particle trajectories using a *Poincaré map* (sometimes called a *first recurrence map*). Add Color Expression, Material Appearance, Transparency, and Visual Effects subnodes as needed.

The Poincaré map is constructed by first defining a **Cut Plane** ( ) on the **Particle** dataset ( ). Then add a **3D Plot Group** or a **2D Plot Group**, depending on the dimension of the particle trajectories, and right-click the plot group node to add these plots from the **More Volume Plots** or **More Surface Plots** submenu, respectively.

This plot type is useful to visualize the particle trajectories in a plot that represents the position of the particles in a section that is usually transversal to the particle trajectories. The Poincaré map represents the particle trajectories in a space dimension that is one dimension lower than the original particle space.

The Poincaré map parent plot group should point to this cut plane (select a **Cut plane** dataset under **Data**). The resulting plot places a dot on the cut plane at the location where a particle crossed the plane. The same particle can cross the cut plane multiple times.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Inherit Style**, and **Coloring and Style**.

This plot is available with the Particle Tracing Module and with 3D models only.

Point

A **Point** plot is available in 2D ( ) and 3D ( ) to plot points using various geometric shapes and to plot torque arrows (2D only). Add Deformation, Filter, Selection (Plot Attribute), Transformation, Transparency (3D only),

and Visual Effects (3D only) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add this plot type from the **More Point Plots** submenu.

Go to Common Results Node Settings for a link to information about the **Data**, **Expression**, **Title**, **Range**, **Quality**, and **Inherit Style** sections.

EVALUATION

In this section, you decide the geometry level for the point evaluation. From the **Geometry level** list, choose **Point** (the default), **Line**, **Surface**, or **Volume** (3D only).

If you chose **Line**, **Surface**, or **Volume**, then also specify the following properties:

From the **Placement** list, choose **Node points** (the default) or **Gauss points**. If you choose **Node points**, also specify the resolution using the **Resolution** list: **Finer**, **Fine**, **Normal** (the default), or **Custom**. With **Custom**, specify a node-point order in the **Lagrange-element node-point order** field (default: 1). If you choose **Gauss points**, also specify the order in the **Gauss-point order** field (default: 1). Use a higher order for a finer resolution.

Select an evaluation data **Smoothing** method — **None**, **Inside material domains** (the default, for smoothing within domains shared by the same material but not across material boundaries), **Inside geometry domains** (for smoothing within each geometry domain but not across interior boundaries), **Everywhere**, or **Expression**. If you choose **Expression**, enter an expression in the **Expression** field such that smoothing occurs where the expression is continuous. The default expression is `dom`, the domain variable, which is equivalent to the **Internal** smoothing. For all **Smoothing** methods except **None**, you can also choose smoothing threshold, if needed. From the **Smoothing threshold** list, select **None** (the default), or select **Manual** to enter a relative smoothing threshold value (default: 0.1) in the **Threshold** field.

If you have chosen **Node points** from the **Placement** list, you can specify accurate derivative recovery using the **Recover** list. The default is **Off** because the accurate derivative recovery takes processing time. This recovery is a polynomial-preserving recovery that recovers fields with derivatives such as stresses or fluxes with a higher theoretical convergence than smoothing. To use accurate derivative recovery, from the **Recover** list select **Within domains** to perform recovery inside domains or **Everywhere** to apply recovery to all domain boundaries.

Specify a limit for the number of points in the **Maximum number of points** field (default: 100,000).

COLORING AND STYLE

In this section, you specify the type of point and the coloring and size of the points.

From the **Point type** list, choose one of the following point types:

- **Point** (the default). You can then specify a point radius in the **Point radius expression** field.
- **Text**, to plot values as text in point plots. See below for special settings in this section and **Text Format** section that appears.
- **Torque**, to plot torque arrows in 2D. You can then specify a point radius in the **Point radius expression** field.
- **Rectangle**, to plot the points as rectangles in 2D. You can then specify the rectangles' size and rotation using the **Width expression**, **Width expression**, and **Rotation expression** fields.
- **Ellipse**, to plot the points as ellipses in 2D. You can then specify the ellipses' size and rotation using the **Width expression**, **Width expression**, and **Rotation expression** fields.
- **Block**, to plot the points as blocks in 3D. You can then specify the blocks' size and rotation using the **Axis 1**, **Axis 2**, and **Axis 3** 3D vectors.
- **Ellipsoid**, to plot the points as ellipsoids in 3D. You can then specify the ellipsoids' size and rotation using the **Axis 1**, **Axis 2**, and **Axis 3** 3D vectors.

Settings for All Point Types Except Text

For all expression fields, click the **Replace Expression** button ( ) to choose from applicable predefined variables to use as part of or the entire expression.

By default, the value in the **Radius scale factor** is determined automatically. To enter another scale factor, select the associated checkbox and then change the value of the scale factor.

To plot points so that they all have the same fixed size, select the **Fixed size** checkbox.

For the coloring settings, see Defining the Coloring and Style.

Settings for the Text Point Type

Change the value in the **Point radius** field (default: 2) to a value between 0 and 1 to adjust the point size.

From the **Color** list, choose the color to use for the annotation text. Choose **From theme** (the default) to use the color from the current color theme, or choose **Custom** to choose a custom color from a color palette. Select the frame background color from the **Background color** list. Choose **From theme** to use a background color that changes with the selected color theme.

From the **Anchor point** list, choose the position of the anchor point relative to the annotation text: **Upper right**, **Upper middle**, **Upper left** (the default), **Middle right**, **Center**, **Middle left**, **Lower right**, **Lower middle**, or **Lower left**.

From the **Orientation** list, choose **Horizontal** (the default) or **Vertical**, if you want the annotation text to be displayed vertically instead of horizontally.

Select the **Show frame** checkbox to display the annotation in a rectangular frame.

TEXT FORMAT

This section is only available if you have selected **Text** from the **Point type** list.

In this section, you can control the text format for the text.

Select the **Include unit** checkbox to add the unit of the expression for which the plot shows the maximum or minimum value.

If you want to add a prefix or a suffix to the labels for the minimum and maximum values, add them in the **Prefix** and **Suffix** fields. The same prefix and suffix are used for the minimum and maximum labels.

From the **Number format** list, choose one of the following formats:

- **Default**: Numerical values that come from the solvers are presented as-is. Numbers formatted during postprocessing use the **Output display precision** preference setting.
- **Automatic**: All numbers are formatted using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Engineering**: All numbers are formatted using engineering notation (such as `31.416E-6`; it is similar to scientific notation but with the powers of ten as multiples of three) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Scientific**: All numbers are formatted using scientific notation (such as `3.1416E-5`) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Stopwatch**: All numbers are formatted in decimal notation with a specified number of integer digits and decimals, which you enter in the **Number of integer digits** field (default: 3) and **Number of decimals** field (default: 2),

respectively. Unnecessary zeros are always shown. For example, with the default settings, 17.1 would be formatted as `017.10`. The specified number of integer digits is not respected if the number is too large or if it is NaN or Inf. Select the **Always show the sign** checkbox to keep the width from changing for a sequence that includes both positive and negative values.

- **Scientific stopwatch**: All numbers are formatted in scientific notation with one integer digit and a specified number of decimals and exponent digits. For example, with the default settings, 17.1 would be formatted as `1.71E1`. The settings are the same as for the **Stopwatch** format, with the addition of an **Always show the sign of the exponent** checkbox. Select it to keep the width from changing for a sequence that includes both positive and negative exponents.

Point Data

A **Point Data** plot node appears in 2D ( ) and 3D ( ) plot groups if you run a method that creates a `PointData` plot. Add a Marker, Material Appearance, Transparency (3D only), or Visual Effects (3D only) subnode as needed.

It is not possible to add a **Point Data** node from the model tree or toolbars in the COMSOL Desktop. It is only available from the COMSOL Multiphysics API and if you run a method from the **Developer** toolbar. See PointData in the *COMSOL Multiphysics Programming Reference Manual*.

DATA

In the **Data** section, the number of points in the data is listed.

Go to Common Results Node Settings for a link to information about the **Title**, **Range**, and **Coloring and Style** sections.

Point Graph

Use a **Point Graph** ( ) to visualize the value in a point along time or a parameter value. It can be a point in the geometry or a cut point. Add Color Expression, Error Bars (Global, Point Graph, and Function), Filter, or Graph Marker subnodes as needed. Right-click a **1D Plot Group** or **Polar Plot Group** to add this plot type.

See Global for these settings: **x-Axis** (or θ **Angle**) **Data** and **y-Axis** (or **r-Axis**) **Data**. Then go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Through-Thickness Location**, and **Coloring and Style**.

SELECTION (SOLUTION DATASETS ONLY)

Select **Manual** from the **Selection** list to choose geometry directly from the **Graphics** window. Select **All** to add the applicable geometry or any other predefined grouping.

Y-AXIS

This section is only available if the **Two y-axes** checkbox is selected in the **Plot Settings** section of the parent **1D Plot Group** node's **Settings** window.

Select the **Plot on secondary y-axis** checkbox to plot the *y*-axis data on the secondary *y*-axis to the right of the plot instead of the primary *y*-axis to the left of the plot.

QUALITY

This section is only available when the dataset refers to a solution using a time-dependent study. You can then increase the time resolution if needed for a smooth graph plot. In the **Refinement** list, enter an integer between 1 (the default value) and 1000. For an increased time resolution, enter a higher refinement value.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed. For 1D point plots, the legend displays the coordinate (or vertex number).

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Point**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes under **Include** to control what to include in the automatic legends (by default, it includes the point and solution only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. It is also possible to evaluate expressions defined in the points that are plotted. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Point Trajectories

Use a **Point Trajectories** plot to visualize trajectories of geometric points in 2D ( ) and 3D ( ). For example, you can use it in a time-dependent multibody dynamics model to plot the trajectory of a geometric point, cut point, or a user-defined trajectory along with the actual moving bodies. Add Color Expression, Deformation, **Filter** (see Filter for Point Trajectories), Material Appearance, Transparency (3D only), and Visual Effects (3D only) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add this plot from the **More Points Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Coloring and Style**, and **Inherit Style**. See below for the sections specific to this plot: **Trajectory Data** and **Selection**. For **Point Trajectories** plots, Particle, Ray, Particle Bin, Ray Bin, Intersection Point 2D and 3D, Receiver 2D and 3D, and Transformation 2D and 3D datasets are allowed as inputs.

The Point Trajectories plot creates trajectories not for the actually selected time, parameter, or frequency value but for all values lower or equal to the selected value.

TRAJECTORY DATA

Select a source for the **Plot data**: **Global** or **Points** (the default).

- If **Global** is selected, enter the coordinates, as global expressions or numbers, for a point in the **x-expression**, **y-expression**, and **z-expression** fields.
- If **Points** is selected, enter expressions that are valid at the location of the points in the **x-expression**, **y-expression**, and **z-expression** fields. The expressions can include the time and the space coordinates, for example. You select the points that you want to plot trajectories for in the **Selection** section below and by clicking directly in the **Graphics** window.

To assist in picking an expression, click the **Replace Expression** button ( ) above the text fields to choose from a number of available scalar variables.

SELECTION

This section is only available when you select **Points** from the **Plot data** list. It contains tools for selecting points in the model geometry by clicking directly in the **Graphics** window, for example (see About Selecting Geometric Entities for details).

Filter for Point Trajectories

You can right-click a Point Trajectories plot node to add a **Filter** subnode ( ), which controls the points to include and whether to render all points or a subset of the points. The Filter node has the following section:

POINT SELECTION

From the **Points to include** list, select the points or subset to include in the point trajectories plot:

- **All** (the default) to include all points.
- **Logical expression** to include a subset of points that fulfill the logical expression that you enter in the **Logical expression for inclusion** field. For example, `x>0` only includes points in areas where the *x* coordinate is positive. Click the **Replace Expression** ( ) button to select predefined expressions for the logical expression.

From the **Particles to render** list, select an option for controlling how many particles to render:

- **All** (the default) to render all points in the point trajectories plot.
- **Fraction** to only render a fraction of the points. You specify the fraction as a number between 0 and 1 in the **Fraction of points** field. The default fraction is 1; that is, to render all points.
- **Number** to only render a certain number of points, which you specify in the **Number of points** field. The default is to render 100 points.

Polarization

Use a **Polarization** ( ) plot to visualize the polarization state for diffraction orders, simulated for periodic structures. A polarization plot displays polarization ellipses for the different diffraction orders in the same diagram. Add a Color Expression subnode as needed. Right-click a **1D Plot Group** to add this plot from the **More Plots** submenu.

This plot is available with the RF Module or the Wave Optics Module.

EXPRESSION

From the **Plane wave** list, choose a predefined expression, if available, or choose **Manual** or **None**. If you chose **Manual**, enter expressions for the polarization plot in the **x-expression** and **y-expression** fields. There can also be other predefined options such as **Order [0,0], reflection side (efwd)** when you have solved a Wavelength Domain study for an Electromagnetic Wave, Frequency Domain interface, for example.

If desired, clear the **Show direction of rotation** checkbox, which is selected by default, to not display the direction of rotation as an arrow head on the polarization ellipses.

The default value in the **Scale** field is 1. Use another value to scale the polarization ellipses.

From the **Center position** list, choose **Auto** (the default) to determine the center position of the polarization ellipses automatically. Choose User defined to enter center positions in the **x-coordinate** and **y-coordinate** fields.

LEGENDS

The **Show legends** checkbox is selected by default to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label** and **Solution** checkboxes to control what to include in the automatic legends (by default it includes the solution only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**.

Principal Stress Volume

Use the **Principal Stress Volume** ( ) to plot the principal stress and principal strain in structural mechanics models. The values of the principal stresses σ_1, σ_2, and σ_3 are the eigenvalues of the stress tensor, ordered such that $\sigma_1 > \sigma_2 > \sigma_3$. The same applies for the principal strains ε_1, ε_2, and ε_3. The plots also show the corresponding eigenvectors using arrows. Add a Color Expression, Deformation, Filter, Material Appearance, Selection (Plot Attribute), Transformation, Transparency, or Visual Effects subnode as needed. Right-click a **3D Plot Group** to add this plot from the **More Volume Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Principal Components**, **Title**, **Positioning**, **Coloring and Style**, and **Inherit Style**. In the **Coloring and Style** section, the **Arrow base** setting is not available because it is not applicable when plotting principal stress or principal strain eigenvectors.

Principal Stress Surface

Use the **Principal Stress Surface** plots in 2D ( ) and 3D ( ) to plot the principal stress and principal strain in structural mechanics models. The values of the principal stresses σ_1, σ_2, and σ_3 are the eigenvalues of the stress tensor, ordered such that $\sigma_1 > \sigma_2 > \sigma_3$. The same applies for the principal strains ε_1, ε_2, and ε_3. The plot also shows the corresponding eigenvectors using arrows. Add a Color Expression, Deformation, Filter, Material Appearance, Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnode as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add this plot from the **More Surface Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Inherit Style**, **Principal Components**, **Positioning**, and **Coloring and Style**. In the **Coloring and Style** section, the **Arrow base** settings is not available because it is not applicable when plotting principal stress or principal strain eigenvectors.

Principal Stress Line

Use the **Principal Stress Line** plots in 2D ( ) and 3D ( ) to plot the principal stress and principal strain in structural mechanics models. The values of the principal stresses σ_1, σ_2, and σ_3 are the eigenvalues of the stress tensor, ordered such that $\sigma_1 > \sigma_2 > \sigma_3$. The same applies for the principal strains ε_1, ε_2, and ε_3. The plot also shows the corresponding eigenvectors using arrows. Add a Color Expression, Deformation, Filter, Material Appearance,

Selection (Plot Attribute), Transformation, Transparency (3D only), or Visual Effects (3D only) subnode as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add this plot from the **More Line Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Inherit Style**, **Principal Components**, and **Coloring and Style**. In the **Coloring and Style** section, the **Arrow base** settings is not available because it is not applicable when plotting principal stress or principal strain eigenvectors.

Radiation Pattern

Radiation Pattern plots are used to plot the value of a global variable for the radiation pattern of an electromagnetic field or acoustic pressure field.

- For the RF Module and the Wave Optics Module, the variables are the far-field norm, `normEfar` and `normdBEfar`; the components of the far-field variable `Efar`; and the axial ratio, `axialRatio` and `axialRatiodB`.
- For the Acoustics Module, the variables are the exterior-field pressure `efc1.pext` and sound pressure level `efc1.Lp_pext`.

The variables are plotted for a selected number of angles on a circle (in 2D) or a sphere (in 3D). The angle interval and the number of angles can be manually specified. Also the circle origin and radius of the circle (2D) or sphere (3D) can be specified. For 3D Radiation Pattern plots, you also specify an expression for the surface color. For 1D Radiation Pattern plots, you can optionally compute the beamwidth.

The radiation pattern plot plots a surface shape by deforming the specified circle or sphere in 2D and 3D or a circular slice in 1D. For each evaluation point on the specified circle or sphere, the plot deforms the specified circle or sphere from the evaluation point in the radial direction so that the deformed surface shape distance from the origin becomes equal to the value of the specified expression on the evaluation point on the specified circle or sphere.

The main advantage with the Radiation Pattern plot, as compared to making a Line Graph, is that the circle or sphere used for defining the plot directions is not part of the geometry for the solution. Thus, the number of plotting directions is decoupled from the discretization of the solution domain.

Radiation Pattern plots always use the spatial frame when evaluating outside the meshed domain.

In 3D, this plot type uses the spherical coordinates r, θ, and φ, so that:

- The radial distance $r = \sqrt{x^2 + y^2 + z^2}$
- The polar angle $\theta = \text{acos}(z/r)$
- The azimuthal angle $\varphi = \text{atan2}(y,x)$

Default Radiation Pattern plots are automatically added to any model that uses exterior-field calculations. You can add a **Radiation Pattern** plot node to any plot group (Polar, 1D, 2D, and 3D):

- 1D or Polar plots ( ) for 2D, 2D axisymmetric, or 3D geometry
- 2D plot ( ) for 2D axisymmetric or 3D geometry
- 3D plot ( ) for 2D axisymmetric or 3D geometry

To add this plot type, right-click a plot group node and choose **Radiation Pattern** from the **More Volume Plots** (3D), **More Surface Plots** (2D), or **More Plots** (1D) submenu. For **Radiation Pattern** nodes, you can right-click to add

Deformation (2D and 3D only), Export Expressions, Graph Marker (1D only), Material Appearance, Transformation, and Transparency (3D only) subnodes if desired.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Range**, **Inherit Style**, and **Coloring and Style**. For 3D plot groups, see the list for **Color**. For **Radiation Pattern** plots, only Solution datasets are available as inputs.

EXPRESSION

For the standard settings, see Expressions and Predefined Quantities. In 3D, you can also select the **Threshold** checkbox and then enter a threshold value as a scalar number in the associated text field. The threshold value corresponds to the evaluated radius that maps to the plotted radius 0. The default, if the **Threshold** checkbox is cleared, is the minimum radius among those evaluated for. Additionally, in 3D, select the **Use as color expression** checkbox to use the radiation pattern plot expression defined in this section also as the color expression. The **Color** section is then not available.

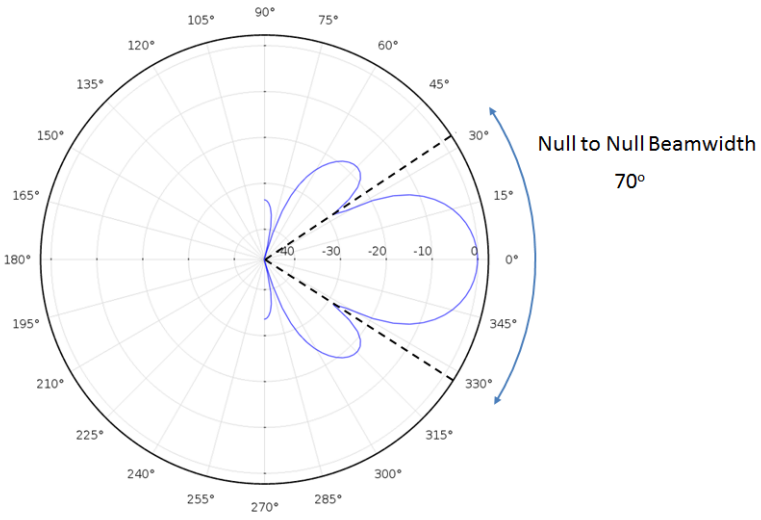
EVALUATION

In this section you specify the samples on the circle or sphere at which you want the evaluation to take place.

1D Plot Group and Polar Plot Group

Under **Angles**, enter the **Number of angles**. The default is 50.

Select a **Restriction**: **None** (the default) or **Manual**. If **Manual** is selected, enter values (SI unit: deg) for φ **start** (the default is 0 degrees) and φ **range** (the default is 360 degrees). If you want to compute the beamwidth, select **On** from the **Compute beamwidth** list. Then, a **Level down** field appears, where you can specify a nonnegative number to compute the beamwidth at a certain level down from the reference direction. The unit for that level is the same as the unit for the expression used in the radiation pattern plot (dB, for example, for an exterior-field sound pressure level). The beamwidth is the width of the lobe around the reference direction (in degrees). When you compute the beamwidth, the computed values appear in a **Beamwidth** table with columns for the parameter (typically a frequency), the beamwidth, and the null-to-null beamwidth (the angular separation from which the magnitude of the radiation pattern decreases to zero away from the main beam; see the figure below).



Note that the beamwidth calculation only makes sense if there is a main lobe in the reference direction.

For 1D Radiation Pattern plot nodes referring to a solution in a 2D axisymmetric or 3D component, under **Center** enter the coordinate at the center of the evaluation circle. Under **Normal** specify the normal to the circular slice of

the far-field bulb. The default normal is {0, 0, 1} for the normal using 3D components and {0, 1, 0} for the normal using 2D axisymmetric components.

If a Pressure Acoustics interface is used in the component from which the dataset is taken, you can also add a **Radius** (SI unit: m) under **Evaluation distance** for a radius-dependent exterior-field expression.

Under **Reference direction** specify a reference direction from which the angle is measured. The entered vector is projected onto the evaluation plane. The default direction is {1, 0, 0} for the reference direction using 3D components, {0, 0, 1} for 2D axisymmetric components, and {1, 0} for 2D components.

A schematic of the evaluation circle is depicted in Figure 21-6. In 3D, you can preview the evaluation circle in the geometry by clicking the **Preview Evaluation Plane** button at the bottom of the **Evaluation** section. An example of the resulting plot is depicted in Figure 21-7.

2D and 3D Plot Groups

Under **Angles**, enter the **Number of elevation angles**. The default is 10. Enter the **Number of azimuth angles**. The default is 20.

Select a **Restriction**: **None** (the default) or **Manual**. If **None** is selected in a 3D plot group, you can also select **On** or **Off** from the **Compute directivity** list. If the **Compute directivity** list is set to **On**, you can enter or select an expression for the directivity in the **Directivity expression** field. The direction for the strongest radiation and the directivity value (also in dB) display in a **Directivity** table window (see The Table Window and Tables Node). So if, for example, you model a speaker that is located in an infinite baffle (and symmetry is used in the radiation pattern calculation), then plot and evaluate the whole field to get the directivity.

If **Manual** is selected, enter values (SI unit: deg) for:

- θ **start** (the default is 0 degrees)
- θ **range** (the default is 180 degrees)
- φ **start** (the default is 0 degrees)
- φ **range** (the default is 360 degrees)

If a pressure acoustics interface is used in the component from which the dataset is taken, you can also specify the following settings for a radius-dependent exterior-field expression. Under **Sphere** from the list, select **Unit sphere** (the default) or **Manual**. If **Manual** is selected, enter values for the **x**, **y**, and **z** coordinates at the center of the sphere (SI unit: m). The default is 0. Enter a **Radius** (SI unit: m). The default is 1 m.

For 2D axisymmetric radiation pattern plots, you can evaluate the azimuthal (φ) angle once for each angle when you specify a name of the variable for the φ angle in the **Azimuthal angle variable** field and use it in the expression for the radiation pattern. Doing so slows down the evaluation, so if the **Azimuthal angle variable** field is empty, an evaluate-once-and-revolve approach is used instead.

LEGENDS

This section is available in 1D plot groups only. Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes under **Include** to control what to include in the automatic legends (by default, it includes the solution only). You can add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Ray (Plot)

Use a **Ray** ( ) plot to visualize the value of a ray variable versus time for all rays, or to plot two ray variables against each other at a set of time steps. The **Ray** plot must point to a Ray (Dataset). Add a Color Expression subnode to color the resulting lines, or add a **Filter** subnode to plot the properties of only a subset of rays in dataset as needed. For the settings in the **Filter** subnode, see Filter for Ray and Ray Trajectories. To add this plot type, right-click a **1D Plot Group** node and choose **Ray** from the **More Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Coloring and Style**, and **Legends**. For **Ray** plots, only Ray datasets are allowed as inputs.

This plot is available with the Ray Optics Module or the Acoustics Module.

Y-AXIS DATA

In the **y-Axis Data** section, you can define an expression, which may be dependent on both particle and field variables.

X-AXIS DATA

Select a **Parameter**: **Solution number** or **Expression**.

For **Solution number**, a distinct line is plotted for every ray, with the y-axis being the user-defined expression from the **y-Axis data** section and the *x*-axis being time. The total number of lines equals the total number of rays (after taking the **Filter** subnode and the selection of the Ray (Dataset), if any, into account) multiplied by the total number of selected outer solutions if applicable.

For **Expression**, the expressions entered in the **y-Axis Data** and **x-Axis Data** sections are plotted against each other for all rays at each specified time — that is, the total number of lines equals the total number of selected times multiplied by the total number of selected outer solutions.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes under **Include** to control what to include in the automatic legends (by default, it includes the solution and description only). If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

DATA SERIES OPERATION

Choose an **Operation**: **Sum** (the default), **None**, **Average**, **Maximum**, **Minimum**, **RMS**, **Standard deviation**, or **Variance**. The operation is applied to the rays only if the *x*-axis is **Time**. If **None** is selected, a distinct line is plotted for each ray; otherwise, the selected data series operation is used to compute a single data point for all rays at each time step. The default setting prevents an extremely large number of lines from being plotted when a new Ray plot is created.

Ray Trajectories

Use a **Ray Trajectories** plot in 2D ( ) or 3D ( ) to visualize the trajectories of rays computed using the Geometrical Optics or Ray Acoustics interface. Add Color Expression, Deformation, **Filter**, Material Appearance, Transformation, Transparency (3D only), and Visual Effects (3D only) subnodes as needed. For the settings in the **Filter** subnode, see Filter for Ray and Ray Trajectories. Right-click a **2D Plot Group** or **3D Plot Group** to add this plot. The plot does not compute the ray trajectories during results processing — the trajectories are computed by one of the physics interfaces (Ray Acoustics or Geometrical Optics). The plot can thereby render tens of thousands of rays quickly because the trajectories have already been computed

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Coloring and Style**, **Extra Time Steps**, and **Inherit Style**. For **Ray Trajectories** plots, Particle, Ray, Particle Bin, Ray Bin, Intersection Point 2D and 3D, Receiver 2D and 3D, and Transformation 2D and 3D datasets are allowed as inputs.

	The Ray Trajectories plot creates trajectories not for the actually selected time, parameter, or frequency value but for all values lower or equal to the selected value.

	This plot is available with the Ray Optics Module or the Acoustics Module.

Filter for Ray and Ray Trajectories

You can right-click a Ray Trajectories plot node to add a **Filter** subnode ( ), which controls the particle types to include and whether to render all particles or a subset of the particles. The **Filter** node has the following section:

RAY SELECTION

From the **Rays to include** list, select the rays types or subset to include in the ray trajectories plot:

- **All** (the default) to include all rays.
- **Primary** to include primary rays only.
- **Secondary** to include secondary rays only. This includes the reflected rays released at material discontinuities.
- **Logical expression** to include a subset of rays that fulfills the logical expression that you enter in the **Logical expression for inclusion** field. For example, `gop.I>1[W/m^2]` only includes rays with an intensity greater than 1 W/m^2, and `x>0` only includes rays in areas where the x coordinate is positive. Click the **Replace Expression** ( ) button to select predefined expressions for the logical expression.

From the **Rays to render** list, select an option for controlling how many rays to render:

- **All** (the default) to render all rays in the ray tracing simulation.
- **Fraction** to only render a fraction of the rays. You specify the fraction as a number between 0 and 1 in the **Fraction of rays** field. The default fraction is 1; that is, to render all rays.
- **Number** to only render a certain number of rays, which you specify in the **Number of rays** field. The default is to render 100 rays.

Reflection Graph

Add a **Reflection Graph** subnode ( ) to a **Smith Plot Group** node to create a reflection Smith plot. After defining the expression to plot (an S-parameter, for example), click **Plot** ( ) to create the reflection Smith plot. If you want to add color to the plotted curve (to represent the frequency, for example) or a filter, add Color Expression or Filter subnodes.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Coloring and Style**.

EXPRESSIONS

For an Reflection Graph, you can plot multiple curves in the same graph (Smith plot) using varying line styles and colors. In the table in this section, add one or more expressions to the rows under **Expression** to define the quantity for each curve, and optionally add descriptions under **Description**. The descriptions appear in the legends.

For this table of expressions, the **Replace Expression** and **Add Expression** buttons have the following effect:

- Click the **Replace Expression** ( ) button to select a predefined quantity and replace the entire contents of the **Expression** table with the corresponding variable as the only expression.
- Click the **Add Expression** (+) button to insert the corresponding variable on a new row in the **Expression** table.

LEGENDS

The **Show legends** checkbox is selected by default to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes to control what to include in the automatic legends (by default it includes the solution and description only). You can also add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

Scatter Surface and Scatter Volume

Use scatter plots to visualize a scalar quantity as scattered spheres on a 2D **Scatter Surface** ( ) or in a 3D **Scatter Volume** ( ) (as functions of spatial coordinates or any quantities).

Scatter plots can be used as alternatives to arrow plots for scalar quantities or to represent the correlation between two or more different variables to get a feeling for how quantities correlate. To display a quantity using the color and radius of scattered spheres in the model geometry, use the spatial coordinates (x, y, and z in 3D) as the expressions for the scatter plot axes.

If you use some other quantities as the variables that determine the scattered spheres' positions on the axes, it is good practice to remove the plotting of the dataset's edges (typically the geometry boundaries) by clearing the **Plot dataset edges** checkbox in the main plot group node's **Settings** window. In those cases, the axes in the **Graphics** window no longer represent the space coordinate for the geometry.

The radius and color can both be functions of independent quantities, so a 3D scatter plot can provide information about up to five different quantities as the three axis directions, color, and radius. Right-click a **2D Plot Group** or **3D Plot Group** to add these plot types from the **More Surface Plots** or **More Volume Plots** submenu, respectively. If you

want to add a material appearance, right-click the **Scatter Surface** or **Scatter Volume** node and add Material Appearance, Transparency (Scatter Volume only), and Visual Effects (Scatter Volume only) subnodes as desired.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Range**, **Radius**, **Color**, **Coloring and Style**, and **Inherit Style**.

EVALUATION POINTS

Under **Evaluation Points**, select an **Entry method** for the **grid points** coordinates based on space dimension (**x grid points** and **y grid points** for 2D; **r grid points** and **z grid points** for 2D axial symmetry; or **x grid points**, **y grid points**, and **z grid points** for 3D).

The evaluation points are located in a block-shaped (3D) or rectangular (2D) grid where the axes represent the expressions defined in the **Expression** section.

- If **Number of points** is selected, enter the number of **Points** in each direction (the default is 15 for 2D Scatter Surface and 7 for 3D Scatter Volume).
- If **Coordinates** is selected, enter **Coordinates** (SI unit: m).

Slice

Use a **Slice** ( ) to display a scalar quantity on slices inside a 3D domain. Add Deformation, Filter, Marker, Material Appearance, Selection (Plot Attribute), Transformation, Transparency, and Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add this plot.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Range**, **Coloring and Style**, **Quality**, and **Inherit Style**.

PLANE DATA

Under **Plane Data**, select a **Plane Type**: **Quick** (the default) to specify planes orthogonal to the coordinate axes or **General** to specify general planes.

If **Quick** is selected:

- From the **Plane** list, select **xy-planes**, **yz-planes**, or **zx-planes** as the set of planes orthogonal to the coordinate axes applicable for the model geometry.
- Select an **Entry method**: **Number of planes** or **Coordinates**.
  - If **Number of planes** is selected, enter **Planes**.
  - If **Coordinates** is selected, enter the applicable (x, y, or z) grid **Coordinates**. Choose a set of cut plane slices to a coordinate axis, specify the transverse coordinate by entering the location along the transverse coordinate axis in the **Coordinates** field.

If **General** is selected:

- Select an option from the **Plane entry method** list: **Three points** or **Point and normal**.
  - If **Three points** is selected, enter **x**, **y**, or **z** coordinates in the **Point 1**, **Point 2**, and **Point 3** fields.
  - If **Point and normal** is selected, enter **x**, **y**, or **z** coordinates in both the **Point** and **Normal** sections.

- If required, select the **Additional parallel planes** checkbox and select an **Entry method**: **Number of planes** or **Distances**.
  - If **Number of planes** is selected, enter the number of grid **Planes** (the default is 4).
  - If **Distances** is selected, enter the **Distances** (SI unit: m).

To move the slices interactively, select the **Interactive** checkbox before plotting. You can then move the slices using the slider or by typing a shift in the **Shift** field. A zero shift represents the original position of the slices.

Sobol Index

The **Sobol Index** plot ( ) can be added to a **1D Plot Group** ( ) to visualize Sobol indices for an uncertainty quantification study. It is also available from a 1D plot group contextual ribbon, under **More Plots**.

	Go to Common Results Node Settings for links to information about these sections: **Title** and **Coloring and Style**.

	The **Sobol Index** plot is available with the Uncertainty Quantification Module.

DATA

From the **Table** list, choose a table with data from an uncertainty quantification study. Also, from the **Quantity of interest** list, choose a column in the chosen table as the quantity of interest for the **Sobol Index** plot. Select the **Sort** checkbox to sort the parameters in decreasing order with respect to the total Sobol index for the quantity of interest.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label** and **Headers** checkboxes to control what to include in the automatic legends (by default it includes the column headers only). You can add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table.

Spot Diagram

The **Spot Diagram** plot ( ) can be added to a **2D Plot Group** ( ) to visualize the intersection of rays with a surface. The surface could be a physical boundary in the model, or it could be a fictitious plane such as the focal plane of a lens. The data source may only be added to a 2D plot group but requires a ray tracing solution in a 3D model. Add a Color Expression subnode if required.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, and **Inherit Style**.

	The **Spot Diagram** plot is available with the Ray Optics Module.

DATA

The type of dataset determines the algorithm for computing the coordinates of each ray in the image plane.

If the dataset for the **Spot Diagram** plot is a **Ray** dataset (see Ray (Dataset)), then the rays are projected onto a 2D surface based on the average position and direction at the selected solution time. Alternatively, an **Intersection Point 3D** dataset can be selected (see Intersection Point 2D and Intersection Point 3D). Then the plot shows the intersection points of the rays with an intersecting plane at the specified location and orientation.

FILTERS

Use the options in the **Filters** section to remove some rays or intersection points from view.

- Select the **Filter by wavelength** checkbox to hide all rays except those of a specified vacuum wavelength. If this checkbox is selected, enter a **Wavelength** (default: 632.8 nm) and a **Tolerance** (default: 1 nm). If the difference between the specified wavelength and the vacuum wavelength of a ray exceeds this tolerance, then the ray will not be plotted.
- Select the **Filter by release feature index** checkbox to hide all rays except those released by a specific physics feature. Then enter an integer value for the index; the default is 1. This field is 1-indexed, meaning that 1 corresponds to the first ray release feature, 2 is the second ray release feature, and so on.
- Select the **Filter by number of reflections** checkbox to show rays only if they have reflected a specified number of times. Then enter an integer for the number of reflections; the default is 0. For this option to work correctly, it is necessary to select the **Count reflections** checkbox in the settings for the Geometrical Optics interface before running the study.
- Select the **Filter by additional logical expression** checkbox to show rays if they satisfy another user-defined expression. The expression is considered to be true if it returns a nonzero value. The default expression is 1, which would cause all rays to be shown.

FOCAL PLANE ORIENTATION

The settings in the **Focal Plane Orientation** section are used to define the direction of the tangential and normal vectors in the local coordinate system defined on the surface.

Select an option from the **Normal to focal plane** list: **Direction based** (the default), **Position based**, or **User defined**.

- For **Direction based**, the normal to the focal plane is the average ray direction. This average is taken over all rays that satisfy the filter criteria given by the **Filters** section above.
- For **Position based**, the normal to the focal plane is determined such that the ray positions are as close to the plane as possible. If the rays are stopped at a curved surface, the normal computed in this way may differ significantly from the surface normal.
- For **User defined**, enter values or expressions for the normal vector components directly. By default, the z-axis is used.

Select an option from the **Transverse direction** list: **Automatic** or **User defined**.

- For **Automatic**, a set of two transverse directions are arbitrarily chosen, such that they are orthogonal to each other and to the normal direction.
- For **User defined**, enter the components of one of the transverse directions directly. By default, the x-axis is used. If necessary, this transverse direction is projected onto the plane perpendicular to the normal direction. Then the other transverse direction is the cross product of the normal with the first transverse direction. The **Transverse direction** should never be parallel to the **Normal to focal plane**.

The **Create Focal Plane Dataset** and **Recompute Focal Plane Dataset** buttons can be used to automatically generate or update an **Intersection Point 3D** ( ) dataset in which the rms spot size is minimized.

Before clicking **Create Focal Plane Dataset**, make sure that the **Dataset** is either a **Ray** dataset ( ) or **From parent** (if the parent is a **Ray** dataset). If rays are released at multiple field angles and you want to locate the image plane that minimizes the rms spot size for one of these fields, first select the **Filter by release feature index** checkbox in the **Filters** section; you can always clear the checkbox after generating the **Intersection Point 3D** dataset.

Before clicking **Recompute Focal Plane Dataset**, make sure that the **Dataset** is already an **Intersection Point 3D** dataset.

When clicking either button, the **Intersection Point 3D** dataset is then created (or updated) to define the intersection points with a plane. This plane is positioned and oriented such that the rms spot size of the intersection points is minimized.

The button commands to create or update an **Intersection Point 3D** dataset indicating the reference hemisphere can also be accessed from the physics API. In a model method or in a model Java® file, you can use commands such as

```
ResultFeature plot = model.result("pg1").feature("oab1");
plot.runCommand("createFocalPlaneDataset");
plot.runCommand("recomputeFocalPlaneDataset");
```

LAYOUT

Use the settings in the **Layout** section to specify whether all rays should be presented as one diagram, or if rays should be organized by wavelength or release feature and then arranged into an array of spots. If the rays are presented as an array of spots, then the displacement between spots in the resulting plot is strictly for visualization purposes and does not accurately depict the relative position of these spots in the image plane.

Select an option from the **Spot arrangement** list: **Sort by release feature** (the default), **Sort by wavelength**, or **Single spot**.

- For **Sort by release feature**, one spot will be shown for each ray release feature for which solution data exists.
- For **Sort by wavelength**, one spot will be shown for each wavelength. Select an option from the **Sorting method** list: **Limits**, **Number of intervals**, or **Tolerance** (the default).
  - For **Limits**, enter a list of **Limits** (SI unit: m). Rays having a vacuum wavelength within any one of the specified intervals will be grouped in the same spot.
  - For **Number of intervals**, enter an integer value for the **Number of intervals**. The default is 10. The rays will be organized into the specified number of subintervals based on wavelength, with each interval creating a spot. Also select an option from the **Distribution** list. If **Equal number of rays** (the default) is selected, then the rays are divided among the specified number of bins so that each bin contains the same number of rays, while trying to keep rays of the same wavelength in the same group. If **Equal interval width** is selected, the rays are distributed among the specified number of intervals so that each interval is the same size.
  - For **Tolerance**, enter a value for the **Tolerance** (SI unit: m). The default is 1 nm. Rays will be grouped into the same spot if the difference between their vacuum wavelengths is less than the specified tolerance.
- For **Single spot**, the relative displacement of rays in the plot will be proportional to their relative displacement in the image plane; the rays will not be moved relative to each other for visualization purposes.

For **Sort by release feature** or **Sort by wavelength**, select an option from the **Layout** list: **Average over rays** (the default) or **Average over area**.

- For **Average over rays**, the coordinates of the center of each spot are defined as the arithmetic mean over the coordinates of rays in that spot.
- For **Average over area**, the coordinates of the center of each spot are defined as the average of the maximum and minimum coordinates of rays in that spot.

Enter values for the **Horizontal padding factor** and **Vertical padding factor**. The default values are 0.5. The padding factors determine the amount of blank space that will be placed between the spots in a spot diagram array. If the value is 0, then the spots might touch if they are equal in size. For negative values the spots may overlap.

ANNOTATIONS

Use the settings in the **Annotations** section to display information about each spot as text in the Graphics window.

- Select the **Show wavelength** checkbox to display the vacuum wavelength of each spot.
- Select the **Show spot coordinates** checkbox to display the position of each spot.
- Select the **Show spot size** checkbox to display the RMS spot size of each spot.*Double Gauss Lens*

For each type of annotation listed above, you can select an option from the **Position** list: **Above spot** or **Below spot**. It is possible to put several lines of text above or below each spot. You can also select a **Length unit**. The length units for each type of annotation are controlled independently; for example, you could display the vacuum wavelength in nanometers and the RMS spot size in microns. Also, for **Show spot coordinates**, you can choose one of the following options from the **Coordinate system** list: **Global** (the default) or **Local**. For **Global** the x, y, and z-coordinates of each spot center are shown. For **Local**, an ordered pair is shown to indicate the position of each spot center relative to the origin of the image plane.

Select the **Show circle** checkbox to draw a circle at the origin in the image plane. This could be used, for example, to draw the Airy disk for reference. You can enter a value or expression in the **Radius** text field.

Select the **Show text frames** checkbox to draw a text frame around each annotation.

Select the **Fit annotations to spot** checkbox to fit the annotations more closely to spots of varying sizes. This applies to spot diagram arrays (see the **Layout** section). If this checkbox is cleared, then the vertical positioning of the annotations will be the same for all spots in each row of a spot diagram array, even if the spots have different heights.

POSITION

In the **Position** section, you can enter value or expressions for the local x- and y-coordinates of the origin of the spot diagram. This can be used, for example, to compare the spot diagrams from different studies or from different parameter values in a **Parametric Sweep**, by positioning them next to each other.

	More information about postprocessing in Ray Optics models can be found in the Ray Optics Modeling chapter of the *Ray Optics Module User's Guide*.

	For an example of the use of Spot Diagram plots: *Double Gauss Lens*: Application Library path **Ray_Optics_Module/Lenses_Cameras_and_Telescopes/double_gauss_lens**.

Streamline

Use a **Streamline** plot in 2D ( ) or 3D ( ) to visualize a vector quantity. A streamline is a curve everywhere tangent to an instantaneous vector field. 3D streamline plot is analogous to the 2D streamline plot except that there is no height data setting and the starting point selection is different. In 3D, you can also use a Streamline Surface plot to plot streamlines on 3D surfaces. Add Color Expression, Deformation, Export Expressions, Filter, Material

Appearance, Selection (Plot Attribute), Transformation, Transparency (3D only), and Visual Effects (3D only) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add these plots.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Quality**, and **Inherit Style**.

	To get the length of the streamlines, use an **Export** > **Plot** node. In its **Settings** window, select the **Only export starting points and endpoints** checkbox to include one row with the starting point, the endpoint, and the length of the streamline for each streamline.

STREAMLINE POSITIONING

Select one of these options from the **Positioning** list: **On selected entities** (the default in 3D), **On selected boundaries** (the default in 2D), **Starting-point controlled**, **Uniform density**, or **Magnitude controlled**. Then follow one of the methods described:

- Method 1: Specifying the Number of Streamlines and Start Boundaries
- Method 2: Specifying Points by Entering Coordinates
- Method 3: Selecting the Specified Number of Starting Points in the Geometry
- Method 4: Creating Streamlines with Uniform Density
- Method 5: Creating Streamlines with Variable Density and Magnitude Controlled

SELECTION

	The **Selection** section is available in for some datasets when you select **On selected entities** (3D) or **On selected boundaries** from the **Positioning** list under **Streamline Positioning**.

In 3D, from the **Geometric entity level** list, select **Boundary** or **Edge** to select the boundaries or edges, respectively, from which the streamlines start. By selecting in the **Graphics** window and using the tools in the **Selection** section, select the boundaries or edges (3D only) for the starting positions for the streamlines.

COLORING AND STYLE

In this section you can control the style and color of the streamlines and add points or arrows to them, if desired.

Line Style

Under **Line style**, choose **None**, **Line** (the default), **Ribbon**, or **Tube** from the **Type** list to determine the type of streamlines.

If you chose **None**, no streamlines appear, but you can plot arrows that are tangential to the streamlines.

If you chose **Ribbon**, then enter an expression for the ribbon width in the **Width expression** field (SI unit: m). If desired, you can also adjust the width by selecting the **Width scale factor** checkbox and enter a scale factor in the corresponding text field.

If you chose **Tube**, then enter an expression for the tube radius in the **Tube radius expression** field (SI unit: m). If desired, you can also adjust the radius by selecting the **Radius scale factor** checkbox and enter a scale factor in the corresponding text field. The **Rounded end caps** checkbox is selected by default. Clear it to remove the rounded end caps from the tubes.

Point Style

Under **Point style**, you can add points or arrows and control their appearance.

From the **Type** list, choose **None** (the default) for no points or arrows, **Arrow** for static arrows that are tangential to the streamlines, **Interactive arrow** for arrows that are tangential to the streamlines and that can move along the streamlines with the local integration time, or **Interactive point** for points that can move along the streamlines with the local integration time.

If you chose **Arrow**, these additional settings are available:

- From the **Arrow distribution** list, choose **Equal arc length** (the default) to distribute the arrows uniformly over the streamlines' arc length, **Equal time** to distribute the arrows using the weight function $dt/d\text{arc}$, or **Equal inverse time** to distribute the arrows using the weight function $d\text{arc}/dt$.
- Select the **Number of arrows** checkbox to enter a number for the total number of arrows, on all streamlines, that are plotted. By default, the COMSOL Multiphysics software provides a reasonable number of arrows.

If you chose **Interactive arrow**, these additional settings are available:

- Specify a value in the **Local time** field (default: 0) for the local integration time along the streamlines for which the arrows are plotted. It is possible for integration times to be negative: For a starting point in the interior of a domain, streamlines are integrated both forward and backward in time unless you clear the **Allow backward time integration** checkbox in the **Advanced** section.
- You can move the arrows along the local time by moving the slider. You can also create this effect using a player animation in an **Animation** node under **Export**, using a **Streamline** sequence type.
- In the **Extra release times** field, enter any additional times for releasing arrows, or click the **Range** button ( ) to define the extra release times. By default, there are no extra times.

The following settings are available for both the **Arrow** and the **Interactive arrow** types:

- From the **Arrow type** list, choose **Arrowhead** (the default), **Arrow**, or **Cone**.
- From the **Arrow length** list, choose **Normalized** (the default), **Logarithmic**, or **Proportional** to make the arrows' sizes depend on the magnitude of the plotted quantity, if desired. If you choose **Logarithmic**, the length of the arrows is proportional to the natural logarithm of the magnitude of the quantity they represent. This makes arrows representing small values relatively larger. The value in the **Range quotient** field (default: 100) determines the ratio between the smallest and largest values in the range of values for the logarithmic arrow length.
- Use the slider, or select the **Scale factor** checkbox and enter a scale factor in the associated text field if you want to use another scaling than the one used by default.

If you chose **Interactive point**, these following settings are available:

- Specify a value in the **Local time** field (default: 0) for the local integration time along the streamlines for which the points are plotted. It is possible for integration times to be negative: For a starting point in the interior of a domain, streamlines are integrated both forward and backward in time unless you clear the **Allow backward time integration** checkbox in the **Advanced** section.
- You can move the points along the local time by moving the slider. You can also create this effect using a player animation in an **Animation** node under **Export**, using a **Streamline** sequence type.
- In the **Extra release times** field, enter any additional times for releasing points, or click the **Range** button ( ) to define the extra release times. By default, there are no extra times.
- Select or enter an expression for the points' radii in the **Point radius expression** field (SI unit: m). By default, the radius is scaled automatically. To enter a scale factor for the radius, select the **Radius scale factor** checkbox and enter a scale factor in the corresponding text field.
- Select the **Fixed size** checkbox if you want to display the points with a fixed onscreen size.

From the **Color** list, choose a color for the streamlines and arrows. Choose **Custom** to add a custom color using a color palette. Choose **From theme** to use a background color that changes with the selected color theme. This list is not available if you use a **Color Expression** subnode to define the colors for the streamlines.

ADVANCED

Define the following advanced streamline settings as needed.

Advanced Settings for the Streamline Plot

Under **Advanced**, set these general settings. See also Advanced Section Setting Effects.

- The **Integration tolerance** field default is 0.01 for 3D and 0.001 for 2D. Edit to specify how accurately streamlines are computed.
- The **Maximum streamline length** field makes it possible to control the length of streamlines. Edit the default (Inf) to control the streamlines' length. Enter the value as a fraction of the mean bounding box's size. When the **Allow backward time integration** checkbox is selected (the default), the maximum length refers to the sum of the lengths of the forward and backward parts.
- The **Maximum number of integration steps** field makes sure that the integration does not continue indefinitely. Edit the default (5000) to control when the computation stops.
- The **Maximum integration time** field sets an upper time limit for the integration. The default is infinity (inf).
- The **Stationary point stop tolerance** can be adjusted to make sure the integration stops near a stationary point in the field. The default is 0.01.
- The **Loop tolerance** field default is 0.01. This is a fraction of the mean of the lengths of the bounding box of the geometry. If a streamline gets closer to its starting point than this distance, the streamline snaps to its starting point and is plotted as a connected loop. See also Method 5: Creating Streamlines with Variable Density and Magnitude Controlled.
- Select the **Allow backward time integration** checkbox to integrate points from the starting points both in the direction of the vector field and in the opposite direction. This checkbox is selected by default.
- Select the **Normalize vector field** checkbox if required. The vector field is normalized pointwise: For each point where the field was evaluated, the vector is replaced by a unit vector in the same direction. If you apply normalization, the speed along the streamline changes. This change means that the other settings in the **Advanced** section (for example, maximum number of integration steps and maximum integration time) are interpreted differently.

STREAMLINE POSITIONING SECTION (CONTINUED)

Method 1: Specifying the Number of Streamlines and Start Boundaries

1 Under **Streamline Positioning**, from the **Positioning** list, select **On selected boundaries**.

The **Selection** section is made available for some datasets when **On selected boundaries** is selected from the **Positioning** list under **Streamline Positioning**.

2 Under **Selection**, select the boundaries from which the streamlines start. By selecting in the **Graphics** window and using the tools in the **Selection** section, select the boundaries for the starting positions for the streamlines.

3 From the **Point distribution** list, choose **Uniform** (the default) or **Mesh based**, to place the starting points in the barycenters of boundary elements.

4 Enter the **Number** of streamlines (the default is 20), if **Point distribution** is **Uniform**. This number is a suggestion for how many streamlines are generated, but there is no guarantee that you get exactly the specified number of streamlines. The reason is that the streamline starting points are placed in a regular grid on the selected

boundaries. If **Point distribution** is **Mesh based**, you can instead specify a refinement as a positive integer (default: 1) in the **Element refinement** field.

Method 2: Specifying Points by Entering Coordinates

1. Under **Streamline Positioning**, from the **Positioning** list, select **Starting-point controlled**.
2. Select **Coordinates** from the **Entry method** list.
3. Enter **x** and **y** (2D) or **x**, **y**, and **z** (3D) coordinates (SI unit: m). You can use a scalar value to represent a fixed value for some of the coordinates.

Method 3: Selecting the Specified Number of Starting Points in the Geometry

1. Under **Streamline Positioning**, from the **Positioning** list, select **Starting-point controlled**.
2. Select **Number of points** from the **Entry method** list.
3. Enter the number of **Points** (the default is 20).
4. From the **Along curve or surface** (3D) or **Along curve** (2D) list, select **None**. The starting points are then distributed semirandomly but deterministically. You can also choose a **Cut Line**, **Cut Plane**, **Parametric Curve**, or **Parametric Surface** dataset, if applicable, to restrict the streamline start positions to a cut line, cut plane, parametric curve, or parametric surface, respectively.

Method 4: Creating Streamlines with Uniform Density

The algorithm saturates the entire domain with evenly spaced streamlines.

1. Under **Streamline Positioning**, from the **Positioning** list, select **Uniform density**.
2. Enter the **Separating distance** between the streamlines (the default is 0.05 in 2D and 0.15 in 3D).

   The value for the separating distance is a fraction of the mean of the lengths of the bounding box of the geometry. In this case, a streamline stops whenever it gets too close to another streamline or itself (or if any of the general termination criteria specified in the **Advanced** section is fulfilled).
3. The **Advanced parameters** list defaults to **Automatic**. If required, select **Manual** to edit these parameters: **Starting distance factor**, **Terminating distance factor**, or **First starting point**.

   - The **Starting distance factor** is a factor multiplied with the distance specified in the **Separating distance** field (as a fraction of the mean of the lengths of the bounding box of the geometry). It sets the minimum distance between streamlines and the starting point for the next streamline.

     When the domain is close to be saturated with streamlines, new starting points tend to be positioned where the streamline has nowhere to go before it gets too close other streamlines, resulting in short streamlines. The higher the value of this factor, the more it disqualifies the starting point and thus reduces the number of short streamlines.
   - The **Terminating distance factor** is a factor multiplied with the distance specified in the **Separating distance** field. It sets the minimum distance between any pair of streamlines. Thus, this distance is the minimal distance under which the integration of a streamline stops. It is possible to make the streamlines extend closer to the boundary by decreasing this factor.
   - By default the **First starting point** list defaults to **Automatic**, and it sets the starting point for the first streamline. It is selected in the element where the highest value of the velocity of the specified vector field occurs. If required, select **Manual** instead to override the default and enter **x** and **y** (2D) or **x**, **y**, and **z** (3D) coordinates.

Method 5: Creating Streamlines with Variable Density and Magnitude Controlled

To create streamlines with a variable density according to the magnitude of the specified vector field:

1 Under **Streamline Positioning**, from the **Positioning** list, select **Magnitude controlled**.

The **Magnitude controlled** setting gives proper streamline plots only for incompressible flow fields. In this case, the algorithm places the streamlines so that the flow between each pair of adjacent streamlines is the same throughout the domain, giving streamlines that are more dense where the magnitude of the field is high.

2 Enter the **Minimum distance** and **Maximum distance** between streamlines (the default **Minimum distance** is 0.025 in 2D and 0.05 in 3D, and the default **Maximum distance** is 0.05 in 2D and 0.15 in 3D). These distances are specified as fractions of the mean of the lengths of the bounding box of the geometry and control what minimum and maximum distances correspond to the minimum and maximum values of the flow magnitude. The minimum velocity in the model is mapped to the minimum distance and the maximum velocity to the maximum distance. Thus every point on a streamline and on the boundary has a separating distance associated with it. Given a set of streamlines, the starting point for the next streamline is selected using these separating distances.

If required, from the **Advanced parameters** list, select **Manual** to set advanced parameters as described in Method 4: Creating Streamlines with Uniform Density.

ADVANCED SECTION SETTING EFFECTS

The **Advanced** settings have the following effects:

- When calculating streamlines, the software selects a set of starting points (controlled by the streamline starting points and the number of starting points).
- The algorithm then finds the vectors of the given vector field at these points by interpolation. It normalizes the vector field if that option is selected.
- The algorithm integrates the points along the direction of the vector using the integration tolerance using a second-order Runge–Kutta algorithm.
- At the new positions, the algorithm finds vector values by interpolation and performs another integration.

This process stops if:

- It reaches a predetermined number of integration steps (controlled by the maximum number of integration steps entry).
- The points end up outside the geometry.
- The points reach a "stationary point" where the vector field is zero. Control the meaning of "zero" with the stationary point stop tolerance.
- It has used a predetermined amount of "time" for integrating (control this parameter with the **Maximum integration time** field).

Finally, the software connects the calculated points for each streamline consecutively with straight lines.

When integrating, the software uses a pseudo-time that has nothing to do with the time in time-dependent problems. Use the massless particle tracing tool to integrate in time-varying fields and to control the real time in stationary fields.

Streamline Multislice

Use a **Streamline Multislice** plot in 3D ( ) to visualize a vector quantity on slices. A streamline is a curve everywhere tangent to an instantaneous vector field. Add Color Expression, Deformation, Export Expressions,

Filter, Material Appearance, Selection (Plot Attribute), Transformation, Transparency, and Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add these plots from the **More Surface Plots** submenu.

	Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Quality**, and **Inherit Style**.

	To get the length of the streamlines, use an **Export** > **Plot** node. In its **Settings** window, select the **Only export starting points and endpoints** checkbox to include one row with the starting point, the endpoint, and the length of the streamline for each streamline.

MULTIPLANE DATA

Under **Multiplane Data**, select an **Entry method** — **Number of planes** or **Coordinates** — for the **x-planes**, **y-planes**, and **z-planes**.

For **Number of planes**, enter the number of planes in the **Planes** field. For **Coordinates**, enter a range of coordinates in the **Coordinates** field.

STREAMLINE POSITIONING

Select one of these options from the **Positioning** list: **Starting-point controlled** (the default), **Uniform density**, or **Magnitude controlled**. Then follow one of the methods described:

- Method 1: Selecting the Specified Number of Starting Points in the Geometry
- Method 2: Creating Streamlines with Uniform Density
- Method 3: Creating Streamlines with Variable Density and Magnitude Controlled

COLORING AND STYLE

In this section you can control the style and color of the streamlines and add points or arrows to them, if desired.

Line Style

Under **Line style**, choose **None**, **Line** (the default), **Ribbon**, or **Tube** from the **Type** list to determine the type of streamlines. If you choose **None**, no streamlines appear, but you can plot arrows that are tangential to the streamlines. If you choose **Ribbon**, then enter an expression for the ribbon width in the **Width expression** field (SI unit: m). If desired, you can also adjust the width by selecting the **Width scale factor** checkbox and enter a scale factor in the corresponding text field.

Point Style

Under **Point style**, you can add points or arrows and control their appearance.

From the **Type** list, choose **None** (the default) for no points or arrows, **Arrow** for static arrows that are tangential to the streamlines, **Interactive arrow** for arrows that are tangential to the streamlines and that can move along the streamlines with the local integration time, or **Interactive point** for points that can move along the streamlines with the local integration time.

If you choose **Arrow**, these additional settings are available:

- From the **Arrow distribution** list, choose **Equal arc length** (the default) to distribute the arrows uniformly over the streamlines' arc length, **Equal time** to distribute the arrows using the weight function $dt/d\text{arc}$, or **Equal inverse time** to distribute the arrows using the weight function $d\text{arc}/dt$.
- Select the **Number of arrows** checkbox to enter a number for the total number of arrows, on all streamlines, that are plotted. By default, the COMSOL Multiphysics software provides a reasonable number of arrows.

If you choose **Interactive arrow**, these additional settings are available:

- Specify a value in the **Local time** field (default: 0) for the local integration time along the streamlines for which the arrows are plotted. It is possible for integration times to be negative: For a starting point in the interior of a domain, streamlines are integrated both forward and backward in time unless you clear the **Allow backward time integration** checkbox in the **Advanced** section.
- You can move the arrows along the local time by moving the slider. You can also create this effect using a player animation in an **Animation** node under **Export**, using a **Streamline** sequence type.
- In the **Extra release times** field, enter any additional times for releasing arrows, or click the **Range** button ( ) to define the extra release times. By default, there are no extra times.

The following settings are available for both the **Arrow** and the **Interactive arrow** types:

- From the **Arrow type** list, choose **Arrowhead** (the default), **Arrow**, or **Cone**.
- From the **Arrow length** list, choose **Normalized** (the default), **Logarithmic**, or **Proportional** to make the arrows' sizes depend on the magnitude of the plotted quantity, if desired. If you choose **Logarithmic**, the length of the arrows is proportional to the natural logarithm of the magnitude of the quantity they represent. This makes arrows representing small values relatively larger. The value in the **Range quotient** field (default: 100) determines the ratio between the smallest and largest values in the range of values for the logarithmic arrow length.
- Use the slider, or select the **Scale factor** checkbox and enter a scale factor in the associated text field if you want to use another scaling than the one used by default.

If you choose **Interactive point**, these following settings are available:

- Specify a value in the **Local time** field (default: 0) for the local integration time along the streamlines for which the points are plotted. It is possible for integration times to be negative: For a starting point in the interior of a domain, streamlines are integrated both forward and backward in time unless you clear the **Allow backward time integration** checkbox in the **Advanced** section.
- You can move the points along the local time by moving the slider. You can also create this effect using a player animation in an **Animation** node under **Export**, using a **Streamline** sequence type.
- In the **Extra release times** field, enter any additional times for releasing points, or click the **Range** button ( ) to define the extra release times. By default, there are no extra times.
- Select or enter an expression for the points' radii in the **Point radius expression** field (SI unit: m). By default, the radius is scaled automatically. To enter a scale factor for the radius, select the **Radius scale factor** checkbox and enter a scale factor in the corresponding text field.
- Select the **Fixed size** checkbox if you want to display the points with a fixed onscreen size.

From the **Color** list, choose a color for the streamlines and arrows. Choose **Custom** to add a custom color using a color palette. Choose **From theme** to use a background color that changes with the selected color theme. This list is not available if you use a **Color Expression** subnode to define the colors for the streamlines.

ADVANCED

Define the following advanced streamline settings as needed.

Advanced Settings for the Streamline Plot

Under **Advanced**, set these general settings. See also Advanced Section Setting Effects.

- The **Integration tolerance** field default is 0.001. Edit to specify how accurately streamlines are computed.
- The **Maximum streamline length** field makes it possible to control the length of streamlines. Edit the default (Inf) to control the streamlines' length. Enter the value as a fraction of the mean bounding box's size. When the **Allow backward time integration** checkbox is selected (the default), the maximum length refers to the sum of the lengths of the forward and backward parts.

- The **Maximum number of integration steps** field makes sure that the integration does not continue indefinitely. Edit the default (5000) to control when the computation stops.
- The **Maximum integration time** field sets an upper time limit for the integration. The default is infinity (Inf).
- The **Stationary point stop tolerance** can be adjusted to make sure the integration stops near a stationary point in the field. The default is 0.01.
- The **Loop tolerance** field default is 0.01. This is a fraction of the mean of the lengths of the bounding box of the geometry. If a streamline gets closer to its starting point than this distance, the streamline snaps to its starting point and is plotted as a connected loop.
- The **Maximum angle threshold** field default value is 0.05 rad. This value, in degrees, is the maximum angle between the stream vector and the slice's normal for its streamlines to be added to the slice. What is plotted in a streamline multislice plot is the projected component of the 3-dimensional streams that pass through the slice, onto the slice. Use this threshold to ignore the streams that are perpendicular to the slice. The value is the threshold angle that determines the perpendicularity.
- Select the **Allow backward time integration** checkbox to integrate points from the starting points both in the direction of the vector field and in the opposite direction. This checkbox is selected by default.
- Select the **Normalize vector field** checkbox if required. The vector field is normalized pointwise: For each point where the field was evaluated, the vector is replaced by a unit vector in the same direction. If you apply normalization, the speed along the streamline changes. This change means that the other settings in the **Advanced** section (for example, maximum number of integration steps and maximum integration time) are interpreted differently.

STREAMLINE POSITIONING SECTION (CONTINUED)

Method 1: Selecting the Specified Number of Starting Points in the Geometry

1. Under **Streamline Positioning**, from the **Positioning** list, select **Starting-point controlled**.
2. Enter the number of **Points** (the default is 20).

Method 2: Creating Streamlines with Uniform Density

The algorithm saturates the entire surface with evenly spaced streamlines.

1. Under **Streamline Positioning**, from the **Positioning** list, select **Uniform density**.
2. Enter the **Separating distance** between the streamlines (the default is 0.05).

   The value for the separating distance is a fraction of the mean of the lengths of the bounding box of the geometry. In this case, a streamline stops whenever it gets too close to another streamline or itself (or if any of the general termination criteria specified in the **Advanced** section is fulfilled).
3. The **Advanced parameters** list defaults to **Automatic**. If required, select **Manual** to edit these parameters: **Starting distance factor** or **Terminating distance factor**.

   - The **Starting distance factor** is a factor multiplied with the distance specified in the **Separating distance** field (as a fraction of the mean of the lengths of the bounding box of the geometry). It sets the minimum distance between streamlines and the starting point for the next streamline.

     When the surface is close to be saturated with streamlines, new starting points tend to be positioned where the streamline has nowhere to go before it gets too close other streamlines, resulting in short streamlines. The higher the value of this factor, the more it disqualifies the starting point and thus reduces the number of short streamlines.
   - The **Terminating distance factor** is a factor multiplied with the distance specified in the **Separating distance** field. It sets the minimum distance between any pair of streamlines. Thus, this distance is the minimal distance under which the integration of a streamline stops.

Method 3: Creating Streamlines with Variable Density and Magnitude Controlled

To create streamlines with a variable density according to the magnitude of the specified vector field:

1 Under **Streamline Positioning**, from the **Positioning** list, select **Magnitude controlled**.

The **Magnitude controlled** setting gives proper streamline plots only for incompressible flow fields. In this case, the algorithm places the streamlines so that the flow between each pair of adjacent streamlines is the same throughout the surface, giving streamlines that are more dense where the magnitude of the field is high.

2 Enter the **Minimum distance** and **Maximum distance** between streamlines (the default **Minimum distance** is 0.025, and the default **Maximum distance** is 0.05). These distances are specified as fractions of the mean of the lengths of the bounding box of the geometry and control what minimum and maximum distances correspond to the minimum and maximum values of the flow magnitude. The minimum velocity in the model is mapped to the minimum distance and the maximum velocity to the maximum distance. Thus every point on a streamline and on the boundary has a separating distance associated with it. Given a set of streamlines, the starting point for the next streamline is selected using these separating distances.

ADVANCED SECTION SETTING EFFECTS

The **Advanced** settings have the following effects:

- When calculating streamlines, the software selects a set of starting points (controlled by the streamline starting points and the number of starting points).
- The algorithm then finds the vectors of the given vector field at these points by interpolation. It normalizes the vector field if that option is selected.
- The algorithm integrates the points along the direction of the vector using the integration tolerance using a second-order Runge-Kutta algorithm.
- At the new positions, the algorithm finds vector values by interpolation and performs another integration.

This process stops if:

- It reaches a predetermined number of integration steps (controlled by the maximum number of integration steps entry).
- The points end up outside the geometry.
- The points reach a "stationary point" where the vector field is zero. Control the meaning of "zero" with the stationary point stop tolerance.
- It has used a predetermined amount of "time" for integrating (control this parameter with the **Maximum integration time** field).

Finally, the software connects the calculated points for each streamline consecutively with straight lines.

When integrating, the software uses a pseudo-time that has nothing to do with the time in time-dependent problems. Use the massless particle tracing tool to integrate in time-varying fields and to control the real time in stationary fields.

Streamline Surface

Use a **Streamline Surface** plot in 3D ( ) to visualize a vector quantity on surfaces. A streamline is a curve everywhere tangent to an instantaneous vector field. Add Color Expression, Deformation, Export Expressions,

Filter, Material Appearance, Transformation, Transparency, or Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add these plots from the **More Surface Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Quality**, and **Inherit Style**.

To get the length of the streamlines, use an **Export** > **Plot** node. In its **Settings** window, select the **Only export starting points and endpoints** checkbox to include one row with the starting point, the endpoint, and the length of the streamline for each streamline.

SURFACE SELECTION

In this section, select the surfaces on which to compute and plot the streamlines (the selected surfaces are not the boundaries where the streamlines should start). By selecting in the **Graphics** window and using the tools in the **Surface Selection** section, select the boundaries (surfaces) on which you want to plot streamlines.

STREAMLINE POSITIONING

Select one of these options from the **Positioning** list: **On selected edges**, **Starting-point controlled** (the default), **Uniform density**, or **Magnitude controlled**. Then follow one of the methods described:

- Method 1: Specifying the Number of Streamlines and Start Edges
- Method 2: Specifying Points by Entering Coordinates
- Method 3: Selecting the Specified Number of Starting Points in the Geometry
- Method 4: Creating Streamlines with Uniform Density
- Method 5: Creating Streamlines with Variable Density and Magnitude Controlled

EDGE SELECTION

The **Edge Selection** section is available for some datasets when you select **On selected edges** from the **Positioning** list under **Streamline Positioning**.

Select the edges from which the streamlines start. By selecting in the **Graphics** window and using the tools in the **Selection** section, select the edges for the starting positions for the streamlines.

COLORING AND STYLE

In this section you can control the style and color of the streamlines and add points or arrows to them, if desired.

Line Style

Under **Line style**, choose **None**, **Line** (the default), **Ribbon**, or **Tube** from the **Type** list to determine the type of streamlines. If you choose **None**, no streamlines appear, but you can plot arrows that are tangential to the streamlines. If you choose **Ribbon**, then enter an expression for the ribbon width in the **Width expression** field (SI unit: m). If desired, you can also adjust the width by selecting the **Width scale factor** checkbox and enter a scale factor in the corresponding text field.

Point Style

Under **Point style**, you can add points or arrows and control their appearance.

From the **Type** list, choose **None** (the default) for no points or arrows, **Arrow** for static arrows that are tangential to the streamlines, **Interactive arrow** for arrows that are tangential to the streamlines and that can move along the

streamlines with the local integration time, or **Interactive point** for points that can move along the streamlines with the local integration time.

If you choose **Arrow**, these additional settings are available:

- From the **Arrow distribution** list, choose **Equal arc length** (the default) to distribute the arrows uniformly over the streamlines' arc length, **Equal time** to distribute the arrows using the weight function $dt/d\text{arc}$, or **Equal inverse time** to distribute the arrows using the weight function $d\text{arc}/dt$.
- Select the **Number of arrows** checkbox to enter a number for the total number of arrows, on all streamlines, that are plotted. By default, the COMSOL Multiphysics software provides a reasonable number of arrows.

If you choose **Interactive arrow**, these additional settings are available:

- Specify a value in the **Local time** field (default: 0) for the local integration time along the streamlines for which the arrows are plotted. It is possible for integration times to be negative: For a starting point in the interior of a domain, streamlines are integrated both forward and backward in time unless you clear the **Allow backward time integration** checkbox in the **Advanced** section.
- You can move the arrows along the local time by moving the slider. You can also create this effect using a player animation in an **Animation** node under **Export**, using a **Streamline** sequence type.
- In the **Extra release times** field, enter any additional times for releasing arrows, or click the **Range** button ( ) to define the extra release times. By default, there are no extra times.

The following settings are available for both the **Arrow** and the **Interactive arrow** types:

- From the **Arrow type** list, choose **Arrowhead** (the default), **Arrow**, or **Cone**.
- From the **Arrow length** list, choose **Normalized** (the default), **Logarithmic**, or **Proportional** to make the arrows' sizes depend on the magnitude of the plotted quantity, if desired. If you choose **Logarithmic**, the length of the arrows is proportional to the natural logarithm of the magnitude of the quantity they represent. This makes arrows representing small values relatively larger. The value in the **Range quotient** field (default: 100) determines the ratio between the smallest and largest values in the range of values for the logarithmic arrow length.
- Use the slider, or select the **Scale factor** checkbox and enter a scale factor in the associated text field if you want to use another scaling than the one used by default.

If you choose **Interactive point**, these following settings are available:

- Specify a value in the **Local time** field (default: 0) for the local integration time along the streamlines for which the points are plotted. It is possible for integration times to be negative: For a starting point in the interior of a domain, streamlines are integrated both forward and backward in time unless you clear the **Allow backward time integration** checkbox in the **Advanced** section.
- You can move the points along the local time by moving the slider. You can also create this effect using a player animation in an **Animation** node under **Export**, using a **Streamline** sequence type.
- In the **Extra release times** field, enter any additional times for releasing points, or click the **Range** button ( ) to define the extra release times. By default, there are no extra times.
- Select or enter an expression for the points' radii in the **Point radius expression** field (SI unit: m). By default, the radius is scaled automatically. To enter a scale factor for the radius, select the **Radius scale factor** checkbox and enter a scale factor in the corresponding text field.
- Select the **Fixed size** checkbox if you want to display the points with a fixed onscreen size.

From the **Color** list, choose a color for the streamlines and arrows. Choose **Custom** to add a custom color using a color palette. Choose **From theme** to use a background color that changes with the selected color theme. This list is not available if you use a **Color Expression** subnode to define the colors for the streamlines.

ADVANCED

Define the following advanced streamline settings as needed.

Advanced Settings for the Streamline Plot

Under **Advanced**, set these general settings. See also Advanced Section Setting Effects.

- The **Integration tolerance** field default is 0.001. Edit to specify how accurately streamlines are computed.
- The **Maximum streamline length** field makes it possible to control the length of streamlines. Edit the default (Inf) to control the streamlines' length. Enter the value as a fraction of the mean bounding box's size. When the **Allow backward time integration** checkbox is selected (the default), the maximum length refers to the sum of the lengths of the forward and backward parts.
- The **Maximum number of integration steps** field makes sure that the integration does not continue indefinitely. Edit the default (5000) to control when the computation stops.
- The **Maximum integration time** field sets an upper time limit for the integration. The default is infinity (inf).
- The **Stationary point stop tolerance** can be adjusted to make sure the integration stops near a stationary point in the field. The default is 0.01.
- The **Loop tolerance** field default is 0.01. This is a fraction of the mean of the lengths of the bounding box of the geometry. If a streamline gets closer to its starting point than this distance, the streamline snaps to its starting point and is plotted as a connected loop.
- Select the **Allow backward time integration** checkbox to integrate points from the starting points both in the direction of the vector field and in the opposite direction. This checkbox is selected by default.
- Select the **Normalize vector field** checkbox if required. The vector field is normalized pointwise: For each point where the field was evaluated, the vector is replaced by a unit vector in the same direction. If you apply normalization, the speed along the streamline changes. This change means that the other settings in the **Advanced** section (for example, maximum number of integration steps and maximum integration time) are interpreted differently.

STREAMLINE POSITIONING SECTION (CONTINUED)

Method 1: Specifying the Number of Streamlines and Start Edges

1 Under **Streamline Positioning**, from the **Positioning** list, select **On selected edges**.

The **Edge Selection** section is made available for some datasets when **On selected edges** is selected from the **Positioning** list under **Streamline Positioning**.

2 Under **Edge Selection**, select the edges from which the streamlines start. By selecting in the **Graphics** window and using the tools in the **Selection** section, select the edges for the starting positions for the streamlines.

3 From the **Point distribution** list, choose **Uniform** (the default) or **Mesh based**, to place the starting points in the barycenters of edge elements.

Enter the **Number** of streamlines (the default is 20), if **Point distribution** is **Uniform**. This number is a suggestion for how many streamlines are generated, but there is no guarantee that you get exactly the specified number of streamlines. The reason is that the streamline starting points are placed in a regular grid on the selected edges. If **Point distribution** is **Mesh based**, you can instead specify a refinement as a positive integer (default: 1) in the **Element refinement** field.

Method 2: Specifying Points by Entering Coordinates

1 Under **Streamline Positioning**, from the **Positioning** list, select **Starting-point controlled**.

2 Select **Coordinates** from the **Entry method** list.

3 Enter **x**, **y**, and **z** coordinates (SI unit: m). You can use a scalar value to represent a fixed value for some of the coordinates.

Method 3: Selecting the Specified Number of Starting Points in the Geometry

1 Under **Streamline Positioning**, from the **Positioning** list, select **Starting-point controlled**.

2 Select **Number of points** from the **Entry method** list.

3 Enter the number of **Points** (the default is 20).

4 From the **Along curve** list, select **None**. The starting points are then distributed semirandomly but deterministically. You can also choose a **Cut Line3D** or **Parametric Curve 3D** dataset, if applicable, to restrict the streamline start positions to a cut line or parametric curve, respectively.

Method 4: Creating Streamlines with Uniform Density

The algorithm saturates the entire surface with evenly spaced streamlines.

1 Under **Streamline Positioning**, from the **Positioning** list, select **Uniform density**.

2 Enter the **Separating distance** between the streamlines (the default is 0.05).

The value for the separating distance is a fraction of the mean of the lengths of the bounding box of the geometry. In this case, a streamline stops whenever it gets too close to another streamline or itself (or if any of the general termination criteria specified in the **Advanced** section is fulfilled).

3 The **Advanced parameters** list defaults to **Automatic**. If required, select **Manual** to edit these parameters: **Starting distance factor** or **Terminating distance factor**.

- The **Starting distance factor** is a factor multiplied with the distance specified in the **Separating distance** field (as a fraction of the mean of the lengths of the bounding box of the geometry). It sets the minimum distance between streamlines and the starting point for the next streamline.

  When the surface is close to be saturated with streamlines, new starting points tend to be positioned where the streamline has nowhere to go before it gets too close other streamlines, resulting in short streamlines. The higher the value of this factor, the more it disqualifies the starting point and thus reduces the number of short streamlines.

- The **Terminating distance factor** is a factor multiplied with the distance specified in the **Separating distance** field. It sets the minimum distance between any pair of streamlines. Thus, this distance is the minimal distance under which the integration of a streamline stops.

Method 5: Creating Streamlines with Variable Density and Magnitude Controlled

To create streamlines with a variable density according to the magnitude of the specified vector field:

1 Under **Streamline Positioning**, from the **Positioning** list, select **Magnitude controlled**.

The **Magnitude controlled** setting gives proper streamline plots only for incompressible flow fields. In this case, the algorithm places the streamlines so that the flow between each pair of adjacent streamlines is the same throughout the surface, giving streamlines that are more dense where the magnitude of the field is high.

2 Enter the **Minimum distance** and **Maximum distance** between streamlines (the default **Minimum distance** is 0.025, and the default **Maximum distance** is 0.05). These distances are specified as fractions of the mean of the lengths of the bounding box of the geometry and control what minimum and maximum distances correspond to the minimum and maximum values of the flow magnitude. The minimum velocity in the model is mapped to the minimum distance and the maximum velocity to the maximum distance. Thus every point on a streamline and on the boundary has a separating distance associated with it. Given a set of streamlines, the starting point for the next streamline is selected using these separating distances.

ADVANCED SECTION SETTING EFFECTS

The **Advanced** settings have the following effects:

- When calculating streamlines, the software selects a set of starting points (controlled by the streamline starting points and the number of starting points).
- The algorithm then finds the vectors of the given vector field at these points by interpolation. It normalizes the vector field if that option is selected.
- The algorithm integrates the points along the direction of the vector using the integration tolerance using a second-order Runge-Kutta algorithm.
- At the new positions, the algorithm finds vector values by interpolation and performs another integration.

This process stops if:

- It reaches a predetermined number of integration steps (controlled by the maximum number of integration steps entry).
- The points end up outside the geometry.
- The points reach a "stationary point" where the vector field is zero. Control the meaning of "zero" with the stationary point stop tolerance.
- It has used a predetermined amount of "time" for integrating (control this parameter with the **Maximum integration time** field).

Finally, the software connects the calculated points for each streamline consecutively with straight lines.

When integrating, the software uses a pseudo-time that has nothing to do with the time in time-dependent problems. Use the massless particle tracing tool to integrate in time-varying fields and to control the real time in stationary fields.

Surface (Plot)

Use a **Surface** plot to display a quantity on a domain in 2D ( ) or on a boundary in 3D ( ). Add Deformation, Filter, Image (Plot Attribute), Marker, Material Appearance, Selection (Plot Attribute), Transformation, Transparency (3D and 2D with a Height Expression), Visual Effects (3D and 2D with a Height Expression), or Height Expression (2D only) subnodes as needed. Right-click a **2D Plot Group** or **3D Plot Group** to add a **Surface** plot. It is possible to use data from a 2D dataset to create an embedded surface plot in 3D, on the xy-plane at $z = 0$. You can also create a **Surface** plot from the **Evaluation Group** contextual ribbon toolbar for plotting an evaluation group.

- Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Range**, **Coloring and Style**, **Quality**, and **Inherit Style**.
- 2D Plot Group and 3D Plot Group
- Plot Groups and Plots

Surface Data

A **Surface Data** plot node appears in 2D ( ) and 3D ( ) plot groups if you run a method that creates a `SurfaceData` plot. Add Marker, Material Appearance, Transparency (3D only) and Visual Effects (3D only) subnodes as needed.

It is not possible to add a **Surface Data** node from the model tree or toolbars in the COMSOL Desktop. It is only available from the COMSOL Multiphysics API and if you run a method from the **Developer** toolbar. See SurfaceData in the *COMSOL Multiphysics Programming Reference Manual*.

DATA

In the **Data** section, the number of points in the data and the number of triangles in the plot are listed.

Go to Common Results Node Settings for a link to information about the **Title**, **Range**, and **Coloring and Style** sections.

Surface Slit

Use a **Surface Slit** plot to display a quantity that is the result of evaluating one expression on one side and another expression on the other side of a boundary in 3D ( ). When you add an expression to plot as a surface slit plot, and it is possible to evaluate it in the surrounding domains, you can use the `up` and `down` operators (see up and down) on each side of the boundary to evaluate an expression's values on the upside and downside, respectively.

Add Deformation, Filter, Marker,Material Appearance, Selection (Plot Attribute), Transformation, Transparency, and Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add a **Surface Slit** plot from the **More Surface Plots** submenu.

- Go to Common Results Node Settings for links to information about these sections: **Data**, **Title**, **Range**, **Coloring and Style**, **Quality**, and **Inherit Style**. From the **Dataset** list, only Solution, Surface, and Mesh datasets are available.
- 2D Plot Group and 3D Plot Group
- Plot Groups and Plots

EXPRESSION ON THE UPSIDE

See Expressions and Predefined Quantities for information about the settings for defining an expression to plot on the upside of the boundary.

EXPRESSION ON THE DOWNSIDE

See Expressions and Predefined Quantities for information about the settings for defining another expression to plot on the downside of the boundary.

For exterior boundaries, the upside is the side toward the outside of the geometry. For interior boundaries, see Tangent and Normal Variables.

If your license includes the Electrodeposition Module, see the following model for an example of the use of Surface Slit plots: *Electrocoating of a Car Door*: Application Library path **Electrodeposition_Module/Tutorials/car_door**.

Table Annotation

Add a **Table Annotation** ( ) plot to add annotations from a table to a plot. Right-click a **1D Plot Group**, **2D Plot Group**, or **3D Plot Group** to add this plot type. First define a table to plot. This plot is also available from the plot groups' contextual ribbon toolbars, under **More Point Plots** (3D and 2D) or **More Plots** (1D). Add Transparency to Visual Effects subnodes if needed (3D only).

Go to Common Results Node Settings for links to information about the **Title** and **Inherit Style** sections.

DATA

From the **Source** list, choose **Table** (the default), **Evaluation group**, or **Local table**. For the two first options, then choose a table or evaluation group table with the data that you want to use for annotations from the **Table** or **Evaluation group** list below. Then, from the **x-coordinates**, **y-coordinates**, and **z-coordinates** (3D only) lists select the columns to use for the x-coordinates, y-coordinates, and z-coordinates, respectively: Select **Row index** to use the table's row indexes (row numbers), or leave it at **Automatic** to let the software determine the input from the data in the table.

If you choose **Local table** from the Source list, a table appear where you can define the annotations by adding rows with coordinates in the **x-coordinate**, **y-coordinate**, and **z-coordinate** (3D only) columns and the corresponding annotations in the **Annotation** column.

When done, click the **Plot** button ( ) to plot the table annotations.

COLORING AND STYLE

The **Show point** checkbox is selected to show a point for the location of the data in the table.

From the **Color** list, select **From theme** (the default) or select one of the available colors. Select **Custom** to define a custom color.

From the **Background color** list, select **None** (the default) for no background color, **From theme** (the default) or select one of the available colors. Select **Custom** to define a custom color.

From the **Anchor point** list, select an anchor point for the annotation: **Upper left** (the default), **Upper right**, **Upper middle**, **Middle right**, **Center**, **Middle left**, **Lower right**, **Lower middle**, or **Lower left**.

From the **Orientation** list, choose **Horizontal** (the default) or **Vertical** for a vertically oriented annotation.

Select the **Show frame** checkbox to display a frame around the annotation.

Select the **Relative padding** checkbox to add optional padding to the annotation in the **x padding**, **y padding**, and **z padding** (when available) fields. The values for the padding are relative. The default value, 0.1, means a padding that is 10% of the bounding box for the annotation.

Table Contour

Add a **Table Contour** ( ) plot to display data from a table as a contour plot. Right-click a **2D Plot Group** to add this plot type. First define a table to plot. This plot is also available from the plot groups' contextual ribbon toolbar by

selecting **Table Contour** from the **More Surface Plots** menu. Add Height Expression, Marker, Material Appearance, and Transparency and Visual Effects (only if Height Expression is used) subnodes if required.

Go to Common Results Node Settings for links to information about these sections: **Title**, **Levels**, **Quality**, **Inherit Style**, and, except for some details below, **Coloring and Style**.

DATA

From the **Source** list, choose **Table** or **Evaluation** group, and then choose a table or evaluation group table with the data that you want to plot as a contour plot from the **Table** or **Evaluation** group list below.

From the **Data format** list, select one of the following formats for interpreting the table data:

- Select **Filled table** if the data is structurally filled (for tables only; this option is not available for evaluation groups). See Filled Table for additional settings for this data format.
- Select **Columns** (the default) if you want to specify what columns to take the data from. See Columns for additional settings for this format.
- Select **Cells** to treat the tables data as cells in a matrix and use the table row and column numbers as the x- and y-coordinates, respectively. There are no additional settings for this format.

Filled Table

Select an option from the **Plot data** list: **From table** (the default) or **Manual**. If **Manual** is selected, select options from the **x-axis data** and **y-axis data** lists, which contain the parameters that define the rows and columns for the table's matrix data, and from the **Data** list, which corresponds to the **Data** list in the **Table** node for the data. If there are additional parameters in a parametric sweep, they need to be kept at fixed values, which you select from the **Parameter value** list, which contains all combinations of parameter values for the parameters that are not used as x-axis or y-axis data.

Columns

From the **x-axis column**, **y-axis column**, and **Data column** lists, choose the columns to use for the x-axis, y-axis, and the data, respectively.

For all data formats, select the **Plot imaginary part** checkbox if you want to plot the imaginary part of complex-valued data. For real-valued data, that plot shows a zero imaginary part.

PREPROCESSING

This section contains settings to preprocess the data in the table contour plot by scaling and shifting the data values, which can be useful to match data from different sources or to scale some data to express the values in another unit, for example.

Under **x-axis column** and **y-axis column**, from the **Preprocessing** list select:

- **None** (the default), for no preprocessing of the data.
- **Linear**, to preprocess the data using a linear transformation of the data values for the x- or y-axis column. You define the linear preprocessing with values for the scaling (default: 1) and the shift or offset (default: 0) in the **Scaling** and **Shift** fields, respectively. The default values do not change the original data values.

COLORING AND STYLE

Select a **Contour type**: **Line** (the default) or **Filled**. Using filled contours creates a plot with color banding rather than isolated contour lines or tubes when using the other contour types.

- If **Line** is selected, you can also select the **Level labels** checkbox to display line labels on the graph.
- If **Filled** is selected, you can also clear the **Fill surfaces outside of contour levels** checkbox (selected by default) to not fill the areas of the geometry's surface that are above the highest and below the lowest contour.

If you select to display level labels (not available for filled contours), select the **Level labels** checkbox and specify the precision (number of significant digits) as a positive integer in the **Precision** field (default: 4). You can also choose a color for the labels from the **Label color** list: Choose **From theme** to use the color from the color theme, choose **Custom** to define a custom color, or choose any of the predefined colors.

For coloring the contours, select one of the following options from the **Coloring** list:

- Select **Color table** (the default) to color the contours using a color table that you choose from the **Color table** list below.
- Select **Uniform** to use a predefined uniform color, or select **Custom** to define a custom color from the colored list below (on Windows) or by clicking the **Color** button (on Linux and macOS) and then selecting a color from the color palette.
- Select **Gradient** to specify the coloring as a gradient between two colors, which you specify using the **Top color** and **Bottom color** lists.

Choose a color table for the isosurfaces from the **Color table** list.

The **Color legend** checkbox is selected by default. Clear it to remove the color legend. Select the **Reverse color table** or **Reverse color gradient** checkboxes as required.

From the **Scale** list, choose **Linear** (the default), **Linear symmetric**, or **Logarithmic** to scale the color legend.

For information about the **Legend type** list, see Legend Type.

Table Graph

Add a **Table Graph** ( ) plot to display data from a table with one line per output column. Right-click a **1D Plot Group**, **Polar Plot Group**, or **Smith Plot Group** to add this plot type. First define a table to plot. This plot is also available from the plot groups' contextual ribbon toolbars, by clicking **Graph Plot** on the **Evaluation Group** contextual ribbon toolbar (to plot the evaluation group in graph plot), or by selecting **Table Graph** ( ) from the **Table** window's toolbar. If desired, right-click the **Table Graph** node to add a **Graph Marker**, **Filter**, or **Error Bars** subnode.

Go to Common Results Node Settings for links to information about the **Coloring and Style** section.

Conditional Exclusion of Data Points from Table Graphs

Consider cases, with or without a **Comparison** subnode, where the COMSOL simulation and the reference values in the table graph have a different x- or y-axis range. Limiting the range of the table graph plot to coincide with

the range of the COMSOL simulation plot can make it easier to interpret the plots. You can do so using two different methods:

- Use the **Preprocessing** section (see below) in a **Table Graph** plot to scale and shift the values in the table, something that can be used to perform unit conversions. It is also possible to restrict the x- and y-axis ranges of the data.
- Add a **Filter** subnode to perform more general filtering of the table data than what is supported by the **Preprocessing** section. You can for example, filter data in Column 1 to values between 0 and 100 using an expression like `(col1>=0) && (col1<=100)`.

DATA

From the **Source** list, choose **Table** or **Evaluation group**, and then choose a table or evaluation group table with the data that you want to plot as a surface plot from the **Table** of **Evaluation group** list below. The list of tables includes Comparison tables, if **Comparison** subnodes have been used under some 1D graph plots (see Comparison).

If the table data refers to a row-based table (that is, a table with data on rows and sample points on columns), select the **Row-based** checkbox to specify row-based plotting of the table data.

From the **x-axis data** list (or θ **angle data** for polar plots), select the column to use as x-axis: Select **Row index** to use the table's row indexes (row numbers) as x-axis, or leave it at **Automatic** to let the software determine the input from the data in the table.

The **Plot columns** or **Plot rows** (depending on if the **Row-based** checkbox is selected or not) list controls which columns or rows to plot. **All excluding x-axis** (or **All excluding** θ **angle list** for polar plots) indicates all columns not used in **x-axis data** (or θ **angle data**). Select **Manual** instead to specify which columns to plot in the **Columns** or **Rows** list.

If available, select a **Transformation** of the data from the table — **None** (the default) to use the data directly without any transformation, or select **Discrete Fourier transform** to use a discrete Fourier transform (DFT) to transform the data from a time-dependent solution to the frequency domain. If you select to display a DFT, choose one of the following options from the **Show** list:

- **Real part**, to show the real part of the output only.
- **Imaginary part**, to show the imaginary part of the output only.
- **Amplitude**, to show the amplitude of the output (the default).
- **Phase**, to show the phase of the output.
- **Frequency spectrum**, to display the function's frequency spectrum by computing the number of frequencies and the frequency range based on the FFT (fast Fourier transform) of the function. The transform is valid for all functions, but what you get corresponds to a periodic continuation of the function outside the chosen bounds. To specify these values manually, select the **Number of frequencies** checkbox and enter a value in the associated field (the default is based on the number of time samples). From the **Scale** list, choose **None** (the default), **Multiply by sampling point**, or **Divide by number of frequencies**. You can choose to scale with the sampling period to show Fourier transform values instead of a pure DFT transform. Select the **Scale** checkbox to scale the values on the y-axis so that their magnitude reflects the magnitude of the original signal. The values then have the same unit as the input data for the FFT. For a pure sinusoid, the scaled value is the peak magnitude divided by the square root of 2 ($u_{\max}/\sqrt{2}$). Select the **Frequency range** checkbox and then enter the bounds of the frequency range in the **Minimum** and **Maximum** fields (in Hz). The FFT algorithm uses resampling based on linear interpolation. The x-axis shows the frequency (in Hz). By default, the y-axis shows the unscaled Fourier coefficients.

  If you have selected **Amplitude** or **Frequency spectrum**, you can select the **In dB** checkbox to present the values in dB. From the **dB type** list, choose **10log** (the default) or **20log**. The display in dB requires a reference value. From

the dB reference list, choose **Maximum** (the default) to use the maximum value as the reference, or choose **Manual** to enter a suitable reference value in the **Reference value** field.

If you have selected **Real part**, **Imaginary part**, **Amplitude**, or **Phase**, the following additional settings are available: To specify this value manually, select the **Number of uniform samples** checkbox and enter a value in the associated field. If desired, select the **Inverse transform** checkbox to use an inverse DFT. Select the **Mask DC** checkbox to set the DC value (zero frequency component) to zero (not available if **Inverse transform** is selected). The **Ignore last sample** checkbox is selected by default to not include the last sample in the transform (not available if **Inverse transform** is selected). The **Shift zero frequency** and **Scale with sampling period** checkboxes are selected by default. Clear one or more of these checkboxes if you want to exclude those steps.

If you have chosen **None** from the **Transformation** list, use the **Sorting** list to sort the data points with respect to x- or y-coordinates. Choose **None** (the default, no sorting), **x-axis data**, or **y-axis data**.

By default, table plots only display the real data in a table, just as other plot types display real data unless you use the `imag` function in the expression. To display the imaginary part of complex-valued data in a table, when available, select the **Plot imaginary part** checkbox. This option is only available when a transformation to the frequency domain is not used.

In the settings for a **Smith Plot Group**, this section includes a **Data interpretation** list, where you can choose **Reflection** (the default), **Impedance**, or **Admittance**.

Y-AXIS

This section is only available if the **Two y-axes** checkbox is selected in the **Plot Settings** section of the parent **1D Plot Group** node's **Settings** window.

Select the **Plot on secondary y-axis** checkbox to plot the y-axis data on the secondary y-axis to the right of the plot instead of the primary y-axis to the left of the plot.

PREPROCESSING

This section contains settings to preprocess the data in the table graph by scaling and shifting the data values, which can be useful to match data from different sources or to scale some data to express the values in another unit, for example.

Under **x-axis column** and **y-axis column**, you can use the following settings for preprocessing of the table data:

From the **Transform** list select:

- **None** (the default), for no preprocessing of the data.
- **Linear**, to preprocess the data using a linear transformation of the data values for the x- or y-axis column. You define the linear preprocessing with values for the scaling (default: 1) and the shift or offset (default: 0) in the **Scaling** and **Shift** fields, respectively. The default values do not change the original data values.

From the **Range** list select:

- **All** (the default), to use the range for all data.
- **Manual**, to specify range limits in the **x minimum** and **x maximum** fields, for the x-axis column, and the **y minimum** and **y maximum** fields, for the y-axis column. The default values for the minimum and maximum fields are –Inf and Inf, respectively.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label** and **Headers** checkboxes to control what to include in the automatic legends (by default it includes the column headers only). You can add a prefix or a suffix to the automatic legend text in the **Prefix** and **Suffix** fields. If **Manual** is selected from the **Legends** list, enter your own legend text into the table.

Filter for Table Graph

You can right-click a Table Graph plot node to add a **Filter** subnode ( ), which controls which columns or rows in the table to include. The **Filter** node has the following section:

POINT SELECTION

Under **Point Selection**, enter the columns (for column-based table data) or rows (for row-based table data) to include in the table graph in the **Logical expression for inclusion** field. You enter them as comma-separated entries such as *col1*, *col2*, … for column-based table data. In the **Logical expression for inclusion** field, you can also use `rowindex` to refer to the row index (for example, in a Boolean expression like `mod(rowindex,3)!=0`) with column-based table data and, similarly, `colindex` to refer to the column index with row-based table data.

Table Histogram

Use a **Table Histogram** node in 1D ( ) or 2D ( ) to plot a histogram that shows how a quantity is distributed over the geometry (mesh volume) based on data from a table or evaluation group. In 1D histograms, the x-axis in the histogram represents the values of the quantity (as a number of bins or a range of values), and the y-axis represents the count of the total element volume in each interval. You can also view the histogram as a plot showing the area between contours or isosurfaces. In 2D histograms, the x-axis and y-axis represent the values of two quantities (as a number of bins or a range of values), and the color surface represents the count of the total element volume in each "bin". The histogram can be normalized and also displayed as a cumulative plot, and it can appear as a discrete or a continuous function. You can use a histogram with settings that provide a bar chart of, for example, the distribution of values in different ranges. To add a table histogram, right-click a **1D Plot Group** or **2D Plot Group** and select this plot from the **More Plots** or **More Point Plots** submenu, respectively. Add Height Expression (2D only), Transparency (with Height Expression only), and Visual Effects (with Height Expression only) subnodes if required.

- Go to Common Results Node Settings for links to information about these sections: **Title**, and **Coloring and Style**.
- For a 2D histogram based on a precomputed matrix of data, see Matrix Histogram.

DATA

From the **Source** list choose **Table** or **Evaluation** as the data source. Depending on the chose type of data source, choose a table or an evaluation group from the **Table** list or **Evaluation group** list, respectively.

From the **x-coordinate** and **y-coordinate** (2D only) lists, choose one of the table columns as the coordinate.

BINS

Select an **Entry method** — **Number of bins** or **Limits** — to define the bins for the histogram's x-axis. Select **Number of bins** (the default) to specify the number of bins (default is 10), or select **Limits** to specify a range of limits (`1 2 3 4`, for example) for the histogram bins.

For 2D Histogram nodes, these settings are available for the x direction and y direction under **x bins** and **y bins**.

OUTPUT

Under **Output**, specify some properties for the appearance of the histogram. Specify whether to use a continuous or discrete function for the histogram, the normalization, and whether to use a standard or a cumulative histogram.

From the **Function** list, select **Continuous** (the default) to plot the histogram as a continuous function or **Discrete** to plot it as a discrete function (that is, using a constant level in each bin). The discrete version is useful to display the histogram as a bar chart, perhaps with the **Integral** normalization setting so that each bin (bar) shows its relative size and the **Type** set to **Solid** under **Coloring and Style** for filled histogram bins.

From the **Normalization** list, select:

- **Sum of values** to normalize the histogram so that the integral is equal to 1 by dividing the absolute count of each bin by the sum of the counts over all bins. Use this normalization to get the relative size (percentage) of values in each bin.
- **Integral** to normalize the histogram by dividing the absolute count of each bin by the sum of the counts over all bins, each multiplied by the width of the bin.
- **None** (the default) to show the actual element volume without any normalization.
- **Peak** to normalize the histogram so that the peak value is equal to 1.

Select the **Cumulative** checkbox to make the histogram cumulative (that is, the value in each bin is the sum of the values for all bins up to the current one).

Table Point

Use a **Table Point** ( ) to plot the points in a table. Right-click a **2D Plot Group** to add this plot type from the **More Point Plots** submenu. This plot is also available by selecting **Table Point** ( ) from the **Table** window's toolbar. If desired, right-click the **Table Point** node to add a Marker subnode.

Go to Common Results Node Settings for links to information about these sections: **Title**, **Range**, **Coloring and Style**, and **Inherit Style**.

DATA

From the **Source** list, choose **Table** or **Evaluation group**, and then choose a table or evaluation group table with the data that you want to plot as a point plot from the **Table** or **Evaluation group** list below.

From the **Data format** list, select one of the following formats for interpreting the table data:

- Select **Filled table** if the data is structurally filled (for tables only; this option is not available for evaluation groups). See Filled Table for additional settings for this data format.
- Select **Columns** (the default) if you want to specify what columns to take the data from. See Columns for additional settings for this format.
- Select **Cells** to treat the tables data as cells in a matrix and use the table row and column numbers as the x- and y-coordinates, respectively. There are no additional settings for this format.

Filled Table

Select an option from the **Plot data** list: **From table** (the default) or **Manual**. If **Manual** is selected, select options from the **x-axis data** and **y-axis data** lists, which contain the parameters that define the rows and columns for the table's matrix data, and from the **Data** list, which corresponds to the **Data** list in the **Table** node for the matrix data. If there are additional parameters in a parametric sweep, they need to be kept at fixed values, which you select from the **Parameter value** list, which contains all combinations of parameter values for the parameters that are not used as x-axis or y-axis data.

Columns

From the **x-axis column**, **y-axis column**, and **Data column** lists, choose the columns to use for the x-axis, y-axis, and the data, respectively.

For all data formats, select the **Plot imaginary part** checkbox if you want to plot the imaginary part of complex-valued data. For real-valued data, that plot shows a zero imaginary part.

PREPROCESSING

This section contains settings to preprocess the data in the table point plot by scaling and shifting the data values, which can be useful to match data from different sources or to scale some data to express the values in another unit.

Under **x-axis column**, **y-axis column**, and **Data column**, from the **Transformation** list select:

- **None** (the default), for no preprocessing of the data.
- **Linear**, to preprocess the data using a linear transformation of the data values for the x- or y-axis column or the data column. You define the linear preprocessing with values for the scaling (default: 1) and the shift or offset (default: 0) in the **Scaling** and **Shift** fields, respectively. The default values do not change the original data values.

Table Surface

Use a **Table Surface** ( ) plot to visualize the data in a table that represents a matrix of values that are functions of two independent parameters (for example, as a response surface plot). See Creating a Surface Plot of Values as Functions of Two Parameters below. Right-click a **2D Plot Group** to add this plot type from the **More Surface Plots** submenu. This plot is also available by selecting **Table Surface** ( ) from the **Table** window's toolbar. If desired, right-click the **Table Surface** node to add Height Expression, Marker, Material Appearance, Transparency (with Height Expression only), and Visual Effects (with Height Expression only) subnodes.

	Go to Common Results Node Settings for links to information about these sections: **Title**, **Range**, **Coloring and Style**, and **Inherit Style**.

	When created from the **Table** window toolbar, the 2D plot group with the **Table Surface** plot uses **None** in the **Dataset** selection. When you add a Table Surface plot to an existing or new 2D plot group, the dataset is typically a solution dataset, and the plot group includes a plot of the dataset edges. This can make the table surface plot hard to see because it uses parameter values on the x- and y-axis and not the 2D geometry's dimension.

Creating a Surface Plot of Values as Functions of Two Parameters

Follow these steps to create a surface plot of values of some quantity as a function of two parameters, where you vary two parameters in a parametric sweep while keeping the other parameters fixed:

1. In the **Study** branch, add a **Parametric Sweep** ( ) node.
2. In the **Settings** window for **Parametric Sweep**, add the parameters that you want to sweep to the parameter list.
3. Select **All combinations** from the **Sweep type** list to get a full parametric sweep of all parameter values.
4. Solve the model.
5. Add a **Point Evaluation** ( ) node under **Derived Values**, select a point where you want to evaluate the solution data, and click **Evaluate**. A table is created.
6. In the **Table** window, click the **Table Surface** ( ) button.
7. In the **2D Plot Group**, select the **Table Surface** node. In its **Settings** window you can select which parameter to plot on the x-axis and on the y-axis, and which values you want to select as fixed for the other parameters.

DATA

From the **Source** list, choose **Table** or **Evaluation group**, and then choose a table or evaluation group table with the data that you want to plot as a surface plot from the **Table** or **Evaluation group** list below.

From the **Data format** list, select one of the following formats for interpreting the table data:

- Select **Filled table** if the data is structurally filled (for tables only; this option is not available for evaluation groups). See Filled Table for additional settings for this data format.
- Select **Columns** (the default) if you want to specify what columns to take the data from. See Columns for additional settings for this format.
- Select **Cells** to treat the tables data as cells in a matrix and use the table row and column numbers as the x- and y-coordinates, respectively. There are no additional settings for this format.

Filled Table

Select an option from the **Plot data** list: **From table** (the default) or **Manual**. If **Manual** is selected, select options from the **x-axis data** and **y-axis data** lists, which contain the parameters that define the rows and columns for the table's matrix data, and from the **Data** list, which corresponds to the **Data** list in the **Table** node for the matrix data. If there are additional parameters in a parametric sweep, they need to be kept at fixed values, which you select from the **Parameter value** list, which contains all combinations of parameter values for the parameters that are not used as x-axis or y-axis data.

Columns

From the **x-axis column**, **y-axis column**, and **Data column** lists, choose the columns to use for the x-axis, y-axis, and the data, respectively.

For all data formats, select the **Plot imaginary part** checkbox if you want to plot the imaginary part of complex-valued data. For real-valued data, that plot shows a zero imaginary part.

PREPROCESSING

This section contains settings to preprocess the data in the table surface plot by scaling and shifting the data values, which can be useful to match data from different sources or to scale some data to express the values in another unit.

Under **x-axis column**, **y-axis column**, and **Data column**, from the **Transformation** list select:

- **None** (the default), for no preprocessing of the data.
- **Linear**, to preprocess the data using a linear transformation of the data values for the x- or y-axis column or the data column. You define the linear preprocessing with values for the scaling (default: 1) and the shift or offset (default: 0) in the **Scaling** and **Shift** fields, respectively. The default values do not change the original data values.

Through Thickness

Use a **Through Thickness** ( ) plot to display the variation of a layered shell quantity in its thickness direction at specified points. Add Color Expression and Filter subnodes as needed. Right-click a **1D Plot Group** to add this plot type from **More Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Title** and **Coloring and Style**.

The Through Thickness plot requires the AC/DC Module, Composite Materials Module, Heat Transfer Module, or Structural Mechanics Module.

DATA

From the **Source** list, choose **Solution** or **Cut Point 3D** dataset. In case of **Solution** dataset, specify the evaluation positions on a layered shell in **Position** and **Selection** sections.

POSITION

When **Solution** is selected as a **Dataset**, this section displays. Select **Position**: **Selection** (the default), or **Point coordinates**.

In case **Selection** option is chosen, select one or more geometric points from the Graphics window. Alternatively, select **Point coordinates** to specify the material coordinates of an array of points.

SELECTION

When **Position** is selected as a **Selection**, this section displays. Select **Manual** from the **Selection** list to choose geometry directly from the **Graphics** window. Select **All** to add the applicable geometry or any other predefined grouping.

X-AXIS DATA

The **X-Axis Data** section is same as that of **Y-Axis Data** section of a Line Graph.

Y-AXIS DATA

For **Parametric Sweep** studies, for each pair of outer solutions or inner solutions, one line is plotted on the graph. For example, if there are 10 outer solutions and each outer solution has five inner solutions, then 50 lines are drawn. The number of inner solutions can vary between outer solutions.

Select **Thickness coordinate** from the **Parameter** list to visualize along the through-thickness direction of a layered shell, or select **Expression** to change the through-thickness coordinate expression. If **Thickness coordinate** is selected, you can choose an appropriate length unit from the **Unit** list. If **Expression** is selected, go to Expressions and Predefined Quantities.

Under **Interface positions**, choose an option from the **Show interface positions** list to enable display of horizontal lines to indicate the positions of the interfaces between layers:

- With the default option, **None**, no interface positions are displayed.
- Choose **All interfaces** to display horizontal lines to indicate the positions of all interfaces between layers.
- Choose **Interfaces between layered materials** to display horizontal lines to indicate the positions of interfaces between layered materials only.

COLORING AND STYLE

For other settings, see Common Results Node Settings.

Under **Interface positions**, the following settings are available for the line style and color of the horizontal lines representing the interface positions:

From the **Line** list, choose a line style: **Solid**, **Dotted** (the default), **Dashed**, or **Dashed-dot**.

From the **Color** list, choose one of the predefined colors (default: **Magenta**), or choose **Custom** to define a custom color using the color palette that appears. If you choose **Cycle** or **Cycle (reset)**, also choose **Default** (7 colors) or **Long** (19 colors) from the **Color cycle** list.

LEGENDS

Select the **Show legends** checkbox to display the plotted expressions to the right of the plot. In plots where each line represents a certain time value, eigenvalue, or parameter value, these values are also displayed.

When **Automatic** is selected from the **Legends** list (the default), select or clear the **Label**, **Point**, **Solution**, **Description**, **Expression**, and **Unit** checkboxes to control what to include in the automatic legends (by default it includes the point

only). If **Manual** is selected from the **Legends** list, enter your own legend text into the table. If **Evaluated** is selected, you can use the `eval` function to create an evaluated legend text in the **Legend** field that include evaluated global expressions such as global parameters used in sweeps. For the numerical evaluation, you can control the precision in the **Precision** field (default: 3).

QUALITY

The **Quality** section in the through thickness plot is similar to the one in a Line Graph. The only difference is in the **Smoothing**, which can only be turned off (the default) or on compared to the Line Graph, in which you get more options.

Tube Data

A **Tube Data** plot node appears in 2D ( ) and 3D ( ) plot groups if you run a method that creates a `TubeData` plot. Add Marker, Transparency (3D only) and Visual Effects (3D only) subnodes as needed.

It is not possible to add a **Tube Data** node from the model tree or toolbars in the COMSOL Desktop. It is only available from the COMSOL Multiphysics API and if you run a method from the **Developer** toolbar. See TubeData in the *COMSOL Multiphysics Programming Reference Manual*.

DATA

In the **Data** section, the number of points in the data and the number of line segments in the plot are listed.

Go to Common Results Node Settings for a link to information about the **Title**, **Range**, and **Coloring and Style** sections.

Volume

Use a **Volume** ( ) plot to display a quantity inside a domain in 3D. Add Deformation, Filter, Image (Plot Attribute), Marker, Material Appearance, Selection (Plot Attribute), Transformation, Transparency, and Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add this plot.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Range**, **Coloring and Style**, **Quality**, **Element Filter**, **Shrink Elements**, and **Inherit Style**.

Waterfall

Use a **Waterfall** ( ) plot to create a waterfall diagram, which is a plot that can illustrate how an expression depends on two parameters in a sweep. The waterfall is plotted as a 3D plot in which z-axis represents the response amplitude and x- and y-axis represent, for example, the frequency and the rotor rpm, respectively. Add Color Expression, Material Appearance, Transparency, and Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add this plot.

Go to Common Results Node Settings for links to information about these sections: **Expression**, **Title**, and **Inherit Style**.

DATA

Choose the dataset for the data to use in the waterfall plot from the **Dataset** list. Depending on the selected study type, you can further select the times, parameters, or eigenfrequencies to use.

SELECTION

Here you select the points for which to plot a waterfall plot. From the **Selection** list, select **Manual** to select points directly in the Graphics window or in the list below, or select **All points**.

X-AXIS DATA AND Y-AXIS DATA

In the **x-Axis Data** and **y-Axis Data** sections, specify what those axes represent by entering an expression (for example, `freq` for the frequency) in the **Expression** field. In addition, choose a compatible unit from the **Unit** list and select the **Description** checkbox to add a description of the expression in the associated text field. Click the **Replace Expression** ( ) or **Insert Expression** ( ) button to select predefined expressions to use in the **Expression** field.

COLORING AND STYLE

From the **Style** list, choose **Line** to only plot the waterfall diagram using lines, **Surface** to only plot it as a surface plot, or **Both** to use lines and a surface plot. For **Surface** and **Both**, you can also choose the color table to use for the surface plot from the **Color table** list.

Whirl

Use a **Whirl** ( ) plot to create a plot of the mode shapes of rotors that are rotated about the rotors' axes at discrete rotation intervals. The whirl plot varies the phase shift between 0 and 360 degrees. That phase shift is relative to the phase defined in the dataset used for the plot. This plot requires the Rotordynamics Module. Add Color Expression, Material Appearance, Transparency, and Visual Effects subnodes as needed. Right-click a **3D Plot Group** to add this plot form the **More Line Plots** submenu.

Go to Common Results Node Settings for links to information about these sections: **Data**, **Expression**, **Title**, **Quality**, and **Inherit Style**.

SELECTION

Here you select the edges on which to plot a whirl plot. From the **Selection** list, select **Manual** to select edges directly in the Graphics window or in the list below, or select **All edges**.

COLORING AND STYLE

By default the scaling of the whirl plot is automatic. Select the **Scale factor** checkbox and enter a scale factor in the associated text field if you want to use another scaling.

You can customize the whirl plot by changing the number of planes and rings in the plot. Enter a positive integer (or 0 for no planes or rings) in the **Number of planes** or **Number of rings** field. For the planes, select the colors to use as a color table from the **Color Table** window. If desired, choose a transformation from the **Color table transformation** list. For the rings, select a color from the **Color ring** list (or choose **Custom** to define another color). Also, for the tubes (one for each plane), enter a **Tube radius expression** for the radius of the tube; click the **Replace Expression** button ( ) to select a predefined expression to replace the current expression, or press Ctrl+Space to insert a predefined expression (SI unit: m). If needed, select the **Radius scale factor** checkbox to enter a scale factor in the associated text field.

Color Expression

Use a **Color Expression** node ( ) to add coloring (according to an expression that you define) to the shapes or lines defined by a plot. You can add this subnode to the following plot types: Line Graph, Point Graph, Global, Nyquist, Arrow Volume, Arrow Surface, Arrow Line, Contour, Isosurface, Particle Trajectories, Point Trajectories, Ray Trajectories, Streamline, Admittance Graph, Impedance Graph, Reflection Graph, Spot Diagram, Waterfall, Whirl.

In the **Model Builder**, add and define a plot group. Right-click the plot node (for example, **Streamline**) and select **Color Expression**.

	The **Color Expression** subnode has no effect for global and point graph plots that show a frequency spectrum.

	Go to Common Results Node Settings for links to information about these sections: **Expression**, **Title**, **Range**, and **Coloring and Style**.

For **Color Expression** subnodes under arrow plot nodes, you can choose **Arrow length** from the **Color data** list to color the arrows according to the arrow length. The default setting is **Expression**, and then you can enter an expression for the color in the **Expression** field below.

	For trajectory plots, the **Color data** list is only available if the point type is set to **Arrow** in the parent trajectory plot node's settings.

Comparison

Add a **Comparison** node ( ) to compare a graph plot and with reference values in a table graph. You can add a **Comparison** subnode to **Global**, **Point Graph**, and **Line Graph** plots. It is only possible to make a comparison if there is a **Table Graph** node to compare to. When you add a **Comparison** node, a corresponding **Table** node, such as **Comparison (Line Graph 1)**, is added under **Tables** and contains the output of the comparison.

REFERENCE DATA

From the **Table graph** list, choose **None** (the default) or any available **Table Graph** in the plot group.

From the **Column** list, choose **First plotted** (the default) or any other available column in the table data. If the **Row-based** checkbox has been selected in the **Table Graph** node's settings, then a **Row** list appears instead, and you can choose **First plotted** (the default) or any other available row in the table data.

COMPARISON

In this section you can specify the mapping for the comparison and the metric to use.

From the **Mapping** list, choose **Difference in y direction** (the default) for data on the form $y = f(x)$, **Difference in x direction** for data on the form $x = f(y)$, or **Closest point**, which maps each point in the table graph to the closest point on the curve.

From the **Metric** list, choose **Maximum** (the default), **All differences**, **RMS** (root mean square), or **Coefficient of determination**. The *coefficient of determination*, or R^2, is the proportion of the variation in the dependent variable that is predictable from the independent variable.

OUTPUT

This section lists the table that contains the output from the comparison.

Deformation

Add a **Deformation** node ( ) to deform the plot according to a vector quantity — for example, the displacement field in structural mechanics. You can add a deformation to most 2D and 3D plots. By default, COMSOL Multiphysics scales the deformation to 10% of the geometry.

	The default scaling often uses a scale factor that is much larger than 1, which means that plotted deformation is exaggerated to clearly show the deformed shape. Use a scale factor of 1 to plot the actual deformation in a structural mechanics simulation, for example.

In the **Model Builder**, add and define a **2D Plot Group** or **3D Plot Group**. Right-click the plot node (for example, **Arrow Surface**) and select **Deformation**.

	Go to Common Results Node Settings for links to information about these sections: **Expression** and **Title**.

SCALE

Select the **Scale factor** checkbox to edit the default value for the scale factor.

	Using a scale factor of 1 and equidistant displacements in the x, y, or z direction, you can plot several instances of the geometry side by side to, for example, visualize the solution at some times, for some parameter values, or to illustrate multiple eigenmodes. In such a plot, you would typically specify the dataset in each plot individually and turn off the color legends and titles for each separate plot.

ADVANCED

To control the automatic scaling of the deformation, you can change the value in the **Maximum relative deformation** field from the default 0.1 (that is, 10% of the geometry) to another scalar, positive value. If you use a manual scale factor in the **Scale** section above, the maximum relative deformation setting is not applicable.

Energy Decay

The **Energy Decay** subnode ( ) adds energy decay to Impulse Response plots. In the **Model Builder**, add and define a 1D **Impulse Response** plot; then right-click the plot node and select **Energy Decay**.

DISPLAY

In this section you define the display of the energy decay. From the **Band type** list, choose **Broadband** (the default) to use all frequencies in a Receiver dataset, or choose **Individual bands**. If you choose **Individual bands**, then choose a frequency from the **Band frequency** list, or choose **All** to include all frequencies.

From the **Plot** list, choose what to plot: **Energy decay** (the default), **Level decay**, or **Modulation transfer function**.

This plot also creates a table with values of some quantities of interest. Under **Include in the table**, choose which quantities to include (by default, all quantities are included):

- **Definition (Deutlichkeit)**

- **C_{50}**
- **C_{80}**
- **t_s**
- **EDT**
- **T_{20}**
- **T_{30}**
- **T_{60}**
- **SNR**
- **STI**

The speech transmission index (STI) gives a measure of the reduction in modulation of speech signals. The metric is based on evaluating the modulation transfer function (MTF) in various frequency bands.

Error Bars (Global, Point Graph, and Function)

The **Error Bars** subnode ( ) adds error bars to Global, Point Graph, and Function 1D plots. In the **Model Builder**, add and define a 1D **Global**, **Point Graph**, or **Function** plot; then right-click the plot node and select **Error Bars**. Error bars provide a graphical representation of some variability in data, and the expressions used for the error bars' lengths can represent quantities such as standard errors or percentages.

The **Error Bars** subnode has no effect for global and point graph plots that show a frequency spectrum.

EXPRESSION

Enter expressions for the down direction and up direction of the error bars in the **Error down direction** and **Error up direction** fields. If you want error bars in the *x* direction, select the **x-axis** checkbox and enter expressions for the left direction and right direction of the error bars in the **Error left direction** and **Error right direction** fields. The default values for all expressions are 0, which means no error bars.

COLORING AND STYLE

From the **Type** list, choose **Bar** (the default) to show error bars, or choose **Filled** to show the error as a filled area.

If you chose **Bar**, then you can use the following settings for the appearance of the error bars:

- From the **Line** list, choose **Solid** (the default), **Dotted**, **Dashed**, or **Dash-dot**.
- From the **Color** list, choose a color for the error bars: **From theme** (the default), predefined basic colors such as **Black**, or choose **Custom** to define a custom color.
- From the **Width** list, choose a line width from 1 to 10 (default: 1), or choose **From preferences** to use the line width for graph plots from the preferences (indicated within parentheses). You can also use the slider underneath the list to change the line width.

If you chose **Filled**, then from the **Color** list, choose a color for the error bars: **From theme** (the default), predefined basic colors such as **Black**, or choose **Custom** to define a custom color.

Error Bars (Table Graph)

The **Error Bars** subnode ( ) adds error bars to Table Graph plots. In the **Model Builder**, add and define a 1D **Table Graph** plot; then right-click the plot node and select **Error Bars**. Error bars provide a graphical representation of some variability in data.

DATA

In this section, you specify the bounds under **Lower bound** and **Upper bound**:

From the **Column** list, choose **Automatic** (the default) or choose any of the available columns in the referenced table. The **Automatic** option uses the first column not used as an x- or y-axis by the plot, or the first column if the plot uses all columns.

If desired, change the value in the **Scaling** field (default: 1) to change the scaling of the error bars.

COLORING AND STYLE

From the **Type** list, choose **Bar** (the default) to show error bars or choose **Filled** to show the error as a filled area.

If you chose **Bar**, then you can use the following settings for the appearance of the error bars:

- From the **Line** list, choose **Solid** (the default), **Dotted**, **Dashed**, or **Dash-dot**.
- From the **Color** list, choose a color for the error bars: **From theme** (the default), predefined basic colors such as **Black**, or choose **Custom** to define a custom color.
- From the **Width** list, choose a line width from 1 to 10 (default: 1), or choose **From preferences** to use the line width for graph plots from the preferences (indicated within parentheses). You can also use the slider underneath the list to change the line width.

If you chose **Filled**, then from the **Color** list, choose a color for the error bars: **From theme** (the default), predefined basic colors such as **Black**, or choose **Custom** to define a custom color.

Export Expressions

Add an **Export Expressions** ( ) subnode to these 2D and 3D plots: streamline, streamline surface, radiation pattern, particle trajectories, point trajectories, and ray trajectories. Use the **Export Expressions** subnode to add expressions for additional quantities to include in plot data export for those plots. For example, you can use it to evaluate and export several expressions on streamlines or to add the frequency as an additional expression for the data export from a far-field plot.

EXPRESSIONS

In the table in this section, add the expressions that you want to export in addition the data in the plot (including an optional description). See Expressions and Predefined Quantities for more information about how to add expressions to the table. The values of the added expressions appear in **Export** columns to the right of the columns with the plot data when exporting that data to a file.

Filter

Add a **Filter** ( ) subnode to the following 1D, 2D, and 3D plots: arrow, contour, global, function (2D only) isosurface, histogram, line graph, line plot, particle trajectories (see Filter for Particle Trajectories), point graph, point trajectories (see Filter for Point Trajectories), ray and ray trajectories (see Filter for Ray and Ray Trajectories), slice, table graph (see Filter for Table Graph) volume, max/min, Nyquist, admittance graph, impedance graph, reflection graph, and through thickness plots. Filters make it possible to filter (limit) the plot using a logical expression that provides a criterion for which parts of the plot to include. In the **Model Builder**, add and define a plot group with one or more plot nodes. Right-click the plot node (for example, a 2D **Surface**) and select **Filter**.

ELEMENT SELECTION

Under **Element Selection**, enter a **Logical expression for inclusion**. Enter any logical expression using predefined variables and unit syntax if desired. For example, `x>2[cm]` filters the plot to only include the part of the geometry where $x > 2$ cm. In 1D, the filter is applied to the points on the curves plotted using the plot node to which you

add a **Filter** subnode. The filter is applied in the same way to all expressions that are plotted. Click the **Replace Expression** ( ) or **Insert Expression** ( ) button to select predefined expressions for the logical expression.

In 2D and 3D, and if the plot uses a Solution or Mesh dataset, you can also select the **Element nodes to fulfill expression**: **All**, **At least one**, **At least one but not all**, or **Smooth** (the default):

- Using the default setting, **Smooth**, edges of the filter domain become smooth instead of consisting of entire elements. For this setting, select the **Use derivatives** checkbox to use cubic (Hermite) interpolation in the smooth plot filter. Using derivatives can improve the plot if the expression that is plotted is not approximated well over each element by a linear function.
- Select **All** to include all elements for which all element nodes (that is, the entire element) fulfill the criterion in the logical expression.
- Select **At least one** to include all elements for which at least one element node fulfills the criterion in the logical expression (that is, elements that fully or partially fulfill the expression).
- Select **At least one but not all** to include all elements for which at least one of the element nodes, but not all of them, fulfill the criterion in the logical expression. The last option is useful for making a filter that shows the plot for a zone around a boundary where the logical expression becomes true.

For the **Filter** nodes under the **Point Graph**, **Global**, **Histogram**, **Nyquist**, **Admittance Graph**, **Impedance Graph**, **Reflection Graph**, and **Point** nodes, this section is called **Point Selection** because the filtering is done for points rather than elements.

LINE SEGMENT SELECTION

This section is only available when a **Filter** subnode is used under a 1D **Global**, **Point Graph**, or **Line Graph** node.

You can filter the displayed line segments to make them monotonic in some direction using the following checkboxes, which are all selected by default:

- **Increasing x**, which you can clear to filter out line segments with increasing x coordinate values.
- **Decreasing x**, which you can clear to filter out line segments with decreasing x coordinate values.
- **Increasing y**, which you can clear to filter out line segments with increasing y coordinate values.
- **Decreasing y**, which you can clear to filter out line segments with decreasing y coordinate values.

Graph Marker

The **Graph Marker** subnode ( ) adds markers such as minimum and maximum values to Global, Point Graph, Table Graph, Radiation Pattern, and Octave Band plots. In the **Model Builder**, add and define a 1D **Global**, **Line Graph**, **Point Graph**, **Radiation Pattern**, or **Octave Band** plot; then right-click the plot node and select **Graph Marker**. You can add multiple **Graph Marker** subnodes to a plot.

When you click the **Plot button** ( ), in addition to the graph marker in the Graphics window, a table is added with numerical values for, for example, **Maximum and Minimum Values** or **Cutoff Points**, for frequency-domain simulations, showing the frequency, coordinate, bandwidth, Q-factor, and damping ratio.

Go to Common Results Node Settings for links to information about the **Line Style** section.

DISPLAY

From the **Display mode** list, choose **Min and max** (the default) to display minimum and maximum values, **Width** to display a bandwidth for S-parameter analyses, for example, or **Line intersection** to add markers at intersections between the plotted curves and straight lines.

If you chose **Min and max**, from the **Display** list choose **Min and max** (the default), **Min**, or **Max** to display both the minimum and maximum or only the minimum or maximum. Additionally, choose **Global** (the default) or **Local** from the **Scope** list. The **Local** scope indicates the local extrema.

If you chose **Width**, from the **Range type** list choose **Width** (to specify a passband, for example) or **Width outside** (to specify a stopband, for example). For **Width**, choose **Global** (the default) or **Local** from the **Scope** list. For **Local**, it shows the width (passband) of each lobe or region relative to its local maximum. From the **Cutoff mode** list, choose **Offset from peak** (the default) or **Relative to peak**. Specify the **Cutoff value** (default: −3) if you chose **Offset from peak**. That value would represent a cutoff at 3dB below the maximum value in an S-parameter plot using dB scale, for example. Specify a **Cutoff ratio** (default: $1/\sqrt{2}$) if you chose **Relative to peak** to make the cutoff value relative to the peak value. Also, if the scope is **Global**, you can choose **Absolute** from the **Cutoff model** list to specify an absolute cutoff in the **Cutoff value** field.

Note that if the data used in the graph to which the **Graph Marker** subnode has been added comes from a frequency-domain simulation, you can instead choose **Bandwidth** from the **Display mode** list. Also, you can instead choose **Passband** (the default) or **Stopband** from the **Range type** list. For **Passband**, choose **Global** (the default) or **Local** from the **Scope** list. See above for the remaining settings, which are identical to the ones for other data as described in the previous section.

If you chose **Line intersection**, from the **Line type** list, choose **Vertical** (the default), **Horizontal**, **Identity line**, or **General**:

- For **Vertical**, specify values in the **x-coordinates** field for the locations of the vertical lines.
- For **Horizontal**, specify values in the **y-coordinates** field for the locations of the horizontal lines.
- The **Identity line** option provides the line $y = x$.
- For **General**, specify the coefficients in the general line equation $Ax + By + C = 0$ in the **A**, **B**, and **C** fields.

To display the lines and not just their intersections, select the **Show lines** checkbox.

TEXT FORMAT

In this section, you can control the text format for the markers.

Enter a **Display precision** for the number of decimals displayed in the labels. The default is 6.

If the **Display mode** is set to **Min and max**, select the **Show x-coordinate** and **Show y-coordinate** checkboxes to include the x- and y-position, respectively, of the marker (its space coordinates) before the maximum and minimum values.

Select the **Include unit** checkbox to add the unit of the expression for which the plot shows the maximum or minimum value.

If you want to add a prefix or a suffix to the labels for the values, add them in the **Prefix** and **Suffix** fields. The same prefix and suffix are used for the labels.

COLORING AND STYLE

The **Show point** check point is selected by default to show the points for the minimum and maximum values. If desired, and if the **Show point** checkbox is selected, change the value in the **Point radius** field (default: 2) to a value between 0 and 1 to adjust the point size.

From the **Color** list, choose the color to use for the maximum and minimum values; choose **From theme** (the default) to use the color from the current color theme; or choose **Custom** to choose a custom color from a color palette.

From the **Background color** list, choose a background color for a rectangular area around the displayed maximum and minimum values; the default is **None**, which means that there is no background color. Choose **From theme** to use a background color that changes with the selected color theme.

From the **Anchor point** list, choose the position of the anchor point relative to the displayed values: **Upper right**, **Upper middle**, **Upper left** (the default), **Middle right**, **Center**, **Middle left**, **Lower right**, **Lower middle**, or **Lower left**.

From the **Orientation** list, choose **Horizontal** (the default) or **Vertical**, if you want the values to be displayed vertically instead of horizontally.

Select the **Show frame** checkbox to display the maximum and minimum values in a rectangular frame. Select the frame background color from the **Background color** list.

Height Expression

The **Height Expression** subnode ( ) introduces 3D height to some 2D plots. Add it to make the height of the plot represent the plotted quantity or some other expression. 2D Surface; 2D Contour; 2D Function; 2D Histogram Matrix Histogram, and Table Histogram; 2D Line; Optical Aberration; and 2D Table Surface plots support the Height Expression attribute. In the **Model Builder**, add and define a 2D **Surface**, **Contour**, **Function**, **Histogram**, **Line**, **Table Surface**, **Histogram**, **Matrix Histogram**, **Table Histogram**, or **Optical Aberration** plot; then right-click the plot node and select **Height Expression**.

As a subnode to 2D Histogram ( ), Table Surface ( ), and Optical Aberration ( ) plots, the **Settings** window for **Height Expression** does not have an **Expression** section and only **Automatic**, **Manual**, and **None** are available as a **Title type**. Also, as a subnode for Table Surface ( ) plots, the **Settings** window for **Height Expression** includes a **Data** section and a **Preprocessing** section.

EXPRESSION

Under **Expression**, the **Height data** defaults to **From parent** to use the same dataset as the parent plot it belongs to. If **Expression** is selected instead, see Expressions and Predefined Quantities. This section is not available for the **Height Expression** node when added under an **Optical Aberration** node.

DATA

When added to a **Table Surface** node where the data format is a filled table or determined by picking columns, you can select **Data** instead of **From parent** (the default setting) from the **Height data** list (this option is also available for the data format where the table data are treated as cells, but then the only option is to plot the imaginary part).

Filled Table

With this data format, you can select the data to use for the height from the **Data** list, if applicable.

Columns

With this data format, you can choose the data column to use for the height from the **Data column** list.

To plot the imaginary part of the height data instead of the real part, select the **Plot imaginary part** checkbox.

PREPROCESSING

When added to a **Table Surface** node, you can use the settings in this section to scale the height data (for example, to convert the values to another unit).

From the **Preprocessing** list, choose **Linear** to apply a linear scaling and shift in the **Scaling** and **Shift** fields, respectively. The default values — a scaling factor of 1 and a shift of 0 — do not change the values of the height data.

TITLE

Select a **Title type**: **Automatic** (the default), **Custom**, **Manual**, or **None**.

AXIS

For a manual scaling of the height data, select the checkbox and enter a **Scale factor** to control the height of the added 3D plot. Enter an **Offset** (default value: 0) or use the associated slider to control the base location (relative to the 2D surface's level). The offset value is relative to the geometry space and is not scaled. The height axis appears by default; clear the **Show height axis** checkbox to hide it.

VIEW

The **Height Expression** subnode makes the plot a 3D plot, which needs a 3D view for the grid, camera, lighting, and other 3D view settings. Select the 3D view to use from the **View** list. The default is **Automatic**, which creates a 3D view if needed. Alternatively, select one of the existing **View 3D** nodes in the model. It is also possible to choose **New view**. The plot then uses that new view, which appears as a **View 3D** ( ) node under **Views**.

Image (Plot Attribute)

The **Image** subnode ( ) adds an image to the plot. You can add it to 3D Volume and 2D and 3D Surface plots as an embedded overlaid image on the surfaces of the plot. In the **Model Builder**, add one of those plot types; then right-click the plot node and select **Image** to embed an image in the plot. You can also add Image plot nodes directly to a 2D or 3D plot group.

FILE

Click the **Browse** button ( ) to browse to and select an image to add. Select it in the **Image** file browser window and then click **Open**. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ). Click the **Plot** button ( ) to add the image to the plot. Click the **Refresh** button ( ) to update the image plot with the latest version of the image file. Click the **Import** button ( ) to store the image in the model. You then get information about the imported image file (the filename and its width and height). Click **Export** to export the image to a file, and click the **Discard** button to remove the imported image file and return to the original settings in this section.

MAPPING

This section controls how the image is mapped to the 2D and 3D surfaces; you can choose an automatic or manual mapping as well as predefined planar, cylindrical, and spherical mappings for 3D surfaces and a rectangular mapping for 2D surface.

- When the **Mapping** list is set to **Auto**, an automatic planar projection algorithm is used to map the image to the surfaces. The **Auto** setting always finds the best fitting plane and projects on it while choosing a suitable projection size. If the **Preserve aspect ratio** check is selected (the default), then the image's aspect ratio is preserved by the automatic mapping algorithm. If the image and the data have aspect ratios, then some padding must be added. The images are centered in the dimension where padding is needed.
- When you select **Manual** from the **Mapping** list, you get access to more detailed control over the mapping. Each point on the surface is mapped to a pixel in the image. This functionality can be used for more advanced

mappings. The following example provides a mapping that embeds a world map that uses an equirectangular projection on a sphere of radius r centered at the origin (when using a relative coordinate interpretation):

- For the **u-coordinate** field, enter `0.5+atan2(y,x)/(2*pi)`.
- For the **v-coordinate** field, enter `1-acos(z/r)/pi`.

The default setting for the **Coordinate interpretation** list is **Relative** (a value in the range of 0–1). Choose **Pixels** to instead enter the coordinates using absolute pixels coordinates.

The following mapping types are available in 3D:

- When you select **Planar** from the **Mapping** list, you can define a plane for the image to be mapped to. From the **Plane type** list, choose one of the following planes: **xy-plane**, **yz-plane**, **zx-plane**, **yx-plane**, **zy-plane**, **xz-plane**, **Auto** (the default), or **General**. For **Auto**, the software chooses the plane type that best suits the selected surfaces.

  Enter a **Width** under **Size**, which is the side length that the image will have, interpreted in the length unit of the geometry that the solution dataset refers to. The **Height** will be computed based on the image's size. Also, provide the coordinates for an anchor point in the **x**, **y**, and **z** fields under **Anchor point**. For **General**, specify a normal vector in the **x**, **y**, and **z** fields under **Normal**. The default is (0, 0, 1); that is, the positive z direction). Also specify a rotation angle, in degrees, if desired, in the **Rotation** field.
- When you select **Cylindrical** from the **Mapping** list, you get a cylindrical mapping of the image. Specify the position of the cylinder (center of the bottom circle) in the **x**, **y**, and **z** fields under **Position**, and from the **Axis type** list under **Axis**, choose **X-axis**, **Y-axis**, **Z-axis** (the default), **Cartesian**, or **Spherical**. For **Cartesian**, specify the axis direction in the **x**, **y**, and **z** fields. For **Spherical**, specify the axis direction in the **theta** and **phi** fields as θ and φ angles in degrees. Also specify a rotation angle, in degrees, if desired, in the **Rotation** field.
- When you select **Spherical** from the **Mapping** list, you get a spherical mapping of the image. Specify the position of the sphere's center in the **x**, **y**, and **z** fields under **Position**, and from the **Axis type** list under **Axis**, choose **X-axis**, **Y-axis**, **Z-axis** (the default), **Cartesian**, or **Spherical**. For **Cartesian**, specify the axis direction in the **x**, **y**, and **z** fields. For **Spherical**, specify the axis direction in the **theta** and **phi** fields as θ and φ angles in degrees. Also specify a rotation angle, in degrees, if desired, in the **Rotation** field.

  The following mapping type is available in 2D:
- When you select **Rectangular** from the **Mapping** list, you define a rectangle for the image to be mapped to. Enter a **Width** under **Size**, which is the side length that the image will have, interpreted in the length unit of the geometry that the solution dataset refers to. The **Height** will be computed based on the image's size.

From the **Extrapolation** list, choose **Repeat** (the default), **Repeat mirrored**, or **Clamp to edge** to control the type of extrapolation to use. The effect of the **Clamp to edge** option is that each coordinate is mapped to the closest valid value at an edge of the image. The **Extrapolation** list is not available when you have selected the **Cylindrical** or **Spherical** mapping from the **Mapping** list.

The coordinate names above are the default names: **x**, **y**, and **z**, but they can vary depending on the physics and setup of the current model.

Marker

The **Marker** subnode (·) adds maximum and minimum markers as well as markers at specified points. You can add it to several plot types, including 3D Volume, 2D and 3D Surface, and 2D and 3D Line plots. In the **Model Builder**, add one of those plot types; then right-click the plot node and select **Marker**. Contrary to adding a Max/Min Line, Max/Min Surface, or Max/Min Volume plot to the plot group, the Marker subnode does not perform any evaluations to generate its data — it uses the data generated by the parent Line, Surface, or Volume plot.

When you click the **Marker Point** button in the **Graphics Interaction** section of a plot group contextual toolbar, you can click in a 2D Surface, 3D Volume, or 2D or 3D Line plot to add markers. The markers are added to an existing **Marker** subnode where **Point evaluation** has been selected for the display or to a new **Marker** subnode.

Click the **Plot** ( ) button at the top of the **Settings** window when needed to update the markers in the plot.

DISPLAY

Select an option from the **Display** list to determine what to display: **Min and max** (the default), **Min**, **Max**, or **Point evaluation**. If you choose **Point evaluation**, then add the coordinates for the points where to evaluate the expression and add markers to display those values in that table underneath the **Display** list. Use the **Move Up** ( ), **Move Down** ( ), and **Delete** ( ) buttons underneath the table as needed. In addition, use the **Clear Table** button ( ) to clear the entire table. Additionally, the **Save to File** button ( ) saves the point coordinates to a text file (or to a Microsoft Excel Workbook spreadsheet if the license includes LiveLink™ *for* Excel®) for reuse in other models. The information is saved in space-separated columns in the same order as displayed on screen. When saving to Excel, an **Excel Save** dialog appears where you can specify the sheet and range and whether to overwrite existing data, include a header, or use a separate column for units. Using the **Load from File** button ( ), you can import or load data in text files created, for example, by a spreadsheet program. You can also click the downward arrow beside the **Load from File** button and choose **Load From** ( ) to open the fullscreen **Select File** window.

TEXT FORMAT

In this section, you can control the text format for the markers.

Select the **Prepend the position** checkbox to include the position of the marker (its space coordinates) before the maximum and minimum values.

Select the **Include unit** checkbox to add the unit of the expression for which the plot shows the maximum or minimum value.

If you want to add a prefix or a suffix to the labels for the minimum and maximum values, add them in the **Prefix** and **Suffix** fields. The same prefix and suffix are used for the minimum and maximum labels.

From the **Number format** list, choose one of the following formats:

- **Default**: Numerical values that come from the solvers are presented as-is. Numbers formatted during postprocessing use the **Output display precision** preference setting.
- **Automatic**: All numbers are formatted using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Engineering**: All numbers are formatted using engineering notation (such as `31.416E-6`; it is similar to scientific notation but with the powers of ten as multiples of three) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Scientific**: All numbers are formatted using scientific notation (such as `3.1416E-5`) using the specified precision that you enter in the **Precision** field (default: 6). Select the **Show trailing zeros** checkbox if you what to display trailing zeros.
- **Stopwatch**: All numbers are formatted in decimal notation with a specified number of integer digits and decimals, which you enter in the **Number of integer digits** field (default: 3) and **Number of decimals** field (default: 2), respectively. Unnecessary zeros are always shown. For example, with the default settings, 17.1 would be formatted as `017.10`. The specified number of integer digits is not respected if the number is too large or if it is NaN or Inf. Select the **Always show the sign** checkbox to keep the width from changing for a sequence that includes both positive and negative values.
- **Scientific stopwatch**: All numbers are formatted in scientific notation with one integer digit and a specified number of decimals and exponent digits. For example, with the default settings, 17.1 would be formatted as `1.71E1`. The settings are the same as for the **Stopwatch** format, with the addition of an **Always show the sign of**

the exponent checkbox. Select it to keep the width from changing for a sequence that includes both positive and negative exponents.

If you have selected the **Prepend the position** checkbox, you can choose a format for the position from the **Position number format** list, which then becomes available. See the **Number format** list above for information about the available options.

COLORING AND STYLE

The **Show point** checkbox is selected by default to show the points for the minimum and maximum values. If desired, and if the **Show point** checkbox is selected, change the value in the **Point radius** field (default: 2) to a value between 0 and 1 to adjust the point size.

From the **Color** list, choose the color to use for the maximum and minimum values; choose **From theme** (the default) to use the color from the current color theme; or choose **Custom** to choose a custom color from a color palette.

From the **Background color** list, choose a background color for a rectangular area around the displayed maximum and minimum values; the default is **None**, which means that there is no background color. Choose **From theme** to use a background color that changes with the selected color theme.

From the **Anchor point** list, choose the position of the anchor point relative to the displayed values: **Upper right**, **Upper middle**, **Upper left** (the default), **Middle right**, **Center**, **Middle left**, **Lower right**, **Lower middle**, or **Lower left**.

From the **Orientation** list, choose **Horizontal** (the default) or **Vertical**, if you want the values to be displayed vertically instead of horizontally.

Select the **Show frame** checkbox to display the maximum and minimum values in a rectangular frame. Select the frame background color from the **Background color** list.

Material Appearance

The **Material Appearance** subnode ( ) replaces the graphics from the parent node with a material appearance, providing the possibility for a mixed-mode visualization, where some surfaces or volumes are colored according to an expression and others are plotted using a given material appearance. You can add a **Material Appearance** subnode to the following plot types: Arrow Line, Arrow Point, Arrow Surface, Arrow Volume, Image, Isosurface, Layered Material Slice, Multislice, Particle Trajectories, Phase Portrait, Poincaré Map, Point Trajectories, Radiation Pattern, Ray Trajectories. Scatter Surface, Scatter Volume, Slice, Streamline, Surface, Surface Data, Surface Slit, Volume, Waterfall, and Whirl. In the **Model Builder**, add one of those plot types; then right-click the plot node and select **Material Appearance**.

APPEARANCE

From the **Appearance** list, choose **From material** (the default) or **Custom**. With the **From material** option, choose the appearance associated to any material in the model or **None**. If you select a material here, the **Use the material's selection** checkbox is selected by default to render the material appearance only for the geometric entities in the material's selection. Clear the checkbox to use the material appearance where the parent plot node is rendered.

Click the **Customize** button to use a custom material. Then choose the type of material appearance from the **Material type** list; the default setting is **Custom**. For the settings that are then available for defining a custom appearance, see Appearance. The default custom properties are taken from the last chosen material in the **Material type** list.

COLOR

If you want to use the color from the plot instead of the material's color, as defined in the parent node's settings as a color table, color gradient, or uniform color, select the **Use the plot's color** checkbox.

Selection (Plot Attribute)

The **Selection** subnode ( ) provides the possibility to define a selection for some plots. Add it to make the plot appear only in some geometric entities (some domains, for example). Arrow Line, Arrow Point, Arrow Surface, Arrow Volume, Contour, Coordinate System Line, Coordinate System Surface, Coordinate System Volume, Isosurface, Line, Max/Min Line, Max/Min Surface, Max/Min Volume, Mesh, Multislice, Principal Stress Volume, Principal Stress Surface, and Principal Stress Line, Slice, Streamline, Streamline Multislice, Surface, and Volume plots support the Selection attribute. In the **Model Builder**, add one of those plot types; then right-click the plot node and select **Selection**.

SELECTION

From the **Geometric entity level** list, choose any geometric entity level between the element dimension where the plot evaluates and the plot group's dimension, if applicable. For example, for a Surface plot in a 3D plot group, **Boundary** (the default) and **Domain** are available. If you choose **Domain** for a surface plot, the boundaries that belong to the selected domains are selected, so it can provide a quick way of selecting multiple boundaries.

From the **Selection** list, choose **Manual** to select the geometric entities (domains or boundaries, for example, depending on the plot type) directly in the Graphics window or using the tools in the **Selection** section. You can also select **All domains** or **All boundaries**, for example, or any applicable selection defined in the model.

REVOLUTION SELECTION

This section is only available for applicable 3D plot types, such as Surface plots, using a Revolution 2D dataset. You can then control which parts of the revolved geometry to evaluate:

- Select the **Evaluate the mantle** to evaluate and plot the solution on the mantle of the revolved 2D geometry.
- Select the **Evaluate the start cap** to evaluate and plot the solution on the start cap (at the start angle) if end caps have been added.
- Select the **Evaluate the end cap** to evaluate and plot the solution on the end cap (at the ending angle) if end caps have been added.

See Selection (Dataset Attribute) for information about adding a **Selection** subnode to a dataset, which can be an alternative to a **Selection** subnode for a plot if you want to apply the same selection to many plots.

Transformation

Use the **Transformation** subnode ( ) to transform a 2D or 3D plot. This subnode transforms the visualization of a 2D or 3D plot, not its coordinates when exported. You can add a transformation to most 2D and 3D plots. In the **Model Builder**, add one of those plot types; then right-click the plot node and select **Transformation**.

TRANSFORMATION

From the **Transformation** list, choose **Structured** (the default) for a structured transformation in terms of scaling, rotating, and moving, or choose **General** to define a general transformation in terms of base vectors and a translation.

For the structured transformation, specify the following settings:

- Select the **Scale** checkbox to apply a scaling. Then specify the scaling of the plot in the **x**, **y**, and (3D only) **z** fields.

- Select the **Rotate** checkbox to apply a rotation.
  - In 3D, choose an axis from the **Axis type** list: **X-axis**, **Y-axis**, **Z-axis** (the default), **Cartesian**, or **Spherical**. For **Cartesian**, specify the axis in the **x**, **y**, and **z** field below. For **Spherical**, specify the θ and φ angles.
  - In 2D and 3D, then specify the rotation angle (in degrees) in the **Angle** field. Under **Center of rotation**, specify the center for the rotation in the **x**, **y**, and (3D only) **z** fields (default unit: m)
- Select the **Move** checkbox to move the plot. Then specify the translation of the plot in the **x**, **y**, and (3D only) **z** fields (default unit: m).

For the general transformation, specify the following settings:

- Under **Base vectors**, specify base vectors with their **x**, **y**, and (3D only) **z** components for the **First**, **Second**, and (3D only) **Third** base vector.
- Under **Translation**, specify the translation of the plot, with the applied base vectors, in the **x**, **y**, and (3D only) **z** fields (default unit: m).

For both transformation types, the **Apply to dataset edges** checkbox is selected by default. Clear it to make the dataset edges remain at the untransformed original position.

Transparency

The **Transparency** subnode ( ) adds transparency to 3D plots and to 2D plots that use a Height Expression subnode. Add it to make the plot more or less transparent. Contour, Image, Isosurface, Layered Material Link, Line, Max/Min, Mesh, Multislice, Radiation Pattern, Particle Tracing, Particle Trajectories, Point, Point Trajectories, Principal Stress, Slice, Streamline, Surface, Surface Slit, Table Annotation, Volume, Waterfall, and Whirl plots in 3D and Contour, Function, Histogram, Matrix Histogram, Table Histogram, Line, Optical Aberration, Surface, and Table Surface plots in 2D with a Height Expression support the Transparency attribute. In the **Model Builder**, add one of those plot types; then right-click the plot node and select **Transparency**.

TRANSPARENCY

In the **Transparency** field, or using the slider underneath, specify the transparency as a value between 0 (no transparency) and 1 (fully transparent).

In the **Fresnel transmittance** field, or using the slider underneath, specify the Fresnel transmittance as a value between 0 (no transmittance) and 1 (full transmittance). Fresnel transmittance results in that the transparency depends on the angle of incidence, which can improve realism.

Visual Effects

The **Visual Effects** subnode ( ) adds visual effects to 3D plots and to 2D plots that use a Height Expression subnode. Add it to control if the plot should be affected by lighting and to control ambient occlusion and direct shadows. You can add a **Visual Effects** subnode to all plots in 3D and to Contour, Function, Histogram, Matrix Histogram, Table Contour, Table Histogram, Line, Optical Aberration, Surface, and Table Surface plots in 2D with a Height Expression. In the **Model Builder**, add one of those plot types; then right-click the plot node and select **Visual Effects**.

The visual effects may not be visible for all plot types that support them, but the effects will be visible for all plots that include surfaces.

VISUAL EFFECTS

The **Affected by lighting** checkbox is selected by default. If you clear this checkbox, there is no effect of lighting on the plotted surfaces for the plot to which this subnode has been added.

Under **Ambient occlusion**, select a mode from the **Mode** list: **Auto** (the default) or **Manual**. The **Auto** setting includes ambient occlusion. With the **Manual** setting, you can select or clear the **Cast shadows** and **Receives shadows** checkboxes.

Under **Direct shadows**, select a mode from the **Mode** list: **Auto** (the default) or **Manual**. The **Auto** setting includes direct shadows. With the **Manual** setting, you can select or clear the **Cast shadows** and **Receives shadows** checkboxes.

Exporting Data and Images

Export Types

After a model is completed, you can add various components to the **Export** branch and then generate outputs (animations, data, images, or export), or export the information to your computer as images, movies, or data files for use in external documents or for other purposes. In the **Model Builder**, under the **Export** node, right-click and select an option as listed in Table 21-2.

TABLE 21-2: EXPORT TYPES.

LINK TO SECTION	DESCRIPTION
Animation	To define and export a movie or series of images based on a plot group. Play the animation in a web browser or use it in presentations or on a website.
Player	To define and play a movie in the COMSOL Desktop. See Animation.
Data	Exports numerical data to file. Data export operates directly on datasets. It is also possible to export mesh data.
Image	To export images to a file or (on Windows) to the clipboard or to PowerPoint and Word.
Mesh (Export)	To export a mesh defined by a dataset to file.
Plot	To export a plot from a 1D Plot Group, 2D Plot Group, or 3D Plot Group.
Radiation Pattern (Export)	To export data from the radiation pattern plot.
Table (Export)	To export the contents of a table to file.
Touchstone	To export data for port networks in the Touchstone format. This export format requires the AC/DC Module, MEMS Module, or RF Module.

Right-click the **Export** node and select **Export All** ( ) to export data from all export nodes added under **Export**.

Depending on the physics interface included in the model, not all export types in the table above may be available. To see all export types, select the **All Export Types** checkbox in the **Show More Options** dialog.

About the Sectionwise Data Format for Data Export

When exporting data on the sectionwise data format, the program evaluates the entered expressions at a number of points in each mesh element. For example, evaluating in Lagrange points of order 1 means that the expressions are evaluated at the vertices of each mesh element. When a vertex is shared by more than one mesh element (as is typically the case) this means that the expressions are evaluated several times at that coordinate, but using the shape functions in the different mesh elements. The values of these evaluations at the same point might not be equal, depending on the expression being evaluated. In particular, derivatives are typically discontinuous across mesh element boundaries and usually have different values.

Once all the evaluations have been made, the data is checked for duplicate values (that is, evaluations with the same coordinates and the same values of the expressions). Such duplicates are removed before the data is exported to file. With smoothing turned on, a smoothed variant of the derivative is evaluated, which is continuous across mesh

element boundaries, so in such cases there are many duplicates. When evaluating at Gauss points, the evaluation points are always in the interior of mesh elements, so there are never any duplicates.

	To avoid the removal of duplicates, you can export several expressions to the same file, and then the values of all expressions must agree to be considered duplicates. Another way to ensure that no duplicates are removed is to add the variable `meshelement` to the list of expressions.

	• Data • See Table 21-2 for links.

Animation

Use **Animation** ( ) to define and export a movie or series of images based on a plot group. Play the animation in a web browser or use it in presentations or on a website. You can also use it as a player directly in the COMSOL Desktop Graphics window. Use this node, for example, to export multiple images for different time steps or eigenvalues.

Right-click **Export** ( ) and choose **Animation** > **Player** to create an **Animation** node set up for a player, or choose **Animation** > **File** to create an **Animation** node set up for exporting a movie or images to files.

SCENE

Select a **Subject**, which is one of the plot groups previously defined, or **None**.

TARGET

From the **Target** list, choose **Player** (the default when the **Animation** node was added as a Player) to play the movie directly in the COMSOL Desktop, or choose **File** (the default when the **Animation** node was added as a File) to export the animation to file as a movie or as an image sequence.

OUTPUT

Select an **Output type**: **Movie** (the default) to generate a single movie file containing all the images, or **Image sequence** to generate multiple image files, one for each frame. This section is only available when the **Target** is set to **File**.

- If **Image sequence** is selected:

  Enter a **Filename** including a path to save it to your computer, or click **Browse** ( ) and navigate to where you want to **Save** the output. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. For example, navigate to the desktop and enter a **Filename** in the **Export Image Sequence** dialog, then select an image file type from the **Save as type** list: **.png**, **.bmp**, or **.jpg**. Click the downward arrow for the **Location** menu ( )to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

  The text entered in the **Filename** field is used for all the images generated. For example, if `image` is entered, select **.png** as the file type, and if there are 11 frames in the movie, 11 files are created: `image01.png`, `image02.png`, …, `image11.png`.

- If **Movie** is selected, select a **Format** for the movie: **GIF** (the default), **AVI**, or **WebM**. For any movie or video format, enter a path and include a **Filename**. Or click **Browse** and navigate to where you want to **Save** the output. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ). Also enter a number of **Frames per second** (the default is 10).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the program to always display a dialog for specifying where to store the movie or images.

Enter information into these fields based on the **Format** for the movie:

- If **AVI** is selected, enter a **Quality**, a scalar value between 0 and 1. The default is 0.75.
- If **WebM** is selected, select the choose a **Codec** (compression format): **VP9** (the default) or **VP8**. VP9 is a compression format that is a successor to VP8 and that is customized for video resolutions greater than 1080p and also enables lossless compression. If you have chosen **VP9**, select the **Lossless** checkbox for a lossless compression. If you do no select the **Lossless** checkbox, you can enter a **Quality** parameter (a value between 0 and 1), where a higher values means a higher quality. The default is 0.6. The encoder uses VBR (variable bit rate), and a higher value for the quality parameter means a higher target bit rate. A higher quality value usually results in large file sizes and longer encoding times.

  The default for the **Advanced parameters** list is **Automatic**. Choose **Manual** to specify the advanced parameters under Advanced Parameters for the WebM Video Format below.
- For **GIF** and **WebM**, select the **Open in browser** checkbox to launch the default web browser to view the output file.

	AVI is a file format that can contain video encoded in different ways. For movies using this format, you might also need to change the codec used for animations (on the **Results** > **Animation_Export** page in the **Preferences** window). Use Windows Media Player to play AVI files.

Enter a value for the number of **Frames per second** when playing the movie (default: 10 frames per second).

Advanced Parameters for the WebM Video Format

The following advanced parameters are available for the WebM format:

The **Enable parallel encoding** checkbox is selected by default. Select the **Enable parallel decoding** checkbox to also enable parallel decoding when the **Enable parallel encoding** checkbox is selected.

From the **Dither** list, choose **Off** (the default) for no dithering or a level 1–5. Dither is low volume noise, and dithering adds white noise to reduce distortion of low-amplitude signals.

From the **Optimize for** list, choose **Speed (faster encoding)** (the default) or **Quality (slower encoding)**. If you have selected the **Lossless** checkbox, this setting is not available.

From the **Color space** list, choose one of the following color spaces: **BT.601 (limited range)**, **BT.601 (full range)**, **BT.709 (limited range)** (the default), or **BT.709 (full range)**.

ANIMATION EDITING

The settings in this section control how the software creates the frames for the animation sequence. Select a **Sequence type**: Stored Solutions (the default), Result Parameter, Global Parameter, Dynamic Data Extension, or Streamline. Define the **Sequence type** parameters as needed.

	Each selected animation sequence component creates a frame in the movie or an individual image file.

Stored Solutions

The default, **Stored solutions**, is useful to animate time-dependent solutions or across the eigenmodes for an eigenvalue or eigenfrequency solution or across the parametric solutions for a solution from a parametric sweep. If **Stored solutions** is selected:

From the **Loop over** list, select the steps or parameter values to **Loop over**: **All solutions** (the default), or if applicable, a parameter or combination of parameters, any parameter in a **Parametric Sweep** study, or the **Time**. If **All solutions** is selected, a list appears that contains all combinations of parameter values and times (if applicable).

- **Parametric Sweep Study**: For parametric sweep studies where there are multiple inner solutions (for example, a parameter sweep around a time-dependent solution), **Inner solutions** and **Outer solutions** are also available, typically corresponding to **Time** and parameter values, respectively. Typically, an animation shows variations looping over a parameter, frequency, or time; animating all solutions might be useful to get an overview of all solutions that the model contains.
  - If you choose to loop over **Inner solutions**, select the **Parameter value** set to animate, then the time steps, which you can select, using the **Select via** list, as **Stored output times** (a **Time** list of all stored times), or **Interpolated times** (a text field where you can specify any times within the time range directly). See Volume Integration, Surface Integration, and Line Integration and Global for more information about the inner and outer solutions.
  - If you choose to loop over **Outer solutions** (that is, the parameters from the parametric sweep), the **Parameter values** list contains all combinations of parameter values. Select as needed, then select an option from the **Inner type** list: **First**, **Last** (the default), or **All**.
- If a parameter or combination of parameters are selected to loop over, choose an option from the **Parameter selection** list: **All** (the default), **From list** to select from a list of all parameter combinations, or **Manual** to enter a range of parameter value indices directly (or click the **Range** button ( )).

  If the model includes other parametric sweeps or frequency sweeps, specify the value of those parameters for the frames in the animation in separate **Parameter value** lists. Also, if the model includes a time-dependent solution, select a time step from the **Time** list, or select **Interpolated** to specify any time within the time span in the text field that appears.
- If you select to loop over the **Time**, for time-dependent problems, choose an option from the **Time selection** list: **All** to use all time steps, **From list** to select from a list of all time steps, **Manual** to enter a range of times as indices directly in the **Time indices** field, or **Interpolated** to enter **Times**. If the model contains a parametric sweep, select an option from the **Parameter value** list.

For animations of 1D graph plot groups where you have a time-dependent, parametric, or eigenvalue solution, you can use the **Cumulative** list to control whether the animation should use the last time or parametric tuple or a cumulative list of such tuples. The default is **Automatic**, which provides a suitable behavior depending on the plot type; if desired, choose **On** or **Off** to make the animation use a cumulative list or not.

Result Parameter

Use a **Result parameter** to animate the changes resulting from a sweep of the values for a defined result parameter (found under **Results** > **Parameters**). Using a parameter you can, for example, animate a sweep of the position of a slice across the geometry in a slice plot using it in the slice coordinates. Typically, you can use a result parameter in text fields for coordinates. It is not possible to use a result parameter in, for example, text fields for expressions.

If **Result parameter** is selected, choose a **Parameter** from the list (or select **None**), which contains all result parameters, and define an interval for the parameter values using the **Start** and **Stop** fields and a unit in the **Unit** field, if desired (the parameter's unit appears here if it exists).

Global Parameter

If **Global parameter** is selected, choose a **Parameter** from the list (or select **None**), which contains all global parameters, and define an interval for the parameter values using the **Start** and **Stop** fields and a unit in the **Unit** field, if desired (the parameter's unit appears here if it exists). It is not possible to use a global parameter in, for example, text fields for expressions.

Dynamic Data Extension

Use a **Dynamic data extension**, for example, to animate the dynamics of an eigenmode in an eigenfrequency or eigenvalue solution. In such a dynamic data extension, the full harmonic cycle (the default) is the normal choice. You can also use it to animate a stationary solution even if there is no obvious interpretation of the animation.

If **Dynamic data extension** is selected, and when animating static and eigenvalue solutions, select a **Cycle type**:

- **Full harmonic** — a full sine wave (the solution phase grows linearly from 0 to 360°)
- **Half harmonic** — half a sine wave (the solution phase grows linearly from 0 to 180°)
- **Linear** — a linear ramp ($\mathrm{Re}(e^{i\alpha})$, where α is the phase, grows linearly from 0 to 1)

The cycle starts from the angle specified in the **Solution at angle (phase)** field when defining a **Solution** dataset.

Streamline

Select **Streamline** when you want to animate streamlines with moving arrows to indicate some fluid flow, for example. From the **Plot** list, choose the streamline plot to animate from any existing **Streamline** plot nodes.

FRAMES

If the selected **Sequence type** is Stored Solutions, choose a **Frame selection**: **All** (to play all solutions in the stored solution) or **Number of frames**. For any sequence type, or if number of frames is selected here, enter the **Number of frames**. The default is 25 frames.

If the **Target** is set to **File**, you can specify the following additional settings:

- From the **Size** list, select **Manual** (the default), **HD**, or **Current**. The high-definition option, **HD**, uses 1280 by 720 pixels. The **Current** option uses the current size of the **Graphics** window.
- For **Manual**, select the **Lock aspect ratio** checkbox to keep the original animation width and height. In the **Width** and **Height** fields, enter the number of pixels (px) for the generated image size. The default value is 640 pixels (width) by 480 pixels (height).
- If required, select the **Record in reverse order** checkbox.
- If required, select the **Zoom extents** checkbox to zoom the output frames to the extents of the plot's subject.

If the **Target** is set to **Player**, and to preview individual frames, enter the **Frame number** or select it using the slider. Observe the geometry in the **Graphics** window to see the **Shown frame** number.

PLAYING

Use this section, when the **Target** is set to **Player**, to adjust some settings that affect the playing of the recorded plots. In the **Display each frame for** field, enter the time to display each frame (in seconds) to control how fast the player runs (default value: 0.1 s). From the **Repeat** list, choose **Off** (the default) to play the sequence of plots once and not repeat it, **Forever** to replay the sequence of plots repeatedly until you stop it, or **Number of iterations** to replay it as many times as you enter in the **Number of iterations** field (default: 1). Note that if you want to use a player in an app, then **Forever** does not apply; instead, use **Number of iterations** if you want to replay the sequence of plots several times.

At the top of the **Settings** window, click **Show Frame** ( ) (or right-click the **Animation** node) to regenerate the animation if it has not already been generated. Then the frame of the animation corresponding to the settings for the player is shown.

Right-click the **Animation** node and select **Play** ( ). Watch each **Frame number** cycle from beginning to end in the **Graphics** window. You can also use the buttons in the **Graphics** window to **Play** ( ) and **Stop** ( ), and **Next** ( ) and **Previous** ( ) to cycle through the animation.

LAYOUT

If the **Target** is set to **File**, you can specify the following layout settings:

- By default, the **Title**, **Legend** (1D graphs) or **Color legend** (2D plots); **Axes**; and **Logo** (1D and 2D plots) or **Title**, **Color legend**, **Grid**, **Axis orientation**, and **Logo** (3D plots) parts of the graphics are included. To edit the default, select the **Include** checkbox and click to clear or select one or several of the available checkboxes.
- Enter a **Font size** (pt) for the text in the animation frames. The default is 9 pt.
- Select a **Background**: **Color** (the default), **From theme**, **Transparent**, or **Current**. If **Color** is selected, click **Color** to select a custom color background to replace the default, which is white. Select **Current** to use the background in the plot group, which is a blue gradient background for 3D plots and white for 2D and 1D plots.

ADVANCED

By default, the **Synchronize scales between frames** checkbox is selected, which means that all frames in the animation use the same color legend, isosurface levels, deformation scale, and so on. This synchronization makes areas with the same solution values keep the same color, for example, during the entire animation. Click to clear the checkbox to make the scales and levels adapt to the solution in each frame. This can be useful, for example, for time-dependent simulations of transient phenomena where the magnitude of the solution changes significantly during the time stepping. With the synchronization active, it can then be difficult to distinguish small variations in the solution.

The remaining settings below are only available if **Target** is set to **File**.

If needed, adjust settings for the resolution and antialiasing:

- Enter a **Resolution** for the images in the animation. The default is 96 DPI.
- The **Antialiasing** checkbox is selected by default to reduce stairstep-like lines and to smooth lines and edges.

Click the **Export** button ( ) in the **Settings** window or right-click the node and select **Export** to export the animation to a file, if **Target** is set to **File**. You can also click the downward arrow beside the **Export** button or right-click and choose **Export To** ( ) to open the fullscreen **Export** window for exporting to a database. The animation file is exported to the location on your computer previously specified. The **Messages** window confirms where the files are exported as specified in the **Output** section. Click the **Refresh** button ( ) to refresh the **Graphics** window. This is useful if you have disabled **Only plot when requested** in the **Results** node's **Settings** window and change the **Subject** in the animation.

Parametric Sweep and Introduction to Solvers and Studies

Data

Use **Data** ( ) to export numerical data to a file. Data export operates directly on datasets. You can use different types of evaluation points other than the ones in the dataset (for example, a grid) and export the data in spreadsheet or sectionwise formats.

To export data, you can right-click **Export** ( ) and select **Data** ( ), or right-click any dataset node, for example, **Solution**, and select **Add Data to Export**. Click the **Data** node under **Export**.

The nodes are numbered sequentially. To make it easier to organize, you can right-click and **Rename** the node.

- Go to Common Results Node Settings for information about the **Expressions** section.
- For detailed information about Data Formats, see the *COMSOL Multiphysics Programming Reference Manual*.

DATA

Go to Common Results Node Settings for more information about the **Data** section.

If you have defined a compatible configuration (see Configurations), which is typically a Multiselect Solution, the you can choose **From configuration** from the **Solution parameters** list (the default is **Manual**). With **From configuration**, choose a compatible configuration from the **Configuration** list to use its settings for the solution parameters such as time, eigenvalue, or parameter values to use.

OUTPUT

From the **File type** list, select the file type for the exported data.

Choose **Text** (the default), for any of these text file types: text files (*.txt), CSV (comma-separated values) files (*.csv), data files (*.dat), or, if the license includes LiveLink™ *for* Excel®, Microsoft Excel workbook (*.xlsx).

Choose **Unstructured VTK file (*.vtu)**, for saving to an unstructured VTK (the Visualization Toolkit) file.

Enter a **Filename** including a path to save the data file to your computer or click **Browse** ( ) and navigate to where you want to **Save** the output. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. For example, navigate to the desktop and enter a **Filename** in the **Export Data** window. When you have chosen **Text** from the **File type** list, you can save the data using any of the supported text file types that you choose from the **Save as type** list. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the program to always display a dialog for specifying where to store the data.

Select the **Points to evaluate in**: **From dataset** (the default), **From file**, **Grid**, or **Regular grid**. Depending on the selected type of points to evaluate in, various settings are available.

From Dataset

The default **From dataset** uses the data points for the data in the dataset. For export to a text file, select a **Data format**: **Spreadsheet** (the default) or **Sectionwise**. Spreadsheet data is useful to use the data in spreadsheet applications and sectionwise data format is useful for unstructured interpolation because it contains the exact mesh used to perform the interpolation.

For either choice, select a **Space dimension**: **From dataset** (the default), **Global**, **0**, **1**, **2**, or **3**. Then select a **Geometry level**: **From dataset** (the default), **Volume**, **Surface**, **Line**, or **Point** (availability is based on the model space dimension).

If **Spreadsheet** is selected (and if required), choose the **Transpose** checkbox to transpose the data from columns to rows.

From File

If **From file** is selected, it uses coordinates from a data file. Enter a **Coordinate file** for a text file with the coordinates for the data output, or click **Browse** to locate the file. The file format for a coordinate file is such that each row contains N coordinates for an N-dimensional geometry. That is, each row contains coordinate values like the following example, for a 3D case:

```
x0 y0 z0 …
x1 y1 z1 …
…
```

You can use any of the following characters to separate the coordinates: space, comma, semicolon, or a tab character. Empty lines and lines that begin with a percent (%) character are ignored.

Grid or Regular Grid

If **Grid** or **Regular grid** is selected, it uses a grid to define the points to evaluate in. Select a **Data format**: **Spreadsheet** (the default) or **Grid**. Spreadsheet data is useful for using the data in spreadsheet applications, whereas the grid data format is more compact and can be useful to store data that can be imported into another model.

If **Grid** is selected as the **Data format**, also specify the **x**, **y**, and **z** coordinates for the grid points in the fields, or, for the **Regular grid**, specify the **Number of x points**, **Number of y points**, and **Number of z points** for the regular grid in the fields (default: 10 points in each direction). The coordinate names can vary depending on the physics and space dimension.

ADVANCED

The following settings apply for the text file format and partially for the VTK (the Visualization Toolkit) file format.

- The **Include header** is selected by default. Click to clear the **Include header** checkbox if you do not want to include a header. When exporting to VTK files, the **Include header** checkbox is not available.
- The **Full precision** checkboxes is selected by default. Click to clear the **Full precision** checkbox to limit the precision in the output to six significant figures (and which provides an output that contains all significant figures for data stored as double-precision numbers).
- By default, the data is unsorted. Select the **Sort** checkbox to sort the data by increasing x, y, and z coordinates.
- By default, the spatial coordinate values are included in the exported data. Clear the **Include coordinates** checkbox to save the data without any coordinate values.
- By default, the data included data points whose values are NaN (Not a Number). Clear the **Include NaN data points** to exclude such data points from the data export. NaN values represent data that is missing, undefined, or unrepresentable, such as the result of zero divided by zero.
- From the **If the file exists** list, select **Overwrite** (the default) to replace the data in the file with the data you export, or choose **Append** to append the data to the end of the file. Appending data can be useful when exporting data for a parametric sweep, for example. When exporting to VTK files, the **If the file exists** list is not available.
- The **Evaluate in** list is available for data from Solution, Particle, Edge 2D, Edge 3D, Surface, Transformation 2D, and Transformation 3D datasets. From the **Evaluate in** list, select **Lagrange points** (the default) or **Gauss points** to specify where COMSOL Multiphysics evaluates the data — the nodes of the Lagrange elements or in the Gauss points for the Gaussian quadrature, respectively.
- Smoothing of the data is available with Solution datasets where the **Evaluation in** list is set to **Lagrange points** and with nonsolution datasets, in both cases when the **Points to evaluate in** list in the **Output** section is set to **From dataset**. Select a data **Smoothing** method — **None**, **Inside material domains** (the default, for smoothing within domains shared by the same material but not across material boundaries), **Inside geometry domains** (for smoothing within each geometry domain but not across interior boundaries), **Everywhere**, or **Expression**. If you choose **Expression**, enter an expression in the **Expression** field such that smoothing occurs where the expression is continuous. The default expression is `dom`, the domain variable, which is equivalent to the **Internal** smoothing. You can also — in a surface plot, for example — use `material.domain`, which is an indicator variable for domains that share the same material (see Material Group Indicator Variables) and is equivalent to the **Inside material domains** setting.
- For all **Smoothing** methods except **None**, you can also choose smoothing threshold, if needed. From the **Smoothing threshold** list, select **None** (the default), or select **Manual** to enter a relative smoothing threshold value (default: 0.1) in the **Threshold** field.
- Select a **Resolution**: **Normal** (default), **Finer**, **Fine**, or **Custom**. If **Custom** is selected, enter a **Lagrange-element node-point order** (the default is 1). Use a higher node-point order for a finer resolution.

- Select a recovery setting from the **Recover** list. The default is **Off** because recovery takes processing time. To use polynomial-preserving recovery and recover fields with derivatives such as stresses or fluxes with a higher theoretical convergence than smoothing, from the **Recover** list, select **Within domains** to perform recovery inside domains or **Everywhere** to apply recovery to all domain boundaries.
- Select a column separator from the **Separator** list: **Column** (the default), **Space**, **Tab**, **Comma**, **Semicolon**, **Colon**, or **Vertical bar (pipe)**.

EXPORTING THE DATA

Click the **Export** button ( ) in the **Settings** window or right-click the node and select **Export**. You can also click the downward arrow beside the **Export** button or right-click and choose **Export To** ( ) to open the fullscreen **Export** window for exporting to a database. The **Messages** window confirms where the files are exported as specified in the **Output** section.

Expressions and Predefined Quantities

Image

Use the **Image** node to export plot images as PNG, BMP, EPS, TIFF, GIF, or JPEG image files.

To export a plot, right-click **Export** ( ) and select **Image**, or right-click any **Plot Group** node, for example, **3D Plot Group** or **1D Plot Group**, and select **Add Image to Export**. Click the **Image** node under **Export**.

By default, the COMSOL Multiphysics generates images using the graphics card. Such hardware-accelerated image export runs fast and can make it possible to export larger images but can become unstable if the image size exceeds or is close to the allowed limit (for example, 4000-by-4000 pixels). To instead use software rendering for creating the images, open the **Preferences** window, and, on the **Graphics** page, select the **Use software rendering for image export** checkbox.

Use the Animation node to export multiple images for different time steps or eigenvalues.

The nodes are numbered sequentially. To make it easier to organize, you can right-click and **Rename** the node.

The default values for the properties below are valid before any image has been exported successfully. After that, the settings from the last successful image export are used as default values the next time you add an **Image** node.

In the **Label** field, enter another label for the node if desired.

From the **Preset** list, you can choose from predefined and user-defined sets of image snapshot settings: **Current**, **Manual (web)**, **Manual (print)** (the default), or **Presentation and document**, which are tailored settings for image snapshots suitable for a web page, for printing, or for a PowerPoint presentation or Word document, respectively. **Manual (web)** and **Manual (print)** both use a white background, but **Manual (web)** uses pixels and a resolution of 96 DPI whereas **Manual (print)** uses millimeters and a resolution of 300 DPI. **Presentation and document** uses a transparent background. The **Current** option uses the current size on the screen (which is displayed), so only the **Zoom extents** and **Antialiasing** checkboxes are available under **Image**. If you have modified the image snapshot, you can save those settings as another preset option. To do so, click the **Save as Preset** button (+) and provide a name for the user-defined preset option in the **Name** field of the **Save as Preset** dialog that opens. If you do not want to

keep an added user-defined preset option, click the **Remove Preset** button ( ). If you have made changes to a preset option and want to return to its default values, click the **Reset Preset to Default** button ( ).

The **Settings** window for **Image** includes the following sections:

SCENE

Select an image source. The tree of nodes contains the 1D, 2D, or 3D plot groups previously defined. It also contains component nodes that are associated with an image such as selections, the geometry (including individual geometry features and work planes in 3D), materials, physics features, and meshes. Click the **Use as Source** button ( ) underneath the tree to define the selected node as the source for the image export. The selected node gets a source overlay ( ) in the tree above and is added to the **Selected source** field below. Click the **Clear Source** button ( ) as needed to remove the source. If you have added an image from a plot group, that plot group is set as the selected source.

Select a **View**: **From plot group** or **From geometry** (the defaults, depending on the selected node) to use the view from the plot group settings or from the component's geometry, respectively, or select another view from the list (if available and previously defined). It is also possible to choose **New view**. The image then uses that new view, which appears as a 2D or 3D **View node** (or ( ) node under **Definitions** (or under **Definitions** > **Views** if the nodes are grouped by type).

In the **Settings** window toolbar, click the **Refresh** button ( ) to refresh the **Graphics** window to get a preview of the image to export. Refreshing can be useful if you have changed the scene or view.

Click the **Export** button ( ) in the **Settings** window or right-click the node and select **Export** to export an image to a file. You can also click the downward arrow beside the **Export** button or right-click and choose **Export To** ( ) to open the fullscreen **Export** window for exporting to a database. The **Messages** window confirms where the file is exported as specified in the **File** section.

IMAGE

- Select a **Unit** of dimension: **Millimeters (mm)** (the default), **Inches (in)**, or **Pixels (px)**.
- Select the **Lock aspect ratio** checkbox to keep the original image width and height.
- In the **Width** and **Height** fields, enter the number of pixels, millimeters, or inches for the final image size.
- Enter a **Resolution**. The default is 96 DPI (dots per inch).

The image size for the exported image is displayed below.

Select the **Zoom extents** checkbox to add a zoom to extents before exporting the image. The **Antialiasing** checkbox is selected by default to reduce stairstep-like lines and to smooth lines and edges.

OUTPUT

Choose a **Target**: **File** (the default), **Clipboard** (Windows only), or **PowerPoint and Word** (Windows only).

Target Set to File

If **Target** is set **File**, choose an image file **Format**: PNG (the default), BMP, JPEG, TIFF, GIF, glTF (GL Transmission Format; 3D only, saved as binary GLB files), or EPS (1D only). If you choose the JPEG format, you can also control the quality of the image using a quality measure (scalar number) between 1 and 100 (a higher number represents a higher quality). The default value is 92. Select the checkbox next to **Quality** to enter another quality number.

JPEG is a format that uses "lossy compression", so using a low quality measure can make the exported image differ from the original image.

Enter a **Filename** including a path to save it to your computer or click **Browse** and navigate to where you want to **Save** the output. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the program to always display a dialog for specifying where to store the image.

Target Set to PowerPoint and Word

Choose this option to use the image in a Microsoft® PowerPoint presentation or Microsoft® Word document. The export will copy the image to the clipboard in a way that it will remain linked to the model for future updates after pasting it into the presentation. See Creating PowerPoint Presentations and Word Documents with Linked Tables and Images for more information on how to insert and update images in a presentation.

Select the **Lock view** checkbox if you want to lock the view in PowerPoint and Word. Saved camera settings are then used when you update the image from PowerPoint or Word. If this checkbox is cleared, the current camera settings are used when updating the image.

LAYOUT

	When importing an image with a transparent background to another Windows application, first save the image as a file rather than saving it to the clipboard. In some cases the transparent background is not preserved if you copy an image via the clipboard.

One additional **Background** option is available for the Image export when using a PNG file format: **Transparent**. Otherwise, see Animation for the rest of the settings. For 1D **Image** nodes, the **Include** checkbox is selected by default.

For the glTF file format, the **Include line segments** checkbox is selected by default. Clear that checkbox to exclude line segments, which can be useful for glTF viewers that do not support line segments.

Mesh (Export)

Use the **Mesh** ( ) node to export a mesh to file. Mesh export operates directly on datasets and exports the mesh in the frame specified by the dataset. The mesh data can also be exported from datasets that contain meshes, for example, a **Mesh** dataset or a **Solution** dataset. Right-click the **Export** node and select **Mesh**, or right-click a supported dataset node, for example, **Solution** or **Mesh**, and select **Add Mesh to Export**. In the **Settings** window for **Mesh**, follow these steps to export mesh data:

DATA

Select a **Dataset**. The **Dataset** list contains the solution and mesh datasets previously defined. Select **None** to not export any mesh data.

OUTPUT

Select a **File type** from the list of available file formats. Enter a **Filename** including a path to save it to your computer or click **Browse** ( ) and navigate to where you want to **Save** the output. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. You can export the mesh to a COMSOL Multiphysics binary file (*.mphbin) or text file (*.mphtxt) or to an STL binary file (*.stl) or text file (*.stl), if a 3D dataset is selected. Click the downward arrow for the **Location** menu ( ) to choose **Edit Location** ( ) (if it is a database location), **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the program to always display a dialog for specifying where to store the mesh.

Click the **Export** button ( ) in the **Settings** window or right-click the node and select **Export** ( ). You can also click the downward arrow beside the **Export** button or right-click and choose **Export To** ( ) to open the fullscreen **Export** window for exporting to a database.

	See Importing and Exporting Meshes for information about exporting mesh data using the **Export** option from the main **Mesh** node. You can use that mesh export if you want to export the mesh using the NASTRAN format and also if you want to export the mesh before solving. If you have a mesh and want to import it into another model (as a mesh without its geometry) or into some other software package, it might be inconvenient to have to solve first.

Radiation Pattern (Export)

Use the **Radiation Pattern** ( ) node to export data from a radiation pattern plot to a text file. To add a node for exporting radiation pattern data, right-click the **Export** node and select **Radiation Pattern**. In the **Settings** window for **Radiation Pattern**, follow these steps to export radiation pattern data:

DATA

Select a **Dataset**. The **Dataset** list contains the solution datasets previously defined. Select **None** to not export any radiation plot data.

When you have selected a solution set, choose parameters for the frequency (freq) and azimuthal angle (phi):

- From the **Parameter solution (freq)** list, choose **All** (the default), **First**, **Last**, **From list**, or **Manual**.
- From the **Parameter solution (phi)** list, choose **All** (the default), **First**, **Last**, **From list**, or **Manual**.

EXPRESSIONS

Go to Common Results Node Settings for information about the **Expressions** section.To be consistent with the radiation pattern plot, only the real parts of the expressions are evaluated. If the expression is complex-valued, you must make it explicit what exactly should be evaluated using the `abs`, `arg`, `real`, and `imag` functions.

EVALUATION

In this section you specify the samples on the sphere at which you want the evaluation to take place.

Under **Angles**, enter the **Number of elevation angles**. The default is 10. Enter the **Number of azimuth angles**. The default is 20.

Select a **Restriction**: **None** (the default) or **Manual**. If **Manual** is selected, enter values (SI unit: deg) for:

- θ **start** (the default is 0 degrees)
- θ **range** (the default is 180 degrees)
- φ **start** (the default is 0 degrees)
- φ **range** (the default is 360 degrees)

You can also specify the following settings for a radius-dependent exterior-field expression. Under **Sphere** from the list, select **Unit sphere** (the default) or **Manual**. If **Manual** is selected, enter values for the **x-coordinate**, **y-coordinate**, and **z-coordinate** at the center of the sphere in 3D (SI unit: m) or the **z-coordinate** for an axisymmetric geometry. The default is 0. Enter a **Radius** (SI unit: m). The default is 1 m.

For 2D axisymmetric radiation pattern plots, you can evaluate the azimuthal (φ) angle once for each angle when you specify a name of the variable for the φ angle in the **Azimuthal angle variable** field and use it in the expression

for the radiation pattern. Doing so slows down the evaluation, so if the **Azimuthal angle variable** field is empty, an evaluate-once-and-revolve approach is used instead.

OUTPUT

Enter a **Filename** including a path to save it to your computer, or click **Browse** and navigate to where you want to **Save** the output. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data**, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the program to always display a dialog for specifying where to store the plot data.

ADVANCED

- The **Include header** and **Full precision** checkboxes are selected by default. Click to clear the checkbox if you do not want to include a header, or to limit the precision in the output to six significant figures (and which provides an output that contains all significant figures for data stored as double-precision numbers). If you save the plot data as a VTK file, the **Include header** checkbox is not available. For export to STL, PLY, and 3FM files, none of these checkboxes are available.
- By default, the **Include NaN data points** checkbox is also selected to include such points in the data export.
- From the **If the file exists** list, select **Overwrite** (the default) to replace the data in the file with the data you export, or choose **Append** to append the data to the end of the file. Appending data can be useful when exporting data for a parametric sweep, for example. If you save the plot data using any other file format than text or STL files, the **If the file exists** list is not available.
- Select a column separator from the **Separator** list: **Column** (the default), **Space**, **Tab**, **Comma**, **Semicolon**, **Colon**, or **Vertical bar (pipe)**.

Plot

Right-click **Export** ( ) and select **Plot** ( ) to export a plot from a plot group. Or right-click any plot — for example, the Slice plot in a 3D Plot Group — and then select **Add Plot Data to Export**.

The nodes are numbered sequentially. To make it easier to organize, you can right-click and **Rename** the node.

PLOT

Select a **Plot group** from the list, which contains any previously defined plot groups. Select a **Plot** to export its data. Plot groups can contain one or more individual plots.

Click the **Refresh** button ( ) in the **Settings** window toolbar to update the display in the **Graphics** window of the plot that you want to export after making changes to the selected plot group and plot.

Click the **Export** button ( ) in the **Settings** window toolbar or right-click the node and select **Export** ( ). You can also click the downward arrow beside the **Export** button or right-click and choose **Export To** ( ) to open the fullscreen **Export** window for exporting to a database. The **Messages** window confirms where the files are exported as specified in the **File** section.

OUTPUT

From the **File type** list, choose a file types for saving the plot data:

- Choose **Text** (the default), for any of these text file types: text files (*.txt), CSV (comma-separated values) files (*.csv), data files (*.dat), or, if the license includes LiveLink™ *for* Excel®, Microsoft Excel workbook (*.xlsx).

- Choose **Unstructured VTK file (*.vtu)**, for saving to an unstructured VTK (the Visualization Toolkit) file.
- Choose **WAV audio file (*.wav)** for saving data on the waveform audio file format (WAV), which is an audio file format standard for storing audio bitstreams. The WAV audio file format is particularly useful for auralization of a processed receiver dataset signal in acoustics (for example, for reconstructed impulse responses). The option to export to WAV audio files is available only for 1D plots like Line Graph, Point Graph, Global, Function, Table Graph, and, in particular, Impulse Response plots.
- Choose **STL binary file (*.stl)** or **STL text file (*.stl)** for saving to an STL file. The options to export to STL files are only available for Volume, Surface (Plot), Slice, Multislice, Isosurface (Plot), and Radiation Pattern plots.
- Choose **PLY binary file (*.ply)** or **PLY text file (*.ply)** for saving to a PLY file, a file format known as the Polygon File Format or the Stanford Triangle Format, principally designed to store 3D data from scanners. The options to export to PLY files are only available for Volume, Surface (Plot), Slice, Multislice, Isosurface (Plot), and Radiation Pattern plots.
- Choose **3MF file (*.3mf)** for saving to a 3MF file, a file format known as the 3D Manufacturing Format principally designed as a 3D printing format for additive manufacturing. The options to export to 3MF files are only available for Volume, Surface (Plot), Slice, Multislice, Isosurface (Plot), and Radiation Pattern plots. A warning appears when the resulting file does not seem fit for 3D printing.

Enter a **Filename** including a path to save it to your computer, or click **Browse** and navigate to where you want to **Save** the output. When you have chosen **Text** from the **File type** list, you can save the data using any of the supported text file types that you choose from the **Save as type** list. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the program to always display a dialog for specifying where to store the plot data.

If the **File type** is set to **Text**, from the **Data format** list, select **Spreadsheet** (the default) or **Sectionwise**. For Streamline plots and Particle Tracing plots, you can also control the amount of data to export. By default, the data contains full information about all points for all particles or streamlines. Select the **Only export starting points and endpoints** checkbox to only include one row with the starting point, the endpoint, and the length of the streamline or particle trajectory for each streamline or particle.

	This checkbox only has an effect on particles plotted as lines because plots of particles as points do not contain full information about the particle trajectories.

	For line plots that are exported using the sectionwise format, if the plots are for a variable that is discontinuous between line segments, the sectionwise data will also be discontinuous. Smoothing can merge points with almost the same data values but not points where the difference is significant.

If a referenced 1D plot group contains multiple curves with the same x-coordinates, you can choose an output format from the **If multiple curves** list:

- Choose **Append as rows** (the default) to append the curve data as rows, which results in a data file where all curves' coordinates appear in rows and two columns for their x-coordinate and y-coordinate values, respectively.
- Choose **Append as columns** to append the curve data as columns, which results in a data file where all curves' coordinates appear in columns, the first one for their common x-coordinate values and subsequent columns, one for each curve's y-coordinate values. This format can be more convenient for use as input to interpolation functions and for further processing in external software products such as MATLAB® and Excel®.

ADVANCED

The following options are not available when exporting plot data to WAV audio files. See below for the advanced settings for WAV audio files.

General Options

- The **Include header** and **Full precision** checkboxes are selected by default. Click to clear the checkbox if you do not want to include a header, or to limit the precision in the output to six significant figures (and which provides an output that contains all significant figures for data stored as double-precision numbers). If you save the plot data as a VTK file, the **Include header** checkbox is not available. For export to STL, PLY, and 3FM files, none of these checkboxes are available.
- By default the data is unsorted. Select the **Sort** checkbox to sort the data by increasing x, y, and z coordinates.
- If you export data on any of the PLY or 3MF formats, select the **Include color** checkbox to include vertex colors in the data export.
- From the **If the file exists** list, select **Overwrite** (the default) to replace the data in the file with the data you export, or choose **Append** to append the data to the end of the file. Appending data can be useful when exporting data for a parametric sweep, for example. If you save the plot data using any other file format than text or STL files, the **If the file exists** list is not available.
- Select a column separator from the **Separator** list: **Column** (the default), **Space**, **Tab**, **Comma**, **Semicolon**, **Colon**, or **Vertical bar (pipe)**. If you save the plot data using any other file format than text, the **Separator** list is not available.

WAV Audio File Options

From the **Normalization** list, choose **Maximum amplitude** (the default) or **User defined** to normalize the signal using the value in the **Reference value** field (default: 1) as the reference for normalization. The user-defined option can be useful for comparing the WAV audio output of two impulse responses from two receivers that receive the sound with different intensities.

From the **Quantization level** list, choose **8-bit** (the default), **16-bit**, or **32-bit float**. A higher level leads to less quantization noise and therefore better quality, but the file size will increase.

From the **Sampling frequency** list, choose **Auto** (the default) for an automatically controlled sampling frequency. That frequency is set as the number of samples minus one divided by the time span after removing negative times or x-values. Choose **User defined** to enter a user-defined sampling frequency (unit: Hz) in the **Frequency** field. The valid range is 0.1–48,000 Hz. If the **Sampling frequency** is set to **Auto**, it calculates the sampling frequency from the curve, but when it is set to **User defined**, interpolation takes place to upsample and downsample the signal.

Table (Export)

Use the **Table** ( ) node to export the contents of a table to file. A table export stores the data from any of the tables in the model, including any evaluation group tables, as a text file. To export a table, right-click a **Table** node under **Tables** ( ) and select **Add Table to Export**, or right-click the **Export** node and select **Mesh**.

Click the **Export** button ( ) in the **Settings** window or right-click the node and select **Export**. The **Messages** window confirms where the files are exported as specified in the **Output** section.

TABLE

First select a source for the table from the Source list: **Table** (the default) or **Evaluation group**. Then select a table or evaluation group from the list below. The **Table** or **Evaluation group** list contains the all tables or evaluation group tables in the model. By default, the selection of a table is the one from which you have selected **Add Table to Export** or the first available table or evaluation group table if you have added the **Table** node directly under **Export**. Select **None** to not export any table data.

OUTPUT

Choose a **Target**: **File** (the default), **Clipboard** (Windows only), or **PowerPoint and Word** (Windows only).

Target Set to File

Enter a **Filename** including a path to save the table data as a file to your computer or click **Browse** and navigate to where you want to **Save** the output and specify the file type as a text file (*.txt), CSV file (*.csv), data file (*.dat), or, if the license includes LiveLink™ *for* Excel®, Microsoft Excel workbook (*.xlsx) from the **Save as type** list. When you save the table data as a Microsoft Excel workbook, you can also specify a **Sheet** and **Range** (by default, those text fields are empty; the program then saves all data), and by default the **Overwrite** checkbox is selected. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the program to always display a dialog for specifying where to store the table data.

Target Set to PowerPoint and Word

Choose this option to use the table in a Microsoft® PowerPoint presentation or Microsoft® Word document. The export will copy the table to the clipboard in a way that it will remain linked to the model for future updates after pasting it into the presentation or document. See Creating PowerPoint Presentations and Word Documents with Linked Tables and Images for more information on how to insert and update tables in a presentation.

LAYOUT

The **Include header** checkbox is selected by default. Click to clear the checkbox if you do not want to include a header.

From the **Precision** list, choose **From preferences** (the default) to use the precision from the **Output display precision** preference setting, **Full** to use full precision, or **Manual** to enter the precision as an integer between 1 and 17 in the **Display precision** field (default: 5).

From the **Notation** list, choose one of the following alternatives for the numeric notation:

- **From selected table** (the default) — use the display notation from the **Table** window.
- **Automatic** — display numbers in either scientific or decimal notation depending on their magnitude.
- **Scientific** — display numbers in scientific notation, for example `8.5E-1`.
- **Engineering** — display numbers in engineering notation, for example `850E-3`.
- **Decimal** — display numbers in decimal notation, for example `0.85`.

From the **Complex notation** list, choose one of the following alternatives for the complex notation:

- **From selected table** (the default)— use the complex notation from the **Table** window.
- **Rectangular** — display complex numbers in terms of real and imaginary parts, for example `1 + 2i`.
- **Polar** — display complex number in terms of magnitude and argument, for example `2.2361∠63.435°`.

From the **If the file exists** list, select **Overwrite** (the default) to replace the data in the file with the data you export, or choose **Append** to append the data to the end of the file. Appending data can be useful when exporting data for a parametric sweep, for example.

The Table Window and Tables Node

Touchstone

Right-click **Export** ( ) and select **Touchstone** ( ) to export data on the Touchstone data format. You specify the export using the **Data** and **Output** sections below; then click the **Export** button ( ). You can also click the downward arrow beside the **Export** button or right-click and choose **Export To** ( ) to open the fullscreen **Export** window for exporting to a database.

Touchstone export requires the AC/DC Module, MEMS Module, or RF Module.

DATA

From the **Dataset** list, choose the dataset that contains the data for which you want to make a Touchstone export. Solution datasets are available from this list. Typically, also select which frequencies to include from the **Parameter selection (freq)** list (default: **All**).

If you have defined a compatible configuration (see Configurations), which is typically a Multiselect Solution, the you can choose **From configuration** from the **Solution parameters** list (the default is **Manual**). With **From configuration**, choose a compatible configuration from the **Configuration** list to use its settings for the solution parameters such as time, eigenvalue, or parameter values to use.

OUTPUT

Specify the filename for the Touchstone export in the **Filename** field. Click **Browse** to open the **Export Data** dialog and browse to the desired location on the file system for a Touchstone file. In most cases, the extension will be *.s*N*p, where *N* is the number of ports (for example, *.s2p for a two-port model). Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not saving to a database) if you want the **Export Data** dialog to appear when you click the **Export** button ( ).

From the **Physics interface** list, choose any of the physics interfaces in the model that support Touchstone export. **None** is always an allowed value. Click the **Go to Source** button ( ) to move to the selected physics interface.

From the **Parameter to export** list, choose one of the following parameters: **S**, **Y**, **Z**, **G**, and **H**. The available parameters are the network parameters that are supported by the chosen physics interface. If you have chosen **None** from the **Physics interface** list, the **Parameter to export** list is not available.

From the **Parameter format** list, choose one of the following formats:

- **Magnitude and angle** (the default)
- **Real and imaginary parts**
- **Magnitude in dB and angle**

Reports and Presentations

About the Report and Presentation Generators

The Report Generator is a tool for reporting and documenting models created in COMSOL Multiphysics. It creates a record of the entire model or selected parts of it, including information about settings made during the modeling process as well as simulation results in the form of tables and images.

Several reports can be created for each model, and you can configure each report by adding, moving, deleting, and disabling the nodes that define the report. You can also define custom templates to generate reports that contain information about specific parts of the model while excluding others. The reports are stored with the model, so you can keep generating reports using the previously configured report contents and update the reports when the model changes.

These reports are easy to publish as electronic documents suitable for the internet or as Microsoft® Word documents (.docx files). The utility generates the HTML report in a file format that makes it possible to customize the report in any HTML editor. A custom style sheet can be used to format the report. You can use HTML tags to create hyperlinks and format the report output in text boxes, headings, and captions.

The Presentation Generator is a tool for creating presentations of models created in COMSOL Multiphysics. It creates a record of the entire model or selected parts of it, including information about settings made during the modeling process as well as simulation results in the form of tables and images, which it outputs as a Microsoft® PowerPoint presentation.

Generating a Model Report

For a model for which you want to create a report, the following steps describe the general procedure:

1. Right-click **Reports** ( ) and choose a report type that creates report nodes that describe the model with a suitable level of detail. The built-in report types, **Brief Report**, **Intermediate Report**, and **Complete Report** are always available. You can also create your own report templates based on either of the built-in ones, which then become accessible from the context menu and the ribbon tab under **From Template**; see Creating, Exporting, and Using Custom Report Templates for details. Alternatively, you can choose **Custom Report** and build the report node by node.
2. In the main Settings window for **Report**, specify the output format (**HTML** or **Microsoft Word**) and the location for the output file and the associated folder with images and style sheet information. You can also specify the style sheet to use for HTML reports and how to enumerate the sections in the report.
3. The top node is typically the **Title Page** node ( ). In its Settings window, you can define the title (defaults to the model's filename), an image to use at the top of the report, author, date, and company information, and add a summary and acknowledgments if applicable.
4. Review the structure and contents of the report. You can add, move, edit, disable, and delete structural elements and report contents. In the **Template** section of the main Settings window for **Report** you can change the template and then click **Generate** ( ) to regenerate the report. The **Template** setting also affects the level of details for any nodes you add manually.

Regenerating a nonempty report replaces the current contents.

The built-in report types define different levels of detail:

- **Brief Report**: contains an overview of the model with all results and plots but no details about the physics interfaces, physics features, solver settings, or variables.
- **Intermediate Report**: contains comprehensive information about the model, including the physics interface settings and variables but not complete information about the underlying equations, for example.
- **Complete Report**: contains all information about the model, including physics interface details such as weak equation expressions and shape functions. This report is suitable for troubleshooting, for example.
- **Custom Report**: contains an initially empty report, which you can configure using the available report components.

For all report types, the templates provide a starting point. It is possible to customize all reports by modifying, moving, adding, disabling, and deleting nodes in the reports. You can also switch the template for an existing report, which affects the report nodes added afterward.

Generating a Model Presentation

For a model for which you want to create a presentation, the following steps describe the general procedure:

1. Right-click **Reports** ( ) and choose a presentation type that creates presentation nodes that describe the model with a suitable level of detail from the **Presentations** submenu. The built-in presentation types, **Standard Presentation** and **Detailed Presentation**, are always available. You can also create your own presentation templates based on either of the built-in ones, which then become accessible from the context menu and the ribbon tab under **From Template**; see Creating, Exporting, and Using Custom Presentation Templates for details. Alternatively, you can choose **Custom Presentation** and build the presentation node by node.
2. In the main Settings window for **Presentation**, specify the location for the output file for the presentation. You can also specify the PowerPoint template to use and other settings for slide headers, images, and slide layouts.
3. The top node is typically the **Title Slide** node ( ). In its Settings window, you can define the title to be taken from the model or to be user defined with a title and subtitle. You can also add an author and company, if desired.
4. Review the structure and contents of the presentation. You can add, move, edit, disable, and delete structural elements and presentation contents. In the **Template** section of the main Settings window for **Presentation** you can change the template and then click **Generate** ( ) to regenerate the report. The **Template** setting also affects the level of details for any nodes you add manually.

Regenerating a nonempty presentation replaces the current contents.

The built-in presentation types define different levels of detail:

- **Standard Presentation**: It contains an overview of the model with all results and plots but excludes details about physics and mesh features as well as materials.

- **Detailed Presentation**: In addition to the default presentation, it contains details about physics and mesh features and materials
- **Custom Presentation**: It contains an initially empty presentation, which you can configure using the available presentation components.

For all presentation types, the templates provide a starting point. It is possible to customize all presentations by modifying, moving, adding, disabling, and deleting nodes in the presentations. You can also switch the template for an existing presentation, which affects the presentation nodes added afterward.

Creating, Exporting, and Using Custom Report Templates

If none of the built-in templates provides the level of detail or formatting that you want for your reports, you can create custom report templates where you can adjust all the settings that you can make in the report nodes to your liking. To add a template to the model, right-click **Reports** ( ) and choose **Template**. Choose settings and generate the template as described in the next section.

When done, you can export the templates you have added to your model to an MPH-file that you save in a dedicated folder, as specified in the **User templates directory** field on the **Results** > **Templates** page of the **Preferences** window; by default, this is the `reporttemplates` folder under your current COMSOL Multiphysics settings directory. Once exported, the templates become available also in future modeling sessions. Established standard templates are best saved in the `data/reporttemplates` folder under the COMSOL Multiphysics installation root.

Saving files under the COMSOL Multiphysics installation root may require administrator privileges.

If you later need to edit an exported template or add new ones, simply open the MPH-file containing your templates and make the desired adjustments. You can choose to have all your templates in a single MPH-file or place them in different ones as long as they are saved in one of the supported folders (user or installation) as described above. The filename for an exported template will be shown within parentheses after the template's label in its context-menu and list items. For example, if the MPH-file `MyTemplates.mph` in your user templates directory contains a template with the label **Plots Only**, you generate a report using this template by choosing **Reports** > **From Template** > **Plots Only (MyTemplates)**.

The Template Node

The **Template** node ( ) contains settings relevant for generating the template as well as the template settings matching the settings available in the main **Report** node described in the next section. The corresponding settings for all other report nodes that can appear when generating a report are made in their respective template node versions; see The Title Page, The Table of Contents, and the sections listed under Model Contents — Report Components.

The template versions of the regular report nodes are restricted to settings that can be meaningfully included in a template. They therefore differ slightly from their regular report counterparts. Specifically, settings in the latter that refer to instances of model reports or model nodes are either not present or replaced by single checkboxes where you specify whether to include or exclude nodes of the corresponding types.

Use the **Label** text field to give your template a descriptive name. This helps you to find the right template to use when generating reports.

TEMPLATE

In the **Template** section, choose the initial level — **Brief**, **Intermediate** (default), or **Complete** — from the **Use initial settings for level** list before you click **Generate** ( ) to generate the template tree. This setting also applies if you build the template node by node. In this section you also choose how nodes that are disabled or not present in the template are interpreted when the template is used for generating a model report. By default, nodes of the same type — for example **Table of Contents**, **Material**, or **Solver** — are not added to the report.

If you change **Default state for deleted or disabled nodes** to **Include**, disabled and absent nodes will be included when generating a report with the settings for the chosen initial level. (Note that the **Exclude** setting in the template does not prevent you from manually adding any type of node to a report after it has been generated.)

The **Generate automatically** checkbox (selected by default) controls if a report created from the template is generated immediately after creation. If you clear this checkbox, reports based on the template will inherit the template's settings for the root node but otherwise be empty. Any nodes you add subsequently, either manually or by clicking **Generate**, will use the settings defined in the template.

FORMAT, IMAGES, AND NUMBER FORMAT

In these sections, you can specify the template's initial values for the report-level settings described next.

Creating, Exporting, and Using Custom Presentation Templates

If none of the built-in templates provides the level of detail or formatting that you want for your presentations, you can create custom presentation templates where you can adjust all the settings that you can make in the presentation nodes to your liking. To add a presentation template to the model, right-click **Reports** > **Presentations** and choose **Presentation Template** ( ). Choose settings and generate the template as described in the next section.

When done, you can export the templates you have added to your model to an MPH-file that you save in a dedicated folder, as specified in the **User templates directory** field on the **Results** > **Templates** page of the **Preferences** window; by default, this is the `reporttemplates` folder under your current COMSOL Multiphysics settings directory. Once exported, the templates become available also in future modeling sessions. Established standard templates are best saved in the `data/reporttemplates` folder under the COMSOL Multiphysics installation root.

Saving files under the COMSOL Multiphysics installation root may require administrator privileges.

If you later need to edit an exported template or add new ones, simply open the MPH-file containing your templates and make the desired adjustments. You can choose to have all your templates in a single MPH-file or place them in different ones as long as they are saved in one of the supported folders (user or installation) as described above. The filename for an exported template will be shown within parentheses after the template's label in its context-menu and list items. For example, if the MPH-file `MyTemplates.mph` in your user templates directory contains a presentation template with the label **Plots Only**, you generate a presentation using this template by choosing **Reports** > **Presentations** > **From Template** > **Plots Only (MyTemplates)**.

The Presentation Template Node

The **Presentation Template** node ( ) contains settings relevant for generating the template as well as the template settings matching the settings available in the main **Presentation** node described in the next section. The corresponding settings for all other presentation nodes that can appear when generating a presentation are made

in their respective template node versions; see The Title Slide and the sections listed under Model Contents — Report Components.

The template versions of the regular presentation nodes are restricted to settings that can be meaningfully included in a template. They therefore differ slightly from their regular presentation counterparts. Specifically, settings in the latter that refer to instances of model presentations or model nodes are either not present or replaced by single checkboxes where you specify whether to include or exclude nodes of the corresponding types.

Use the **Label** text field to give your template a descriptive name. This helps you to find the right template to use when generating presentations.

PRESENTATION TEMPLATE

In the **Presentation Template** section, choose the initial level — **Standard** or **Detailed** — from the **Use initial settings for level** list before you click **Generate** ( ) to generate the template tree. This setting also applies if you build the template node by node. In this section you also choose how nodes that are disabled or not present in the template are interpreted when the template is used for generating a model presentation. By default, nodes of the same type — for example **Material** or **Solver** — are not added to the presentation.

If you change **Default state for deleted or disabled nodes** to **Include**, disabled and absent nodes will be included when generating a presentation with the settings for the chosen initial level. (Note that the **Exclude** setting in the template does not prevent you from manually adding any type of node to a presentation after it has been generated.)

The **Generate automatically** checkbox (selected by default) controls if a presentation created from the template is generated immediately after creation. If you clear this checkbox, presentations based on the template will inherit the template's settings for the root node but otherwise be empty. Any nodes you add subsequently, either manually or by clicking **Generate**, will use the settings defined in the template.

FILE, IMAGES, SLIDE LAYOUTS, AND NUMBER FORMAT

In these sections, you can specify the template's initial values for the presentation-level settings described for the **Presentation** node below.

The Report Node

The main **Report** node ( ) contains information about the formatting and defaults for the report.

If you have added a custom report, you can generate a report tree based on the available templates as specified in the **Template** section (described below) by clicking **Generate** ( ). If the report tree is not empty, you will be asked if you want to replace the current tree.

Any manual changes that you have made in the model tree, such as rearrangements of the section structure or settings adjustments will be lost if you confirm that you want to replace the current report tree.

Regenerating the report tree can be useful if you want to update the tree to reflect changes you have made in the model or if you want to change the report template without replacing the entire report.

Click the **Preview Selected** ( ) or **Preview All** ( ) button to show a preview of the report in the **Preview** window. Click the **Write** button ( ) in the toolbar for the Settings window for **Report**, right-click the **Report** node, or press F8 to create a report. You can also click the downward arrow beside the **Write** button or right-click and choose **Write To**( ) to open the fullscreen **Write** window for writing the report to a database. The **Write** and **Write To**

options are also available by right-clicking any node in the report tree. Selecting **Write** from any report node's context menu generates the entire report.

TEMPLATE

This section, which is collapsed by default, contains the setting for the level of detail in new nodes that are added to the report manually. It also determines which nodes are added as well as their level of detail if you click **Generate** ( ) in the main **Report** node's toolbar. The **Template** list takes its initial value from the template used to create the initial report contents. Alternatively, if you added an empty report, the default value is **Intermediate**. The options available for selection include the values **Brief**, **Intermediate**, and **Complete** as well as any custom report templates found in your user and installation report templates folders and in the current model (see Creating, Exporting, and Using Custom Report Templates).

FORMAT

You can select to create a report in one of the following formats, which you choose from the **Output format** list:

- **HTML**, for creating the report as an HTML file for display in a web browser.
- **Microsoft Word**, for creating the report as a docx file for use as a document in Microsoft® Word (version 2007 or later).

When adding a new report, the initial setting for the output format is that of the last report you wrote (or previewed).

The Report Generator stores the report in a file with the chosen name and by default gives it the extension `.html` or `.docx`. For HTML reports, it stores images included in the report and the style sheet in a subdirectory with the same name as the report plus the suffix `_files`. Reports in Microsoft Word format are self-contained.

Specify the report's directory path and filename in the **Filename** text field or click **Browse** ( ) to launch the **Specify Report File** dialog, browse to the desired location, and enter the filename in the **File name** text field. If the text field is empty, you will be asked to specify the filename when you click **Write**. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

If you select **Always ask for filename** (only available if you are not writing to a database), the **Specify Report File** dialog will always prompt you for a filename; if specified, the current name is the default choice.

When you add a new report, the filename will by default be empty. You can override this behavior by specifying a default report directory in the **Preferences** window; see the subsection Edit the Default Report Settings below.

Select **Open finished report** to directly open the generated report in a web browser (HTML) or Microsoft Word.

By default, report output data that refers to model contents will be rendered as hyperlinks if there is a report section for the referenced object. For example, in the report section for a solver you can follow a link to get to the section describing the study step that defines the solver. If you want to disable hyperlinks, for example when printing a report, select the **Disable cross-reference hyperlinks** checkbox.

To customize the style of reports in the HTML output format, you can specify the CSS-file to use in the **Style sheet** list:

- Select **Default** to use the default style file specified in the **Preferences** window (see Edit the Default Report Settings) or the built-in style in COMSOL Multiphysics if no valid default style file has been given.
- Select **Custom** if you want to use a custom style sheet for a particular report. If you select **Custom**, specify a style sheet in the **Style-sheet file** field, or click **Browse** to locate the style-sheet file (CSS file). Click **Refresh** to reread the style-sheet file. Click **Import** to import the style-sheet file into the model; otherwise, COMSOL Multiphysics references it on your file system. When you have imported a style-sheet file, the **Imported style-sheet file** field

shows its filename. Click **Export** to save an imported style-sheet file on the file system at a location of your choice. The **Style-sheet file** field will be updated accordingly. Click **Discard** to remove an imported style-sheet file from the model.

Also for reports in the HTML format, select a level from the **Generate separate files a section level** list: **None** (the default; one file only), **Level 1**, **Level 2**, or **Level 3**.

For reports in the Microsoft Word format, you can control the layout using the **Template** list:

- Select **Default** to use as the style template the default Microsoft Word template (.dotx) or Microsoft Word document (.docx) file specified in the **Preferences** window, on the **Results** > **Reports** page. If no such file has been specified, COMSOL's built-in template will be used.
- Select **Custom** and type a path to the .dotx or .docx file of your choice in the **Template file** text field or click **Browse** to navigate to its location on the file system. Click **Refresh** to reread the template file. Click **Import** to import the template file into the model; otherwise, COMSOL Multiphysics references it on your file system. When you have imported a template, the **Imported template file** field shows its filename. Click **Export** to save an imported template file on the file system at a location of your choice. The **Microsoft Word template file** field will be updated accordingly. Click **Discard** to remove an imported template file from the model.

From the **Start new page at section level** list, choose the section level at which to start a new page of your report in Microsoft Word format: **None** (no page breaks), **Level 1** (the default), **Level 2**, or **Level 3**.

For both output formats, choose the section level to which the report should enumerate each section from the **Enumerate section to level** list: **None** (no enumerated section), **Level 1**, **Level 2**, **Level 3** (the default), **Level 4**, **Level 5**, **Level 6**, or **All** (enumerate all sections).

Publishing and Editing an HTML Report

Once an HTML report is created, it can be published or edited in any HTML editor. If you want to publish a report on the internet or send it to a colleague, also send the HTML file and the folder with the images and style sheet.

IMAGES

From the **Size** list, you can select the image size as **Extra small** (240-by-180 pixels for HTML screen output/2.4-by-1.8 inches for print-optimized output), **Small** (320-by-240 pixels/3-by-2.4 inches), **Medium** (480-by-360 pixels/4-by-3 inches; the default), **Large** (600-by-450 pixels/6-by-4.5 inches), or **Extra large** (720-by-540 pixels/7.2-by-5.4 inches)).

The width and height values above apply to the default **Orientation** setting, **Landscape**, for which all images have an aspect ratio of 4:3. If you change **Orientation** to **Portrait** instead, width and height are interchanged, resulting in images with the aspect ratio 3:4.

From the **Type** list, select the image file type: **PNG** (the default), **JPEG**, or **BMP** (not supported for reports in Microsoft Word format; choosing this option gives PNG images).

For the best image quality, use PNG images.

From the **Color theme** list, specify which color theme to use for the report: **Global theme** (the default), **Default from preferences**, **Basic**, **COMSOL**, **Dark**, **DarkSelection**, **Default**, **Light**, **LightSelection**, or **RYB**.

From the **Background** list, choose which background to use for the report. **Current**, **From theme**, **Color** (the default), or **Transparent**. If you chose **Color**, then specify a color using the color palette that become available.

There are three options for controlling image generation:

- **Generate images** (default): Report images are generated in accordance with the settings for the individual report features each time you write the report.
- **Suppress image regeneration**: Images are generated if they are not available. Use this option if you want to quickly rewrite the report to include changes that only affect the text.
- **Disable image generation**: Images are not generated. This option can be useful, for example, when troubleshooting models with a very large number of nodes.

When the output format is Microsoft Word, use the **Link information for Word add-in** setting to control if images in the report will be possible to update from Microsoft Word using the COMSOL add-in (see The COMSOL Add-Ins for PowerPoint and for Word for details):

- **From preferences** (default) — Image linking is controlled by the **Include image link information for the COMSOL add-in for Word** checkbox on the **Results** > **Reports** page in the **Preferences** window.
- **On** — Link information will be included for all images whose source entities support linking.
- **Off** — No link information will be included.

METADATA

In this section, collapsed by default, you can specify metadata for reports in HTML and Microsoft Word formats.

For HTML reports, you can specify keywords in the **Keywords** text field. The entered text will be included in the main HTML-file's `head` section as the value of the `content` attribute in the `meta` element with the `name` attribute value `keywords`. Similarly, the text entered in the **Description** field will be included in the `head` section as the value of the `content` attribute in the `meta` element with the `name` attribute value `description`.

For Microsoft Word reports, you can specify information to include in text fields with the same names on the **Info** page in Microsoft Word, which you access via the **File** ribbon button. For the fields indicated by "(all)" below to be visible in Microsoft Word, you have to click **Show All Properties** in that program:

- **Tags**
- **Comments**: If you leave the field empty, the text in the **Comments** field of the Report node's **Properties** page will be used instead.
- **Status** (all)
- **Categories** (all)
- **Subject** (all)

NUMBER FORMAT

Using the controls in this section, you can customize how numbers are formatted in report table output. The available **Format** settings are:

- **Default** — Numbers in report tables are displayed in the same way as in the **Value** column of the table in a **Parameters** node in the COMSOL Desktop. In particular, the precision is then controlled by the **Display precision** setting on the **Results** > **Tables** page of the **Preferences** window.

- **Custom** — Choose this option if you want to customize number formatting for your report. You can then specify the **Precision** as an integer between 1 and 15 (the default is the current **Display precision** preference setting); the **Notation**, with the alternatives
  - **Automatic** (default) — display numbers in either scientific or decimal notation depending on their magnitude.
  - **Decimal** — display numbers in decimal notation, for example `0.85`.
  - **Engineering** — display numbers in engineering notation, for example `850E-3`.
  - **Scientific** — display numbers in scientific notation, for example `8.5E-1`.

  and the **Complex notation**:
  - **Rectangular** — display complex numbers in terms of real and imaginary parts, for example `1 + 2i`.
  - **Polar** — display complex number in terms of magnitude and argument, for example `2.2361∠63.435°`.

For **Scientific** and **Decimal** notation, select the **Display all significant digits** if you want to keep trailing zeros within the chosen precision.

Select the **Right align numeric columns** checkbox to right align table columns with purely numeric data.

You can override the report-wide number format settings for individual report feature nodes that generate table data. The **Settings** window for such a report feature node contains a **Number Format** section where you can specify the **Format** as either **From report** (the default) or **Custom**. The former option gives the number formatting defined in the corresponding section of the parent Report node, whereas the latter allows you to specify dedicated settings.

Edit the Default Report Settings

Open The Preferences Window and navigate to **Results** > **Reports** to control some properties for the report generator.

- If the **Report directory** refers to an existing directory, the default filename for a new report will be based on the model's name. When the report directory is set in this way, a nonabsolute path in the **Filename** text field in the **Format** section of the Report **Settings** window will be interpreted as relative to this directory.
- In the **Default report style-sheet file** field, type the full path and filename to a style sheet (.css-file) that you want to use as the default style sheet for reports in HTML format. Click **Browse** to browse to the file's location.
- In the **Default Microsoft Word template file** field, type the full path and filename to a Microsoft Word template (.dotx-file) that you want to use as the default style template for reports in Microsoft Word format. Click **Browse** to browse to the file's location. You can also use a Microsoft Word document (.docx-file) as your default template.
- In the **Logo file** field, type the full path and filename for an image file (on PNG or JPEG format) to use as the logo. Click **Browse** to browse to the logo file. If empty, the COMSOL logo appears in the report.
- In the **Company** field, type the name of a company associated with the report if desired.
- From the **Default image size** list, you can select the default size for report images; choose between **Extra small**, **Small**, **Medium**, **Large**, and **Extra large**. Similarly, use the **Default image type** list to specify the default type for the report images: **PNG**, **JPEG**, or **BMP**.
- Select the **Prompt for update of table of contents in Microsoft Word** checkbox to make Microsoft Word ask whether you want to update the table of contents when you first launch a report in this format. Such an update is necessary to generate page numbers in the table of contents, but you can choose to do the update after you have opened the document in Microsoft Word. By default this checkbox is not selected.

The Title Page

By default, all nonempty reports start with a title page (if it is not needed, right-click the applicable node and choose **Delete**). The **Title Page** node ( ) defines general settings and information about the model. The default name is the model's filename.

FRONT MATTER

In the **Report title** list, choose between linking the report's title to the MPH-file's name (**From model**) or specifying it independently (**Custom**). If you choose **Custom** (the default), use the **Title** field to give the title of the report (the default text is the title specified in the root node's **Title** field; see The Root Settings Window).

From the **Image** list, select an option for an image in the report title: **None**, **Thumbnail** (the default), or any of the plot groups' plots in the model. See Setting and Clearing the Thumbnail Image for information about the thumbnail. The **Zoom extents** setting applies to the case when the image source is a plot group. Select one of the following options:

- **On** — perform a zoom to extents action when the image is generated
- **Automatic** (default) — perform a zoom to extents action when the image is generated if the referenced plot group is associated with a view whose camera (3D) or axis (2D) is not locked or is a graph plot whose axis limits are not fixed
- **Off** — do not perform a zoom to extents action when the image is generated

From the **Layout** list, select **Table** (the default) to present the model settings such as author and date in a table, or select **Headings** to present these settings using headers.

The **Logo** list offers the alternatives **None**, **Default** (the default), and **Custom**. Choose **None** if you want a report without a logo on the title page. The **Default** option gives a report with the logo that you have specified on the **Results** > **Reports** page in the **Preferences** window or, if no such logo is available, the COMSOL logo. Choosing **Custom** activates a **Logo file** field with an associated **Browse** button ( ), allowing you to specify a custom logo. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Show in Auxiliary Data** ( ) to move to the row for this file in the **Auxiliary Data** window, **Copy Location** ( ), and (if you have copied a file location) **Paste Location** ( ).

Use the **Author**, **Company**, and **Report version** fields if desired to provide that information in the report. Clear the checkbox for each setting to exclude it from the report.

In the **Report date** list, you can choose between **None**, **Current** (the default), and **Custom**. Choose **None** to leave out the report date from the title page, **Current** to use the date and time when the report is written, or **Custom** to enter a date string of your choice in the **Date** text field (where the current date appears by default).

The **Summary** text box contains the comments from the model's root node (the model description) by default. Clear the associated checkbox to exclude the summary from the report.

The **Acknowledgment** text box is empty by default. Clear the associated checkbox to exclude the acknowledgment from the report.

Each of the fields **Author**, **Company**, **Report date**, **Report version**, **Summary**, and **Acknowledgment** has an associated **Label** list that lets you choose the label to show next to the corresponding text in the report output. The default setting is the same as the field label. If you want a different label for any of these fields, choose **Custom** from the associated list and enter a label of your choice in the **Text** field. This option can be useful, for example, if you want to write reports in a language other than those supported by COMSOL Multiphysics.

The Table of Contents

The **Table of Contents** node ( ) contains the table of contents for the report.

SETTINGS

In the **Heading** list you can choose the heading text for the table of contents in the generated report. The default text is **Contents**. If you want a different heading, choose **Custom** and type it in the **Text** field.

The **Section levels in table of contents** list determines how many section levels to include in the table of contents: 1–5 (default: 2).

TABLE OF CONTENTS

This section contains the current table of contents.

The Presentation Node

The main **Presentation** node ( ) contains information about the formatting and defaults for the presentation.

If you have added a custom presentation, you can generate a presentation tree based on the available templates as specified in the **Template** section (described below) by clicking **Generate** ( ). If the presentation tree is not empty, you will be asked if you want to replace the current tree.

Any manual changes that you have made in the model tree, such as rearrangements of the section structure or settings adjustments will be lost if you confirm that you want to replace the current presentation tree.

Regenerating the presentation tree can be useful if you want to update the tree to reflect changes you have made in the model or if you want to change the presentation template without replacing the entire presentation.

Click the **Preview Selected** ( ) or **Preview All** ( ) button to show a preview of the presentation in the **Preview** window. Click the **Write** button ( ) in the toolbar for the Settings window for **Presentation**, right-click the **Presentation** node, or press F8 to create a PowerPoint presentation. You can also click the downward arrow beside the **Write** button or right-click and choose **Write To**( ) to open the fullscreen **Export** window for writing the report to a database. The **Write** and **Write To** options are also available by right-clicking any node in the presentation tree. Selecting **Write** from any presentation node's context menu generates the entire presentation.

TEMPLATE

This section, which is collapsed by default, contains the setting for the level of detail in new nodes that are added to the presentation manually. It also determines which nodes are added as well as their level of detail if you click **Generate** ( ) in the main **Presentation** node's toolbar. The **Template** list takes its initial value from the template used to create the initial presentation contents. Alternatively, if you added an empty presentation, the default value is **Standard**. The options available for selection include the values **Standard** and **Detailed** as well as any custom presentation templates found in your user and installation presentation templates folders and in the current model (see Creating, Exporting, and Using Custom Presentation Templates).

FILE

In the **Filename** field, specify a filename and path for the presentation, or click **Browse** ( ) to specify the file to save the presentation to. You can also click the downward arrow beside the **Browse** button and choose **Browse From** ( ) to open the fullscreen **Select File** window. Click the downward arrow for the **Location** menu ( ) to choose **Copy Location** ( ) and (if you have copied a file location) **Paste Location** ( ).

Select the **Always ask for filename** checkbox (only available if you are not writing to a database) if the software should ask for a filename if needed.

The **Open finished presentation** checkbox is selected by default so that the presentation is opened when finished. Clear this checkbox if you do not want to see the presentation directly.

From the **Microsoft PowerPoint template** list, choose **Default** to use the template file specified in the **Preferences** window (see Edit the Default Presentation Settings) or the built-in template if no template has been specified. If you choose **Custom** you can specify another PowerPoint template (*.potx file) in the **Microsoft PowerPoint template file** field. Click **Refresh** to update the slide layouts in the model if the template file has changed. Note that this will reset all slide layout settings to the default values for the chosen template. Click **Import** to import the template file into the model; otherwise, COMSOL Multiphysics references it on your file system. When you have imported a template, the **Imported template file** field shows its filename. Click **Export** to save an imported template file on the file system at a location of your choice. The **Microsoft PowerPoint template file** field will be updated accordingly. Click **Discard** to remove an imported template file from the model. This will reset all slide layouts to the default values for the template.

From the **Include section header slides to level** list, choose a level to which you want to include section header slides: **None**, **Level 1**, **Level 2** (the default), or **Level 3**.

In the **Maximum number of table rows** field, enter a value between 5 and 2000 to limit the number of rows per table (default: 50). This setting allows you to prevent generating presentations with possibly several hundred slides.

IMAGES

From the **Size** list, you can select the default image size for the presentation, which determines the fraction of the content placeholder's width that the image occupies on the title and content slide: **Extra small** (35%), **Small** (42.5%), **Medium** (50%), **Large** (57.5%), or **Extra large** (65%). The sizes of the generated image files are those for print-optimized output listed under Images in The Report Node section.

With the default **Orientation** setting, **Landscape**, all images have an aspect ratio of 4:3. If you change **Orientation** to **Portrait** instead, width and height are interchanged, resulting in images with the aspect ratio 3:4.

From the **Type** list, select the image file type: **PNG** (the default) or **JPEG**.

For the best image quality, use PNG images.

From the **Color theme** list, specify which color theme to use for the presentation: **Global theme** (the default), **Default from preferences**, **Basic**, **COMSOL**, **Dark**, **DarkSelection**, **Default**, **Light**, **LightSelection**, or **RYB**.

From the **Background** list, choose which background to use for the presentation. **Current**, **From theme**, **Color** (the default), or **Transparent**. If you chose **Color**, then specify a color using the color palette that become available.

There are three options for controlling image generation:

- **Generate images** (default) — Report images are generated in accordance with the settings for the individual report features each time you write the report.
- **Suppress image regeneration** — Images are generated if they are not available. Use this option if you want to quickly rewrite the report to include changes that only affect the text.
- **Disable image generation** — Images are not generated. This option can be useful, for example, when troubleshooting models with a very large number of nodes.

Use the **Link information for PowerPoint add-in** setting to control if images in the presentation will be possible to update from PowerPoint using the COMSOL add-in (see The COMSOL Add-Ins for PowerPoint and for Word for details):

- **From preferences** (default) — Image linking is controlled by the **Include image link information for the COMSOL add-in for PowerPoint** checkbox on the **Results** > **Presentations** page in the **Preferences** window.
- **On** — Link information will be included for all images whose source entities support linking.
- **Off** — No link information will be included.

SLIDE LAYOUTS

The generated presentations use four different slide layouts, all based on standard PowerPoint slide layouts. For a layout in a template to be valid it must satisfy certain criteria, which depend on the layout type:

- **Title slide** — Must contain one of either a centered title or a title placeholder and one of either a subtitle or a body placeholder.
- **Title and content** — Must contain one of either a title or a centered title placeholder and one content placeholder.
- **Section header** — Must contain one of either a title or a centered title placeholder and one body placeholder.
- **Two content** — Must contain one of either a title or a centered title placeholder and, in addition, *either*
  - two content placeholders *or*
  - one content placeholder and either a picture placeholder or a body placeholder.

The placeholders used for text content must satisfy a minimum height requirement to be considered. Excluding placeholders not meeting this requirement, the slide layouts must not contain any placeholders other than those listed above, not counting date and time, header, footer, and slide number placeholders, which are ignored.

If you try to choose a template file that does not contain at least one valid layout for each of the four slide layout types, you will get an error message stating which criterion or criteria were not fulfilled. If this happens, choose a different template or try to adjust your template in PowerPoint.

In the **Content with image layout** list you can choose which layout to use for slides with an image:

- **Automatic** — The current **Two content** layout is used with the following exception: The current **Title and content** layout is used for Plot Group nodes with no text and with **Slide with image only** set to **Center image** (see below).
- **Title and content** — Always use the current **Title and content** layout.
- **Two content** — Always use the current **Two content** layout.

Content slides without an image always use the current **Title and content** layout.

In the **Slide with image only** list you can choose how to handle title and content slides with an image on the right that contain no text except for the title and possibly a figure caption:

- **Center image** (the default) — The image will be centered horizontally within the slide's content placeholder. For plot groups, the image size will also be scaled up to extra large.

- **Add text box** — An empty text box will be added to the left of the image. To locate this text box, hover below the title field near the left edge of the slide and click when a text cursor appears if you want to add text manually.
- **No action** — The image will be shown on the slide's right-hand side, while the left-hand side will be empty.

By default, text added in the **Comments** text area on the Properties page for a node reported on, will be shown on the left-hand side of the slide, each line generating a separate bullet. You can use this to make the presentations in your model self-contained and reduce the need for subsequent editing in PowerPoint.

The **Title suffix for continuation slides** setting controls how to handle the title when the contents generated for a presentation node with the layout Title and content or Two content does not fit on a single slide:

- **None** — No suffix is added to the title on the continuation slides.
- **Default** — The suffix " (Continued)" (or the applicable translation) is appended to the title on the continuation slides.
- **Custom** — Choose this option if you want to specify your own title suffix in the **Suffix** text field. Unless the text you enter starts with one of the characters (, [, {, -, –, —, or nonbreaking space, surrounding parentheses will be added automatically.

When a presentation section contains more than one child node, the node labels for the children are by default used as heading texts on the slides. You can suppress these headings by clearing the **Use labels as headings** checkbox.

METADATA

In this section, collapsed by default, you can specify information to include in text fields with the same names on the **Info** page in Microsoft PowerPoint, which you access via the **File** ribbon button. For the fields indicated by "(all)" below to be visible in Microsoft PowerPoint, you have to click **Show All Properties** in that program:

- **Tags**
- **Comments** (all): The text is shown in the **Comments** field on the **Info** page in Microsoft Word. If you leave the field empty, the text in the **Comments** field of the Report node's **Properties** page will be used instead.
- **Status** (all)
- **Categories**
- **Subject** (all)

NUMBER FORMAT

Using the controls in this section, you can customize how numbers are formatted in presentation table output. The available **Format** settings are:

- **Default** — Numbers in presentation tables are displayed in the same way as numbers are displayed by default in the Table window in the COMSOL Desktop. In particular, the precision is then controlled by the **Display precision** setting on the **Results** > **Tables** page in the **Preferences** window.

- **Custom** — Choose this option if you want to customize number formatting for your presentation. You can then specify the **Precision** as an integer between 1 and 15 (the default is the current **Output display precision** preference setting); the **Notation**, with the alternatives
  - **Automatic** (default) — display numbers in either scientific or decimal notation depending on their magnitude.
  - **Decimal** — display numbers in decimal notation, for example `0.85`.
  - **Engineering** — display numbers in engineering notation, for example `850E-3`.
  - **Scientific** — display numbers in scientific notation, for example `8.5E-1`.

  and the **Complex notation**:
  - **Rectangular** — display complex numbers in terms of real and imaginary parts, for example `1 + 2i`.
  - **Polar** — display complex number in terms of magnitude and argument, for example `2.2361∠63.435°`.

For **Scientific** and **Decimal** notation, select the **Display all significant digits** if you want to keep trailing zeros within the chosen precision.

Select the **Right align numeric columns** checkbox to right align table columns with purely numeric data.

You can override the presentation-wide number format settings for individual presentation feature nodes that generate table data. The **Settings** window for such a presentation feature node contains a **Number Format** section where you can specify the **Format** as either **From presentation** (the default) or **Custom**. The former option gives the number formatting defined in the corresponding section of the parent Presentation node, whereas the latter allows you to specify dedicated settings.

Edit the Default Presentation Settings

Open The Preferences Window and click **Reports and Presentations** to control some properties for the presentation generator.

- If the **Presentation directory** refers to an existing directory, the default filename for a new presentation will be based on the model's name. When the presentation directory is set in this way, a nonabsolute path in the **Filename** text field in the **Format** section of the Presentation **Settings** window will be interpreted as relative to this directory.
- In the **Default Microsoft PowerPoint template file** field, type the full path and filename to a Microsoft PowerPoint template (.potx-file) that you want to use as the default template for presentations. Click **Browse** to browse to the file's location. You can also use a Microsoft PowerPoint document (.pptx-file) as your default template.
- In the **Company** field, type the name of a company associated with the presentation if desired.
- From the **Default image size** list, you can select the default size for presentation images; choose between **Extra small**, **Small**, **Medium**, **Large**, and **Extra large**. Similarly, use the **Default image type** list to specify the default type for the presentation images: **PNG** or **JPEG**.
- With the **Include image link information for the COMSOL add-in for PowerPoint** selected, it will by default be possible to update some presentation images in Microsoft PowerPoint provided that you have installed the COMSOL add-in. See the Images and The COMSOL Add-Ins for PowerPoint and for Word sections for further information.
- The **Maximum number of slides** setting helps to avoid generating excessively long presentations. The default value is 200. You can specify any value between 20 and 1000. If more slides than the specified maximum number are needed, an error message is shown. A truncated presentation is saved at the specified location but it does not open automatically even if **Open finished presentation** has been selected in the Presentation settings.

The Title Slide

By default, all nonempty presentations start with a title slide (if it is not needed, right-click the applicable node and choose **Delete**). The **Title Slide** node ( ) defines general settings and information about the model. The default presentation title is the model's filename.

SETTINGS

In the **Presentation title** list, choose between linking the presentation's title to the MPH-file's name (**From model**) or specifying it independently (**Custom**). If you choose **Custom** (the default), use the **Title** field to give the title of the presentation (the default text is the title specified in the root node's **Title** field; see The Root Settings Window). You can also add a subtitle to the presentation, if desired, in the **Subtitle** field.

Use the **Author** and **Company** fields if desired to provide that information in the presentation. Clear the checkbox in front of each setting to exclude it from the title slide.

Sections in the Report

The **Section** nodes ( ) provide the structure of the report. You can add sections in several levels by right-clicking a **Section** node to add additional **Section** nodes as subsections. The **Section** node's context menu also contains three submenus:

- **Custom Contents** — for adding custom report component such as paragraphs, images, and tables
- **Model Contents** — for adding information about the model such as the geometry, mesh, physics interfaces, and plot groups
- **Declaration Contents** — for adding information about data declarations defined under the **Declarations** branch in the **Application Builder**.

In addition, you can add **Arrays** and **Scalars** nodes from this menu.

SECTION TITLE

From the **Source** list, select the source of the section's title:

- **Custom** (the default) — specify the title in the **Title** field.
- **From first child node** — the section title is the name of the first child node under the **Section** node.

IMAGES

See the section Images for Reports and Presentations.

Sections in the Presentation

The **Section** nodes ( ) provide the structure of the presentation; they can, but need not, generate section header slides in the finished presentation. You can add sections in several levels by right-clicking a **Section** node to add additional **Section** nodes as subsections. The **Section** node's context menu also contains three submenus:

- **Custom Contents** — for adding custom presentation component such as paragraphs, images, and tables
- **Model Contents** — for adding information about the model such as the geometry, mesh, physics interfaces, and plot groups
- **Declaration Contents** — for adding information about data declarations defined under the **Declarations** branch in the **Application Builder**.

In addition, you can add **Arrays** and **Scalars** nodes from this menu.

SETTINGS

From the **Source** list, select the source of the section's title:

- **Custom** (the default). You then specify the title in the **Title** field.
- **From first child node**. The section title is the name of the first child node under the **Section** node.

Add a title in the **Title** field (default: the name of the Section node). Optionally, you can also add text for the section header slide's body in the **Text** field.

From the **Include section header slide** list you can choose between the following options:

- **Automatic** (the default) — If the section has section children only, this setting is interpreted as **By section level** described below. If, instead the section has at least one content child node, the behavior depends on the number of children. If there is only one child, the section's title will appear as the title on the child's slide or slides. If there are two or more children, the title of the slides for the children of content type will be determined by the section's settings and the node labels for these children will be shown as headings of level 1. Section children are handled in the same way as sections in a list with only section siblings. For the cases when no section header slide is generated, any text entered in the **Text** field will be ignored.
- **By section level** — A section header slide with the specified title and text is included if the section's level does not exceed the value specified in the **Include section header slides to level** list in the Presentation parent node's Settings window.
- **From parent** — The setting is inherited from the parent Section or Presentation node. In the latter case, the **Include section header slides to level** list setting **None** gives the setting **Automatic**.
- **Exclude** — No section header slide is generated and the section's title is not used.
- **Include** — A section header slide with the specified title and text is generated.

If the **Title** and **Text** fields are both empty no section header slide will be generated, irrespectively of the **Include section header slide** setting.

IMAGES

See the section Images for Reports and Presentations.

SLIDE LAYOUTS

See the section Slide Layouts (Presentations Only).

Custom Report, Documentation, and Presentation Components

Right-click nodes to select and add these report, documentation, or presentation nodes from the **Custom Contents** submenu or directly in the context menu for **Section** nodes under **Documentation**: **Bibliography**, **Code**, **Equation**, **Heading**, **Image**, **List**, **Note**, **Table**, and **Text**.

The custom components provide basic building blocks for a report or a presentation as described in Table 21-3.

TABLE 21-3: CUSTOM REPORT, DOCUMENTATION, AND PRESENTATION COMPONENTS.

ICON	COMPONENT	DESCRIPTION
	Bibliography	Adds a reference or bibliography to the document. Right-click to add **Reference** www nodes. Available under a **Documentation** node only.
	Code	Adds a text block for code using a code (monospace) font. You can also make part of the text using an italic or bold variant of the code font.
	Equation	Adds an equation to the report, document, or presentation. You can use LaTeX markup directly or import the equation as an image. Under **Equation preview** you can see the equation that the LaTeX commands that you enter create.
	Heading	Adds a heading to the report, document, or presentation with a text from the **Text** field and a layout for the level (Level 1–Level 6) from the **Level** list. The default is to use the level where the Heading node appears.

TABLE 21-3: CUSTOM REPORT, DOCUMENTATION, AND PRESENTATION COMPONENTS.

ICON	COMPONENT	DESCRIPTION
	Image	Adds an image to the report, document, or presentation. Select the image source from the **Source** list: **Plot group** to select the plot from available plots in the Plot group list; **External** to use any external image file in PNG, Windows Bitmap (BMP), or JPEG format; or **From Export** to use an Image node under **Results** > **Export** as the source. Add a **Caption** if desired.
	List	Adds a list. By default, the **Numbered** checkbox is selected, giving a numbered list; clear the checkbox for an unordered (bullet) list. Right-click the **List** node to add **List Item** nodes.
	List Item	Right-click the **List** node to add this node with a **Text** area for the list item's contents. Right-click to add **Code**, **Equation**, **Image**, **Table**, **Text**, or other **List** nodes for inserted texts, equations, images, or tables in the list or for creating nested lists.
	Note	Adds a **Note** node for adding one of the following note types, which you select from the **Type** list: **Note** (the default), **Caution**, **Important**, **Model**, **See also**, or **Tip**. From the **Show** list, select **Icon** (the default) to display the icon only, **Description** (the type), or **Icon and description**. Then add the text for the note. Available under a **Documentation** node only.
www	Reference	Right-click a **Bibliography** node to add references. The reference information that you provide is formatted based on the type of reference that you select from the **Type** list: **Journal article** (the default), **Book**, **Conference paper, Thesis**, or **Web**. Available under a **Documentation** node only.
	Table	Adds a table with a **Title** and a **Number of columns** (default: 3 columns). Right-click to add a **Table Heading Row** and **Table Rows**.
	Table Heading Row	Right-click the **Table** node to add this node and then define headings for each column.
	Table Rows	Right-click the **Table** node to add this node and then add the contents for each column in a row of a table.
	Text	Provides a **Text** area where text can be added (including HTML tags for formatting and links).

TEXT FORMATTING TOOLS

For all **Text**, **List Item**, and **Note** nodes' settings, a set of tools above and below the text field provides a quick way to add formatting to the text:

- The formatting tools above the text provide:
  - Character formats for user-interface labels; emphasis; code (standard, bold, and italic); equation components (bold, variables, and constants); subscript; and superscript. To convert a part of the text to any of these character formats, highlight the text that you want to format and then click , say, to mark the text as a user-interface label (a sans serif boldface font) enclosed by the opening and closing tags `<1>` and `</1>` before and after the text, respectively.

> Each line in the text editor corresponds to a separate paragraph in the output. Therefore, matching opening and closing tags must appear on the same line.

  - Buttons for enclosing text in single (' ') and double (" ") quotes.
  - Buttons for increasing and decreasing the list levels for bullet and numbered lists, including combinations of these list types. Select a line and click **Increase Bullet-List Level** ( ) to increase the bullet-list level by one step; this is indicated in the text area by the addition of a highlighted asterisk (*) symbol at the beginning of the line or to the right of any already added asterisks or hash symbols (#). The latter character represents a

numbered-list level, which can be increased by clicking **Increase Numbered-List Level** ( ). Clicking **Decrease List Level** ( ) removes the innermost (highest) list level at the selected line, which can be either a bullet or numbered level.

- From the character tools below the text, click the character that you want to insert; for example, click Ω to insert an uppercase omega as `\Omega` in the text. The character tools include lowercase and uppercase Greek letters and the en-dash (–) and em-dash (—) punctuation symbols.

Click **Preview Selected** ( ) to display a preview of the text, including formatting, in the **Preview** window.

Declaration Components

Use these report and presentation components, available from the Section node's **Declaration Contents** context menu, to add standard tables for data declarations added to the Application Builder's Declarations branch; see the section The Declarations Branch in the *Application Builder Reference Manual* for more information.

Arrays and Scalars

Use the Arrays and Scalars report and presentation components to create customized tables for data from the Declaration and Model branches, as described in Table 21-4.

TABLE 21-4: THE ARRAYS AND SCALARS REPORT AND PRESENTATION COMPONENTS.

ICON	COMPONENT	DESCRIPTION
	Arrays	Adds a table with data from Array 1D and Array 2D declaration nodes defined under the Application Builder's Declarations branch. Under **Columns**, add rows with array data from the **Declarations** branch. 2D arrays are also available and, when added, a 2D array makes up all columns in the table. You can also add a column heading.
	Scalars	Adds a table where the columns to include and the table data rows can be customized. Under **Rows**, add rows with applicable data from the **Declarations** and **Model** branches. Under **Columns**, define which data columns to include and their headings. In the **Columns** section, add the columns you want to display. For each column, enter the heading in the **Heading** column. In the **Data** column, choose the corresponding data to display: **Description**, **Value**, **Name**, **Expression**, or **Unit**.

Mathematical Symbols and Special Characters

COMSOL Multiphysics supports a subset of the LaTeX language for creating equations as part of the documentation or in user-developed physics interfaces and other applications. You can also use the LaTeX commands in plot titles. Commands include Greek and other characters, mathematical symbols and operators, arrows, text and font formats, and environments for text and mathematical typesetting. The following tables and lists contain the commands that are available for creating equations and other mathematical text.

If the LaTeX syntax is not correct or not included in the COMSOL Multiphysics software, the equation preview is empty, but no error appears. Also, for symbols in math mode, surround the LaTeX syntax with `$` to indicate that the text inside of the `$` signs is LaTeX when used as an annotation text, for example.

GREEK AND OTHER CHARACTERS

The following table contains the supported lowercase and uppercase Greek letters and the Swedish character Å in math mode:

TABLE 21-5: GREEK AND OTHER CHARACTERS (IN MATH MODE).

COMMAND (UPPERCASE)	CHARACTER	COMMAND (LOWERCASE)	CHARACTER
		\alpha	α
		\beta	β
\Gamma	Γ	\gamma	γ
\Delta	Δ	\delta	δ
		\varepsilon	ε
		\epsilon	ϵ
		\zeta	ζ
		\eta	η
\Theta	Θ	\theta	θ
		\vartheta	ϑ
		\iota	ι
		\kappa	κ
\Lambda	Λ	\lambda	λ
		\mu	μ
		\nu	ν
\Xi	Ξ	\xi	ξ
\Pi	Π	\pi	π
		\varpi	ϖ
		\rho	ρ
\Sigma	Σ	\sigma	σ
		\varsigma	ς
		\tau	τ
\Upsilon	Υ	\upsilon	υ
\Phi	Φ	\phi	ϕ
		\varphi	φ
		\chi	χ
\Psi	Ψ	\psi	ψ
\Omega	Ω	\omega	ω
\AA	Å		

The following tables contain the supported lowercase and uppercase Greek letters and other characters in text mode (so that no math mode enclosures using $ are needed):

TABLE 21-6: GREEK CHARACTERS (TEXT MODE).

COMMAND (UPPERCASE)	CHARACTER	COMMAND (LOWERCASE)	CHARACTER
\textAlpha	A	\textalpha	α
\textBeta	B	\textbeta	β
\textGamma	Γ	\textgamma	γ
\textDelta	Δ	\textdelta	δ
\textEpsilon	E	\textepsilon	ϵ

TABLE 21-6: GREEK CHARACTERS (TEXT MODE).

COMMAND (UPPERCASE)	CHARACTER	COMMAND (LOWERCASE)	CHARACTER
		\straightepsilon	ε
\textZeta	Z	\textzeta	ζ
\textEta	H	\texteta	η
\textTheta	Θ	\texttheta, \scripttheta	ϑ
		\straighttheta	θ
\textIota	I	\textiota	ι
\textKappa	K	\textkappa	κ
\textLambda	Λ	\textlambda	λ
\textMu	M	\textmu, \textmugreek	μ
\textNu	N	\textnu	ν
\textXi	Ξ	\textxi	ξ
\textOmikron, \textOmicron	O	\textomikron, \textomicron	ο
\textPi	Π	\textpi	π
\textRho	P	\textrho	ρ
\textSigma	Σ	\textsigma	σ
		\textvarsigma	ς
\textTau	T	\texttau	τ
\textUpsilon	Y	\textupsilon	υ
\textPhi	Φ	\textphi	φ
		\straightphi	ϕ
\textChi	X	\textchi	χ
\textPsi	Ψ	\textpsi	ψ
\textOmega	Ω	\textomega	ω

TABLE 21-7: OTHER SYMBOLS (TEXT MODE).

COMMAND	SYMBOL	COMMAND	SYMBOL
\textdegree	°	\textonequarter	¼
\textdiv	÷	\textonesuperior	¹
\textdownarrow	↓	\textpm	±
\textfractionsolidus	/	\textrightarrow	→
\textleftarrow	←	\textsurd	√

ARROWS

The following table includes the available types of arrows:

TABLE 21-11: ARROWS.

COMMAND	SYMBOL	COMMAND	ARROW
\leftarrow or \gets	←	\rightarrow or \to	→
\Leftarrow	⇐	\Rightarrow	⇒
\Leftrightarrow	⇔	\leftrightarrow	↔
\hookleftarrow	↩	\leftharpoonup	↼
\leftharpoondown	↽	\leftrightharpoons	⇌
\nearrow	↗	\swarrow	↙
\leadsto	⇝	\hookrightarrow	↪
\rightharpoonup	⇀	\rightharpoondown	⇁
\searrow	↘	\nwarrow	↖
\downarrowtobar	↧	\uparrowtobar	↥
\downtrianglefilled	▼	\uptrianglefilled	▲

\longleftrightarrow	⟷	\Longleftarrow	⟸
\Longrightarrow	⟹	\Longleftrightarrow	⟺
\iff	⇔		

DELIMITERS AND ENVIRONMENTS

The following tables includes the available delimiter, spaces, and environments, including Unicode characters:

TABLE 21-12: DELIMITERS, SPACES, ENVIRONMENTS, BOXES.

COMMAND	SYMBOL/EXPLANATION	COMMAND	SYMBOL/EXPLANATION
\uparrow	↑	\updownarrow	↕
\downarrow	↓	\Uparrow	⇑
\Updownarrow	⇕	\Downarrow	⇓
\lbrack	[	\rbrack	]

TABLE 21-12: DELIMITERS, SPACES, ENVIRONMENTS, BOXES.

COMMAND	SYMBOL/EXPLANATION	COMMAND	SYMBOL/EXPLANATION
\lbrace	{	\rbrace	}
\vert	|	\backslash	\
\Vert	‖	\lfloor	⌊
\lceil	⌈	\rfloor	⌋
\rceil	⌉	\langle	⟨
\rangle	⟩	\left	Delimiter sizing (see Note below)
\right	Delimiter sizing (see Note below)	\quad	Explicit horizontal spacing
\qquad	Double explicit horizontal spacing	\raisebox	Creates a box containing text; it is used to raise or lower text.
\mbox	Enclose text in a box	\phantom	Adds an invisible component to, for example, balance subscripts
\makebox	Enclose text in a box with a specified width (see Note below)	\end	End the *array* environment (see Note below)
\begin	Invoke the *array* environment (see Note below)	\hspace	Horizontal space
\unicode	Display Unicode characters as supported by the font: \unicode{ÅÄÖ}, for example		

The `\left` and `\right` commands must be used in pairs to provide flexible delimiters that fit the formula inside. Put the desired delimiter — (and), for example — immediately after the `\left` and `\right` commands. For example, `\left( \frac{x}{y} \right)` provides x/y as a fraction within parentheses that fit the expression's size.

The `\makebox` command creates a box for the text. In addition to the `\makebox{`*`text`*`}` syntax, you can also use `\makebox[`*`width`*`]{`*`text`*`}`, where the width can be `\depth`, `\height`, `\width`, and `\totalheight` (which is the box's height plus its depth), or a multiple of those widths. You can also use a width with a unit such as `10em` for 10 "M" widths or `20mm` for 20 mm width. The `\makebox[`*`width`*`][`*`position`*`]{`*`text`*`}` syntax provides an optional position of the text within the box: `c` for centered text (the default), `l` for flush left, or `r` for flush right.

The `\begin` and `\end` commands must be used in pairs to mark the beginning and end of an environment. The only supported environment is the `array`. For example, `\begin{array}{clcr} 1 & 2 & 3 \\ 4 & 5 & 6\end{array}` creates a matrix with 2 rows and three columns.

MATHEMATICAL FUNCTION NAMES

The following function commands provide the function name using a Roman font:

TABLE 21-13: FUNCTIONS.

COMMAND	SYMBOL	COMMAND	SYMBOL
\arccos	arccos	\cos	cos
\csc	csc	\exp	exp

TABLE 21-13: FUNCTIONS.

COMMAND	SYMBOL	COMMAND	SYMBOL
\ker	ker	\limsup	limsup
\arcsin	arcsin	\cosh	cosh
\deg	deg	\gcd	gcd
\lg	lg	\ln	ln
\arctan	arctan	\cot	cot
\det	det	\hom	hom
\lim	lim	\log	log
\arg	arg	\coth	coth
\dim	dim	\inf	inf
\liminf	liminf	\max	max
\sinh	sinh	\sup	sup
\tan	tan	\tanh	tanh
\min	min	\Pr	Pr
\sec	sec	\sin	sin

SPECIAL MATHEMATICAL TYPESETTING

There are two mathematical formula components with a special syntax: `\frac` for fractions and `\sqrt` for roots:

- Use the syntax `\frac{`*`numerator`*`}{`*`denominator`*`}` to create a fraction. For example, the expression `\frac{n!}{k!(n-k)!}` produces the following output:

$$\frac{n!}{k!(n-k)!}$$

- Use the syntax `\sqrt[`*`order`*`]{`*`expression`*`}` to create a root surrounding an expression. The `[`*`order`*`]` argument is optional; without it, the syntax produces a square root. For example, `\sqrt[n]{1+x^2}` produces the following output:

$$\sqrt[n]{1+x^2}$$

TEXT AND FONT ELEMENTS

The following syntax elements are available for creating different text elements and fonts:

TABLE 21-14: VARIOUS TEXT AND FONT OPERATIONS.

COMMAND	EXPLANATION	COMMAND	EXPLANATION
\textsuperscript	Superscripts	^	Superscripts
\textsubscript	Subscripts	_	Subscripts
\overline	Overlining	\underline	Underlining
\overleftarrow	Overlining using a left-pointing arrow	\underleftarrow	Underlining using a left-pointing arrow
\overrightarrow	Overlining using a right-pointing arrow	\underrightarrow	Underlining using a right-pointing arrow
\overbrace	Overlining using a brace	\underbrace	Underlining using a brace
\textnormal	Normal text	\textbf	Boldface text
\textit	Text in italics	\textrm	Text in Roman font
\mathnormal	Normal mathematical mode (the default)	\mathbf	Mathematical boldface text

TABLE 21-14: VARIOUS TEXT AND FONT OPERATIONS.

COMMAND	EXPLANATION	COMMAND	EXPLANATION
\mathit	Mathematical text in italics	\mathrm	Mathematical text in Roman font
\displaystyle	Size for equations in Display math mode	\textstyle	Size for equations in Inline (text) math mode
\scriptstyle	Size for first subscript or superscript	\scriptscriptstyle	Size for subsequent subscripts and superscripts
\emph	Emphasize text in normal (Roman) text mode	\tiny	Smallest font size in text mode
\scriptsize	Second smallest fontsize in text mode	\footnotesize	Third smallest font size in text mode
\small	Fourth smallest fontsize in text mode	\normalsize	Normal font size in text mode
\large	Fifth largest font size in text mode	\Large	Fourth largest font size in text mode
\LARGE	Third largest font size in text mode	\huge	Second largest font size in text mode
\Huge	Largest font size in text mode		

The `\textsuperscript` and `^` syntax alternatives are identical for creating superscripts. Likewise, `\textsubscript` and _ are identical for creating subscripts.

SPECIAL CONTROL SEQUENCES AND CHARACTERS

The following special control sequences and special characters are available:

TABLE 21-15: SPECIAL CONTROL SEQUENCES AND SPECIAL CHARACTERS.

SEQUENCE/CHARACTER	DESCRIPTION	SEQUENCE/CHARACTER	DESCRIPTION
\#	# character	\:	Medium space
\$	$ character	\;	Thick space
\%	% character	\!	Negative thin space
\&	& character	$, or /[to start and /] to end	Start and end mathematical mode in text mode
_	_ character	%	Insert comments
\{	{ character	&	Separate items in arrays
\}	} character	~	Nonbreaking space
|	|| character	_	Subscript
\<*space*>	Space	^	Superscript
\,	Thin space	\, {, }, [,]	Command syntax elements

Model Contents — Report Components

Right-click nodes to select items from the **Model Contents** submenu. This group of report components which provide information about the model are detailed in these sections:

- Root Report Node
- Component Report Node
- Definitions Report Nodes
- Geometry Report Node
- Material Report Node
- Physics Interface Report Node
- Multiphysics Coupling Report Node
- Mesh Report Node
- Study Report Node
- Solver Report Node
- Results Report Nodes

Root Report Node

Use the **Root** report node ( ), selected from the **Model Contents** submenu, to include information from the model's root node: model name and path, COMSOL version, the used products, and unit system.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

GLOBAL SETTINGS

Select the **Include name**, **Include path**, **Include COMSOL version**, **Include unit system**, and **Include used products** checkboxes as needed.

Component Report Node

Use the **Component** report node ( ), selected from the **Model Contents** submenu or, on Windows only, the **Model Contents** menu button in the **Report** or **Presentation** ribbon, to include information from a Component node in the model.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

COMPONENT SETTINGS

Select the **Component** from the list. Select or clear the **Include unit system**, **Include frames**, and **Include geometry shape function** checkboxes as needed.

Definitions Report Nodes

Right-click report section nodes to select items from the **Model Contents** submenu or, on Windows only, click the **Model Contents** menu button in the **Report** or **Presentation** ribbon and select gallery items to add the nodes described in this section. These report components provide information about nodes added to the model under the Definitions and the Global Definitions nodes (for parameters, variables, and functions).

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

PARAMETERS REPORT NODE (GLOBAL DEFINITIONS)

Use the **Parameters** report node ( ) to include global parameters. Select a Parameters node from the **Source** list. All parameters for the selected node are reported by default; change the settings in the **Include** column in the **Parameters** table if you want to exclude some parameters from your report. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Include** column at once.

ABSORBING LAYER

Use the **Absorbing Layer** report node ( ) to include the selection and settings for an absorbing layer present in the model. From the **Source** list, select the Absorbing Layer node to report. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom**

to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault absorbing layer settings.

BUCKLING IMPERFECTION

Use the **Buckling Imperfection** report node ( ) to include the properties of a buckling imperfection node in the model.

Note: The Buckling imperfection feature requires the Structural Mechanics Module.

COORDINATE SYSTEM

Use the **Coordinate System** report node ( ) to add coordinate system settings information to the report. Select a **Coordinate system** from the list. Select the **Include settings** checkbox as needed.

DEFORMED GEOMETRY

Use the **Deformed Geometry** report node ( ) to include the settings and a selection image for a deformed geometry.

Select the node to include from the **Source** list. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault settings in the report.

EQUATION CONTRIBUTION

Use the **Equation Contribution** report node ( ) to include the settings and a selection image for an equation contribution node. Select the equation contribution node from the **Source** list. Select the **Include selection image** checkbox to include an image of the referenced node's selection, if it has a selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption (applies to any subfeatures as well), or **Custom** to specify a caption of your choice in the **Caption** text field (any subfeatures get the standard caption). Select the **Include settings** checkbox to include nondefault settings in the report.

EXPRESSION OPERATOR

Use the **Expression Operator** report node ( ) to include the settings and a selection image for an expression operator.

Select the node to include from the **Source** list. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption (applies to any subfeatures as well), or **Custom** to specify a caption of your choice in the **Caption** text field (any subfeatures get the standard caption). Select the **Include settings** checkbox to include nondefault settings in the report. The report will include any **Operator Contribution** subnodes using the settings for the parent **Expression Operator** node, except the predefined caption will be used instead of a custom caption text.

EXTRA DIMENSION

Use the **Extra Dimension** report node ( ) to add extra dimension settings information to the report. Select an **Extra dimension** from the list. Select or clear the **Include unit system**, **Include frames**, and **Include geometry shape function** checkboxes as needed.

FUNCTION

Use the **Function** report node (f(x)) to add a function image and the function's settings to the report. Under **Referenced Function**, select a **Function** from the list. Select or clear the **Include type**, **Include image**, and **Include settings** checkboxes as needed.

INFINITE ELEMENT DOMAIN

Use the **Infinite Element Domain** report node ( ) to include the selection and settings for an infinite element domain if it is present in the model. From the **Source** list, select the Infinite Element Domain node to report. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault infinite element settings.

LOAD AND CONSTRAINT GROUPS

Use the **Load and Constraint Groups** report node ( ) to include information about load and constraint groups in the model.

MASS PROPERTIES

Use the **Mass Properties** report node ( ) to include the settings and a selection image for a Mass Properties node. Select the **Mass Properties** node from the list. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption (applies to any subfeatures as well), or **Custom** to specify a caption of your choice in the **Caption** text field (any subfeatures get the standard caption). Select the **Include settings** checkbox to include nondefault settings in the report. The report will include any **Mass Contributions** subnodes using the settings for the parent **Mass Properties** node, except the predefined caption will be used instead of a custom caption text.

MATRIX VARIABLE

Use the **Matrix Variable** report node (A) to include the settings and a selection image for a matrix variable node. Select the **Matrix Variable** node from the list. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption (applies to any subfeatures as well), or **Custom** to specify a caption of your choice in the **Caption** text field (any subfeatures get the standard caption). Select the **Include settings** checkbox to include nondefault settings in the report.

MESH PART

Use the **Mesh Part** report node ( ) to include the settings and an image for a mesh part.

Select a **Mesh Part** from the list. Select or clear the **Include image** and **Include statistics** checkboxes as needed. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to use the mesh part's label as the figure caption, **None** to not include a caption (applies to any subfeatures as well), or **Custom** to specify a caption of your choice in the **Caption** text field (any subfeatures then get the standard caption).

In the **Features** table, all the mesh part's features are listed. To add or remove settings, click in the **Settings** column to cycle between inclusion and exclusion of a feature's settings. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** column at once.

METHOD CALL

Use the **Method Call** report node ( ) to include information about model methods. Clear the **Include method code** checkbox (selected by default) if you do not want the report to include the code.

MOVING MESH

Use the **Moving Mesh** report node ( ) to include the settings and a selection image for a moving mesh.

Select the node to include from the **Source** list. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault settings in the report.

NONLOCAL COUPLING

Use the **Nonlocal Coupling** report node ( ) to include the settings and a selection image for a nonlocal coupling if it is present in the model. Select the nonlocal coupling from the **Source** list. Select the **Include selection image** checkbox as needed. The image shows the selection for the nonlocal coupling and is not present if the nonlocal coupling has no selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault settings in the report.

OPTIMIZATION

Use the **Optimization** report node ( ) to include the settings and a selection image for an optimization node, such as Density Topology or Free Shape Domain.

Select the node to include from the **Source** list. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption (applies to any subfeatures as well), or **Custom** to specify a caption of your choice in the **Caption** text field (any subfeatures then get the standard caption). Select the **Include settings** checkbox to include nondefault settings in the report.

Note: The Optimization features require the Optimization Module.

PAIR

Use the **Pair** report node ( ) to include the settings and a selection image for identity pairs and contact pairs if present in the model. Select the **Pair** from the list. Select the **Include selection image, source** (**Include selection image, destination**) checkbox to include an image of the node's source (destination) selection. For both source and destination you can independently select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault settings in the report. The image shows the selection for the pair and is not present if the pair has no selection.

PARAMETER ESTIMATION

Use the **Parameter Estimation** report node ( ) to include the properties of a Global Least-Squares Objective node in the model.

Note: The Global least-squares objective feature require the Optimization Module.

PART

Use the **Part** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add the image, units (length and angular), and statistics to the report for specific part features.

In the **Referenced Part** section, select a part from the **Source** list. Select or clear the **Include image**, **Include units** and **Include statistics** checkboxes as needed. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field.

In the **Features** table, all the features used in the part's geometry sequence are listed. Click in a feature's table cell in the **Settings** column to toggle between including it in and excluding it from the report. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** column at once. For loaded parts, the features are not shown in the COMSOL Desktop, and reporting on their settings is therefore disabled by default.

PARTICIPATION FACTORS

Use the **Participation Factors** report node ( ) to include the properties of a Participation Factors node in the model.

Note: The Participation factors feature requires the Acoustics Module, the MEMS Module, the Multibody Dynamics Module, or the Structural Mechanics Module.

PERFECTLY MATCHED LAYER

Use the **Perfectly Matched Layer** report node ( ) to include the selection and settings for a perfectly matched layer (PML) if it is present in the model. From the **Source** list, select the **Perfectly Matched Layer** node to report. Select the **Include selection image** checkbox to include an image of the referenced node's selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault PML settings.

PROBE

Use the **Probe** report node ( ) to include the settings and a selection image for a Probe if it is included in the model. Select the **Probe** from the list. Select the **Include selection image** checkbox as needed. The image shows the selection for the probe and is not present if the probe has no selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault probe settings.

REDUCED MODEL

Use the **Reduced Model** report node ( ) to include information about any reduced model defined in the model.

RESPONSE SPECTRUM

Use the **Response Spectrum** report node ( ) to include the properties of a Response Spectrum node in the model.

Note: The Response spectrum feature requires the MEMS Module or the Structural Mechanics Module.

SELECTION

Use the **Selection** report node ( ) to include the settings and a selection image for selections. Choose the **Selection** from the list. Select the **Include selection image** checkbox as needed. The image is not present if the selection is empty. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field. Select the **Include settings** checkbox to include nondefault settings.

THERMODYNAMICS

Use the **Thermodynamics** report node ( ) to include information about any thermodynamics property packages present in the model.

Note: The Thermodynamics functionality requires the Chemical Reaction Engineering Module.

SHARED PROPERTIES

Use the **Shared Properties** node ( ) to include information about Ambient Properties or Model Inputs nodes. Select the node to include from the **Source** list.

VARIABLES

Use the **Variables** report node ( ) to include global or local variable definitions. Select a Variables node from the **Source** list and, optionally, modify the **Include** column in the table to exclude individual variables from the report as desired. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Include** column at once.

Geometry Report Node

Use the **Geometry** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add the image, units (length and angular), and statistics to the report for specific geometry features.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

REFERENCED GEOMETRY

Select a **Geometry** from the list. Select or clear the **Include image**, **Include units**, and **Include statistics** checkboxes as needed. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field.

In the **Features** table, all the features used in the geometry sequence are listed. Click in a feature's table cell in the **Settings** column to toggle between including it in and excluding it from the report. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** column at once.

Material Report Node

Use the **Material** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add the image, selection, and settings to the report for the material property groups in the material.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

MATERIAL

Select a **Material** from the list. Select or clear the **Include image**, **Include selection**, and **Include settings** checkboxes as needed. The image shows the selection for the material and is not present if the material has no selection or is completely overridden by other materials' selections. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) use the label of the selected material as the figure caption, **None** to not include a caption (applies to the images of any function subfeatures as well), or **Custom** to specify a caption of your choice in the **Caption** text field. Note that a custom caption applies only to the material itself; any function-subfeature images will get the standard caption.

In the **Features** table, all the material properties used in the material are listed. Click in a property group's cell in the **Settings** column to toggle between including its settings in and excluding it from the report. Similarly, the settings in the **Functions** column determine whether to include plots of the function subfeatures of a property group. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** and **Functions** columns at once.

Physics Interface Report Node

Use the **Physics Interface** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add an image and table showing the selection, equations, settings, and a table of all included physics features to the report.

Go to Common Results Node Settings for links to information about this section: **Node Properties**. For physics interfaces, you can also choose whether to include a table of used products or not.

REFERENCED PHYSICS INTERFACE

Select a **Physics interface** from the list. Select or clear the **Include selection image**, **Include feature table**, **Include selection table**, **Include equations**, and **Include settings** checkboxes as needed. If you choose to include equations, use the **Heading** list to specify whether or not to include a heading before the equations. The options are:

- **None** — Do not include a heading
- **Equations** (default) — Use a heading with the text "Equations" (localized to match the current COMSOL Desktop language)
- **Custom** — Selecting this option, you can enter the heading to use in the **Text** field

If you choose **None** or an empty custom heading, no heading will be included for any equations for physics features either. Otherwise, the default heading is used.

An image in the report shows the selection for the physics interface and is not present if the physics interface has no selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to use the label of the selected physics interface as the figure caption, **None** to not include a caption (applies to the images for any physics-feature children as well), or **Custom** to specify a caption of your choice in the **Caption** text field. Note that a custom caption applies only to the physics interface itself; any physics-feature images will get the standard label caption.

In the **Features** table, all the physics interface features are listed. To add or remove settings, selections, and equations, click in the **Settings**, **Selection**, and **Equations** columns to toggle between inclusion and exclusion of a feature's settings, selection image, and equations, respectively. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings**, **Selection**, and **Equations** columns at once.

Under the **Features** table, you can also select from the checkboxes to include variables, shape functions, weak expressions, and constraints contained in the physics node's **Equation View** subnode.

Select the **Include variables**, **Include shape functions**, **Include weak expressions**, and **Include constraints** checkboxes as needed.

Multiphysics Coupling Report Node

Use the **Multiphysics Coupling** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add an image and table showing the selection, equations, and settings to the report.

Go to Common Results Node Settings for links to information about this section: **Node Properties**. For multiphysics couplings, you can also choose whether to include a table of used products or not.

REFERENCED MULTIPHYSICS COUPLING

Select a **Multiphysics coupling** from the list. Select or clear the **Include selection image**, **Include selection table**, **Include equations**, and **Include settings** checkboxes as needed. If you choose to include equations, use the **Heading** list to specify whether or not to include a heading before the equations. The options are:

- **None** — Do not include a heading
- **Equations** (default) — Use a heading with the text "Equations" (localized to match the current COMSOL Desktop language)
- **Custom** — Selecting this option, you can enter the heading to use in the **Text** field

An image in the report shows the selection for the multiphysics coupling and is not present if the multiphysics coupling has no selection. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field.

You can also select to include variables, shape functions, weak expressions, and constraints contained in the multiphysics coupling node's **Equation View** subnode.

Select the **Include variables**, **Include shape functions**, **Include weak expressions**, and **Include constraints** checkboxes as needed.

Mesh Report Node

Use the **Mesh** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add the image and statistics to the report.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

MESH

Select a **Mesh** from the list. Select or clear the **Include image** and **Include statistics** checkboxes as needed. When the latter is selected, you can choose which **Quality measure** to use; for descriptions of the available options, see Mesh Element Quality. Optionally, select a custom view for the image from the **View** list or keep the default setting, **Automatic**, to use the current view. From the **Caption source** list you can choose between **Automatic** (default) to use the label of the selected mesh as the figure caption, **None** to not include a caption (applies to the images for any mesh-feature children as well), or **Custom** to specify a caption of your choice in the **Caption** text field. Note that a custom caption applies only to the mesh itself; any mesh-feature images will get the standard label caption.

In the **Features** table, all the mesh features are listed. To add or remove settings, click in the **Settings** column to cycle between inclusion and exclusion of a feature's settings. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** column at once.

Study Report Node

Use the **Study** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add settings for a Study in the model to the report.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

STUDY

Select a **Study** from the list. Optionally, you can include a table with information about computation time, CPU, and operating system in the report by selecting **Include computation information** (the default setting). To include a table listing the names of the study steps, select **Include feature table** (excluded by default).

In the **Features** table, all the study steps are listed. To add or remove settings, click in the **Settings** column to cycle between inclusion and exclusion of a feature's settings. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** column at once.

Solver Report Node

Use the **Solver** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add settings for the solver nodes in the solver sequence that is referenced in the Sequence list.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

SOLVER

Select a **Sequence** from the list. Select the **Include log** to include the solver log.

In the **Features** table, all the solver features are listed. To add or remove settings, click in the **Settings** column to cycle between inclusion and exclusion of a feature's settings. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** column at once.

Results Report Nodes

Right-click to select items from the **Model Contents** submenu and to add the nodes described in this section. These report components provide information about nodes added to the model under Results. For any of these, click the **Go to Source** button ( ) to move to the source node under the applicable node under **Results**.

Go to Common Results Node Settings for links to information about this section: **Node Properties**.

PARAMETERS REPORT NODE (RESULTS)

Use the **Parameters** report node ( ), selected from the lower part of the **Model Contents** submenu or ribbon menu button, to include the Parameters in the model. All parameters are reported by default; change the settings in the **Include** column in the **Parameters** table if you want to exclude some parameters from your report.

CONFIGURATION

Use the **Configuration** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to include the settings for the referenced configuration. Select a configuration from the **Source** list.

DATASET

Use the **Dataset** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to include the settings and a selection image for the referenced dataset. Select a dataset from the **Source** list. Select or clear the **Include settings** and **Include selection image** checkboxes as needed.With **include selection image** selected, the **Caption source** list is activated. Here you can choose between **Automatic** (default) to get a predefined figure caption, **None** to not include a caption, or **Custom** to specify a caption of your choice in the **Caption** text field.

DERIVED VALUES

Use the **Derived Values** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add derived values settings information to the report. Select the derived values node to use from the **Source** list. Select or clear the **Include settings** checkbox as needed.

TABLE

Use the **Table** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add the table settings to the report. Select the **Table** from the **Source** list in the **Table** section. See Number Format for information about settings in that section.

COLOR TABLE

Use the **Color Table** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to include the settings for the referenced color table. Select a Dataset from the **Source** list in the **Color Table** section.

PLOT GROUP

Use the **Plot Group** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add plots to the report. Select the **Plot group** from the list. From the **Caption source** list, select **From plot group title** (the default) to use the plot's title as the caption, **Custom** to enter a different **Caption** in the field, or **None** for no caption.

For **Zoom extents**, select one of the following options:

- **On** — perform a zoom to extents action when the image is generated

- **Automatic** (default) — perform a zoom to extents action when the image is generated if the referenced plot group is associated with a view whose camera (3D) or axis (2D) is not locked or is a graph plot whose axis limits are not fixed
- **Off** — do not perform a zoom to extents action when the image is generated

EVALUATION GROUP

Use the **Evaluation Group** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add information about an evaluation group and its subnodes to the report. Select the evaluation group to use from the **Source** list. Select or clear the **Include settings** checkbox as needed. If the associated result table is very large, you can choose to clear the **Include result table** checkbox, which is selected by default for all report types.

In the **Features** table the selected group's evaluation-feature subnodes are listed. To add or remove settings, click in the **Settings** column to cycle between inclusion and exclusion of a feature's settings. The **Clear Selection** ( ) and **Select All** ( ) toolbar buttons apply to all rows of the **Settings** column at once.

EXPORT

Use the **Export** report node ( ), selected from the **Model Contents** submenu or ribbon menu button, to add any of the images or animations added to the model Export branch. From the **Object** list, select from any available image or animation objects to include in the report (or select **None**).

Animations are not supported for reports in Microsoft Word format. For Microsoft PowerPoint presentations, animations in GIF format are supported.

After selecting the **Object**, select an option from the **Size** list — **Object setting** to use the width and height specified in the image or animation settings or **Report image type** to use the image format specified in the report's root node settings.

Select an option from the **File format** list — **Object setting** to use the file format for the selected object or **Report image type** to be determined by the image type setting specified in the report's root node.

In the **Caption** field, enter text as needed. By default, this field is left empty and no caption is included in the report.

Declaration Contents

Right-click nodes to select items from the **Declarations Contents** submenu. This group of report components provides information about declarations in applications created using the Application Builder. See The Declarations Branch in the Application Builder documentation.

CHOICE LIST

The **Choice List** report node ( ) adds a list of combo boxes, lists, and radio buttons.

UNIT SET

The **Unit Set** report node ( ) adds a unit set from an application to the report.

STRING

The **String** report node ( ) adds a list of named strings that are included with form objects and methods.

DOUBLE

The **Double** report node ( ) adds a list of named scalar double floating-point values that are included with form objects and methods.

BOOLEAN

The **Boolean** report node (☑) adds a list of named scalar Booleans that are included with form objects and methods.

INTEGER

The **Integer** report node (123) adds a list of named scalar integers that are included with form objects and methods.

ARRAY ID STRING

The **Array 1D String** report node (abc) adds a list of named string arrays that are included with form objects and methods.

ARRAY ID DOUBLE

The **Array 1D Double** report node (8.5) adds a list of named double floating-point arrays that are included with form objects and methods.

ARRAY ID BOOLEAN

The **Array 1D Boolean** report node (☑) adds a list of named Boolean arrays that are included with form objects and methods.

ARRAY ID INTEGER

The **Array 1D Integer** report node (123) adds a list of named integer arrays that are included with form objects and methods.

ARRAY 2D STRING

The **Array 2D String** report node (abc) adds a list of named 2D string arrays (matrices) that are included with form objects and methods.

ARRAY 2D DOUBLE

The **Array 2D Double** report node (8.5) adds a list of named 2D arrays (matrices) of double floating-point values that are included with form objects and methods.

ARRAY 2D BOOLEAN

The **Array 2D Boolean** report node (☑) adds a list of named 2D Boolean arrays (matrices) that are included with form objects and methods.

ARRAY 2D INTEGER

The **Array 2D Integer** report node (123) adds a list of named 2D integer arrays (matrices) that are included with form objects and methods.

Printing and Capturing Screenshots

Printing from the COMSOL Desktop

To print the contents in the **Graphics** window or other plot windows, click the **Print** button ( ) in the Graphics window toolbar or press Ctrl+P.

In the **Print** dialog, follow these steps:

1. Under **Image**, from the **Size** list, select **Current** to use the current size of the **Graphics** window. Of the settings below, only the **Zoom extents** and **Antialiasing** checkboxes are then available. Alternatively, select **Manual (web)**, **Manual (print)**, or **Presentation and document** to set the print size and resolution manually. Choosing **Manual (web)** provides default settings identical to those used when creating an image snapshot for web use.
2. Select a **Unit** to define the image size: **Millimeters (mm)** (the default for print), **Inches (in)**, or **Pixels (px)** (the default for web).
3. Select the **Lock aspect ratio** checkbox to maintain the calculation of the width and height (if one or the other is changed).
4. Enter the **Width** and **Height** in the units selected for the image.
5. Enter the **Resolution** for the image in DPI (dots per inch) as a value between 10 and 1200 DPI. The default value is 300 DPI for print and 96 DPI for web.

   Under these settings, the dialog shows the resulting image size and the size on the screen in pixels.
6. The **Zoom extents** checkbox is cleared by default. Select it to add a zoom to extents before printing.
7. The **Antialiasing** checkbox is cleared by default. Click to select if required. Antialiasing minimizes distortion such as jagged edges in the image.
8. Under **Layout**, the **Title**, **Legend**, **Axes**, and **Logo** checkboxes are selected by default to display the information on the screenshot if you select the **Include** checkbox. You can then also edit the selections for including these parts of the plot.
9. Enter a **Font** size in points (pt) as a number between 1 and 1000 pt. The default value is 9 pt.
10. If desired, specify the **Color theme** to use for the printed image. The default is to use the **Global theme**, but you can also use the **Default from preferences**, **Basic**, **COMSOL**, **Dark**, **DarkSelection**, **Default**, **Light**, **LightSelection**, and **RYB**.
11. Select a **Background**: **Current** or **Color**. Current is the background color in the plot window on the COMSOL Desktop. For **Color**, click the **Color** button to select a custom color from the color palette that opens.
12. Click **OK** to print the contents of the plot window. Typically the operating system's **Print** dialog first opens for selecting a printer, the number of copies, and other printer settings.

For generating snapshots of a plot window to a file or the clipboard, click the **Image Snapshot** button ( ) in the **Graphics** window toolbar (see below).

Capturing and Copying Screenshots

To quickly capture a screenshot image of a plot, click the **Quick Snapshot** button ( ) in the **Graphics** window toolbar, or press Ctrl+L. From the **Quick Snapshot** button you can choose any of the available preset image snapshot settings. The screenshot image is then available for the output specified for the chosen preset (the clipboard, a file, or PowerPoint) so that you can paste it or add it to, for example, a document or a presentation. You can also use the **Image Snapshot** button ( ) in the **Graphics** window toolbar to capture an image snapshot of a plot and to access image settings for more control of the snapshot. To do so, follow the steps below. For the image generation, you

can enable hardware-accelerated image export as an alternative to software rendering; see Image for more information.

1 In the **Graphics** window or any other plot window, click the **Image Snapshot** button ( ) to open the **Image Snapshot** dialog.

2 From the **Preset** list, you can choose from predefined and user-defined sets of image snapshot settings: **Current**, **Manual (web)**, **Manual (print)** (the default), or **Presentation and document**, which are tailored settings for image snapshots suitable for a web page, for printing, or for a PowerPoint presentation or Word document, respectively. **Manual (web)** and **Manual (print)** both use a white background. **Presentation and document** uses a transparent background. The **Current** option uses the current size on the screen (which is displayed), so only the **Zoom extents** and **Antialiasing** checkboxes are available under **Image**. If you have modified the image snapshot, you can save those settings as another preset option. To do so, click the **Save as Preset** button (+) and provide a name for the user-defined preset option in the **Name** field of the **Save as Preset** dialog that opens. If you do not want to keep an added user-defined preset option, click the **Remove Preset** button ( ). If you have made changes to a preset option and want to return to its default values, click the Reset **Preset to Default** button at the bottom of the **Image Snapshot** dialog.

3 Under **Image**, you can choose from a number of predefined image size settings from the **Size** list, where **Current** is the default. Select **Manual (web)** to define the image size manually using the settings below set up for a snapshot suitable for the web (using pixels as the default unit and 96 DPI as the default resolution) or select **Manual (print)** to define the image size manually using the settings below set up for a printout of the snapshot (using millimeters as the default unit and 300 DPI as the default resolution).

4 Under **Image**, select a **Unit** to define the image size: **Millimeters (mm)**, **Inches (in)**, or **Pixels (px)**.

5 Select the **Lock aspect ratio** checkbox to maintain the calculation of the width and height.

6 Enter the **Width** and **Height** in the units selected for the image.

7 Enter the **Resolution** for the image in DPI (dots per inch) as a value between 10 and 1200 DPI.

The software computes and displays values for **Image size** and **Size on screen** based on the inputs above so that you can check that the image size is suitable. If you select **Current** from the **Size** list, only the **Size on screen** appears.

8 The **Zoom extents** checkbox is cleared by default. Select it to add a zoom to extents before printing.

9 The **Antialiasing** checkbox is selected by default. Click to clear if required. Antialiasing minimizes distortion such as jagged edges in the image.

10 Under **Layout**, the **Title**, **Legend** (1D graphs) or **Color legend** (2D plots), **Axes**, **Grid** (1D graphs), and **Logo** checkboxes (1D and 2D images) or the **Title**, **Color legend**, **Grid**, **Axis orientation**, and **Logo** checkboxes (3D images) are selected by default to display the information on the screenshot if you select the **Include** checkbox. You can then also edit the selections for including or excluding these parts of the plot. The **Include** checkbox is selected by default for 1D images.

For the glTF file format (3D result plots only), the **Include line segments** checkbox is selected by default. Clear that checkbox to exclude line segments, which can be useful for glTF viewers that do not support line segments.

11 Enter a **Font** size in points (pt) as a value between 1 and 1000 pt. The default value is 9 pt. This font size overrides the system font size used in the COMSOL Desktop.

12 If desired, specify the **Color theme** to use for the printed image. The default is to use the **Global theme**, but you can also use the **Default from preferences (Default)**, **Basic**, **COMSOL**, **Dark**, **DarkSelection**, **Default**, **Light**, **LightSelection**, and **RYB**.

13 Select a **Background**: **Current**, **From theme**, **Color**, or **Transparent**. The **Current** setting is the background color in the plot window on the COMSOL Desktop. The **From theme** uses the background color from the current color theme. For **Color**, click the **Color** button to select a custom color from the color palette that opens. For image

snapshots saved to file, the **Transparent** option (which is the default background) is only applicable for the PNG file format.

	Transparent image support includes two parts: Raw data of the PNG image and an external renderer (image viewer). The COMSOL Multiphysics software can provide a correct PNG image itself but cannot control the external renderer.

	When importing an image with a transparent background to another Windows application, first save the image as a file rather than saving it to the clipboard. In some cases, the transparent background is not preserved if you copy an image via the clipboard.

I4 Under **Output**, select the target: **Clipboard** (the default) to copy the image to the clipboard, **File** to save the image to a file, or **PowerPoint and Word** to use the image in Microsoft® PowerPoint and Microsoft® Word. The **PowerPoint and Word** target is only applicable to, for example, a geometry, mesh, or plot because the output is an image of the selected feature rather than the image in the **Graphics** window.

Choose the **PowerPoint and Word** target to use the image in a Microsoft® PowerPoint presentation or a Microsoft® Word document. The image will be copied to the clipboard in a way that it will remain linked to the model for future updates after pasting it into the presentation. See Creating PowerPoint Presentations and Word Documents with Linked Tables and Images for more information on how to insert and update images in a presentation.

I5 If **File** is selected:

- **a** Select a file **Format**: **BMP**, **EPS** (1D plots only), **JPEG**, **TIFF**, **GIF**, **PNG** (the default), or **glTF** (results plots in 3D only. For the JPEG format, you can also enter a quality parameter by selecting the **Quality** checkbox and entering a quality level between 1 and 100 (default: 92). Usually, a high quality level in the range of 90–95 is recommended.
- **b** Enter a file path in the **Filename** field, or click **Browse** to specify the name and location of the file.
- **c** Select the **Create unique filename by adding incremental number** checkbox (cleared by default) to make the filenames unique by appending a numerical suffix.

I6 If **PowerPoint and Word** is selected:

- **a** Select the **Lock view** checkbox if you want to lock the view in PowerPoint. Saved camera settings are then used when you update the image from PowerPoint. If this checkbox is cleared, the current camera settings are used when updating the image.

I7 Click **OK** to generate an image snapshot and close the **Image Snapshot** dialog.

	Printing from the COMSOL Desktop

Setting and Clearing the Thumbnail Image

To illustrate the application, you can save a thumbnail image that displays in The Root Settings Window and when opening a model in the **Application Libraries** window. By default, this image is also included on the title page when you generate a report of your model. You can set the thumbnail from a view in the Graphics window or by importing an external file.

To set the thumbnail from the Graphics window:

1 Decide which plot to use as the thumbnail. In the **Model Builder** under **Results**, click the plot group of the plot you want to use so that it displays in the **Graphics** window.

2 Click the root node (the first node in the model tree).

3 In the **Settings** window for the root node under **Thumbnail** in the **Presentation** section, click **Set from Graphics Window**. Save the model file to update the image.

If required, make adjustments to the image in the Graphics window using the toolbar buttons until the image is one that is suitable to your purposes, or choose another plot and repeat the steps.

To set the thumbnail from an external image file of PNG or JPEG format:

1 Click the root node.

2 In the **Settings** window for the root node under **Thumbnail** in the **Presentation** section, click **Load from File**.

3 Browse to the folder where your image file is located, select the file, and then click **Open**.

The imported image is displayed in the **Thumbnail** area. While a large image may not fit inside this area, it can still be suitable for a report's title page. For best results in reports, use images with a resolution of at least 150 DPI.

When a thumbnail has been set, you can clear it by clicking the **Clear** button.

Creating PowerPoint Presentations and Word Documents with Linked Tables and Images

The COMSOL Add-Ins for PowerPoint and for Word

The COMSOL interface for Microsoft® PowerPoint® and interface for Microsoft® Word® are installed together with COMSOL Multiphysics and make it possible to work with images and tables that are linked to COMSOL models. The installer registers the COMSOL add-in with PowerPoint and Word, where it is then listed on the **Add-ins** page of the **Options** window that is accessible from the **File** Backstage view in both PowerPoint and Word. When the interface add-in is loaded, it provides the following additions to the user interface in PowerPoint and Word:

- The **COMSOL** ribbon tab, where you can insert and update images and tables
- The **COMSOL** tab in the File Backstage view, where you can manage the source references for the linked images and tables
- The **COMSOL Image** tools tab, where you can change image settings
- The **COMSOL Table** tools tab, where you can change table settings
- The **COMSOL** context menu, where you can quickly access the most often used commands

INSERTING IMAGES AND TABLES IN DOCUMENTS

To insert tables and screenshot images of, for example, geometry and result plots in a PowerPoint presentation or Word document in a way that keeps them linked to the model for future updates, start inside COMSOL Multiphysics by doing one of the following:

- From the Table window toolbar, click the **Copy Table and Headers to PowerPoint and Word** ( ) button.
- Use the **Table** node to copy the table as described in the section Table (Export), and make sure that the output target is set to **PowerPoint and Word**.
- Follow the steps in the section Capturing and Copying Screenshots for generating the image screenshot, and make sure that in Step 14 you select the output target **PowerPoint and Word**.
- Use the **Image** node to generate plot images as described in the section Image, and make sure that the output target is set to **PowerPoint and Word**.

After the image or table is generated, switch to PowerPoint or Word and place the cursor in the desired location. From the **COMSOL** ribbon tab, click **Paste** ( ) (or press Ctrl+V) to insert the last generated item. Alternatively, to insert any previously generated item, on the **COMSOL** tab click **Clipboard** ( ) and select the image or table that you want to insert. Images and tables that are added to a presentation or document according to the above steps retain a reference to their source models and can be updated from PowerPoint or Word, or by using a batch tool that can update several documents.

See Generating a Model Presentation and Generating a Model Report for information about generating PowerPoint presentations and Word documents with linked images from COMSOL Multiphysics models.

UPDATING IMAGES AND TABLES IN DOCUMENTS

Images and tables that are linked to models can be easily updated when needed, while preserving the formatting applied in the PowerPoint presentation or Word document. During the update process the images and tables are generated by COMSOL Multiphysics (if the source models are open) or by an automatically started COMSOL

Multiphysics server that opens the referenced models. To update linked images and tables from inside PowerPoint or Word, follow one of the methods below:

- From the **COMSOL** ribbon tab, click **Update All** ( ) to update all linked images and tables in the document.
- In the document, select the image or table that you want to update and do one of the following:
  - From the **COMSOL** ribbon tab, click **Update** ( )
  - From the **COMSOL Image** or **COMSOL Table** tools tab, click **Update Image** ( ) or **Update Table** ( )
  - Right-click the image or table and select **COMSOL** > **Update Image** ( ) or **COMSOL** > **Update Table** ( )

To prevent an image or a table from being updated when you update all linked content in a presentation or document, select the image or table, then from the **COMSOL Image** or **COMSOL Table** tools tab click the **Lock Image** ( ) or **Lock Table** ( ) toggle button, or right-click the image and select **COMSOL** > **Lock Image** or **COMSOL** > **Lock Table**.

Changing the Image Settings

When you generate a snapshot with the output target set to **PowerPoint and Word**, as described in the section Capturing and Copying Screenshots, the image settings are saved together with the inserted image. To edit the image settings for a linked image in a presentation or document, select the image and then select the **COMSOL Image** tools tab, where in the **Image** and **Layout** sections you can do the following:

- Enter the **Width** and **Height** in the units selected for the image.
- Enter the **Resolution** for the image in DPI (dots per inch) as a value between 10 and 1200 DPI.
- Select the **Lock Aspect Ratio** checkbox to maintain the ratio of width to height if one is changed.
- The **Antialiasing** checkbox is selected by default. Click to clear if required. Antialiasing minimizes distortion such as jagged edges in the image.
- Select a **Unit** to define the image size: **Millimeters (mm)**, **Inches (in)**, or **Pixels (px)**.
- Select the **Lock View** checkbox if you want to lock the view for the image. Saved camera settings are then used when you update the image from PowerPoint or Word. If this checkbox is cleared, the current camera settings are used when updating the image.
- The **Zoom Extents** checkbox is cleared by default. Select it to add a zoom to extents before regenerating the image.
- The **Title**, **Legend**, **Grid**, **Axes**, **Logo** (1D images); or **Title**, **Legend**, **Axes**, **Logo** (2D images); or **Title**, **Legend**, **Grid**, **Axis Orientation**, **Logo** checkboxes (3D images) control the information displayed on the screenshot. You can edit the selections for including or excluding these parts of the plot.
- Enter a **Font Size** in points (pt) as a value between 1 and 1000 pt. The default value is 9 pt. This font size overrides the system font size used in the COMSOL Desktop.
- Select a **Background**: **Basic Colors**, **Transparent**, or **Define Custom Colors**. For **Basic Colors**, select a color from the color palette. For **Define Custom Colors**, define a color in the **Define Custom Colors** window that opens.

To regenerate the image after changing the settings, from the **COMSOL Image** tools tab click **Update Image** ( ).

Changing the Table Settings

The settings for linked tables are saved together with the tables in the PowerPoint presentation or Word document. To edit the table settings, select the table and then select the **COMSOL Table** tools tab, where in the **Table** section you can do the following:

- Select the **Full Precision** checkbox to use full precision.

- Select the **Include Header** checkbox if you want to include a header.
- Select the **Include Title** checkbox if you want to include a title.
- Enter the **Precision** (when the checkbox **Full Precision** is cleared) as an integer between 1 and 17.
- From the **Notation** list, choose one of the following alternatives for the numeric notation:
  - **Automatic** — display numbers in either scientific or decimal notation depending on their magnitude.
  - **Engineering** — display numbers in engineering notation, for example `850E-3`.
  - **Scientific** — display numbers in scientific notation, for example `8.5E-1`.
  - **Decimal** — display numbers in decimal notation, for example `0.85`.
- From the **Complex Notation** list, choose one of the following alternatives for the complex notation:
  - **Rectangular** — display complex numbers in terms of real and imaginary parts, for example `1 + 2i`.
  - **Polar** — display complex number in terms of magnitude and argument, for example `2.2361∠63.435°`.

To regenerate the table after changing the settings, from the **COMSOL Table** tools tab click **Update Table** ( ).

Managing Source References

Linked images and tables in a PowerPoint presentation or Word document retain a reference to their source node and model. You can view and edit all references in a presentation or document from the **References** page on the **COMSOL** tab of the **File** Backstage view in PowerPoint or Word. To access this page from the **COMSOL** ribbon tab, click the **View All References** ( ) button. Alternatively, select the **File** tab and then select **COMSOL** > **References** ( ).

REFERENCED MODELS

The source models for linked content in the presentation or document are listed in the **Referenced Models** column of the **References** page. To change a source model, click the link for the model, select a model file in the **Browse** window that opens, and then click **Use As Source** to confirm your selection and close the window.

Select the **Use relative paths** checkbox to enable using file paths relative to the **Working directory**. Click the link to change the working directory. Note that when switching to relative paths or changing the working directory the software will not move any files, and you will have to make sure to move or copy the necessary files to the new location.

By default the absolute path to the referenced models is saved with the images and tables. To change this behavior, select the preference option **In new documents use** > **Relative paths**, located on the **COMSOL** tab of the **File** backstage view.

To share a presentation or document without revealing personal information, click the **Clear File Paths** ( ) button to keep only the filename portion of the paths. Updating linked content will still be possible if the source models are found in the same folder as the presentation, or by using the model links to find and save their location again.

REFERENCED NODES

The source feature nodes for the images and tables are listed in the **Referenced Nodes** column. To select a different source node, click the source node link to open the **Edit Reference** window. You can also open the **Edit Reference** window by clicking the source node displayed in the **COMSOL Image** or **COMSOL Table** tools tab after selecting the item, or by right-clicking the item and from the menu selecting **COMSOL** > **Edit Reference**.

The **Edit Reference** window displays the source Model Tree with only the feature nodes that are possible to use as image sources. To display the Model Tree when you open the window a COMSOL Multiphysics server is automatically started in the background and the model is loaded, unless it is already open in COMSOL Multiphysics or a connected COMSOL Multiphysics server. Double click a node from the Model Tree to set it as source. Alternatively, select the node and then click **Use as Source**. To change the source model, click the model link

in the **Model** section of the window and browse to a new model. To accept the changes and to close the **Edit Reference** window click **OK**.

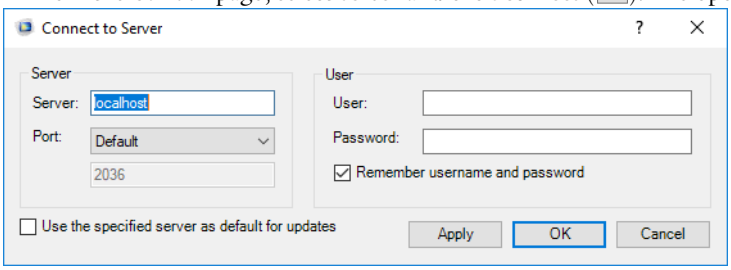
To check that all referenced source models and feature nodes in a presentation or document can be found, click the **Verify All** button. The result of the check is displayed in the **Status** section, and any missing models and nodes are indicated by a small warning triangle.

To remove all references to models from the presentation and keep only the images and tables, click the **Delete All** ( ) button. To delete the reference for a single item, select it and then from the **COMSOL Image** or **COMSOL Table** tools tab click the **Delete Reference** ( ) button. Alternatively, right-click the item and select **COMSOL** > **Delete Reference**. Note that after deleting a reference the image or table will not be linked to a COMSOL model and will not be possible to update.

Managing Server Connections

The default settings using the interface for PowerPoint® and Word® consist of starting a new COMSOL Multiphysics server on the local machine when required for updating images and tables. To connect to an already running COMSOL Multiphysics server or COMSOL Server, follow these steps:

1. In PowerPoint or Word, go to the **File** ribbon tab and select **COMSOL**.
2. From the **COMSOL** page, select **Server** and click **Connect** ( ).This opens the **Connect to Server** window.



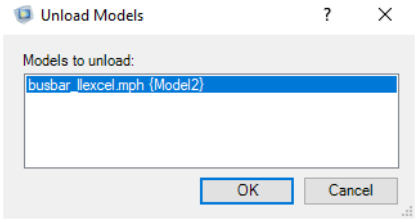
3. In the **Server** text field, enter the name of the COMSOL Multiphysics server or COMSOL server (or server IP address). Enter `localhost` if the server and PowerPoint or Word are running on the same machine.
4. In the **Port** menu list, select **manual** if the server is not listening to the default port number (2036). The port number is displayed in the server window and can then be entered in the text field.
5. In the **User** and **Password** text fields, enter the login information requested by the server.
6. Optionally select the **Use specified server as default for updates** checkbox to automatically connect to the specified server when updating images in the future.
7. Click **OK** to connect to the server.

DISCONNECTING FROM A COMSOL SERVER

To disconnect the interface in PowerPoint or Word from a connected COMSOL server, go to the **File** ribbon tab and select **COMSOL**. In the **COMSOL** Backstage view, select **Server** and click **Disconnect** ( ).

UNLOADING MODELS FROM THE SERVER

To remove models from a connected COMSOL Multiphysics server or COMSOL server, go to the **File** ribbon tab and click **COMSOL**. In the **COMSOL** backstage view click **Server** ( )and then **Unload Models** ( ).



In the **Unload Models** window, select the models that you want to unload from the server and click **OK**.

22

Running COMSOL Multiphysics

This chapter provides an overview of the different ways that you can run the COMSOL Multiphysics® software in addition to running the COMSOL Desktop® graphical user interface on a dedicated computer, including client–server and distributed-memory architectures. For information about COMSOL Server™ and running COMSOL Multiphysics applications as a client, see the *COMSOL Server Manual*. COMSOL Multiphysics and COMSOL Server support cloud computing. See https://www.comsol.com/running-comsol-software-in-the-cloud.

In this chapter:

- Running COMSOL Multiphysics
- The COMSOL Software Architecture
- Running COMSOL Multiphysics in Client–Server Mode
- Running COMSOL in Parallel
- The COMSOL Commands

Running COMSOL Multiphysics

The primary way to access the COMSOL Multiphysics functionality is through the COMSOL Desktop. This section describes alternative means of accessing the functionality in the COMSOL Multiphysics software, such as running COMSOL Multiphysics in batch mode and in different client–server configurations.

Windows and the Cross-Platform Desktop

COMSOL Multiphysics has a Windows® graphical user interface that is started by default. There is also a cross-platform graphical user interface, which is the same on Windows, Linux®, and macOS. You can start the cross-platform interface on Windows by double-clicking the file `comsolxpl.exe` in the `bin\win64` folder in the COMSOL installation directory. The cross-platform interface is the only one available on Linux and macOS.

COMSOL Multiphysics Client–Server Architecture

The COMSOL Multiphysics client–server architecture lets you access the COMSOL Multiphysics server — the computational engine in COMSOL Multiphysics — as a separate process. The COMSOL Multiphysics server is a single-user server allowing multiple connections by the same user.

You must have a floating network license (FNL) to run a COMSOL Multiphysics server and a COMSOL Multiphysics client on separate computers. Any valid COMSOL Multiphysics license is sufficient to run the Multiphysics client and the Multiphysics server on the same computer.

To start the COMSOL Multiphysics server under windows, just click **COMSOL Multiphysics Server 6.3** under your COMSOL Multiphysics installation in the Start menu (in **COMSOL Launchers**). On Linux and macOS, type the command `comsol mphserver` to start the COMSOL Multiphysics server.

For more options for starting the COMSOL Multiphysics server, see the section The COMSOL Commands for your platform. Also see the section Running COMSOL Multiphysics in Client–Server Mode for detailed general information about client–server options.

The license server is not the same as a COMSOL Multiphysics server. The license manager can run on a computer different from both the ones used by COMSOL Desktop and COMSOL Multiphysics server.

Parallel Computing with COMSOL Multiphysics

COMSOL Multiphysics supports two mutual modes of parallel operation: shared-memory parallel operations and distributed-memory parallel operations, including cluster support.

SHARED-MEMORY PARALLEL MODE

The shared-memory parallel mode is suitable for running COMSOL Multiphysics on modern multicore or multiprocessor computers. This parallel mode of operation is available for all platforms and all license types. By default, COMSOL Multiphysics uses the shared-memory parallel mode and allocates all cores on the computer.

For options for controlling the number of cores used and other options, see the section The COMSOL Commands for your platform. Also see the section Shared-Memory Parallel COMSOL for detailed general information.

DISTRIBUTED-MEMORY PARALLEL MODE

The distributed-memory parallel mode lets you run COMSOL Multiphysics on a Windows HPC cluster or a Linux cluster.

See Distributed-Memory Parallel COMSOL for details about running the COMSOL software in parallel architectures, including Windows and Linux clusters. For more options on how to run COMSOL Multiphysics on a cluster from the command line, see the section The COMSOL Commands for your platform.

LiveLink for MATLAB

The LiveLink™ *for* MATLAB® provides access to COMSOL Multiphysics from MATLAB. From the MATLAB prompt, you access COMSOL models through a client–server connection to a COMSOL Multiphysics server. You access the model through the COMSOL API and its Java® interface in MATLAB. In addition, there are M-file wrapper functions that help you perform tasks such as displaying graphics using MATLAB figure windows or fetching data from the model object. The model can be accessed simultaneously from the COMSOL Desktop running in client mode connected to the same server as MATLAB. See the LiveLink™ *for* MATLAB® manuals for more information.

LiveLink for Excel

The LiveLink™ *for* Excel® provides access to COMSOL Multiphysics from Excel. From an Excel sheet, you can access a COMSOL model through a client–server connection to a running COMSOL Multiphysics server. The model can be accessed simultaneously from the COMSOL Desktop running in client mode connected to the same server as Excel. See the LiveLink™ *for* Excel® manuals for more information.

COMSOL Batch

The COMSOL Multiphysics batch mode provides a way to run COMSOL Multiphysics without a graphical user interface. The COMSOL batch mode allows you to run both Model MPH-files and compiled model files for Java (class files).

You can control the options for running the COMSOL software in batch mode from the **Study** node in the **Model Builder**. To enable the Batch feature, click the **Show More Options** button ( ) and select **Batch** or **Batch and Cluster** (if your license includes cluster computing) in the **Show More Options** dialog. Then in the **Model Builder**, right-click a **Study** node and select **Batch**. Also see Batch (Job Configurations).

You can also run COMSOL batch using a command-line interface, as described in COMSOL Batch Commands (Windows), COMSOL Batch Commands (Linux), and COMSOL Batch Commands (macOS).

In batch mode, you can monitor the memory usage reported in the log as lines of the form

```
Memory: RAM/MAXRAM VIRT/MAXVIRT
```

where `RAM` is the current memory usage in MB, and `VIRT` is the current virtual memory usage in MB. The maximum measured usage is reported in `MAXRAM` and `MAXVIRT`, respectively. The log only reports changes to the memory usage. You can also monitor the current progress, which is reported as lines in the log of the form

```
Current Progress: 53%
```

where the percentage indicates the currently estimated progress.

For options for controlling the batch command, see the section The COMSOL Commands for your platform.

COMSOL BATCH UNDER A FLOATING NETWORK LICENSE

If you have licensed a floating network license, you are allowed to run a simultaneous "batch job" along with your COMSOL Multiphysics Desktop. Such batch jobs have the capacity to run parametric sweeps on multiple computers, as long as the changes to your model include only changes to parameters. This batch license functionality is only available for Cluster Computing and Cluster Sweep nodes, and you must select the **Use batch license** checkbox in the **Cluster Computing** and **Cluster Sweep** nodes' **Settings** windows. Each additional floating network license lets you run a separate independent batch job (with different models) on multiple computers.

RUNNING COMSOL BATCH WITH MODELS IN DATABASES

It is possible to run the COMSOL batch command-line interface using models stored in a Model Manager database as both input and output for the simulation. See Running COMSOL Batch with Models in Databases for more details. Note that this functionality is not supported for `-mode desktop`.

The COMSOL API and Compiling Java Code

This section is about compiling Java code created using the COMSOL API. With the COMSOL Compiler™, you can create standalone runnable apps developed using the Application Builder. See the Application Builder documentation for more information.

The COMSOL API is a Java-based programming interface for COMSOL Multiphysics. The COMSOL API can be used for a variety of purposes, such as running a model file for Java from the COMSOL Desktop or using the available batch command.

To run a model file for Java from the COMSOL Desktop, compile it using the `comsol compile` command. This command is called `comsolcompile` on Windows® and `comsol compile` on other platforms. The same commands can also compile model files into runnable apps with the COMSOL Compiler. The compilation gets you a model class file corresponding to the model file for Java. Launch the model class file by choosing **Open** in the **File** menu and then selecting a **Model Class File** under **File name**.

To create an application using the COMSOL API, you need to develop a text-based or UI-based interface to the functionality and compile it using the COMSOL compile command. The application can be run in *standalone mode* that links your Java® application directly to the COMSOL code (as a single process), but it requires a license for COMSOL Multiphysics. You can also choose to run the application in client–server mode by connecting to a COMSOL Multiphysics server or COMSOL Server.

To see options for compiling Java files, see The COMSOL Commands for your platform. For more comprehensive information about the COMSOL API, see the *COMSOL Programming Reference Manual* and the *Application Programming Guide*.

Security Settings

The COMSOL software includes security settings for controlling access to, for example, system properties, file systems, and runtime security settings from methods and external libraries, primarily for use in applications created using the Application Builder.

If you have configured a permanent security policy when installing the COMSOL software, none of these security settings are available.

The following security settings are available on the **Security** page in the **Preferences** window (the top four checkboxes are selected by default):

- Select the **Allow batch jobs** checkbox to allow batch jobs. This restriction affects the Batch, Batch Sweep, Cluster Computing, and Cluster Sweep nodes in the COMSOL Desktop model tree.
- Select the **Allow running methods** checkbox to allow running applications that include methods. If you clear this checkbox, it is not possible to run methods in applications.
- Select the **Allow running applications** checkbox to allow running applications in general. If you clear this checkbox, it is not possible to run any applications.
- Select the **Allow settings forms** checkbox to allow settings forms and dialog forms in the Model Builder. If you clear this checkbox, an error message appears if you try to create a new settings form or show a dialog form.
- Select the **Allow external processes** checkbox to allow applications to start external processes on the computer. This includes using the built-in `executeOS()` method.

The external process security settings refer to method code being able to launch arbitrary executables, not COMSOL or its LiveLink products launching their helper executables.

- From the **Allow external libraries** list, choose **No** (the default), **Yes**, or **Ask** to allow external C libraries to be called from methods in an application, directly or by first asking, or not.
- From the **Allow external MATLAB® functions** list, choose **No** (the default), **Yes**, or **Ask** to call functions written in MATLAB (requires LiveLink™ *for* MATLAB®), directly or by first asking, or not. If you change this preference setting, click **Clear Functions** in the **Settings** window for a **MATLAB** function node before running a simulation that calls MATLAB functions.

On the **Methods and Java Libraries** subpage:

- The **Enforce security restrictions** checkbox is selected by default. The following settings are available for easing parts of the restrictions on methods and Java libraries (none selected by default):
  - Select the **Allow access to system properties** checkbox to allow methods and Java libraries to read and write values to system properties such as `System.getProperty("cs.np")`, which can be used to determine the number of cores that COMSOL Multiphysics currently uses.
  - Select the **Allow changes to the runtime system** checkbox to allow methods and Java libraries to change the runtime system — for instance, by modifying class loaders.
  - From the **File system access** list, select **Temporary and application files** (the default) to restrict methods and Java libraries to only have access to such files, or select **All files** to allow methods and Java libraries to access all files that you have permissions to access on the file system.
  - Select the **Allow access to network sockets** checkbox to allow methods and Java libraries to open sockets for network access.
  - Select the **Allow control of the network authentication method** checkbox to allow methods and Java libraries to control the network authentication method used.
  - Select the **Allow access to classes through reflection** checkbox to allow access to all members in a class through reflection.
  - Select the **Allow access to runtime security settings** checkbox to allow methods and Java libraries to access security settings.
  - Select the **Allow access to Model Manager databases** checkbox to allow methods and Java libraries to access Model Manager databases, including both reading and writing data.

To allow methods and Java libraries to run with security completely disabled, clear the **Enforce security restrictions** checkbox and, on the **Security** page, select the **Allow external processes** checkbox.

On the **Internet** subpage:

- Select the **Use a restrictive security policy for model files downloaded from the internet** checkbox to use a restrictive security policy (Mark of the Web) for model and app files downloaded from the internet.
- Under **Trusted sites**, you can add internet sites that you want the COMSOL Multiphysics software to consider as trusted when the restrictive security policy is enabled. By default, the apps and models on the COMSOL Application Gallery web pages (`https://www.comsol.com/model/`, `https://www.comsol.de/model/`, and so on) are considered as trusted. Click the **Add** button (+) to add a row for entering another trusted site. Use the **Move Up** (↑), **Move Down** (↓), and **Delete** ( ) buttons as required.

If a model or app file originating from an untrusted site is opened in the COMSOL Desktop, a banner appears, notifying you that the security preferences have been temporarily restricted. You can click the **Remove Restrictions** button in the banner or on the **Security** subpages in the **Preferences** window, if desired, to restore the normal values and close the banner. If you keep the restrictions, then the settings on the **Security** subpages in the **Preferences** window are disabled.

If the security preferences are using a restrictive security policy for model files downloaded from the internet, clicking the **Factory Settings** button will not take effect for the concerned pages until the restrictions are removed.

This functionality is not available on Linux.

COMSOL and the Java Heap Space

The COMSOL executable programs are Java applications, which are only allowed to use a limited amount of memory. This limit, the *Java heap space*, is specified during application startup. By default, COMSOL allocates 2 GB of Java heap space memory, which should be sufficient for almost all cases. If you, for a large and complex COMSOL model, get a Java out-of-memory error, you can increase the size of the Java heap by specifying the Java virtual machine (JVM) parameters `-Xmx`. You find that parameter in the configuration settings (`*`.ini) files for all COMSOL programs, in the platform directory for your COMSOL Installation. For example, for the COMSOL Multiphysics main desktop program:

```
C:\Program Files\COMSOL\COMSOL63\Multiphysics\bin\win64\comsol.ini
```

In that file, change the line

```
-Xmx2g
```

to

```
-Xmx3g
```

to increase the Java heap space from 2 GB to 3 GB, for example.

The COMSOL Software Architecture

Overall Architecture

The following diagram shows the overall architecture of a network, including computers running COMSOL Multiphysics, COMSOL Multiphysics server, COMSOL Client, compiled COMSOL apps; external mobile devices or web browsers running COMSOL apps; COMSOL Server nodes; Model Manager Server; FlexNet license server; database server; and an HPC cluster with computation nodes running COMSOL batch jobs.

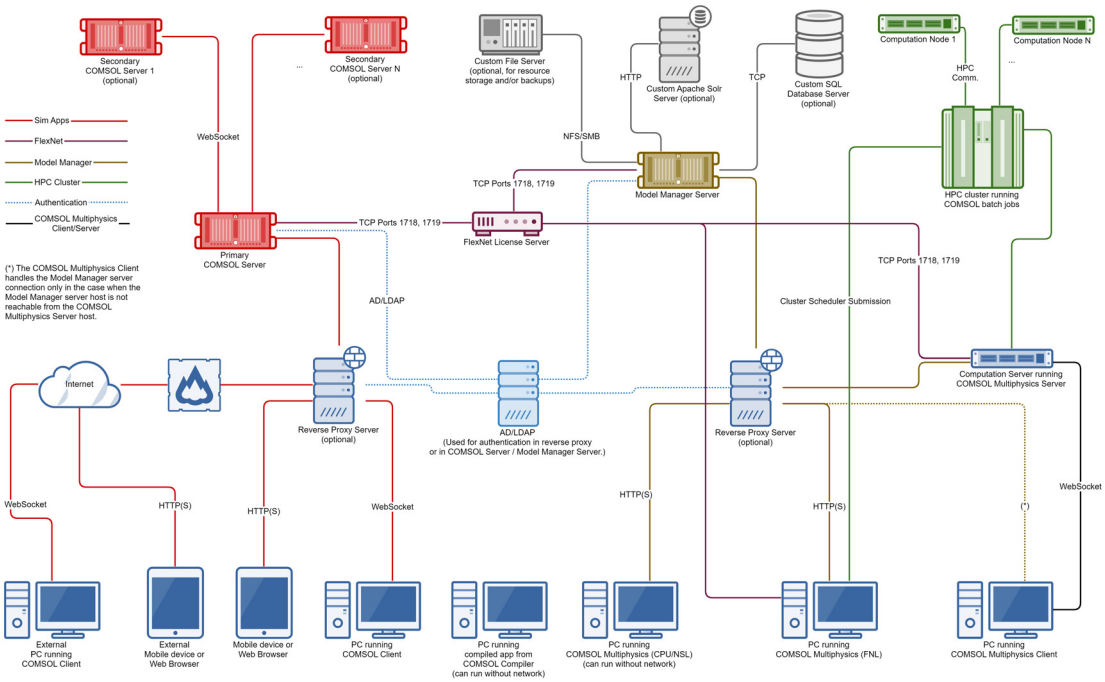


Figure 22-1: Diagram showing all possible components in a network architecture for running COMSOL software.

Standalone COMSOL

The most straightforward way of running COMSOL Multiphysics is as a standalone application on a single computer. In this configuration, the COMSOL Desktop runs within a single process.

Running COMSOL Multiphysics in Client–Server Mode

The COMSOL Multiphysics client and server applications are available on all platforms.

RUNNING COMSOL MULTIPHYSICS IN CLIENT–SERVER MODE ON THE SAME COMPUTER

The COMSOL Multiphysics client and the COMSOL Multiphysics server can run on the same computer and with all available license types: named single user license (NSL), CPU-locked license (CPU), and floating network license (FNL). In this configuration, the COMSOL Multiphysics client and the COMSOL Multiphysics server run as separate processes within a single computer. The client and server communicate through a local TCP (Transmission Control Protocol) connection.

RUNNING COMSOL MULTIPHYSICS IN CLIENT–SERVER MODE ON DIFFERENT COMPUTERS

The COMSOL Multiphysics client and COMSOL Multiphysics server can also run on different computers. This configuration requires a floating network license (FNL).

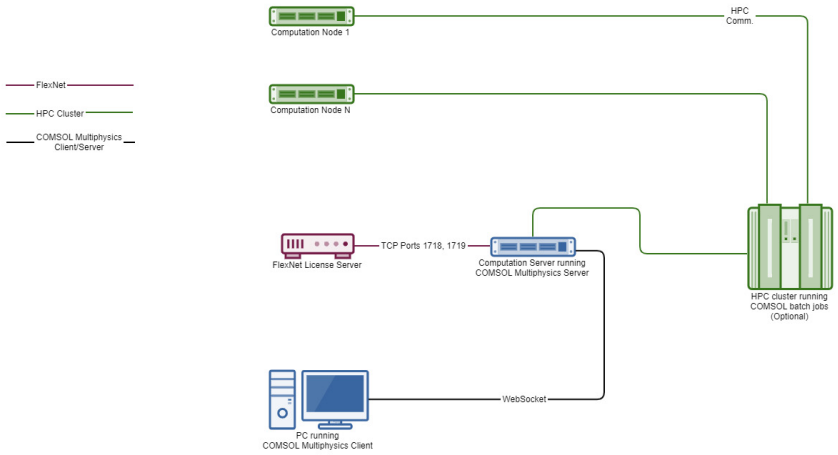

Figure 22-2: Diagram showing the COMSOL Multiphysics client–server connections.

The diagram illustrates the client–server TCP connection between different computers and TCP connections to the default ports 1718 and 1719 for the license server. (A license server is required for the FNL license.) The diagram also illustrates that the COMSOL Multiphysics server can submit batch jobs to a HPC cluster. Typically, a separate network is used for the communication between the compute nodes and the head node.

Running COMSOL with MATLAB, Simulink, or Excel

COMSOL can run together with MATLAB, Simulink, or Excel on the same machine using the client–server architecture. The command `comsol mphserver matlab` launches this configuration. The command `comsol matlab` can be used to launch just the client and to connect to a remote server. Excel launches a COMSOL Multiphysics server when you open a model. The diagram below shows computers running MATLAB and Simulink, Excel, and the COMSOL Java API, and how they are connected to a COMSOL Multiphysics server, a FlexNet license server, and an optional HPC cluster running COMSOL batch jobs.

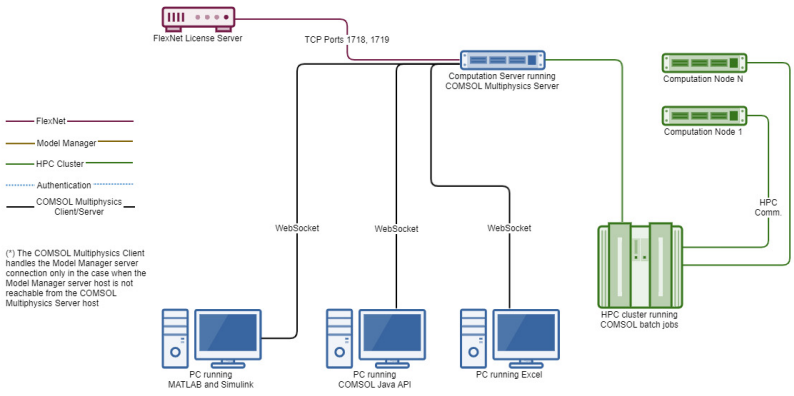

Figure 22-3: Diagram of the connections between computers running MATLAB and Simulink, Excel, and the COMSOL Java API through a COMSOL Multiphysics server. A FlexNet license server and an optional HPC cluster are also included.

See the documentation for LiveLink™ *for* MATLAB®, LiveLink™ *for* Simulink®, and LiveLink™ *for* Excel® for more information.

Running a COMSOL Model Manager Server and Client

The following diagram shows how the COMSOL Model Manager Server can be connected to a computer running COMSOL Multiphysics, to a FlexNet license server, and to optional SQL database severs and custom file servers.

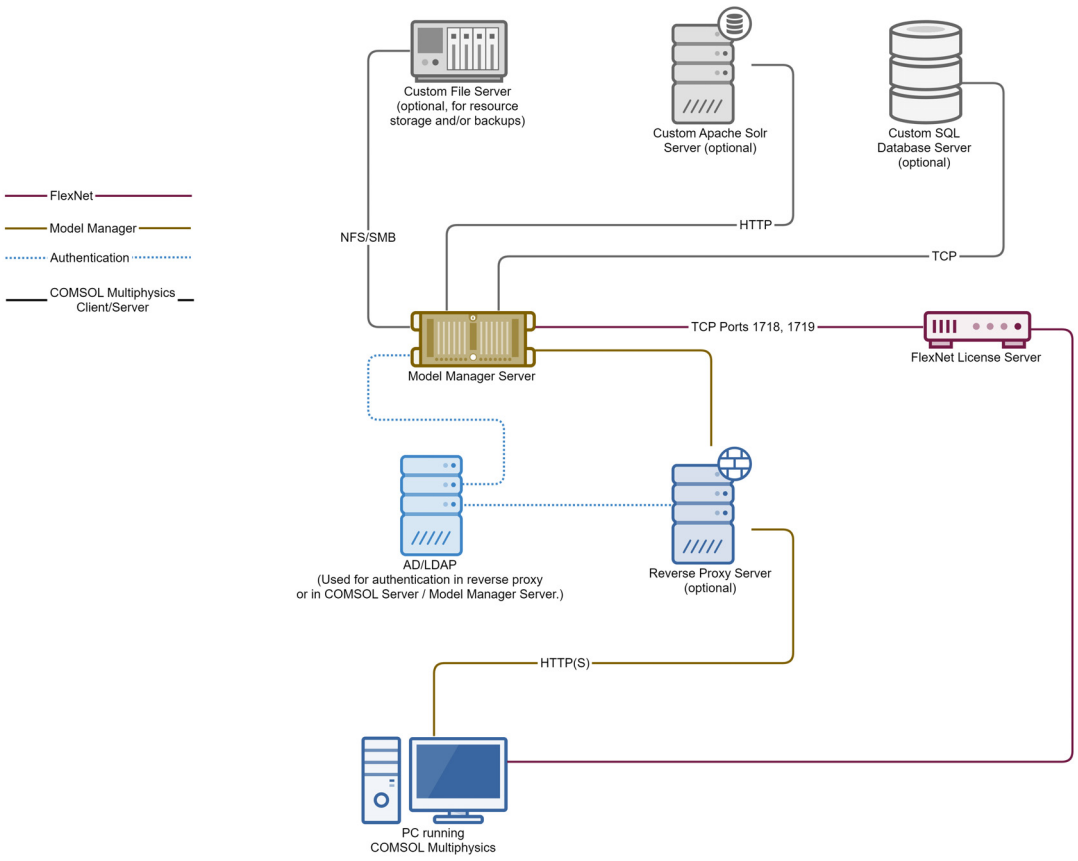

Figure 22-4: Diagram showing a COMSOL Model Manager Server with its connected servers and a computer running COMSOL Multiphysics.

The diagram shows the setup for running COMSOL Multiphysics to a Model Manager server through a reverse proxy server. This configuration is useful for managing a corporate website a common login for the Model Manager server and other web-based tools in a corporate environment. The Model Manager can also manage its own logins through an AD or LDAP server. Running the Model Manager server in this way requires a license server and at least one FNL license. When using an FNL license for COMSOL Multiphysics, you also need to communicate with the license server from COMSOL Multiphysics. When using a CPU or NSL license, you typically use a local license server or a license file. The Model Manager server can use local storage and a local database but can optionally communicate with separate database servers and a separate custom Apache Solr server, and use a separate server for backup and storage.

The following diagram shows a COMSOL Model Manager Server connected to a COMSOL Multiphysics client-server setup:

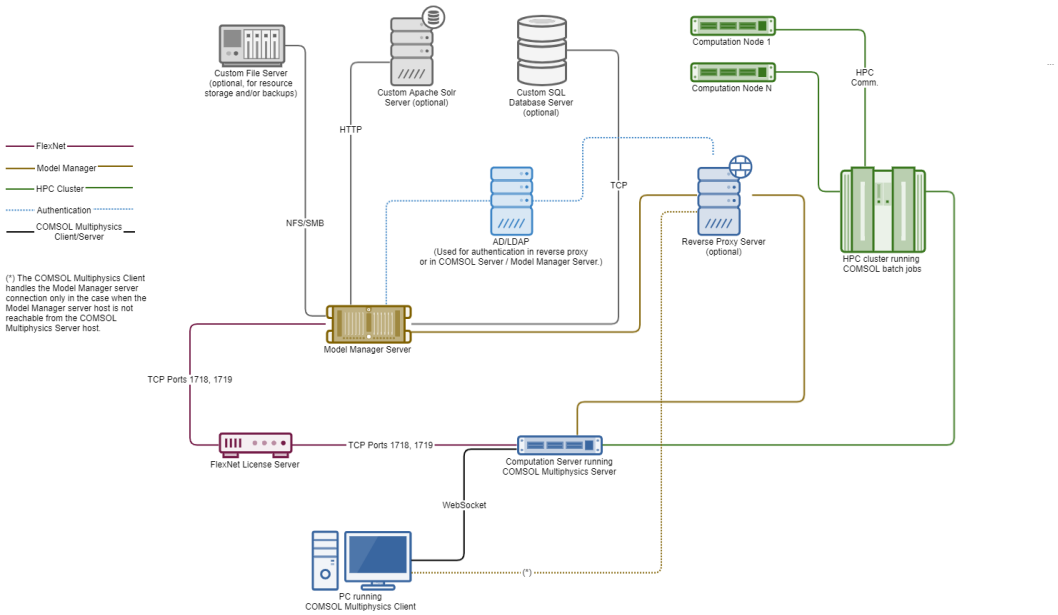

Figure 22-5: Diagram showing a COMSOL Model Manager Server with its connected servers and COMSOL Multiphysics running in a client-server configuration.

The diagram shows a setup with where you run COMSOL Multiphysics client and COMSOL Multiphysics server on separate computers. This configuration requires an FNL license. Both the COMSOL Multiphysics server and the Model Manager server communicate with the license server. The diagram shows the optional reverse proxy server with communicating with an AD or LDAP user database server. (The Model Manager server can manage logins through AD or LDAP itself.) This figure also shows an optional HPC cluster as well as optional storage servers, database server, and a custom Apache Solr server.

For more information about setting up and running the Model Manager, see the *Model Manager Reference Manual* and the *Model Manager Server Manual*.

Running COMSOL Multiphysics in Client–Server Mode

The COMSOL Desktop can run in a separate process as a client to a COMSOL Multiphysics server. The COMSOL Desktop client uses a TCP/IP connection to connect to the COMSOL Multiphysics server. The client and server need not run on the same platform. You must have a floating network license (FNL) to run the COMSOL Multiphysics server and the COMSOL Multiphysics client on separate computers. The COMSOL Multiphysics server has been designed to work as a single user server. Both client and server should be started by the same system user. The COMSOL Multiphysics server is not designed to run as a service, serving multiple users.

When you use LiveLink™ *for* MATLAB® and LiveLink™ *for* Excel®, a COMSOL Multiphysics client runs within MATLAB and Excel and connects to a COMSOL Multiphysics server, which is typically started automatically.

Advantages of Using COMSOL Multiphysics in Client–Server Mode

SOLVING LARGER MODELS

Run the COMSOL Multiphysics server on a computer that has more memory and a faster CPU than your desktop computer. This frees your desktop computer from lengthy computations, dispatching your jobs to a dedicated computer. Almost all data for the model is stored on the server. The only bigger chunks of data that the client maintains are those related to the graphical user interface, such as the rendering data and table contents, which are produced on the server and sent to the client. Files are read and written on the client but streamed to and from the server.

CROSS-PLATFORM CONNECTIONS

The client and server need not run on the same platform. For example, you can run the COMSOL Desktop on Windows® as a client, connecting to a COMSOL Multiphysics server on a Linux or macOS server. In this way, you can interactively access a more powerful remote computer.

MULTIPLE CONNECTIONS

Only one graphical user interface can be connected to a COMSOL Multiphysics server at a given time. However, additional clients can be connected to the same server from LiveLink™ *for* MATLAB® and LiveLink™ *for* Excel® and also standalone clients using the COMSOL API. For example, the COMSOL Desktop can act as a COMSOL Multiphysics client when connected to a COMSOL Multiphysics server, and a MATLAB session can be connected to the same server using LiveLink™ *for* MATLAB®.

Running COMSOL Multiphysics in Client–Server Mode

STARTING A COMSOL MULTIPHYSICS SERVER

- When you have access to the Windows® desktop, start the COMSOL Multiphysics server from the **Start** menu. Go to **All Programs**, select **COMSOL 6.3** and then select **COMSOL Launchers**. In the **COMSOL Launchers** window, double-click **COMSOL Multiphysics Server 6.3**. If starting the COMSOL Multiphysics server from a terminal window in Windows, use the command `<COMSOL Multiphysics installation directory>\bin\win64\comsolmphserver.exe`.
- On Linux®, use the `comsol mphserver` command to start a COMSOL Multiphysics server.
- On macOS, use the **COMSOL Multiphysics Server** application, or if you connect to macOS from another computer, use the `comsol mphserver` command in the terminal window.

INITIALIZING THE COMSOL MULTIPHYSICS SERVER

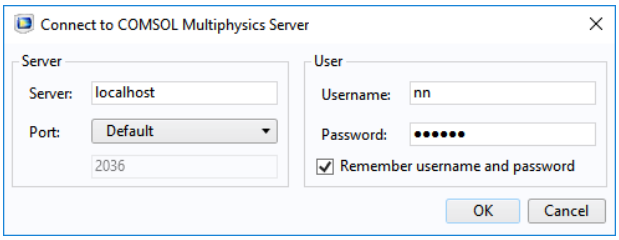
The first time you start a COMSOL Multiphysics server on a computer, you are asked for a username and password. By default, your username and a hashed password is stored on your computer's hard drive. You can avoid storing your username and password on disk by providing the `-passwd nostore` target option to the COMSOL Multiphysics server command. When the COMSOL Multiphysics server is started, the server displays the port number. The server also displays a message each time you log in from a client.

Connecting, Disconnecting, and Reconnecting to and from the Desktop

CONNECTING TO A COMSOL MULTIPHYSICS SERVER

To connect to a COMSOL Multiphysics server from the COMSOL Desktop, select **File** > **COMSOL Multiphysics Server** > **Connect to Server** ( ). For Windows users, you can also customize the Quick Access Toolbar and then click the **Connect to Server** button.

Then in the **Connect to Server** dialog, specify the hostname of the server in the **Server** field. The **Port** list setting specifies the TCP/IP port number of the server. Select **Default** to use the default port number, or select **Manual** to specify the port number in the field below. Then enter your user credentials under **User**.



The port number is displayed by the server as you start it. The port number can change if you, for example, have several COMSOL Multiphysics servers running at the same time on the same computer. Each server is assigned a separate port number. The username and password are the ones you used when you started the server the first time.

When you connect to a server, you may be asked if you want to save your current model. We recommend that you respond *yes* to get the most current version of your model transferred to the server. If you answer *no*, the latest saved copy of your model is transferred to the server.

When you connect to a server, your model is transferred to the server by default. If there is already a model in the server, you may be asked if you want to work with your current model in the desktop or the model on the server.

Windows Toolbars and Menus

DISCONNECTING FROM A COMSOL MULTIPHYSICS SERVER

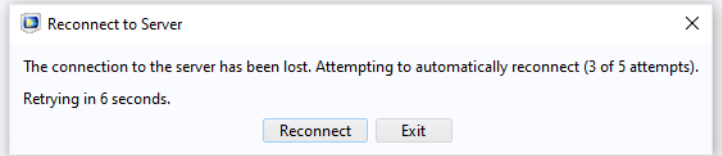
To close the connection to the server or MATLAB, select **File** > **COMSOL Multiphysics Server** > **Disconnect from Server** ( ). For Windows users, you can also customize the Quick Access Toolbar and then click the **Disconnect from Server** button.

Disconnecting from the server transfers the current model from the server to the COMSOL Desktop, which no longer runs as a client. By default, the option `-multi` is set to `auto`, which provides an option to choose if you want the server to keep running (if you use another client than the COMSOL Desktop, the server exits by default). It can also be set to `-multi off` to always exit. Start the server with the option `-multi on` to keep it running after the disconnect. When you have used the option `-multi on`, or if you use the default option and choose to keep the server running, your model is kept in memory in the server, and you can attach to the model from another client later on. If you close the COMSOL Desktop when connected to a server, the client–server session is

automatically disconnected, and the server continues to run with the model in memory if you have specified `-multi on`.

RECONNECTING TO A COMSOL MULTIPHYSICS SERVER

If you lose the connection between the COMSOL Desktop and a COMSOL Multiphysics server, the COMSOL Multiphysics software makes five attempts to reconnect to the COMSOL Multiphysics server. The following window appears:



After five failed attempts, you get a possibility to manually attempt to reconnect to the server. If the connection remains lost, check the network and cables and the computer where the COMSOL Multiphysics servers is installed.

PREFERENCES FOR EXITING AND DISCONNECTING

In the **Preferences** window, the following settings are available on the **Client–Server** page to control how the software handles the COMSOL Multiphysics server when exiting a COMSOL Multiphysics client and when disconnecting from a server:

- From the **When exiting the COMSOL Multiphysics client** list, choose **Ask** (the default) to get a question if you want to shut down the COMSOL Multiphysics server when you exit the COMSOL Multiphysics client, choose **Leave server running** to exit the client but keep the COMSOL Multiphysics server running, or choose **Shut down server** to shut down the COMSOL Multiphysics server.
- From the **When disconnecting from a server** list, choose **Ask** (the default) to get a question if you want to shut down the COMSOL Multiphysics server when you disconnect from it, choose **Leave server running** to disconnect but keep the COMSOL Multiphysics server running, or choose **Shut down server** to shut down the COMSOL Multiphysics server when disconnecting.

WORKING WITH MATLAB, EXCEL, OR THE COMSOL API

From MATLAB, you can use the commands `Modelutil.connect` and `Modelutil.disconnect` to connect and disconnect from a COMSOL Multiphysics server, respectively. The connection to the server is necessary to access and manipulate a model.

From MATLAB (and the COMSOL API), you can create multiple models using the `ModelUtil.create` and `ModelUtil.model` commands.

Import Application from Server

If several applications are present on the server, to get access to a particular application, select **File** > **COMSOL Multiphysics Server** > **Import Application from Server** ( ). For Windows users, you can also customize the Quick Access Toolbar and then click the **Import Application from Server** button.

Remove Applications from Server

To delete applications (remove them from the server) that you have created using `ModelUtil`, select **File** > **COMSOL Multiphysics Server** > **Remove Applications from Server** ( ). For Windows users, you can also customize the Quick Access Toolbar and then click the **Remove Applications from Server** button.

Windows Toolbars and Menus

Shared Libraries

When running in a Java application, and from MATLAB, the COMSOL Multiphysics client uses Java only and does not load shared libraries. When the COMSOL Desktop operates as a COMSOL Multiphysics client, it loads several shared libraries.

Running COMSOL in Parallel

COMSOL supports two mutual modes of parallel operation:

- The distributed memory model runs on several nodes on a Linux® or Windows® cluster; see Distributed-Memory Parallel COMSOL.
- A parallel shared memory model. See Shared-Memory Parallel COMSOL

Overview of Simulations on Shared- and Distributed-Memory Computers

The following terms occur frequently when describing the hardware for cluster computing and shared memory parallel computing:

A *cluster* is defined as any networked system of computers. A single cluster is composed of a set of computing *hosts*, often interchangeably called *physical nodes*, which are networked together via *interconnects*. When instances of a software program such as COMSOL Multiphysics running on a cluster need to communicate with each other, they do so via MPI, the *message-passing interface*. Each computing hosts will have one or more CPUs, and each CPU has multiple *cores*. All of the CPUs on a single hosts (and all of the cores within these CPUs) can share the same memory space, so each host is a *shared-memory* computer. The physical processor cores are used in shared-memory parallelism by a computational node running on a host with a multicore processor. For example, a host with two quad-core processors has eight available cores.

The entire cluster, on the other hand, is a *distributed-memory* computer. In this case, the *compute nodes* are where the distributed computing occurs. A COMSOL Multiphysics instance resides in each compute node and communicates with other compute nodes using MPI (message-passing interface). A compute node is a process running on the operating system, and multiple compute nodes can be assigned to run on a single host.

When a single COMSOL Multiphysics model is solved on a single host, there is no information being passed over the interconnects, and MPI does not need to be used. This is desirable because the data transfer speed between hosts via the interconnects is slower than the data transfer within a single host. When a single model requires so much memory that it cannot be solved on a single host, then multiple hosts have to be allocated to the model, and the MPI is used to share date between processes running on different hosts. The interconnect speed can become a significant computational bottleneck. It is therefore typically desirable to minimize the number of hosts used per single model. At least one compute node must run on each host. Depending on the specific hardware and the COMSOL Multiphysics model being solved, it may be beneficial to assign two or more computational nodes per host.

When a single COMSOL Multiphysics model contains a parametric sweep, it is possible to solve each case of that sweep completely separately of each other. In this scenario, using the Distributed Parametric Sweep functionality is highly motivated because there will be relatively little data passed via MPI; only the problem definition and the solution. Since each host can contain several CPUs, each of which can have many cores, it is also possible to solve several cases of a parametric sweep on the same host. This is motivated if the individual cases have low computational requirements.

The following command-line options are relevant for controlling how a problem is divided over a cluster:

- `-mpihosts`: This option specifies the names of the hosts that will be used during the solution.
- `-f`: This option specifies the path to the hostfile that will be used during the solution.
- `-nn`: This option specifies the number of instances of COMSOL Multiphysics that are created. The instances communicate to each other via MPI.

- `-nnhost`: The numbers of instances of COMSOL Multiphysics that are allocated to run on each host.
- `-np`: The number of cores used for each instance of COMSOL Multiphysics.

The *Introduction to COMSOL Multiphysics* includes a tutorial to learn how to build the busbar geometry. See the PDF-file included with COMSOL Multiphysics.

Shared-Memory Parallel COMSOL

Modern computer hardware supports the shared-memory model, which allows data in memory to be accessed by all of the CPU cores. When running on a cluster, COMSOL Multiphysics uses shared-memory parallelism on each node; and distributed parallelism across the cluster nodes. The solvers, assembly, and meshing in COMSOL Multiphysics benefit from shared-memory parallelism. By default, the COMSOL software uses all cores available on the machine for shared-memory parallelism.

BENEFITS OF RUNNING COMSOL IN SHARED-MEMORY PARALLEL MODE

All iterative solvers and smoothers except Incomplete LU are parallelized. Some smoothers have blocked versions. The blocked versions usually benefit more from running in parallel than the nonblocked versions. The finite element assembly also runs in parallel. Usually the speedup depends on the problem size; problems using a lot of memory usually have better speedup.

The PARDISO and SPOOLES sparse direct linear solvers and the MUMPS direct solver all run in parallel.

The orthonormal null-space function runs in parallel.

The tet mesher in 3D runs in parallel over the faces and domains of the geometry object being meshed. For this reason, the speedup when running on several processors depends strongly on the domain partitioning of the corresponding geometry. Meshing a geometry with only one domain, such as an imported CAD part, gives almost no speedup at all. However, meshing a geometry with several domains, such as an imported CAD assembly with many parts, can give significant speedup, especially if the number of elements in the mesh is large.

The evaluation part of all plot types runs in parallel. In addition, the computations of contours, isosurfaces, and streamlines run in parallel.

A significant part of the parallel speedup in computations comes from functions of the BLAS type (basic linear algebra subprogram; see the next section). If you want to run the software in parallel, it is important that the BLAS library you use supports parallelism. The BLAS libraries shipped with COMSOL Multiphysics do that.

Running in parallel usually requires extra memory. If you run out of memory, try to lower the number of used cores as explained in the *COMSOL Multiphysics Installation Guide*. The speedup depends on the processor load. For instance, if your system has m processors and n of them are used by other active programs, do not set the number of cores to a number that is greater than $m - n$. The reason is that the programs compete for the same resources, which slows all of them considerably.

COMSOL and BLAS

BLAS is a set of functions for basic linear algebra operations. Vendors often supply BLAS libraries optimized for their hardware. A large portion of the computational engine in COMSOL Multiphysics relies on BLAS. Included with COMSOL Multiphysics is the Intel® MKL (Intel® Math Kernel Library) BLAS library, which is the default BLAS library. For AMD® processors with the Zen architecture, COMSOL provides the AMD Optimizing CPU Libraries. COMSOL Multiphysics also includes the standard BLAS and LAPACK libraries. For ARM Processors on Linux, COMSOL includes the Arm Performance Libraries (default) and the OpenBLAS library. For Apple silicon, COMSOL uses Apple's vecLib library by default, and COMSOL also includes the OpenBLAS library and the Arm Performance Libraries. It is also possible to supply another BLAS library optimized for your hardware. See BLAS Options (Windows), BLAS Options (Linux), or BLAS Options (macOS) for information about how to override the default BLAS library (MKL). If the library you want to use is unavailable or incorrectly installed, COMSOL Multiphysics switches to the default BLAS library.

Distributed-Memory Parallel COMSOL

See also Overview of Simulations on Shared- and Distributed-Memory Computers.

The Linux® and Windows® versions of COMSOL Multiphysics support a distributed memory mode. The *distributed mode* starts a number of computational nodes set by the user. Each computational node is a separate process running a COMSOL instance. A computational node is not the same as a physical node (computer), but they can coincide. When running in distributed mode, COMSOL Multiphysics uses MPI for communicating between the processes in the distributed environment.

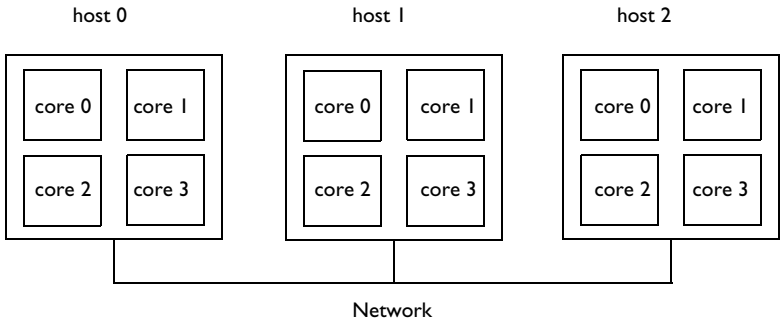

Figure 22-6: Schematic of a cluster with 3 hosts (physical nodes) with 4 processor cores each.

The distributed-memory mode can be combined with the ability of COMSOL Multiphysics to benefit from the shared-memory model. All modes that COMSOL Multiphysics can run in are able to use distributed-memory mode.

In client–server mode, the computer or cluster acting as server must be accessible from the client through a TCP/IP connection. If you cannot connect to the server, you can use a COMSOL Batch job to solve models on the cluster or do parametric sweeps. You can also use a Cluster Computing study to set up a COMSOL Batch job from within the COMSOL Desktop.

For the schematic in Figure 22-6, you can choose any number of computational nodes between 1 and 12. Each node, in turn, can use between 4 and 1 processor cores for shared memory. By default, COMSOL Multiphysics

uses as many cores as are available on each physical node for shared-memory parallelism. This is suboptimal if the number of computational nodes is not the same as the number of physical nodes. It is recommended that you explicitly set the number of cores. For the schematic example, if you run 6 computational nodes, the optimal value for number of cores per compute node is 2. The total number of cores used is then $6 \cdot 2 = 12$.

For the same example, assuming you are the sole user of the system for the duration of the computation and that your problem requires a lot of memory, use 3 computational nodes with 4 shared-memory cores each.

You do not need a cluster to benefit from the ability to utilize the distributed-memory model. On a multiprocessor computer, you can use multiple computational nodes. This can be useful for small-sized parameter sweeps, for example. Make sure that the number of computational nodes times the number of cores does not exceed the number of available cores; otherwise performance deteriorates significantly.

Benefits of Running COMSOL in a Distributed Mode

The following direct solvers are supported by COMSOL Multiphysics when running in a distributed mode:

- MUMPS
- SPOOLES

PARDISO is not supported in distributed mode. The Intel MKL Parallel Direct Sparse Solver for Clusters is used instead if the **Parallel Direct Sparse Solver for Clusters** checkbox is selected; otherwise, MUMPS is used instead.

The following iterative solvers are supported:

- Iterative solvers: BiCGStab, CG, GMRES, and FGMRES
- Smoothers and preconditioners: SOR, SOR Gauge, SOR Line, SOR Vector, SCGS, and Vanka
- Geometric multigrid
- Algebraic multigrid
- Domain decomposition

All nonlinear or segregated stationary, time-dependent, parametric, eigenvalue, and optimization solvers run in parallel in the distributed mode. Assembling is also performed in parallel in the distributed mode. In addition, the orthonormal null-space function runs in parallel in the distributed mode. The primary benefit is that the memory usage per node is lower than when COMSOL Multiphysics is run in a nondistributed mode. Therefore, if you run COMSOL Multiphysics in the distributed mode on a cluster distributed over several computer nodes, you can solve a larger problem compared to when you run in a nondistributed mode.

COMSOL Multiphysics can also run parametric sweeps using the distributed mode. This setting is available for all parametric solvers when **Advanced Study Options** is active. The simplest way to start a distributed parametric sweep is to select the **Distribute parametric sweep** checkbox in the **Settings** window for **Cluster Computing** in the **Cluster Settings** section. The simplest way to modify an existing model is to add the **Cluster Computing** study and select **Compute** in the study node's **Settings** window. When running a parametric sweep in distributed mode, the memory usage is still limited by the memory size of a single computer node. Because the problems are solved in parallel, you will solve for all parameter values faster compared to solving on a single computer node.

If you want to combine the benefits from distributed parametric sweeps and the distributed solvers, it is possible to run in a hybrid mode where you can limit the maximum number of groups to distribute the sweep over. Use the **Show Default Solver** command to access this setting, which you find in the **Cluster Settings** section of the **Settings** window for the **Parametric** solver node.

Running COMSOL in Parallel on Clusters

You control the options for running COMSOL Multiphysics on a cluster from the **Study** node in the **Model Builder**. To enable the cluster computing feature, click the **Show More Options** button ( ) and select **Batch and Cluster** in the **Show More Options** dialog. Then in the **Model Builder**, right-click a **Study** node and select **Cluster Computing** ( ). You must have a floating network license (FNL) to run COMSOL Multiphysics in distributed-memory parallel mode.

	Cluster Computing and Cluster License Handling. See also Cluster Installation in the *COMSOL Multiphysics Installation Guide* for information about cluster installations.

	The *Micromixer — Cluster Version* and *Joule Heating of a Microactuator — Distributed Parameter Version* models show how to set up a model for running COMSOL Multiphysics in parallel on a cluster: in one case for decreased per node memory usage of a large fluid flow model using distributed memory computing, and in the second case for speeding up solution of a distributed parameter sweep.

The following sections describe how to run cluster jobs on Windows and Linux.

RUNNING A CLUSTER JOB ON WINDOWS

This section outlines the main steps for running a cluster job on Windows®. Before you start, check that the installation of COMSOL Multiphysics follows these guidelines:

- Make sure that the COMSOL installation directory is shared between all the compute nodes and the head node on a shared network disk.
- Make sure that the license manager is available and up and running.
- If you work on a desktop PC, which is recommended, install the COMSOL software on that local PC. Also install Microsoft® HPC Pack on the desktop PC before you start. Microsoft® HPC Pack makes it possible to access the cluster from your workstations. The latest version can be downloaded from Microsoft. An alternative is to log in to the cluster via Remote Desktop, for example.

Running Cluster Jobs in the COMSOL Desktop

To run a cluster job using COMSOL Desktop, follow these steps:

1. Start COMSOL Multiphysics.
2. In a complete model, right-click the **Study** node and select **Cluster Computing** ( ).
3. In the **Settings** window for **Cluster Computing**, select **Microsoft® HPC Pack** from the **Scheduler type** list (this is typically a preference setting). This provides access to all parameters that you need for communication with the cluster.
4. To submit the job, click **Compute** ( ).
5. You can define more details in the **Settings** window for the **Cluster Computing** node ( ).under **Job Configurations** ( ). When you submit a job, COMSOL Multiphysics adds a **Cluster Computing** node. If you want to change or inspect its settings before submitting the first job, right-click the **Study** node ( ) and select **Show Default Solver** ( ).
6. After submitting the job to the cluster, you can monitor the progress in the **Progress** window and the **Log** window. The **Progress** window shows the progress of the batch data and external processes, and the **Log** window contains a log with information about the solver operations for each parameter in a parametric sweep, for example. You can also get details about a cluster job in the Windows Job Manager, which is available in the HPC Pack.

Running Cluster Jobs from the Command Line

You can do the same cluster simulation from the command line using, for example, a scheduler script. The **Cluster Computing** node is not needed in this case.

This command launches a COMSOL MPI job on a cluster without involving the scheduler:

```
mpiexec -n 2 comsolclusterbatch.exe -inputfile comsoltest.mph -outputfile output.mph -batchlog b.log
```

You can use the command `job submit` to launch COMSOL Multiphysics to the Windows scheduler.

For additional information about running COMSOL Multiphysics on clusters from the command line, see the section COMSOL Cluster Commands for Windows.

RUNNING A CLUSTER JOB ON LINUX

Before you begin, make sure that the license manager is up and running and reachable from all compute nodes and the head node.

Running Cluster Jobs in the COMSOL Desktop

To run a cluster job using COMSOL Desktop, use the steps below. Skip Steps 1 and 3 if you are running COMSOL Multiphysics on the machine from where you want to start the cluster job.

1. Start the COMSOL Multiphysics server on the Linux® system with the command `comsol mphserver`. Notice the port number that is displayed (for example, *COMSOL 6.3 started listening on port 2036*).
2. Start COMSOL Multiphysics on your desktop computer.
3. From the **File** menu, choose **COMSOL Multiphysics Server** > **Connect to Server** ( ). In the **Connect to Server** dialog, use the login credentials that you entered at the startup of the COMSOL Multiphysics server.
4. In a complete model, right-click the **Study** node and select **Cluster Computing** ( ).
5. In the **Settings** window for **Cluster Computing**, select **General** from the **Scheduler type** list for Linux clusters. This provides access to all parameters that you need for communication with the cluster.
6. To submit the job, click **Compute** ( ).
7. You can define more details in the **Settings** window for the **Cluster Computing** node ( ) under **Job Configurations** ( ). When you submit a job, COMSOL Multiphysics adds a **Cluster Computing** node. If you want to change or inspect its settings before submitting the first job, right-click the **Study** node ( ) and select **Show Default Solver** ( ).
8. After submitting the job to the cluster, you can monitor the progress in the **Progress** window and the **Log** window. The **Progress** window shows the progress of the batch data and external processes, and the **Log** window contains a log with information about the solver operations for each parameter in a parametric sweep, for example.

Running Cluster Jobs from the Command Line

You can do the same cluster simulation from the command line using, for example, a scheduler script. The **Cluster Computing** node is not needed in this case.

This command launches a COMSOL MPI job on a cluster without involving the scheduler:

```
comsol -nn 2 batch -inputfile comsoltest.mph -outputfile output.mph -batchlog b.log
```

For additional information about running COMSOL Multiphysics on clusters from the command line, see the section COMSOL Cluster Commands for Linux.

RUNNING CLUSTER SWEEPS

A **Cluster Sweep** node that you add to a study can be viewed as combinations of a **Parametric Sweep** node with a **Cluster Computing** subnode under **Job Configurations**. Each parameter tuple results in a start of a **Cluster Computing**

job. Therefore, most settings can be derived from these two. The main additions are the following options in the **Batch Settings** section:

- Under **Before sweep**: the **Clear meshes** and **Clear solutions** checkboxes that specify what to do before saving the model.
- Under **During sweep**: The **Synchronize solutions** and **Synchronize accumulated probe table** checkboxes that specify what data to insert back into the original model.
- Under **After sweep**: The **Output model to file** checkbox that controls if the batch jobs save a model file or not.

CLUSTER LICENSE HANDLING

To run COMSOL Multiphysics simulations in distributed-memory parallel mode (on a cluster), you must have a floating network license (FNL). Look for the keyword CLUSTERNODE in your license file. When running a cluster job, COMSOL Multiphysics uses the following license components and license check-out procedures:

- On the head node, one seat of the COMSOL and COMSOLGUI features each are checked out.
- On each of the compute nodes, only one CLUSTERNODE feature is checked out, and it is not counted. This means that you have an unlimited number of cluster nodes available for every seat (job) of the floating network license.
- When running a batch job through a scheduler, the COMSOL license manager checks out the noncluster COMSOL license keys (COMSOL, COMSOLGUI, CADIMPORT, CHEM, and so on) from one of the distributed processes. All other processes in the batch job only check out a CLUSTERNODE license key. So, license keys can be checked out from any physical node in the cluster depending on where the scheduler starts the processes.

STOPPING AND OUTPUTTING THE SOLUTION RUNNING A CLUSTER JOB OR BATCH JOB

If you have a model running on a cluster in batch mode, for example, you can monitor the solver log. If you notice that the solver starts diverging, you may want to stop the solution process and output the available solutions. To do so, use one of the following commands, for example:

```
echo "Cancel" > outputfile.mph.status
```

to cancel the solution, or

```
echo "Stop 2" > outputfile.mph.status
```

to stop the solution on progress level 2, or

```
echo "Stop"
```

to stop immediately.

In those commands, replace `outputfile` with `inputfile` if a separate output file is not specified.

SPECIFYING THE SOLUTION STORAGE FORMAT

The COMSOL Multiphysics software supports three different solution storage formats on clusters. With the first format the entire solution is stored on all nodes. With the second format only a single node stores the entire solution. The third format is intended for storing the solution using a distributed storage on clusters. The savings in disk space when using a single node can be significant for time-dependent problems, eigenvalue problems, and for solutions using a parametric solver. To select the first format, go to the **Solution** node under **Solver Configurations** and choose **Solution** > **Store on All Nodes**. To select the second format, choose **Solution** > **Store on a Single Node**. Choose the third format, **Solution** > **Store Solution Using Distributed Storage**, to store the solution using a distributed storage on clusters, which can improve performance using parallel I/O.

RUNNING FEAST IN A PARALLEL MPI MODE

The main computational cost for the FEAST eigenvalue solver consists of assembling the Jacobian matrix and solving independent linear systems for each quadrature points along the complex contour. Parallelism is therefore central to speeding up the FEAST solver, especially for large problems with many integration points. The parallel version of FEAST distributes the quadrature points to different computational nodes, forms the Jacobian matrix, and solves the corresponding linear system independently and locally. The performance of the parallel version is dominated by the node who takes care of the maximum number of quadrature points. In order to get optimal use of the parallel code, define the number of nodes according to the number of quadrature points, such that the quadrature points can be equally distributed on the nodes. For example, if running a model in parallel with 3 nodes, then the performance of using 15 integration points for the eigenvalue solver would be a bit better than the performance of using 16 integration points. Furthermore, the COMSOL Multiphysics software supports OpenMP parallelism when assembling the matrix and solving the linear system. That is, with hybrid configurations (MPI plus OpenMP), the best performance on parallel platforms could be achieved. For small problems that fit well in the memory of a workstation, the hybrid configuration is always an interesting alternative. On a 16-core workstation, for example, it might be advantageous for 16 integration points to run COMSOL Multiphysics in hybrid mode with 4 nodes and 4 cores on each node; that is, specify `-nn 4 -np 4`.

To enable the MPI parallelism for the FEAST eigenvalue solver, you must run COMSOL Multiphysics in cluster mode (requires a floating network license). In the COMSOL Desktop, under **Model Builder**, click **Show More Options** and select the **Study** > **Batch and Cluster** checkbox. The option to select the **Distribute linear system solution** checkbox then appears for the FEAST eigenvalue solver in both the **Eigenvalue** and **Eigenfrequency** study nodes' and the **Eigenvalue Solver** node's **Settings** windows. Select it to run FEAST in parallel.

Grid Computing and Remote Computing in COMSOL Multiphysics

The Cluster Sweep and Cluster Computing studies can be configured to start COMSOL simulations on other machines. This is useful if you want to perform a parametric study and you have multiple machines that are free (often referred to as *grid computing*) or if you have a cluster with a job scheduler to which you want to submit COMSOL Multiphysics simulations. The COMSOL Multiphysics software supports a number of common configurations. The main requirement is that you can start COMSOL Multiphysics on the machines you run simulations on and that one of the supported methods can be used to access the machines. Some example configurations are:

- You have COMSOL Multiphysics installed on your desktop computer and want to run on a cluster where COMSOL Multiphysics is installed.
- You have COMSOL Multiphysics installed on your desktop computer and want to start simulations on other computers that you have login access to — for instance, using the secure shell protocol (SSH).
- You have access to a remote computer through a client–server connection and want to start simulations on computers that you can login to from the remote computer.
- You have a job scheduler that can schedule jobs to remote computers.

In the first case, you can configure the **Remote and Cloud Access** section of the **Cluster Computing** or **Cluster Sweep** studies to log in to the cluster's job submit node and use the **Batch Settings** section to configure the scheduler. If the login to the cluster can be done using a locally installed SSH client, you can use an SSH key file pair to login. You can also configure your own login command. Use secure copy (SCP, based on secure shell) or configure a command to copy the files from the local directory to the remote directory. The hostname of the cluster login node should be set in the Remote hosts section. In the **Batch Settings** section, it is important to distinguish between settings for the local machine and settings for the remote machine. The **Directory** settings apply to the local machine while the **Specify external COMSOL batch directory path** refers to the remote machine. The paths have to be accessible for the respective computers. The **Specify external COMSOL installation directory path** can be used to start COMSOL

Multiphysics when the installation path on the remote machine is different than on the local machine. Use the **Scheduler type** setting to select the job scheduler to use.

In the second case above, you can configure the **Remote and Cloud Access** section of the Cluster Computing or Cluster Sweep studies to log in to other computers and use the **Batch Settings** section to configure the start command used on the other computers. If the login to the cluster can be done using a locally installed SSH client, you can use an SSH key file pair to log in. You can also configure your own login command. Use SCP or configure a command to copy the files from the local directory to the remote directory. The hostnames of the remote computers should be set in the **Remote hosts** list in the **Remote and Cloud Access** section. In the **Batch Settings**, it is important to distinguish between settings for the local machine and settings for the remote machine. The **Directory** settings apply to the local machine while the **Specify external COMSOL batch directory path** refers to the remote machine. The paths have to be accessible for the respective computers. The **Specify external COMSOL installation directory path** can be used to start COMSOL Multiphysics when the installation path on the remote machines is different than on the local machine.

In the third case, you can use similar settings as in the second case. The only difference is that you should set the **Specify server directory path** if you want the data stored in a special place on the server side.

In the fourth and last case above, you only need to use the **Batch Settings** section of the Cluster Computing or Cluster Sweep study. In this case it is important that the **Directory** setting and the **Specify external COMSOL batch directory path** refer to the same physical path. The paths are usually different because you have set a hard drive path in the **Directory** setting and a network path in the **Specify external COMSOL batch directory** path. Use the **Scheduler type** setting to select the job scheduler to use.

The COMSOL Commands

The following sections describe the `comsol` commands on the Windows®, Linux®, and macOS platforms:

- COMSOL Commands on Windows. For COMSOL Compiler™, see The COMSOL Compile Command.
- COMSOL Commands on Linux. For COMSOL Compiler™, see The COMSOL Compile Command.
- COMSOL Commands on macOS. For COMSOL Compiler™, seeThe COMSOL Compile Command.

COMSOL Commands on Windows

Use a COMSOL command to start COMSOL products with detailed startup options.

The general syntax of the COMSOL commands is

```
<command> [<target>] [<options>] [<target arguments>]
```

where square brackets indicate optional arguments. There are several different commands (See *<command>* in the command syntax) that can be combined with optional targets to achieve various results. The table below lists the major available commands and targets (if the **Availability** column is empty, the command is always available):

TABLE 22-1: COMSOL COMMANDS AND TARGETS.

COMMAND AND TARGET	DESCRIPTION	AVAILABILITY
`comsol`	Run standalone COMSOL Desktop	
`comsolbatch`	Run a COMSOL MPH-file or class file in batch mode	
`comsolcluster`	Run COMSOL Desktop on a cluster	Requires a floating network license (FNL)
`comsolclusterbatch`	Run COMSOL cluster version in batch mode	Requires a floating network license (FNL)
`comsolclustermphserver`	Run COMSOL Multiphysics cluster server	Requires a floating network license (FNL)
`comsolclusterxpl`	Run cross-platform COMSOL Desktop on a cluster	Requires a floating network license (FNL)
`comsolcompile`	Compile a model file for Java or compile an application into an executable application (the latter option requires COMSOL Compiler)	
`comsoldoc`	Launch the COMSOL Documentation window	
`comsolmphclient`	Run COMSOL Multiphysics client	
`comsolmphserver`	Start COMSOL Multiphysics server	
`comsolmphserver matlab`	Start MATLAB® and connect to a COMSOL Multiphysics server	Requires a LiveLink™ *for* MATLAB® license
`comsolpowerpointbatch`	Update images in PowerPoint presentations	
`comsoltrust`	Trust methods in add-ins	
`comsolxpl`	Run cross-platform COMSOL Desktop	

The commands are available in the `bin\win64` subdirectory in the COMSOL installation directory. The COMSOL installer sets up a few of the possible commands on your Start menu and your desktop. In Windows 8, 8.1, and 10, you can click the shortcut **COMSOL Launchers** on the Apps screen. This makes a folder with shortcuts to all COMSOL commands available.

To create additional customized commands, you can create shortcuts including all argument and put them on your desktop. You can also issue COMSOL commands in a command window. To conveniently access the command in a command window, you need to set up the Windows path to include the path `bin\win64` in the COMSOL installation directory.

INI FILES

For each launcher file, there is a corresponding `.ini` file in the same directory. It is sometimes recommended that these files are edited. For example, you can add options to any of the above commands by modifying the corresponding INI file. To change the option `opt` to value *`val`*, add the line

```
-Dopt = val
```

to the file `comsol.ini`. Change the file `comsolbatch.ini` for `comsolbatch`, and similarly for the other COMSOL targets.

In general, for a system property or option, add `-D` as a command option. For example, to set the system property `cs.precmp` to *`val`*, use the command option `-Dcs.precmd = val`.

OPTIONS

You can enter various options after the COMSOL command and target. Table 22-2 lists the options (See [*<options>*] in the command syntax) available for all COMSOL commands. Always issue these options between the command and the target (if any).

TABLE 22-2: COMSOL OPTIONS ON WINDOWS (CURLY BRACKETS INDICATE DEFAULT VALUES).

COMSOL OPTION	DESCRIPTION
<target> `-h`	Print target-specific help.
`-3drend ogl | sw`	3D renderer: OpenGL or software rendering.
`-alloc native | scalable`	Memory allocator: Select from using the Windows® native memory allocator or the scalable memory allocator from the Intel® Threading Building Blocks library. COMSOL defaults to the scalable allocator for computers with more than 8 cores.[3]
`-applicationsroot` *<path>*	Specify custom path to the COMSOL Application Libraries root directory.[1]
`-autosave {on}|off`	Control saving of recovery files.
`-blas {auto}|mkl|aocl|blas|path`	BLAS library to use.[4]
`-blaspath` *<path>*	BLAS library path.[4]
`-c` *<path>*	License file path.
`-ckl`	Use class-kit license.
`-clusterpartmethod {off}|mo|nd|wnd`	Cluster partitioning method. Choose from mesh ordering (`mo`), nested dissection (`nd`), or weighted nested dissection (`wnd`).
`-clusterstorage all | single | shared`	Cluster storage format. The `single` format does I/O only from the root node, while the `shared` format does I/O using distributed I/O operations. The shared format requires that all nodes have access to the same storage area and the same temporary storage area.
`-comsolinifile` *<path>*	Specify custom path to .ini-file used when starting COMSOL.

TABLE 22-2: COMSOL OPTIONS ON WINDOWS (CURLY BRACKETS INDICATE DEFAULT VALUES).

COMSOL OPTION	DESCRIPTION
`-configuration` *<path>*	Path to directory for storing the state for the GUI between sessions and for performing different caching tasks. The configuration directory is by default a subdirectory to the preference directory. When running in batch or cluster mode, add `@process.id` to get a unique identifier to the path (for example, `-configuration /tmp/comsol_@process.id`).
`-data`	Path to a workspace directory for storing internal workspace information. The workspace directory is by default a subdirectory to the preference directory. *The workspace directory is cleared when COMSOL is launched.* When running in batch or cluster mode, add `@process.id` to get a unique identifier to the path (for example, `-data /tmp/comsol_@process.id`).
`-docroot` *<path>*	Specify custom path to the COMSOL documentation root directory.[1]
`-h`	Print general help.
`-keeplicenses on` | `{off}`	Keep checked-out licenses when creating or opening an application.
`-memoptassem {off}` | `matrix` | `vector` | `on`	Control of scalability assembling mode.
`-migrateprefs {auto}` | `on` | `off`	Migrate preferences from previous version.[2]
`-mpmode throughput` | `turnaround` | `owner`	Multiprocessor mode.[3]
`-np` *<no. of cores>*	Number of cores.[3]
`-numafirst` *<numa number>*	Set first NUMA node to bind process to.[3]
`-numasets` *<no. of sets>*	Number of NUMA sets.[3] `-numasets 1` represents the case where there is only one nonuniform memory access node — that is, the entire computer.
`-prefsdir` *<path>*	Preference directory.
`-recoverydir` *<path>*	Path to recovery directory. The recovery directory is by default a subdirectory to the preference directory.
`-tmpdir` *<path>*	Temporary file directory.
`-v, -version`	Print COMSOL version.
REFERENCE	

[1] See Documentation and Application Libraries Root Directories.

[2] See Preference Migration

[3] See Shared-Memory Options.

[4] See BLAS Options.

For the `-tmpdir` option, the COMSOL Multiphysics software uses the specified directory to store temporary files. As an alternative, you can use the `COMSOL_TMPDIR` environment variable. Use the `-prefsdir` option to specify the directory where COMSOL Multiphysics stores the preference file.

Remote Desktop and Graphics Rendering

For a Floating Network License, you can access COMSOL Multiphysics with a Windows Remote Desktop connection. OpenGL rendering usually works, but it ultimately depends on your graphics driver.

Documentation and Application Libraries Root Directories

In a default COMSOL installation, the documentation files are located in the directory `doc` under the installation root directory. You can use the `-docroot` option if you want to move the documentation directory to a different location. Similarly, use the `-applicationsroot` option if you want to move the Application Libraries root directory `applications` from its default location under the COMSOL installation root. Relocating the

documentation and Application Libraries root directories can be useful for administering an Application Library update; see The Application Library Update Window.

Setting the paths to the documentation and Application Libraries root directories using these options does not in itself move the directories and their contents.

Preference Migration

By default, most preference settings are migrated from a previous COMSOL Multiphysics version when you start an instance of a new COMSOL Multiphysics version. To change this behavior, start COMSOL Multiphysics using

```
comsol.exe -migrateprefs on
```

to force a migration of preferences from the previous version and then overwrite the current preferences, or

```
comsol.exe -migrateprefs off
```

to not migrate any preferences.

Using the automatic preference migration, preferences are only migrated from the most recent previous version, they are only migrated on first launch, and the preference migration is only done once.

Some preferences for settings such as the root directories for documentation and application libraries are not migrated.

It is also possible to import and export preference settings using the **Preferences** window in the COMSOL Desktop.

Shared-Memory Options

Use the option `-np` to control the number of cores used. The default is to use all available cores (processing units).

Use the option `-numasets` to control the number of nonuniform memory access (NUMA) node sets that the COMSOL Multiphysics software should take into account. This is usually the number of processor sockets that the hardware is using. Note that `-numasets 1` represents the case where there is only one nonuniform memory access node — that is, the entire computer. If you only set the `-np` option, the number of sockets is determined automatically so that a sufficient number of sockets are used by default. The `-np` flag, together with the `-numasets` flag, decides the size of a NUMA set (that is, `-np` divided by `-numasets`). The purpose of `-numafirst` is to decide which processor core number to place the first NUMA set on (that is, the size of the NUMA set times `numafirst`).

Depending on how loaded the machine is, you can control how COMSOL Multiphysics uses the available processors with the `-mpmode` option. The following options are available:

TABLE 22-3: COMSOL MULTIPROCESSOR MODE OPTIONS.

MPMODE OPTION	DESCRIPTION
`owner`	Provides the highest performance in most cases.
`throughput`	Is expected to give the best performance when several different processes are running actively at the same time as COMSOL Multiphysics.
`turnaround`	Typically provides the best performance when no other processes than COMSOL Multiphysics are active.

Use the option `-alloc` to specify memory allocator type. The default is to use the native memory allocator for computers with less than eight cores and otherwise the scalable memory allocator. The scalable memory allocator can increase performance significantly for computers with many cores but uses more memory.

You can also specify the number of cores and sockets and the use of the scalable allocators as preferences on the **Computing** > **Multicore** page in the **Preferences** window. To specify those numbers manually, select the **Number of cores** and **Number of sockets** checkboxes to enter a number in the associated text fields. By default, all cores are used and the number of sockets are set automatically. If you lower the number of cores, it is good practice to also lower the number of sockets. The preference option for the scalable allocator is called **Optimized for multicore**. If you want to choose another memory allocator than the default setting, select the **Memory allocator** checkbox and the choose **Native** or **Optimized for multicore**. To control the scalability assembling mode, which can be useful even when running on a single node, select the **Memory scalability optimization for assembling** checkbox. You can then select **Off** (the default, for no scalability mode), **Matrix** for activating scalability mode only for matrix assembling, **Vector** for activating scalability mode only for vector assembling, or **All** for activating scalability mode for all cases. You can also control these options with the command-line argument `-memoptassem`.

BLAS Options

BLAS is a set of functions for basic linear algebra operations. A large portion of the computational engine in the COMSOL software relies on BLAS. The COMSOL software provides for the following BLAS-related options:

TABLE 22-4: COMSOL BLAS OPTIONS.

BLAS OPTION	DESCRIPTION
`auto`	The default option is to use the Intel MKL library.
`mkl`	Use the Intel MKL library (included with installation).
`aocl`	Use the AMD Optimizing CPU Libraries (included with installation).
`blas`	Use the standard BLAS library (included with installation).
`path`	Use a BLAS library specified using the option `-blaspath` or the environment variable `COMSOL_BLAS_PATH`.

If you want to use a different BLAS library than the ones provided by COMSOL, make sure that COMSOL Multiphysics can find the library. The simplest way for COMSOL Multiphysics to find a library is to put it in `/lib/win64` or somewhere in the standard search path. Also provide the path to any sublibraries needed by the library. Set the search path to point to the directory where the library is installed. To do so, use the environment variable `PATH`. Your library must support both the standard FORTRAN LAPACK interface and the standard FORTRAN BLAS interface. If your LAPACK and BLAS interface consists of several libraries, use the path to the LAPACK library.

Application Options

The following options are used to specify inputs to an application with command-line options. You can find more information about these options in the section *The Application Argument Node* in the *Application Builder Reference Manual*.

TABLE 22-5: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL APPLICATIONS OPTIONS	DESCRIPTION
`-appargnames` *<names>*	Comma-separated list of argument names.
`-appargvalues` *<values>*	Comma-separated list of argument values.
`-appargsfile` *<filename>*	A file with arguments to the application. Each line in the file should have the format <name>=<value>.

TABLE 22-5: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL APPLICATIONS OPTIONS	DESCRIPTION
`-appargvarlist <names>`	Comma-separated list of argument names whose values are on file.
`-appargfilelist <filenames>`	Comma-separated list of filenames. Each file contains the value for one argument.

COMSOL COMMANDS FOR APPLICATIONS

In additions to the options in Table 22-2, the standalone COMSOL command supports the following options on Windows:

TABLE 22-6: COMSOL COMMAND-LINE ARGUMENTS.

COMSOL OPTIONS	DESCRIPTION
`-edit <file>`	Edit application.
`-open <file>`	Open application.
`-run <file>`	Run application.

For example, use `comsol -open myapp.mph` to open an application. Applications can be run or edited with the two other options.

CHANGING THE BACKGROUND COLOR OF THE GRAPHICS WINDOW

To change the default blue color scheme for the background of the 3D Graphics window, you can start the COMSOL Multiphysics software with the following command-line option:

```
-Dcs.canvascolor=255,0,0,0,255,0
```

In this example, the background becomes red and green. The first three numbers are the RGB (red, green, blue) values for the top color, and the last three numbers are the RGB values for the bottom color, with interpolated hues between those two colors. All numbers are between 0 and 255 (inclusive). This option is also available when running COMSOL Multiphysics on Linux and Macintosh.

COMSOL MULTIPHYSICS SERVER COMMANDS

Use a COMSOL Multiphysics server command to start a COMSOL process ready to process computational requests. A COMSOL Multiphysics server listens for TCP/IP connections from COMSOL Multiphysics clients. A COMSOL Desktop can become a COMSOL Multiphysics client by connecting to a COMSOL Multiphysics server. The LiveLink™ *for* MATLAB® also needs to connect to a COMSOL Multiphysics server.

The Windows syntax for the COMSOL Multiphysics server command is

```
comsolmphserver [<options>] [<target arguments>]
```

The following target arguments are available for a COMSOL Multiphysics server command:

TABLE 22-7: COMSOL MULTIPHYSICS SERVER TARGET COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS SERVER OPTION	DESCRIPTION
`-graphics`	Start the server with graphics libraries. This displays plots on the server when you are connected with a client (that is, not with the COMSOL GUI).
`-ipv6`	Make COMSOL Multiphysics server listen on an IPv6 port.
`-login {info} | force | never | auto`	Ask for login information. `info` means that only missing information is asked for. `force` resets the password. `never` requires that the login information is available. `auto` automatically creates a new username and password.
`-mode batch | {desktop}`	Ignore Batch and Cluster Computing settings or use them as desktop settings.
`-multi {auto} | on | off`	Accept repeated client connections.
`-passwd reset | nostore`	Specify that you want to provide a new password. To avoid storing the new password on file, use `nostore`.

TABLE 22-7: COMSOL MULTIPHYSICS SERVER TARGET COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS SERVER OPTION	DESCRIPTION
`-port` *<port>*	Specify a TCP/IP port, *<port>*, to listen for attempts to connect. The *<port>* is the server port, or 0 for a random free port.
`-portfile` *<path>*	Specify that COMSOL Multiphysics writes its server port to the given *<path>* when it has started listening.
`-silent`	Do not listen to standard input.
`-user` *<user>*	Specify login name for a user.

Accessing the COMSOL Multiphysics Server Computer

The server computer can be accessed in several ways. You can log in to a machine that is dedicated to a single person. You can also connect to the server computer by using Remote Desktop. Start the COMSOL Multiphysics server from the **Start** menu. If several people want to access a single Windows computer to run the COMSOL Multiphysics server, you must use Windows Terminal Server or another tool that allows multiple users to log in on the same Windows server. In some Windows versions, Microsoft® provides a Telnet Server with which you can log in through a terminal window. When using a terminal window to log in on Windows, use the `comsolmphserver` command to start the COMSOL Multiphysics server.

Login Information

When a COMSOL Multiphysics server is started for the first time, you are asked for a username and password. Select a username and a password, which COMSOL Multiphysics then uses in communications between the COMSOL Multiphysics client and the server. You must also specify a matching username and password in the **Connect to Server** dialog. The software writes this login information in the subdirectory `.comsol/v63/login.properties` in your Windows home directory.

Client–Server Security Issues

COMSOL Multiphysics can operate in a client–server mode where COMSOL Multiphysics runs as a separate client and a server. COMSOL uses a TCP/IP connection to send data between the server and the client.

Always make sure that untrusted users cannot access the COMSOL login information. Protect the file `.comsol/v63/login.properties` in your home directory. This is important when running COMSOL Multiphysics in client–server mode. Alternatively, start the COMSOL Multiphysics server with the `-passwd nostore` option, and clear the **Remember username and password** checkbox when connecting to the server. This ensures that your login information is not stored on file.

Once a COMSOL Multiphysics server is started, a person with access to your login information could potentially connect to your COMSOL Multiphysics server. When a COMSOL Multiphysics client connects or disconnects from a remote computer, the COMSOL Multiphysics server displays a message. The connection from the client to the server is made with the TCP protocol.

The server and client are mutually authenticated using a challenge handshake authentication protocol, which means that login information cannot be easily obtained by someone eavesdropping on the network communication. The TCP connection between the client and the server is otherwise not encrypted. If you require encryption of the TCP connection, you can use third-party software based on protocols such as SSH or IPSEC.

To enhance security, you can limit the address range that can access the COMSOL Multiphysics server, both in your firewall and by changing the COMSOL Multiphysics server configuration. To limit the allowed address range in the server, edit the file *<COMSOL Installation Directory>*`\bin\tomcat\conf\server.xml` and find the lines:

```
<!-- To restrict access to the COMSOL server you can uncomment the block below.
```

and follow the instructions. The default port for the COMSOL Multiphysics server is 2036. You can change this by using the option `-port` *<port>* when launching COMSOL and COMSOL Multiphysics server.

Documentation Security Issues

To serve the COMSOL Desktop with documentation, COMSOL opens a separate documentation server on the client computer when you open the documentation.

To enhance security, you can limit the address range that can access the documentation server, both in your firewall and by changing the documentation server configuration. To limit the allowed address range in the server, edit the file *<COMSOL Installation Directory>*`\doc\help\conf\server.xml` and find the lines:

```
<!-- To restrict access to the documentation server you can uncomment the block below.
```

and follow the instructions. The default port for the documentation server is 8090. You can change this by using the option `-docport` *<docport>* when launching COMSOL Multiphysics.

COMSOL MULTIPHYSICS CLIENT COMMANDS

Use a COMSOL Multiphysics client command to start a COMSOL Desktop with a the Connect to Server dialog open.

The syntax for the COMSOL Multiphysics client command is

```
comsolmphclient [<options>] [<target arguments>]
```

The following target arguments are available for a COMSOL Multiphysics client command:

TABLE 22-8: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS CLIENT OPTIONS	DESCRIPTION
`-open` *<file>*	Open file
`-port` *<port>*	Specify a TCP/IP port to connect to
`-server` *<server name>*	Specify server to connect to

COMSOL BATCH COMMANDS

Use the COMSOL batch command to run COMSOL jobs without a user interface. Run both Model MPH-files and model files for Java with the COMSOL batch command. Model files for Java need to be compiled before running.

The Windows syntax for the COMSOL batch command is

```
comsolbatch [<options>] [<target arguments>]
```

Its detailed target arguments are:.

TABLE 22-9: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH TARGET ARGUMENTS	DESCRIPTION
`-alivetime` *<seconds>*	The time between writing status on disc.
`-batchlog` *<filename>*	File to store log in. If not used, the log appears in the command window.
`-batchlogout`	Log to standard out when storing on file.
`-cancel`	Stop the current solver without returning any data. See below.
`-checklicense` *<filename>*	Print license requirements for a Model MPH-file.
`-classpathadd` *<classpath>*	Additional classpath.
`-clearmesh`	Clear all meshes,
`-clearsolution`	Clear all solutions (except probe data),
`-client`	Run as client. Unless running in `-mode desktop`, the server must also be started with `-mode batch`.

TABLE 22-9: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH TARGET ARGUMENTS	DESCRIPTION
`-continue`	Continue computing an interrupted batch job.
`-createplots`	Create default plots when running.
`-dev <filename>`	Path to a JAR-file with additional classes to call from the batch class file.
`-error {on}|off`	Stop if an error occurs. This argument is only applicable when `-plist` and `-pname` represent multiple parameter tuples. It is otherwise ignored.
`-external` *<process tag>*	The external process target *<process tag>* for an operation.
`-graphics`	Start COMSOL batch with graphics libraries. This displays plots during analysis.
`-host` *<hostname>*	Connect to host *<hostname>*.
`-inputfile` *<filename>*	Run a Model MPH-file or class file. Also supports a model version location (`dbmodel:///` URI) to run a model version stored in a Model Manager database. See Running COMSOL Batch with Models in Databases for more details.
`-job` *<job tag>*	The batch job to run. See The Job Option below.
`-jobfile` *<filename>*	Specify a text file using the following format: *<inputfile0> <outputfile0>* *<inputfile1> <outputfile1>* *<inputfile2> <outputfile2>* … If the filename <inputfile0> or <outputfile0> contains spaces, surround the path by double quotation marks (`"..."`). Each input-output pair will be run as a batch job consecutively. Other batch-specific options specified at the command line are applied to each of the listed jobs. In addition, the list can be updated continuously during the batch process.
`-methodcall` *<tag>* *<filename>*	Run a method call with the given tag. The file in *<filename>* contains the method call. See the documentation for model.methodCall() in the *COMSOL Multiphysics Programming Reference Manual* for additional input arguments that can be used from batch commands with `-methodcall` for passing input values as arguments to a method call.
`-mode {batch}|desktop`	Ignore Batch and Cluster Computing settings. See Ignoring Batch and Cluster Computing Settings below.
`-norun`	Do not compute the model. This option is useful if you, for example, just want to run `-clearsolution` or `-clearmesh` on a model that already includes a solution or mesh and then save it, without a solution or mesh, without computing the model first.
`-nosave`	Do not save the resulting model.
`-operation progress|cancel|stop|update|clear|rerun`	The operation to run on the batch job.
`-outputdir`	Sets the location on the file system where output files produced by a batch run will be stored. If not used, the files will be stored in the same directory as the output model, or if the output model is stored in the database, in the standard batch directory (specified by the preference setting **Computing** > **Cluster** > **Batch directory**).
`-outputfile` *<filename>*	Save a Model MPH-file using the given filename. If output is not given, the input file is overwritten with the output. Also supports a model version location (`dbmodel:///` URI) to save a model version to a Model Manager database. See Running COMSOL Batch with Models in Databases for more details. Note that a class file as input cannot currently be combined with a model version location as output.

TABLE 22-9: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH TARGET ARGUMENTS	DESCRIPTION
`-paramfile <filename>`	Table file containing parameter names in the first row and corresponding parameter value tuples in the following rows. That is, the parameter names should be on the first row (space separated), and the parameter values (if only one tuple) should be space separated on the second row. If you want to solve for more tuples, more rows are added in the same manner.
`-pindex <parameter indices>`	Comma-separated list of parameter indices (integers). The number of indices given has to correspond to the number of arguments given by `-plist`.
`-plist <parameter value>`	Comma-separated list of parameter values. For information about providing parameters using argument, see About Providing Parameters below.
`-pname <parameter name>`	Comma-separated list of parameter names. For information about providing parameters using argument, see About Providing Parameters below.
`-port <port number>`	Connect to port `<port number>`.
`-prodargs`	Add extra command-line arguments using `-prodargs` followed by the arguments last in the call to COMSOL batch.
`-recover`	Recover and continue computation. See The Recover Option below.
`-resethistory`	Compact the history before saving. This argument can be useful, together with `-clearmesh` and `-clearsolution`, to reduce the size of the saved file.
`-stop`	Stop the current solver when it has finished, returning available data. See below.
`-stoptime <time to stop>`	Stop the batch job after a certain time (in seconds).
`-study <study tag>`	The study to compute. See The Study Option below.
`-usebatchlic`	Use batch license (requires batch licenses). See The Usebatchlic Option below.

It is not possible to run model files protected with a password using the `comsolbatch` command.

Example

To use the COMSOL Batch mode to solve a model, run the following command:

```
comsolbatch -inputfile in.mph -outputfile out.mph -study std1
```

This command starts COMSOL Batch, solves the model in the Model MPH-file with the given filename (`in.mph` in this example) using the active solver settings in the model, and stores the solution in the `out.mph`. You can also use multiple sets of input files and output files, stored in a file using the `-jobfile` option.

The Study Option

The `-study` option directs COMSOL Multiphysics to run a certain study. The study is identified by its tag. In the COMSOL Desktop, select **Show Name and Tag** under **Model Builder Node Label** to see the tags of the jobs under **Study** within curly braces in the Model Builder. In the model object, determine the tags of the jobs by the command `model.study().tags()`. You can determine the name of each study by `model.study(<tag>).name()` using one of the job tags.

The Job Option

The `-job` option works similar to the `-study` option. It directs COMSOL Multiphysics to start a certain job. The job is identified by its tag. In the model object, determine the tags of the jobs by the command `model.batch().tags()`. You can determine the name of each job by `model.batch(<tag>).name()` using one of the job tags.

The Usebatchlic Option

The `-usebatchlic` option makes COMSOL use batch licenses for the job. This option is equivalent to the **Use batch license** checkbox available in the **Cluster Computing** and **Cluster Sweep** study nodes. For floating network licenses (FNL), a separate set of batch features are available for COMSOL Multiphysics and the licensed add-on products. Using batch licenses for a cluster computing or cluster sweep job means that you can continue working in the COMSOL Desktop locally while running batch jobs on remote computers and clusters using only a single FNL license.

Stopping and Canceling a Batch Job

You can stop a batch job using the following command:

```
comsolbatch -stop <level> -inputfile <filename>
```

where *<level>* is the level to stop the process on. Set the level to a high value in order to stop as soon as possible. By default, it is set to 100. The `-inputfile` option indicates the filename of the model that another process is running. The inputfile arguments should be consistent with the one specified to launch another process. That is, either the same inputfile arguments should be provided or the `-inputfile` should be the same as the `-outputfile` specified to launch another process.

You can cancel a batch job using the following command:

```
comsolbatch -cancel -inputfile <filename>
```

The `-inputfile` option indicates the filename of the model that another process is running. The inputfile arguments should be consistent with the one specified to launch another process. That is, either the same inputfile arguments should be provided or the `-inputfile` should be the same as the `-outputfile` specified to launch another process.

The Recover Option

For the `-recover` option, the working directory (where all .log, and .status files are generated) will contain the recovery file, which contains information about the recovery folder in the case that the COMSOL software stops working. If the `-recover` option is specified, the model from the recovery directory will be opened. If opening that model succeeds, a continue operation will be performed; otherwise, the input filename model will be simulated.

Ignoring Batch and Cluster Computing Settings

When `-mode` is `batch` (the default), all Batch and Cluster Computing settings are ignored: that is, Batch and Cluster Computing features will not start any batch jobs as they will do when you click **Compute** in the COMSOL Desktop.

When `-mode` is `desktop`, Batch and Cluster Computing settings will be used. This case corresponds to clicking **Compute** in the COMSOL Desktop. All paths in the **Batch** and **Cluster Computing** nodes must correspond to paths that you would set up in the COMSOL Desktop if you started it and clicked **Compute** instead of running the COMSOL batch command.

About Providing Parameters

You can provide parameters as parameter names and corresponding values using the `-pname` and `-plist` arguments, respectively. For example, `-pname a,b -plist 1,2` corresponds to

```
model.param().set("a",1);
model.param().set("b",2);
```

which means that any global parameters with the same names are overwritten by these new values. The model will then use these new values. Also note that the model is saved with a new name that contains the parameter tuple. Parametric sweeps will work as if you set the global parameters `a` to 1 and `b` to 2 and then compute a parametric sweep. Multiple tuples (such as `-plist 1,2,3,4`) will be saved in multiple files.

THE COMSOL BATCH COMMANDS FOR UPDATING IMAGES IN POWERPOINT PRESENTATIONS

The `comsolpowerpointbatch` command updates linked images in PowerPoint® presentations. The command is available on Windows only, and it requires that PowerPoint is installed. The command syntax is

```
comsolpowerpointbatch [<options>] [<target arguments>]
```

The following optional target arguments are available:

TABLE 22-10: COMSOLPOWERPOINTBATCH ARGUMENTS FOR UPDATING IMAGES IN PRESENTATIONS.

COMSOLPOWERPOINTBATCH ARGUMENTS	DESCRIPTION
`-update <path1;path2;path3>`	Required. Specifies the PowerPoint files, or folders to update. If multiple inputs are specified each input is separated using semicolon. An input path can be file path (ends with .pptx), or a folder path. If an input path is a folder path, all files ending with .pptx will be added as files to update. Only PowerPoint presentations with the file ending .pptx can be updated with the batch update.
`-outputfolder <folder path>`	Required. Specifies the folder where the updated PowerPoint files should be saved.
`-help`	Display the help for the command.
`-h`	Display the help for the command.
`-batchlog <filename>`	Optional. File to store the log in. If not used, the log appears in the command window. The log file is saved as plain text. The filename can be specified with or without a file extension. Allowed file extensions are: .log, .txt, and .text.
`-applications <path1;path2;path3>`	Optional. Provides a list of paths for overriding the paths saved in the PowerPoint presentations. All the model paths in the PowerPoint presentations that have the same short name as provided by -applicationnames will be overruled by the provided paths. If the -applicationnames argument is not used the short names are considered to be the filenames, without the file extension as given by -applications. Each provided path must be a .mph file path.
`-applicationnames <shortName1,shortName2,shortName3>`	Optional. Can only be used if the -applications argument is also used, and must then match the number of paths provided by the -applications argument. Provides a list of model short names for overriding the paths saved in the PowerPoint presentations. All stored model paths that have the same short name as in the provided list will be overruled with the corresponding path given by -applications.
`-applicationsfile <path>`	Optional. Provides a file containing short names and paths for remapping applications. Each remapped application is specified in a single line and where the short name and the path is separated by an equal sign.
`-applicationsroot <path>`	Optional. This argument overrules the -applications, and -applicationsfile arguments. The specified path replaces the root part of the stored application paths in the presentations. This is done by replacing different parts of the model paths until a match is found.
`-applicationpaths <path1;path2;path3>`	Optional. Provides a list of additional folders where to look for the .mph files. If multiple folders are specified each folder is separated using semicolon.
`-onlysavemphname`	Optional. When used only the .mph filename, without the folder path, will be saved in the updated PowerPoint presentation.

THE COMSOL COMPILE COMMAND

The `comsolcompile` command compiles a model file for Java for use by the COMSOL batch command or for loading class files into the GUI. With the COMSOL Compiler, you can also use it to compile COMSOL applications into standalone executable applications. The Windows syntax for the COMSOL compile command is

```
comsolcompile [<options>] [<target arguments>] <file>.java
```

The Java file is mandatory. The following optional target arguments are available:

TABLE 22-11: COMSOL COMPILE ARGUMENTS FOR COMPILING JAVA-FILES.

COMSOL COMPILE TARGET ARGUMENTS	DESCRIPTION
`-classpathadd <classpath>`	Additional classpath.
`-jdkroot <path>`	Path to the JDK root.
`-verbose`	Verbose output.

To compile an application in an MPH-file into a standalone executable application using COMSOL Compiler, use

```
comsolcompile <full path to MPH-file> [<compile arguments>]
```

Compiling applications requires a license for COMSOL Compiler™.

The following arguments are available:

TABLE 22-12: COMSOL COMPILE ARGUMENTS FOR COMPILING APPLICATIONS.

COMSOL COMPILE ARGUMENTS	DESCRIPTION
`-iconmacos <path>`	Path to image file for application icon on macOS.
`-iconwindows <path>`	Path to image file for application icon on Windows.
`-outputdir <path>`	Specify where the compiled application should be saved. The default is the directory where the application's MPH-file is located.
`-phbarchive <path>`	Path to an external physics archive (folder or .jar file).
`-platforms windows, linux, macos`	The platforms to compile for. Specify as a comma-separated list. The default is the platform where the compiler is run.
`-runtimetype {download} | embed`	The type of runtime to include when compiling.
`-splash <path>`	Path to image file for splash screen.

Options not given are taken from the application's **Compiler** node, except for `-outputdir` and `-platforms`.

COMSOL CLUSTER COMMANDS

All COMSOL cluster commands require a floating network license.

See also Overview of Simulations on Shared- and Distributed-Memory Computers.

To start a COMSOL Desktop running in distributed mode interactively on a Windows cluster, type

```
mpiexec -n <number of nodes> comsolcluster.exe <options> [<target arguments>]
```

To start a COMSOL Multiphysics server running in distributed mode, for interactive use from a COMSOL Multiphysics client, on a Windows cluster, type

```
mpiexec -n 1 comsolmphserver.exe [<options>] <target arguments>] -cluster on : -n <number of nodes-1>
comsolclustermphserver.exe <options> [<target arguments>]
```

Note that all options and target arguments need to be repeated twice, when using the above command.

To start a cross-platform COMSOL Desktop running in distributed mode interactively on a Windows cluster, type

```
mpiexec -n <number of nodes> comsolclusterxpl.exe <options> [<target arguments>]
```

To start a COMSOL batch command running in distributed mode on a Windows cluster, type

```
mpiexec -n <number of nodes> comsolclusterbatch.exe <options> [<target arguments>]
```

The following cluster commands are available:

TABLE 22-13: COMSOL CLUSTER TARGETS.

COMSOL CLUSTER COMMANDS	DESCRIPTION
`comsolcluster`	Run COMSOL Desktop in distributed mode interactively on a cluster
`comsolclusterbatch`	Run a COMSOL batch job on a cluster in distributed mode
`comsolclustermphserver`	Helper command to run COMSOL Multiphysics server on a cluster
`comsolclusterxpl`	Run the cross-platform COMSOL Desktop in distributed mode interactively on a cluster
`comsolmphserver -cluster on`	Run a COMSOL Multiphysics server in distributed mode, for interactive use from COMSOL Multiphysics client

The preferred way of starting COMSOL jobs is from the Job Configurations node in the COMSOL Desktop's model tree.

Micromixer — Cluster Version: Application Library path
COMSOL_Multiphysics/Cluster_and_Batch_Tutorials/micromixer_cluster

If you need to start COMSOL cluster jobs from the command line, the preferred way is to use the `comsolclusterbatch` command because the `comsolclustermphserver` and `comsolcluster` commands require TCP/IP access from your client computer to the cluster node where COMSOL Multiphysics runs.

The Windows Configuration

- Make sure that Windows HPC Server 2008, Windows Server 2012 with HPC Pack 2012, or Windows Server 2016 with HPC Pack 2016 job scheduler is installed. Running distributed COMSOL on other Windows versions is not supported.
- Make sure that the Windows HPC Server working directory is set to point to the `comsol` command directory (*<path to COMSOL install directory>*`\bin\win64`). The install directory must be shared between the nodes on your cluster. In some network configurations, the firewall prevents you from starting MPI on a shared executable. To register the executable with the firewall, use the `clusrun` command to execute the `hpcfwutil` command on all nodes (for instance, to register `comsolclusterbatch`) use

  ```
  clusrun /all hpcfwutil register comsolclusterbatch.exe
      <shared path to COMSOL install directory>\bin\win64\comsolclusterbatch.exe
  ```

- You need to install Microsoft Visual Studio® runtime libraries on each compute node. You can install them from the `\ext` directory of the DVD using the `clusrun` command, for instance. (See https://www.comsol.com/support/knowledgebase/1083.)
- Also make sure that all nodes that you intend to run COMSOL Multiphysics on have access to the license manager and that you can start COMSOL Multiphysics running in nondistributed mode. The nodes require access to the license manager to check out licenses.
- Make sure you have installed the latest version of Microsoft MPI that is supported by your Windows version. Download and install the latest supported version of Microsoft MPI from Microsoft on your cluster nodes.

Using Microsoft MPI and SMPD on Standalone Computers

If you do not have Windows HPC Server installed on your Windows computers, you can still use the COMSOL cluster commands if you install COMSOL and Microsoft MPI on each computer that you want to use in the cluster. On each computer, you must then run the command

```
smpd
```

which is located in the Microsoft MPI installation subfolder `Bin`, as the user that will run the MPI job. You can then start the distributed mode by replacing the previous `mpiexec -n` *<number of nodes>* syntax with

```
mpiexec -hosts <number of nodes> <list of computer names> …
```

Here the `mpiexec` command is located in the same folder as `smpd`, and the local node should be listed first in the list of computer names if you want to run interactively. To start COMSOL Desktop in distributed mode, use the syntax

```
mpiexec -hosts <number of nodes> <list of computer names> comsolcluster.exe <options>
[<target arguments>]
```

Example of the COMSOL Batch Command

Schedule a job with the command

```
mpiexec -n -1 comsolclusterbatch.exe -np 2 -inputfile <filename>
```

to run a COMSOL batch job on a number of computational nodes given by `mpiexec`. For further information about the `mpiexec` command and Windows HPC Server, consult the documentation that was shipped with the product and the online manuals.

Example of the COMSOL Multiphysics Server Command

When a COMSOL Multiphysics server cluster job is created, a preference directory must be set and be reachable from all nodes to avoid problems with the server login; see The COMSOL Commands and Login Information. The preferences can be generated by starting COMSOL Multiphysics server once on the head node using the following command:

```
comsolmphserver.exe -prefsdir <prefsdir>
```

where *<prefsdir>* is a preference directory ***common*** to all nodes.

When the COMSOL Multiphysics server is started on the cluster, the port number is written to standard output, so a standard output file and a standard error file must be set for the cluster job. To start a COMSOL Multiphysics server, schedule a job with the following command:

```
mpiexec -n 1 comsolmphserver.exe -np 2 -prefsdir <prefsdir> -cluster on :
-n <number of nodes-1> comsolclustermphserver.exe -np 2 -prefsdir <prefsdir>
```

You must be able to access the cluster node where the COMSOL Multiphysics server runs from the COMSOL Multiphysics client computer.

COMSOL MPI Options

The COMSOL cluster target arguments specify what MPI library to use and what Scalapack version to use. There are several implementations of MPI. COMSOL by default uses the Windows HPC Server libraries. It is also possible to use other MPI libraries based on MPICH using the option `-mpipath` *<path to shared library>*. The following options are available for COMSOL cluster commands:

TABLE 22-14: COMSOL CLUSTER OPTIONS ON WINDOWS.

COMSOL CLUSTER OPTIONS	DESCRIPTION
`-mpi {auto} | whpc2008 | user | path`	MPI library to use.
`-mpiio {on} | off`	Set the MPI I/O mode. Setting this property to `off` means that COMSOL does not search for a distributed file system.

TABLE 22-14: COMSOL CLUSTER OPTIONS ON WINDOWS.

COMSOL CLUSTER OPTIONS	DESCRIPTION
`-mpipath <file>`	MPI shared library file.[1]
`-scalapack {auto} | whpc2008 | user | path`	Scalapack library to use.
`-scalapackpath <path>`	Scalapack library path.

The Cluster Computing study allows you to set up a batch job for submission to a Windows HPC Server job scheduler. There are several settings that you can configure in the `comsol.ini` file to get default settings:

```
-Dcs.scheduler=<IP or network address>
-Dcs.clusteruser=<Username on cluster>
-Dcs.rundir=<Where the model file is located on the cluster>
-Dcs.comsoldir=<Installation path to comsol on the cluster>
```

Additionally you can configure the following commands to get default settings:

```
-Dcs.precmd=<Command line>
-Dcs.postcmd=<Command line>
```

These two lines add commands prior to the `comsol` command and after the `comsol` command, respectively. You can add `{nn}` or `{perhost}` to any of these pre- and postcommands, which configures the Cluster Computing study to use the number of nodes and number of nodes on each host from the corresponding settings for the Cluster Computing study. For more information, see Cluster Computing.

COMSOL MATLAB COMMAND

Use the COMSOL `matlab` command to access the COMSOL API through MATLAB. Enter the following command:

```
comsolmphserver matlab
```

which launches a COMSOL Multiphysics server in a console window, starts MATLAB, and connects MATLAB to the COMSOL Multiphysics server.

The following options are available for the `comsolmphserver matlab` command:

TABLE 22-15: COMSOL MATLAB OPTIONS.

COMSOL MATLAB OPTIONS	DESCRIPTION
`-desktop`	Start with Desktop.
`-graphics`	Start the server with graphics libraries. This enables plotting on the server. Available only when running `comsolmphserver matlab [<options>]`.
`-host <hostname>`	Connect to host.
`-mlnosplash`	Start without MATLAB splash screen.
`-mlroot <path>`	MATLAB installation directory.
`-mlstartdir <path>`	Start in directory path <path>
`-nodesktop`	Start without Desktop.
`-port <hostname>`	Connect to port.

THE COMSOLTRUST COMMAND

Use the `comsoltrust` command to trust methods used in add-ins. The following commands are supported:

- `comsoltrust list`, to list the content of the trust store (all trusted add-in methods).

- `comsoltrust add -addinfile` *<path_to_addin>* `[-addinmethods` *<method_name1>* `[,`*method_name2*`,...]`, to trust the listed methods for an add-in as a comma-separated list. If no methods are given, all methods in the add-in are trusted. A TrustID is created for the trusted methods
- `comsoltrust revoke` *<TrustID>*, to revoke the privilege from an add-in method. You can see the TrustID in the list view.

COMSOL Commands on Linux

Use the `comsol` command to start COMSOL products with detailed startup options.

The general syntax of the COMSOL command is

```
comsol [<target>] [<options>] [<target arguments>]
```

where square brackets indicate optional arguments. The `comsol` command can be combined with optional targets to achieve various results. The table below lists the command and targets:

TABLE 22-16: COMSOL COMMANDS AND TARGETS.

COMMAND AND TARGET	DESCRIPTION	AVAILABILITY
`comsol`	Run standalone COMSOL Multiphysics	
`comsol batch`	Run a COMSOL MPH-file or class file	
`comsol compile`	Compile a model file for Java or compile an application into an executable application (the latter option requires COMSOL Compiler)	
`comsol doc`	Launch the COMSOL Documentation window	
`comsol mphclient`	Run COMSOL Multiphysics client	
`comsol mphserver`	Start COMSOL Multiphysics server	
`comsol mphserver matlab`	Start MATLAB® and connect to a COMSOL Multiphysics server	Requires LiveLink™ *for* MATLAB® license
`comsol hydra`	Run COMSOL Hydra commands	Requires CLUSTERNODE license.
`comsol trust`	Trust methods in add-ins	

The `comsol` command is located in the `bin` folder in the COMSOL installation directory.

INI FILES

There is a number of `.ini` files in the subdirectories `glnxa64` and `glnxarm64` in the `bin` directory. It is sometimes recommended that you edit these files. For example, you can add options to any of the above commands by modifying the corresponding `ini` file. To change the option `opt` to value `val`, add the line

```
-Dopt=val
```

to the file `comsol.ini`. Change the file `comsolbatch.ini` for `comsol batch`, and similarly for the other COMSOL targets.

OPTIONS

You can enter various options after the `comsol` command and target. Table 22-17 lists the options (See [*<options>*] in the command syntax) available for all `comsol` commands. Always issue these options between the command and the target (if any).

TABLE 22-17: COMSOL OPTIONS ON LINUX (CURLY BRACES INDICATE DEFAULT VALUES).

COMSOL OPTION	DESCRIPTION
<target> `-h`	Print target-specific help.
`-3drend ogl | sw`	3D renderer: OpenGL or software rendering.
`-alloc {native} | scalable`	Memory allocator: Select from using the Linux® native memory allocator or the scalable memory allocator from the Intel® Threading Building Blocks library.[2]
`-applicationsroot` *<path>*	Specify custom path to the COMSOL Application Libraries root directory.[1]
`-autosave {on} | off`	Control saving of recovery files.
`-blas {auto} | mkl | aocl | armpl | openblas | blas | path`	BLAS library to use.[3] `mkl` and `aocl` are supported for Intel and AMD processors. `armpl` and `openblas` are supported for ARM processors.
`-blaspath` *<path>*	BLAS library path.[3]
`-c` *<path>*	License file path.
`-ckl`	Use class-kit license.
`-clusterpartmethod {off}|mo|nd|wnd`	Cluster partitioning method. Choose from mesh ordering (`mo`), nested dissection (`nd`), or weighted nested dissection (`wnd`).
`-clusterstorage all | single | shared`	Cluster storage format. The `single` format does I/O only from the root node, while the `shared` format does I/O using distributed I/O operations. The shared format requires that all nodes have access to the same storage area and the same temporary storage area.
`-comsolinifile` *<path>*	Specify custom path to .ini-file used when starting COMSOL.
`-configuration` *<path>*	Path to directory for storing the state for the GUI between sessions and for performing different caching tasks. The configuration directory is by default a subdirectory to the preference directory. However, the default location of the configuration directory is not affected if you use the `-prefsdir` option. When running in batch or cluster mode, add `@process.id` to get a unique identifier to the path (for example, `-configuration /tmp/comsol_@process.id`).
`-data`	Path to a workspace directory for storing internal workspace information. The workspace directory is by default a subdirectory to the preference directory. However, the default location of the workspace directory is not affected by the `-prefsdir` option. *The workspace directory is cleared when COMSOL is launched.* When running in batch or cluster mode, add `@process.id` to get a unique identifier to the path (for example, `-data /tmp/comsol_@process.id`).
`-docroot` *<path>*	Specify custom path to the COMSOL documentation root directory. [1]
`-forcegcc`	Force load of GCC libraries.

TABLE 22-17: COMSOL OPTIONS ON LINUX (CURLY BRACES INDICATE DEFAULT VALUES).

COMSOL OPTION	DESCRIPTION
`-h`	Print general help.
`-keeplicenses on | {off}`	Keep checked-out licenses when creating or opening an application.
`-memoptassem {off} | matrix | vector | on`	Control of scalability assembling mode.
`-mpmode throughput | turnaround | owner`	Multiprocessor mode.[2]
`-np` *<no. of cores>*	Number of cores.[2]
`-numafirst` *<numa number>*	Set first NUMA node (socket) to bind process to.[2]
`-numasets` *<no. of sets>*	Number of NUMA sets (sockets).[2]
`-prefsdir` *<path>*	Preference directory.
`-recoverydir` *<path>*	Path to recovery directory. The recovery directory is by default a subdirectory to the preference directory.
`-tmpdir` *<path>*	Temporary file directory. Whitespace is not supported in the file directory path,
`-v`, `-version`	Print COMSOL version.
REFERENCE	

1 See Documentation and Application Libraries Root Directories.

2 See Shared-Memory Options.

3 See BLAS Options.

For the `-tmpdir` option, the COMSOL Multiphysics software uses the specified directory to store temporary files. Use the `-prefsdir` option to specify the directory where COMSOL Multiphysics stores the preference file.

Documentation and Application Libraries Root Directories

In a default COMSOL Multiphysics installation, the documentation files are located in the directory `doc` under the installation root directory. You can use the `-docroot` option if you want to move the documentation directory to a different location. Similarly, use the `-applicationsroot` option if you want to move the Application Libraries root directory `applications` from its default location under the COMSOL Multiphysics installation root. Relocating the documentation and Application Libraries root directories can be useful for administering Application Library Update; see The Application Library Update Window.

Setting the paths to the documentation and Application Libraries root directories using these options does not in itself move the directories and their contents.

Shared-Memory Options

Use the option `-np` to control the number of cores used. The default is to use all available cores (processing units).

Use the option `-numasets` to control the number of nonuniform memory access (NUMA) node sets that the COMSOL Multiphysics software should take into account. This is usually the number of processor sockets that the hardware is using. If you only set the `-np` option, the number of sockets is determined automatically so that sufficient number of sockets are used by default.

Depending on how loaded the machine is, you can control how COMSOL Multiphysics uses the available processors with the `-mpmode` option. The following options are available:

TABLE 22-18: COMSOL MULTIPROCESSOR MODE OPTIONS.

MPMODE OPTION	DESCRIPTION
`owner`	Provides the highest performance in most cases.
`throughput`	Is expected to give the best performance when several different processes are running actively at the same time as COMSOL Multiphysics.
`turnaround`	Typically provides the best performance when no other processes than COMSOL Multiphysics are active.

Use the option `-alloc` to specify memory allocator type. The default is to use the native memory allocator. The scalable memory allocator can increase performance significantly for computers with many cores but uses more memory.

You can also specify the number of cores and sockets and the use of the scalable allocators as preferences on the **Computing** > **Multicore** page in the **Preferences** window. To specify those numbers manually, select the **Number of cores** and **Number of sockets** checkboxes to enter a number in the associated text fields. By default, all cores are used and the number of sockets are set automatically. If you lower the number of cores, it is good practice to also lower the number of sockets. The preference option for the scalable allocator is called **Optimized for multicore**. If you want to choose another memory allocator than the default setting, select the **Memory allocator** checkbox and the choose **Native** or **Optimized for multicore**. To control the scalability assembling mode, which can be useful even when running on a single node, select the **Memory scalability optimization for assembling** checkbox. You can then select **Off** (the default, for no scalability mode), **Matrix** for activating scalability mode only for matrix assembling, **Vector** for activating scalability mode only for vector assembling, or **All** for activating scalability mode for all cases. You can also control these options with a command-line argument `-memoptassem`.

Sometimes you might want to experiment to find the options that work best for your configuration.

BLAS Options

BLAS is a set of functions for basic linear algebra operations. A large portion of the computational engine in the COMSOL software relies on BLAS. The COMSOL software provides for the following BLAS-related options:

TABLE 22-19: COMSOL BLAS OPTIONS.

BLAS OPTION	DESCRIPTION
`auto`	The default option is to use the Intel MKL library for Intel and AMD processors. For ARM processors, the default option is Arm Performance Libraries.
`mkl`	Use the Intel MKL library (included with installation for Intel and AMD processors).
`aocl`	Use the AMD Optimizing CPU Libraries (included with installation for Intel and AMD processors). (The obsolete BLAS option `blis` uses the AMD Optimizing CPU Libraries.)
`armpl`	Use the Arm Performance Libraries (included with installation for ARM processors).
`openblas`	Use the OpenBLAS library.
`blas`	Use the standard BLAS library (included with installation).
`path`	Use a BLAS library specified using the option `-blaspath` or the environment variable `COMSOL_BLAS_PATH`.

If you want to use a different BLAS library than the ones provided by COMSOL, make sure that COMSOL Multiphysics can find the library. The simplest way for COMSOL Multiphysics to find a library is to put it in `/lib/win64` or somewhere in the standard search path. Also provide the path to any sublibraries needed by the

library. Set the search path to point to the directory where the library is installed. To do so, use the environment variable PATH. Your library must support both the standard FORTRAN LAPACK interface and the standard FORTRAN BLAS interface. If your LAPACK and BLAS interface consists of several libraries, use the path to the LAPACK library.

GCC Options

By default COMSOL Multiphysics uses the GCC libraries installed on the system. If COMSOL Multiphysics is unable to start, the software uses the GCC libraries shipped with COMSOL Multiphysics. The option `-forcegcc` is intended for use together with the LiveLink™ *for* MATLAB®; use it if you are unable to make function callbacks to MATLAB.

Application Options

The following options are used to specify inputs to an application with command-line options. Find more information about these options in the section *The Application Argument Node* in the *Application Builder Reference Manual*.

TABLE 22-20: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL APPLICATIONS OPTIONS	DESCRIPTION
`-appargnames` *<names>*	Comma-separated list of argument names.
`-appargvalues` *<values>*	Comma-separated list of argument values.
`-appargsfile` *<filename>*	A file with arguments to the application. Each line in the file should have the format <name>=<value>.
`-appargvarlist` *<names>*	Comma-separated list of argument names whose values are on file.
`-appargfilelist` *<filenames>*	Comma-separated list of filenames. Each file contains the value for one argument.

COMSOL COMMANDS

In additions to the options in Table 22-17, the standalone COMSOL command supports the following options on Linux.

TABLE 22-21: COMSOL COMMAND-LINE ARGUMENTS.

COMSOL OPTIONS	DESCRIPTION
`-open` *<file>*	Open application
`-run` *<file>*	Run application

COMSOL MULTIPHYSICS SERVER COMMANDS

Use a COMSOL Multiphysics server command to start a COMSOL process ready to process computational requests. A COMSOL Multiphysics server listens for TCP/IP connections from COMSOL Multiphysics clients. A COMSOL Desktop can become a COMSOL Multiphysics client by connecting to a COMSOL Multiphysics server. The LiveLink™ *for* MATLAB® also needs to connect to a COMSOL Multiphysics server.

The syntax for the COMSOL Multiphysics server command is

```
comsol [<options>] mphserver [<target arguments>]
```

The following target arguments are available for a COMSOL Multiphysics server command.

TABLE 22-22: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS SERVER OPTIONS	DESCRIPTION
`-graphics`	Start the server with graphics libraries. This displays plots on the server when you are connected with a client (that is, not with the COMSOL GUI).
`-ipv6`	Make COMSOL Multiphysics server listen on an IPv6 port.

TABLE 22-22: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS SERVER OPTIONS	DESCRIPTION
`-login {info} | force | never | auto`	Ask for login information. `info` means that only missing information is asked for. `force` resets the password. `never` requires that the login information is available. `auto` automatically creates a new username and password.
`-mode batch | {desktop}`	Ignore Batch and Cluster Computing settings or use them as desktop settings.
`-multi {auto} | on | off`	Accept repeated client connections.
`-passwd reset | nostore`	Specify that you want to provide a new password. To avoid storing the new password on file use <nostore>.
`-port` *<port>*	Specify a TCP/IP port to listen for connect attempts.
`-portfile` *<path>*	Specify that COMSOL Multiphysics writes its server port to the given <*path*> when it has started listening.
`-silent`	Do not listen to standard input.
`-user` *<user>*	Specify login name for a user.

Accessing the COMSOL Multiphysics Server Computer

To access the computer running the COMSOL Multiphysics server, log in on the server computer using `ssh` or a similar command and then enter the `comsol mphserver` command.

Login Information

When you start a COMSOL Multiphysics server for the first time, you are asked for a username and password. Select a username and a password, which COMSOL then uses in communications between the COMSOL Multiphysics client and the server. You must also specify a matching username and password in the **Connect to Server** dialog. The software writes this login information in the subdirectory `.comsol/v63/login.properties` in your home directory.

Client–Server Security Issues

COMSOL Multiphysics can operate in a client–server mode where COMSOL Multiphysics runs as a separate client and a server. The COMSOL software uses a TCP/IP connection to send data between the server and the client.

Always make sure that untrusted users cannot access the COMSOL login information. Protect the file `.comsol/v63/login.properties` in your home directory. This is important when using the COMSOL Multiphysics client–server configuration. Alternatively, start the COMSOL Multiphysics server with the `-passwd nostore` option, and clear the **Remember username and password** checkbox when connecting to the server. This ensures that your login information is not stored on file.

Once you start a COMSOL Multiphysics server, a person with access to your login information could potentially connect to your COMSOL Multiphysics server. When a COMSOL Multiphysics client connects or disconnects from a remote computer, the COMSOL Multiphysics server displays a message. The connection from the client to the server is made with the TCP protocol.

The server and client are mutually authenticated using a challenge handshake authentication protocol, which means that login information cannot be easily obtained by someone eavesdropping on the network communication. The TCP connection between the client and the server is otherwise not encrypted. If you require encryption of the TCP connection, you can use third-party software based on protocols such as SSH or IPSEC.

To enhance security, you can limit the address range that can access the COMSOL Multiphysics server, both in your firewall and by changing the COMSOL Multiphysics server configuration. To limit the allowed address range in the server, edit the file *<COMSOL Installation Directory>*`/bin/conf/server.xml` and find the lines:

```
<!-- To restrict access to the COMSOL server you can uncomment the block below.
```

and follow the instructions.

The default port for the COMSOL Multiphysics server is 2036. You can change this by using the option `-port` *<port>* when launching COMSOL and COMSOL Multiphysics server.

Documentation Security Issues

To serve the COMSOL Desktop with documentation, COMSOL Multiphysics opens a separate documentation server on the client computer when you open the documentation. The documentation server program, `comsoldocserver.exe`, is always installed, even when you choose online documentation. It is nontrivial to start the documentation server, so it is typically only started from `comsol.exe` or `comsoldoc.exe`.

To enhance security, you can limit the address range that can access the documentation server, both in your firewall and by changing the documentation server configuration. To limit the allowed address range in the server, edit the file *<COMSOL Installation Directory>*`/doc/help/conf/server.xml` and find the lines:

```
<!-- To restrict access to the documentation server you can uncomment the block below.
```

and follow the instructions. The default port for the documentation server when started from `comsol.exe` is 8090 or the nearest higher free port. You can change this by using the option `-docport` *<docport>* when launching COMSOL. The port used by the documentation server when started from `comsoldoc.exe` is 8390 or the nearest higher free port.

The communication via the COMSOL documentation server is not protected by a password or encrypted but can only access the locally installed COMSOL Multiphysics documentation. If you do not want the documentation server to access any locally installed data, use the online documentation.

Port Summary

The following table lists the default ports used by the COMSOL Multiphysics servers:

TABLE 22-23: PORT USAGE.

PORT NUMBER	SERVER	DESCRIPTION
2036	COMSOL Multiphysics server	For communication between the client and server when COMSOL Multiphysics operates in a client–server mode. The connection is password protected.
8090	Documentation server	Documentation server port when started from `comsol.exe`.
8390	Documentation server	Documentation server port when started from `comsoldoc.exe`.

COMSOL MULTIPHYSICS CLIENT COMMANDS

Use a COMSOL Multiphysics client command to start a COMSOL Desktop with the Connect to Server dialog open.

The syntax for the COMSOL Multiphysics client command is

```
comsol [<options>] mphclient [<target arguments>]
```

The following target arguments are available for a COMSOL Multiphysics client command:

TABLE 22-24: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS CLIENT OPTIONS	DESCRIPTION
`-open` *<file>*	Open file.
`-port` *<port>*	Specify a TCP/IP port to connect to.
`-server` *<server name>*	Specify server to connect to.

COMSOL BATCH COMMANDS

Use the COMSOL batch command to run COMSOL jobs without a GUI. You can run both Model MPH files and model files for Java with the COMSOL batch command. Model files for Java need to be compiled before running.

The syntax for the COMSOL batch command is

```
comsol [<options>] batch [<target arguments>]
```

Its detailed target arguments are:

TABLE 22-25: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH OPTIONS	DESCRIPTION
`-alivetime <seconds>`	The time between writing status on disc.
`-batchlog <filename>`	File to store log in. If not used, the log appears in the command window.
`-batchlogout`	Log to standard out when storing on file.
`-cancel`	Stop the current solver without returning any data. See below.
`-checklicense <filename>`	Print license requirements for a Model MPH-file.
`-classpathadd <classpath>`	Additional classpath.
`-clearmesh`	Clear all meshes,
`-clearsolution`	Clear all solutions (except probe data),
`-client`	Run as client. If `-mode` is `batch` (the default), then the server that the client connects to should also be launched with `-mode batch`. Unless running in `-mode desktop`, the server must also be started with `-mode batch`.
`-continue`	Continue computing an interrupted batch job.
`-createplots`	Create default plots when running.
`-dev <filename>`	Path to a JAR-file with additional classes to call from the batch class file.
`-error {on}|off`	Stop if an error occurs.
`-external <process tag>`	The external process target *<process tag>* for an operation.
`-graphics`	Start COMSOL batch with graphics libraries. This displays plots during analysis.
`-host <hostname>`	Connect to host *<hostname>*.
`-inputfile <filename>`	Run a Model MPH-file or class file. Also supports a model version location (`dbmodel:///` URI) to run a model version stored in a Model Manager database. See Running COMSOL Batch with Models in Databases for more details.
`-job <job tag>`	The batch job to run. See The Job Option below.
`-jobfile <filename>`	Specify a text file using the following format: *<inputfile0> <outputfile0>* *<inputfile1> <outputfile1>* *<inputfile2> <outputfile2>* … If the filename <inputfile0> or <outputfile0> contains spaces, surround the path by double quotation marks (`"..."`). Each input-output pair will be run as a batch job consecutively. Other batch-specific options specified at the command line are applied to each of the listed jobs. In addition, the list can be updated continuously during the batch process.
`-methodcall <tag> <filename>`	Run a method call with the given tag. The file in *<filename>* contains the method call.

TABLE 22-25: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH OPTIONS	DESCRIPTION
`-mode {batch}|desktop`	Ignore Batch and Cluster Computing settings. See Ignoring Batch and Cluster Computing Settings above. If `-mode` is `batch` (the default), then the server that the client connects to should also be launched with `-mode batch`.
`-norun`	Do not compute the model. This option is useful if you, for example, just want to run `-clearsolution` or `-clearmesh` on a model that already includes a solution or mesh and then save it, without a solution or mesh, without computing the model first.
`-nosave`	Do not save the resulting model.
`-operation progress|cancel|stop|update|clear|rerun`	The operation to run on the batch job.
`-outputdir`	Sets the location on the file system where output files produced by a batch run will be stored. If not used, the files will be stored in the same directory as the output model, or if the output model is stored in the database, in the standard batch directory (specified by the preference setting **Computing** > **Cluster** > **Batch directory**).
`-outputfile` *<filename>*	Save a Model MPH-file using the given filename. If output is not given, the input file is overwritten with the output. Also supports a model version location (`dbmodel:///` URI) to save a model version to a Model Manager database. See COMSOL Batch under a Floating Network License for more details. Note that a class file as input cannot currently be combined with a model version location as output.
`-paramfile` *<filename>*	Table file containing parameter names in the first row and corresponding parameter value tuples in the following rows. That is, the parameter names should be on the first row (space separated), and the parameter values (if only one tuple) should be space separated on the second row. If you want to solve for more tuples, more rows are added in the same manner.
`-pindex` *<parameter indices>*	Comma-separated list of parameter indices (integers). The number of indices given has to correspond to the number of arguments given by `-plist`.
`-plist` *<parameter value>*	Comma-separated list of parameter values.
`-pname` *<parameter name>*	Comma-separated list of parameter names.
`-port` *<port number>*	Connect to port *<port number>*.
`-prodargs`	Add extra command-line arguments using `-prodargs` followed by the arguments last in the call to COMSOL batch.
`-recover`	Recover and continue computation. See The Recover Option below.
`-resethistory`	Compact the history before saving. This argument can be useful, together with `-clearmesh` and `-clearsolution`, to reduce the size of the saved file.
`-stop`	Stop the current solver when it has finished, returning available data. See below.
`-stoptime` *<time to stop>*	Stop the batch job after a certain time (in seconds).
`-study` *<study tag>*	The study to compute. See The Study Option below.
`-usebatchlic`	Use batch license (requires batch licenses). See The Usebatchlic Option below.

Example

To use the COMSOL batch mode to solve a model, run the following command:

```
comsol batch -inputfile in.mph -outputfile out.mph -study std1
```

This command starts COMSOL Multiphysics in batch mode, solves the model in the Model MPH-file with the given filename using the active solver settings in the model, and stores the solution in the `out.mph`.

The Study Option

The `-study` option directs COMSOL Multiphysics to run a certain study. The study is identified by its tag. In the COMSOL Desktop, select **Show Name and Tag** under **Model Builder Node Label** to see the tags of the jobs under **Study** within curly braces in the Model Builder. In the model object, determine the tags of the jobs by the command `model.study().tags()`. You can determine the name of each study by `model.study(`*`<tag>`*`).name()` using one of the job tags.

The Job Option

The `-job` option works similarly to the `-study` option. It directs COMSOL Multiphysics to start a certain job. The job is identified by its tag. In the model object, determine the tags of the jobs by the command `model.batch().tags()`. You can determine the name of each job by `model.batch(`*`<tag>`*`).name()` using one of the job tags.

If the model uses an inner parametric solver (in a nested parametric sweep), the **Job Configurations** node is ignored by the batch job. In such cases, you need to switch to an outer parametric solver.

The Usebatchlic Option

The `-usebatchlic` option makes COMSOL use batch licenses for the job. This option is equivalent to the **Use batch license** checkbox available in the **Cluster Computing** and **Cluster Sweep** study nodes. For floating network licenses (FNL), a separate set of batch features are available for COMSOL Multiphysics and the licensed add-on products. Using batch licenses for a cluster computing or cluster sweep job means that you can continue working in the COMSOL Desktop locally while running batch jobs on remote computers and clusters using only a single FNL license.

Stopping and Canceling a Batch Job

You can stop a batch job using the following command:

```
comsol batch -stop <level> -inputfile <filename>
```

where *`<level>`* is the level to stop the process on. Set the level to a high value in order to stop as soon as possible. By default, it is set to 100. The `-inputfile` option indicates the filename of the model that another process is running. The inputfile arguments should be consistent with the one specified to launch another process. That is, either the same inputfile arguments should be provided or the `-inputfile` should be the same as the `-outputfile` specified to launch another process.

You can cancel a batch job using the following command:

```
comsol batch -cancel -inputfile <filename>
```

The `-inputfile` option indicates the filename of the model that another process is running. The inputfile arguments should be consistent with the one specified to launch another process. That is, either the same inputfile arguments should be provided or the `-inputfile` should be the same as the `-outputfile` specified to launch another process.

The Recover Option

For the `-recover` option, the working directory (where all .log, and .status files are generated) will contain the recovery file, which contains information about the recovery folder in the case that the COMSOL software stops working. If the `-recover` option is specified, the model from the recovery directory will be opened. If opening that model succeeds, a continue operation will be performed; otherwise, the input filename model will be simulated.

THE COMSOL COMPILE COMMAND

The `comsol compile` command compiles a model file for Java for use by the COMSOL batch command or for loading class files into the GUI. With the COMSOL Compiler, you can also use it to compile COMSOL applications into standalone executable applications. The Linux syntax for the COMSOL compile command is

```
comsol [<options>] compile [<target arguments>] <file>.java
```

The Java file is mandatory. The following optional target arguments are available:

TABLE 22-26: COMSOL COMPILE OPTIONS.

COMSOL COMPILE OPTIONS	DESCRIPTION
`-classpathadd <classpath>`	Additional classpath
`-jdkroot <path>`	Path to the JDK root
`-verbose`	Verbose output

To compile an application in an MPH-file into a standalone executable application using COMSOL Compiler, use

```
comsol compile <full path to MPH-file> [<compile arguments>]
```

Compiling applications requires a license for COMSOL Compiler™.

The following arguments are available:

TABLE 22-27: COMSOL COMPILE ARGUMENTS FOR COMPILING APPLICATIONS.

COMSOL COMPILE ARGUMENTS	DESCRIPTION
`-icon <path>`	Path to image file for application icon.
`-libraries cad,weatherdata`	Optional data to include. Specify as a comma-separated list. CAD data is only applicable with the CAD Import Module or CAD LiveLink products. Weather data is only applicable with the Heat Transfer Module.
`-outputdir <path>`	Specify where the compiled application should be saved. The default is the directory where the application's MPH-file is located.
`-platforms windows,linux,macos`	The platforms to compile for. Specify as a comma-separated list. The default is the platform where the compiler is run.
`-runtime default | ask | <path>`	Specify where to store the runtime when running the application. The `default` option is the platform's default location. The `ask` option asks the user for the location of the runtime when running the application. The `<path>` option provides a location where the runtime should be unpacked and stored. Only specify a path when compiling for a single platform.
`-runtimewindows <path>`	Specify where the runtime should be unpacked on Windows.
`-runtimelinux <path>`	Specify where the runtime should be unpacked on Linux.
`-runtimemacOS <path>`	Specify where the runtime should be unpacked on macOS.
`-runtimetype {download} | embed`	The type of runtime to include when compiling.
`-splash <path>`	Path to image file for splash screen.

Options not given are taken from the application's **Compiler** node, except for `-outputdir` and `-platforms`.

COMSOL CLUSTER COMMANDS

Use the `comsol` command with the option `-nn <no. of nodes>`. `-nn` specifies the total number of compute nodes created. A COMSOL instance resides in each compute node and communicates with other compute nodes using

MPI. A compute node is a process running on the operating system, and multiple compute nodes can be assigned to run on a single host.

See also Overview of Simulations on Shared- and Distributed-Memory Computers.

The syntax for the COMSOL cluster command is

```
comsol -nn <no. of nodes> [<options>] [<target>] [<target arguments>]
```

The following cluster commands are available:

TABLE 22-28: COMSOL CLUSTER TARGETS.

COMSOL CLUSTER COMMANDS	DESCRIPTION
`comsol -nn <nn> batch`	Run a COMSOL batch job on a cluster in distributed mode.
`comsol -nn <nn> mphserver`	Run COMSOL Multiphysics server in distributed mode on a cluster, for interactive use from a COMSOL Multiphysics client.
`comsol -nn <nn>`	Run COMSOL Desktop in distributed mode interactively on a cluster.

The preferred way of starting COMSOL cluster jobs is from the Study node in the COMSOL Desktop. If you need to start COMSOL cluster jobs from the command line, the preferred way is to use the `comsol -nn <nn> batch` command because the `comsol -nn <nn> mphserver` and `comsol -nn <nn>` commands require TCP/IP access from your client computer to the cluster node where COMSOL runs.

There are several implementations of MPI. COMSOL Multiphysics is shipped with the Intel MPI library and a version of the MPICH library. The ARM version uses the MPICH library by default and does not include Intel MPI. COMSOL also supports most MPI implementations based on MPICH. It is recommended that you use the default MPI library.

The following options are available for clusters on Linux:

TABLE 22-29: COMSOL CLUSTER OPTIONS ON LINUX.

COMSOL CLUSTER OPTIONS	DESCRIPTION
`-clustersimple`	Simple startup of cluster.
`-f <path>`	Path to hostfile.
`-mpi {auto} | intel | intelmt | mpich2 | user | path`	MPI library to use. The Intel MPI libraries are not supported for ARM processors. The option can be used for troubleshooting. See Troubleshooting Distributed COMSOL with Intel MPI.
`-mpiarg <arg>`	MPI cluster-specific command arguments.
`-mpibootstrap {ssh} | fork | slurm | ll | lsf | sge | jmi`	Set bootstrap server for Hydra.
`-mpibootstrapexec <path>`	Executable used by bootstrap server.
`-mpidebug <debug level>`	Set the MPI output level.
`-mpienablex`	Enable Xlib forwarding.
`-mpifabrics fabric1:fabric2`	Select network fabrics where `fabric1` is one of <shm | ofi>, and `fabric2` is <ofi>. This option is not supported for ARM processors.
`-mpihosts <hostnames>`	MPI hosts. Use a comma-separated list of hostnames as `<hostnames>`.
`-mpiio {on} | off | gpfs | lustre | panfs`	Set the MPI I/O mode. Setting this property to `off` means that COMSOL does not search for a distributed file system. Setting this property to `gpfs`, `lustre`, or `panfs` makes COMSOL assume it is running on the selected file system. The arguments `gpfs`, `lustre`, and `panfs` are not supported for ARM processors.

TABLE 22-29: COMSOL CLUSTER OPTIONS ON LINUX.

COMSOL CLUSTER OPTIONS	DESCRIPTION
`-mpiofiprovider mlx | tcp | psm2 | psm3 | sockets | efa | rxm | verbs`	Choose an OFI (Open Fabrics Interface). This option is not supported for ARM processors.
`-mpiofiroot <path>`	Set path to Open Fabrics installation root. This option is not supported for ARM processors.
`-mpipath <file>`	MPI shared library file.
`-mpirmk <pbs>`	Select resource management kernel for a PBS scheduler. This option is not supported for ARM processors.
`-mpiroot <path>`	MPI library installation root path.
`-nn <no. of nodes>`	Number of compute nodes.
`-nnhost <no. of nodes>`	Number of compute nodes on each host.
`-scalapack {auto} | mkl | scalapack | user | path`	Scalapack library to use. For the `path` option, the environment variable `COMSOL_SCALAPACK_PATH` must be set. The argument `mkl` is not supported for ARM processors.
`-scalapackpath <path>`	Scalapack library path.

1 See Using an Installed MPI Library.

Running on Linux

COMSOL Multiphysics uses Hydra to initialize the MPI environment. To launch COMSOL Multiphysics with MPI, use the command line

```
comsol -nn <number of compute nodes> -f <filename>
```

The file *<filename>* should contain the hostnames of the physical nodes (or, alternatively, host) that you intend to use. You can find out the hostname of each physical node from the `hostname` command. Each physical node should be listed on a separate line in the file. You can also list the IP address of each physical node. The file can contain more hosts than you intend to use.

- You can set the remote node access mechanism that is used for connecting using the switch `-mpibootstrap`. The valid options are `ssh`, `rsh`, `fork`, `slurm`, `ll`, `lsf`, `sge`, and `jmi`. This is important if the cluster only supports a different remote node access mechanism than `ssh` because `ssh` is the default protocol used.
- Use the switch `-mpibootstrapexec` to set the path to the remote node access mechanism such as `/usr/bin/ssh`.
- The option `-mpidebug` sets the output level from MPI. The default is level 4.
- You can control the network fabrics used for communication with the option `-mpifabrics fabric1:fabric2`, where `fabric1` is one of `shm` or `ofi`, and `fabric2` is `ofi`. The option `-mpiofiprovider` controls the network provider used by the OFI (Open Fabrics Interfaces). The options are the following: `mlx`, `tcp`, `psm2`, `psm3`, `sockets`, `efa`, `rxm`, or `verbs`. Use these options if you are having trouble with the default fabrics used. This option is not supported for ARM processors.
- Use `-mpienablex` to enable Xlib forwarding. Xlib forwarding is off by default.

Previously there was a shorthand for performing the COMSOL MPI environment initialization and starting COMSOL Multiphysics. The `-clustersimple` option is still supported but performs the same Hydra MPI initialization as other COMSOL command with cluster options specified. For example,

```
comsol -clustersimple batch -inputfile input.mph -outputfile output.mph
```

is equivalent to the following command when the specified number of compute nodes is 4:

```
comsol -nn 4 batch -inputfile input.mph -outputfile output.mph
```

So when no COMSOL cluster options are included in the command, the use of `-clustersimple` instructs the Intel MPI library to automatically detect the number of nodes that were scheduled to the program. However, explicitly setting the number of processes with the `-nn` option is common practice, as COMSOL Multiphysics can combine MPI with multithreading to obtain more efficient performance. The `-nn` option will override some of the effects that the `-clustersimple` option has.

Starting Distributed COMSOL — Linux Examples

Make sure that COMSOL Multiphysics is able to start on all nodes where you intend to run it.

Each node requires access to the license manager. If the node is unable to check out a license, it aborts the startup process.

The following three examples show the command for starting distributed computing with COMSOL Desktop, COMSOL Multiphysics server, and COMSOL batch mode, respectively. Each starts 4 computational nodes, one on each of the 4 hosts listed in the file `hostfile`:

```
comsol -nn 4 -f hostfile
comsol -nn 4 -f hostfile mphserver
comsol -nn 4 -f hosts batch -inputfile in.mph -outputfile out.mph
```

It is possible to specify the number of CPU cores for each COMSOL process. The following command uses the option `-np 2` to assign 2 CPU cores to each compute node:

```
comsol -nn 4 -np 2 -f hostfile
```

It is also possible to have more compute nodes than hosts. The following command initializes 8 compute nodes, assigning 2 compute nodes to each host:

```
comsol -nn 8 -nnhost 2 -f hostfile
```

For additional command-line options, see COMSOL Cluster Options in Table 22-29.

Cluster Computing Study

Additionally, the COMSOL MPI arguments are configurable inside the COMSOL start script. To configure COMSOL to work with a job scheduler through the Cluster Computing study, you can set the options

```
-Dcs.precmd=<Command line>
-Dcs.postcmd=<Command line>
```

in the `comsol.ini` file. This configuration adds commands prior to the `comsol` command and after the `comsol` command. You can add `{nn}` or `{perhost}` to any of these pre- or postcommands. These additions configure the Cluster Computing study to use the number of nodes and number of nodes on each host from the corresponding settings for the Cluster Computing study. For more information, see Cluster Computing.

Using an Installed MPI Library

COMSOL Multiphysics ships with the Intel MPI library and a version of MPICH library. COMSOL should work with most MPICH-ABI compatible libraries. To download the latest version of Intel MPI library runtime visit https://software.intel.com/en-us/intel-mpi-library. To run COMSOL Multiphysics with another version of Intel MPI or other MPI library, set `-mpiroot` to the root path of the MPI library. In case the downloaded library is not compatible with the version COMSOL Multiphysics uses (this should usually not be the case), also set `-mpipath` to the dynamically loaded library that should be used.

For running COMSOL Multiphysics with an installed MPICH library, the COMSOL software also has a compatibility mode that you can activate by adding the option `-mpi mpich2`. When using this option, both the variables `PATH` and `LD_LIBRARY_PATH` must include your MPI implementation. It is also possible to use other MPI libraries based on MPICH using the option `-mpipath` *`<path to shared library>`* and `-mpiroot` *`<path to root of mpi library installation>`*. Table 22-17 lists the MPI-related options: `-mpi`, `-mpipath`,

`-scalapack`, and `-scalapackpath`. To use the MPICH library shipped with COMSOL you do not need to set `-mpiroot`, just specify `-mpi mpich2`.

Troubleshooting Distributed COMSOL

The following syntax can be used to troubleshoot the Intel MPI library environment without running a COMSOL Multiphysics model:

```
comsol [<options>] hydra [<Hydra command>] [<target arguments>]
```

TABLE 22-30: COMSOL HYDRA COMMANDS.

COMSOL HYDRA COMMANDS	DESCRIPTION
`cpuinfo`	Run `cpuinfo` command[1]
`fiinfo`	Run `fi_info` command[1]
`fipingpong`	Run `fi_pingpong` command[1]
`killjobs`	Run `parakill` command
`help`	Run `help` command
`mpitest`	Run a distributed test program[1]
`tune`	Run `mpitune` command[1]
`tunefast`	Run `mpitune_fast` command[1]

[1] Only supported for Intel MPI.

Use a call like the following, for example, for more information about each command: `comsol hydra cpuinfo`.

Troubleshooting Distributed COMSOL with Intel MPI

The default of the Intel MPI library is to use `ssh` as communication protocol. If you require another communication protocol, use the option `-mpibootstrap` *<protocol>*. If you are using a scheduler, the Intel MPI library can often detect the environments it is running in automatically, in which case you may not need to provide additional cluster options in the COMSOL command.

- If you are using a PBS-based scheduler, add `-clustersimple` or `-mpirmk pbs` to the command line in order for Intel MPI to interpret the environment correctly.
- If you are using an LSF-based scheduler, `-clustersimple` or `-mpirmk lsf` to the command line in order for Intel MPI to interpret the environment correctly.
- The Intel MPI library automatically tries to detect the best option for communication and uses InfiniBand if it detects it. To verify that COMSOL is using InfiniBand, check the output from the startup of COMSOL with `-mpidebug 10`; it should not mention TCP transfer mode.
- If you have problems with correct selection of your network card, add the `-mpiofiprovider` <*network type*> option to the command line.
- The `-mpiofiprovider sockets` option selects general TCP network communication and can be used for finding out if there is some problem in the Open Fabrics interface stack of the machine.
- Use the `-mpi mpich2` option to switch from the default Intel MPI library to the MPICH2 library.

In some cases it helps if you combine the `-mpiofiprovider` option with the environment variable `PSM_SHAREDCONTEXTS_MAX` set to 1. You can control the fabrics used for communication with the option `-mpifabrics fabric1:fabric2`, where `fabric1` is equal to `fabric2` or `fabric1` is `shm`. Additionally, the `-mpiofiprovider` option controls the fabric provider.

If COMSOL Multiphysics aborts during start, make sure that all nodes can access the license manager and that COMSOL Multiphysics can be started on each node when not running distributed. Sometimes there is additional information in the log files located in `$HOME/.comsol/v63/configuration/comsol/*.log`. If this does not help, start the MPI test program to make sure that the MPI library is working as it should using the following command:

```
comsol -nn <number of nodes> -f <hostfile> hydra mpitest
```

For more verbose information about the startup process when using Hydra, use `-mpiarg -verbose`, or set `-mpidebug` to a value greater than the default 0.

COMSOL MATLAB COMMAND

Use the COMSOL `matlab` command to access the COMSOL API through MATLAB®. Enter:

```
comsol mphserver matlab [<options>]
```

which launches a COMSOL Multiphysics server in a console window, starts MATLAB, and connects MATLAB to the COMSOL Multiphysics server.

The following options are available for the `comsol mphserver matlab` command:

TABLE 22-31: COMSOL MATLAB OPTIONS.

COMSOL MATLAB OPTIONS	DESCRIPTION
`-desktop`	Start with Desktop.
`-graphics`	Start the server with graphics libraries. This enables plotting on the server. Available only when running `comsolmphserver matlab [<options>]`.
`-host <hostname>`	Connect to host.
`-mlnosplash`	Start without MATLAB splash screen.
`-mlroot <path>`	MATLAB installation directory.
`-mlstartdir <path>`	Start in directory path *<path>*.
`-nodesktop`	Start without Desktop.
`-port <hostname>`	Connect to port.

THE COMSOL TRUST COMMAND

Use the `comsol trust` command to trust methods used in add-ins. The following commands are supported:

- `comsol trust list`, to list the content of the trust store.
- `comsol trust add -addinmethods <path_to_addin> [<method_name1> ...]`, to trust the listed methods for an add-in. If no methods are given, all methods in the add-in are trusted. A TrustID is created for the trusted methods
- `comsol trust revoke <TrustID>`, to revoke the trust in the methods for the named TrustID.

COMSOL Commands on macOS

Use the `comsol` command to start COMSOL products with detailed startup options.

The general syntax of the COMSOL command is

```
comsol [<target>] [<options>] [<target arguments>]
```

where square brackets indicate optional arguments. The `comsol` command can be combined with optional targets to achieve various results. The following table lists the command and targets:

TABLE 22-32: COMSOL COMMANDS AND TARGETS.

COMMAND AND TARGET	DESCRIPTION	AVAILABILITY
`comsol`	Run standalone COMSOL Multiphysics	
`comsol batch`	Run a COMSOL MPH file or class file	
`comsol compile`	Compile a Model Java file	
`comsol doc`	Launch the COMSOL Documentation window	

TABLE 22-32: COMSOL COMMANDS AND TARGETS.

COMMAND AND TARGET	DESCRIPTION	AVAILABILITY
`comsol mphclient`	Run COMSOL Multiphysics client	
`comsol mphserver`	Start COMSOL Multiphysics server	
`comsol mphserver matlab`	Start MATLAB and connect to a COMSOL Multiphysics server	Requires LiveLink™ *for* MATLAB® license
`comsol trust`	Trust methods in add-ins	

The `comsol` command is located in the `bin` folder in the COMSOL installation directory.

INI FILES

There is a number of `.ini` files in the subdirectories `maci64` and `macarm64` in the `bin` directory. It is sometimes recommended that you edit these files. For example, you can add options to any of the above commands by modifying the corresponding INI file. To change the option `opt` to value `val`, add the line

```
-Dopt=val
```

to the file `comsol.ini`. Change the file `comsolbatch.ini` for `comsol batch`, and similarly for the other COMSOL targets.

OPTIONS

You can enter various options after the COMSOL command and target. Table 22-17 lists the options (see [*<options>*] in the command syntax) available for all comsol commands. Always issue these options between the command and the target (if any).

TABLE 22-33: COMSOL OPTIONS ON MACOS (CURLY BRACKETS INDICATE DEFAULT VALUES).

COMSOL OPTION	DESCRIPTION
<target> `-h`	Print target-specific help.
`-3drend ogl` | `sw`	3D renderer: OpenGL or software rendering.
`-alloc {native}` | `scalable`	Memory allocator: Select from using the Macintosh native memory allocator or the scalable memory allocator from the Intel® Threading Building Blocks library.[2]
`-applicationsroot` *<path>*	Specify custom path to the COMSOL Application Libraries root directory.[1]
`-autosave {on}` | `off`	Control saving of recovery files.
`-blas {auto}` | `mkl` | `veclib` | `armpl` | `openblas` | `blas` | `path`	BLAS library to use.[3] `mkl` is supported for Intel processors. `openblas` and `armpl` is supported for Apple silicon.
`-blaspath` *<path>*	BLAS library path.[3]
`-c` *<path>*	License file path.
`-ckl`	Use classkit license.
`-clusterpartmethod {off}` | `mo` | `nd` | `wnd`	Cluster partitioning method. Choose from mesh ordering (`mo`), nested dissection (`nd`), or weighted nested dissection (`wnd`).
`-clusterstorage all` | `single` | `shared`	Cluster storage format. The `single` format does I/O only from the root node, while the `shared` format does I/O using distributed I/O operations. The shared format requires that all nodes have access to the same storage area and the same temporary storage area.
`-comsolinifile` *<path>*	Specify custom path to .ini-file used when starting COMSOL.
`-configuration` *<path>*	Path to directory for storing the state for the GUI between sessions and for performing different caching tasks. The configuration directory is by default a subdirectory to the preference directory. However, the default location of the configuration directory is not affected by the `-prefsdir` option.

TABLE 22-33: COMSOL OPTIONS ON MACOS (CURLY BRACKETS INDICATE DEFAULT VALUES).

COMSOL OPTION	DESCRIPTION
`-data`	Path to a workspace directory for storing internal workspace information. The workspace directory is by default a subdirectory to the preference directory. However, the default location of the workspace directory is not affected by the `-prefsdir` option. *The workspace directory is cleared when COMSOL is launched.*
`-docroot` *<path>*	Specify custom path to the COMSOL documentation root directory.[1]
`-h`	Print general help.
`-keeplicenses on` | `{off}`	Keep checked-out licenses when creating or opening an application.
`-memoptassem {off}` | `matrix` | `vector` | `on`	Control of scalability assembling mode.
`-mpmode throughput` | `turnaround` | `owner`	Multiprocessor mode.[2]
`-np` *<no. of cores>*	Number of cores.[2]
`-prefsdir` *<path>*	Preference directory.
`-recoverydir` *<path>*	Path to recovery directory. The recovery directory is by default a subdirectory to the preference directory.
`-tmpdir` *<path>*	Temporary file directory. Whitespace is not supported in the file directory path,
`-v`, `-version`	Print COMSOL version.
REFERENCES	

1 See Documentation and Application Libraries Root Directories.

2 See Shared-Memory Options.

3 See BLAS Options.

For the `-tmpdir` option, the COMSOL Multiphysics software uses the specified directory to store temporary files. Use the `-prefsdir` option to specify the directory where the COMSOL Multiphysics software stores the preference file.

Documentation and Application Libraries Root Directories

In a default COMSOL Multiphysics installation, the documentation files are located in the directory `doc` under the installation root directory. You can use the `-docroot` option if you want to move the documentation directory to a different location. Similarly, use the `-applicationsroot` option if you want to move the Application Libraries root directory `applications` from its default location under the COMSOL Multiphysics installation root. Relocating the documentation and Application Libraries root directories can be useful for administering Application Library Update; see The Application Library Update Window.

Setting the paths to the documentation and Application Libraries root directories using these options does not in itself move the directories and their contents.

Shared-Memory Options

Use the option `-np` to control the number of core and processors used. The default is to use all available cores and processors.

Depending on how loaded your machine is, you can control how COMSOL Multiphysics uses the available processors. The following options are available:

TABLE 22-34: COMSOL MULTIPROCESSOR MODE OPTIONS.

MPMODE OPTION	DESCRIPTION
`owner`	Provides the highest performance in most cases.
`throughput`	Is expected to give the best performance when several different processes are running actively at the same time as COMSOL.
`turnaround`	Typically provides the best performance when no other processes than COMSOL are active.

Use the option `-alloc` to specify memory allocator type. The default is to use the native memory allocator. The scalable memory allocator can increase performance significantly for computers with many cores but uses more memory.

You can also specify the number of cores and the use of the scalable allocators as preferences on the **Computing** > **Multicore** page in the **Preferences** window. To specify the number of cores manually, select the **Number of cores** checkbox to enter a number in the associated text field. By default, all cores are used. The preference option for the scalable allocator is called **Optimized for multicore**. If you want to choose another memory allocator than the default setting, select the **Memory allocator** checkbox and the choose **Native** or **Optimized for multicore**. To control the scalability assembling mode, which can be useful even when running on a single node, select the **Memory scalability optimization for assembling** checkbox. You can then select **Off** (the default, for no scalability mode), **Matrix** for activating scalability mode only for matrix assembling, **Vector** for activating scalability mode only for vector assembling, or **All** for activating scalability mode for all cases. You can also control these options with a command-line argument, `-memoptassem`.

Sometimes you might want to experiment to find the options that work best for your configuration.

BLAS Options

BLAS is a set of functions for basic linear algebra operations. A large portion of the computational engine in the COMSOL software relies on BLAS. The COMSOL software provides for the following BLAS-related options:

TABLE 22-35: COMSOL BLAS OPTIONS.

BLAS OPTION	DESCRIPTION
`auto`	For Intel processors, the default option is to use the Intel MKL library. On Apple silicon, the default option is Arm Performance Libraries.
`mkl`	Use the Intel MKL library (included with installation for Intel processors).
`openblas`	Use the OpenBLAS library.
`armpl`	Use the Arm Performance Libraries (included with installation for Apple silicon).
`veclib`	Use Apple's vecLib (included with macOS).
`blas`	Use the standard BLAS library (included with installation).
`path`	Use a BLAS library specified using the option `-blaspath` or the environment variable `COMSOL_BLAS_PATH`.

If you want to use a different BLAS library than the ones provided by COMSOL, make sure that COMSOL Multiphysics can find the library. The simplest way for COMSOL Multiphysics to find a library is to put it in `/lib/win64` or somewhere in the standard search path. Also provide the path to any sublibraries needed by the library. Set the search path to point to the directory where the library is installed. To do so, use the environment variable `PATH`. Your library must support both the standard FORTRAN LAPACK interface and the standard FORTRAN BLAS interface. If your LAPACK and BLAS interface consists of several libraries, use the path to the LAPACK library.

Application Options

The following options are used to specify inputs to an application with command-line options. Find more information about these options in the section *The Application Argument Node* in the *Application Builder Reference Manual*.

TABLE 22-36: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL APPLICATIONS OPTIONS	DESCRIPTION
`-appargnames <names>`	Comma-separated list of argument names.
`-appargvalues <values>`	Comma-separated list of argument values.
`-appargsfile <filename>`	A file with arguments to the application. Each line in the file should have the format <name>=<value>.
`-appargvarlist <names>`	Comma-separated list of argument names whose values are on file.
`-appargfilelist <filenames>`	Comma-separated list of filenames. Each file contains the value for one argument.

COMSOL COMMANDS

In additions to the options in Table 22-17, the standalone COMSOL command supports the following options on macOS:

TABLE 22-37: COMSOL COMMAND-LINE ARGUMENTS.

COMSOL OPTIONS	DESCRIPTION
`-open <file>`	Open application.
`-run <file>`	Run application.

COMSOL MULTIPHYSICS SERVER COMMANDS

Use a COMSOL Multiphysics server command to start a COMSOL process ready to process computational requests. A COMSOL Multiphysics server listens for TCP/IP connections from COMSOL Multiphysics clients. A COMSOL Desktop can become a COMSOL Multiphysics client by connecting to a COMSOL Multiphysics server. The LiveLink™ *for* MATLAB® also needs to connect to a COMSOL Multiphysics server.

The syntax for the COMSOL Multiphysics server command is

```
comsol [<options>] mphserver [<target arguments>]
```

The following target arguments are available for a COMSOL Multiphysics server command:

TABLE 22-38: COMSOL MULTIPHYSICS SERVER COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS SERVER OPTIONS	DESCRIPTION
`-graphics`	Start the server with graphics libraries. This displays plots on the server when you are connected with a client (that is, not with the COMSOL Desktop).
`-ipv6`	Make COMSOL Multiphysics server listen on an IPv6 port.
`-login {info}|force|never|auto`	Ask for login information. `info` means that only missing information is asked for. `force` resets the password. `never` requires that the login information is available. `auto` automatically creates a new username and password.
`-mode batch | {desktop}`	Ignore Batch and Cluster Computing settings or use them as desktop settings.
`-multi {auto}|on|off`	Accept repeated client connections.
`-port <port>`	Specify a TCP/IP port to listen for connect attempts.
`-portfile <path>`	Specify that COMSOL Multiphysics writes its server port to the given <*path*> when it has started listening.
`-silent`	Do not listen to standard input.

TABLE 22-38: COMSOL MULTIPHYSICS SERVER COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS SERVER OPTIONS	DESCRIPTION
`-passwd reset|nostore`	Specify that you want to provide a new password. To avoid storing the new password on file use <nostore>.
`-user` *<user>*	Specify login name for a user.

Accessing the COMSOL Multiphysics Server Computer

To access the computer running the COMSOL Multiphysics server, log in on the server computer using `ssh` or a similar command and then enter the `comsol server` command.

Login Information

When you start a COMSOL Multiphysics server for the first time, you are asked for a username and password. Select a username and a password, which the COMSOL software then uses in communications between the COMSOL Multiphysics client and the server. You must also specify a matching username and password on the settings page in the **Model Navigator**, which opens when you start the COMSOL Multiphysics client. The software writes this login information in the file `login.properties`. The login information is located in `Library/Preferences/COMSOL/v63/login.properties` in your home directory.

Client–Server Security Issues

COMSOL can operate in a client–server mode where COMSOL Multiphysics runs as a separate client and a server. COMSOL uses a TCP/IP connection to send data between the server and the client.

Always make sure that untrusted users cannot access the COMSOL login information. Protect the file `Library/Preferences/COMSOL/v63/login.properties`. This is important when using the COMSOL Multiphysics client–server configuration. Alternatively, start the COMSOL Multiphysics server with the `-passwd nostore` option, and clear the **Remember username and password** checkbox when connecting to the server. This ensures that your login information is not stored on file.

Once you start a COMSOL Multiphysics server, a person with access to your login information could potentially connect to your COMSOL Multiphysics server. When a COMSOL Multiphysics client connects or disconnects from a remote computer, the COMSOL Multiphysics server displays a message. The connection from the client to the server is made with the TCP protocol.

The server and client are mutually authenticated using a challenge handshake authentication protocol, which means that login information cannot be easily obtained by someone eavesdropping on the network communication. The TCP connection between the client and the server is otherwise not encrypted. If you require encryption of the TCP connection, you can use third-party software based on protocols such as SSH or IPSEC.

To enhance security, you can limit the address range that can access the COMSOL Multiphysics server, both in your firewall and by changing the COMSOL Multiphysics server configuration. To limit the allowed address range in the server, edit the file *<COMSOL Installation Directory>*`/bin/conf/server.xml` and find the lines:

```
<!-- To restrict access to the COMSOL server you can uncomment the block below.
```

and follow the instructions. The default port for the COMSOL Multiphysics server is 2036. You can change this by using the option `-port` *<port>* when launching COMSOL and COMSOL Multiphysics server.

Documentation Security Issues

To serve the COMSOL Desktop with documentation, COMSOL opens a separate documentation server on the client computer when you open the documentation.

To enhance security, you can limit the address range that can access the documentation server, both in your firewall and by changing the documentation server configuration. To limit the allowed address range in the server, edit the file *<COMSOL Installation Directory>*/doc/help/conf/server.xml and find the lines:

```
<!-- To restrict access to the documentation server you can uncomment the block below.
```

and follow the instructions. The default port for the documentation server is 8090. You can change this by using the option -docport *<docport>* when launching COMSOL Multiphysics.

COMSOL MULTIPHYSICS CLIENT COMMANDS

Use a COMSOL Multiphysics client command to start a COMSOL Desktop with a Connect to Server dialog open.

The syntax for the COMSOL Multiphysics client command is

```
comsol [<options>] mphclient [<target arguments>]
```

The following target arguments are available for a COMSOL Multiphysics client command.

TABLE 22-39: COMSOL TARGET COMMAND-LINE ARGUMENTS.

COMSOL MULTIPHYSICS CLIENT OPTIONS	DESCRIPTION
-open *<file>*	Open file
-port *<port>*	Specify a TCP/IP port to connect to
-server *<server name>*	Specify server to connect to

COMSOL BATCH COMMANDS

Use the COMSOL batch command to run COMSOL jobs without a user interface. You can run both Model MPH-files and model files for Java with the COMSOL batch command. Model files for Java need to be compiled before running. The syntax for the COMSOL batch command is

```
comsol [<options>] batch [<target arguments>]
```

Its detailed target arguments are:

TABLE 22-40: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH OPTIONS	DESCRIPTION
-alivetime *<seconds>*	The time between writing status on disc.
-batchlog *<filename>*	File to store log in. If not used, the log appears in the command window.
-batchlogout	Log to standard out when storing on file.
-cancel	Stop the current solver without returning any data. See below.
-checklicense *<filename>*	Print license requirements for a Model MPH-file.
-classpathadd *<classpath>*	Additional classpath.
-clearmesh	Clear all meshes,
-clearsolution	Clear all solutions (except probe data),
-client	Run as client. Unless running in -mode desktop, the server must also be started with -mode batch.
-continue	Continue computing an interrupted batch job.
-createplots	Create default plots when running.
-dev *<filename>*	Path to a JAR-file with additional classes to call from the batch class file.
-error {on}|off	Stop if an error occurs.
-external *<process tag>*	The external process target *<process tag>* for an operation.
-graphics	Start COMSOL batch with graphics libraries. This displays plots during analysis.
-host *<hostname>*	Connect to host *<hostname>*.

TABLE 22-40: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH OPTIONS	DESCRIPTION
`-inputfile` *<filename>*	Run a Model MPH-file or class file. Also supports a model version location (`dbmodel:///` URI) to run a model version stored in a Model Manager database. See Running COMSOL Batch with Models in Databases for more details.
`-job` *<job tag>*	The batch job to run. See The Job Option below.
`-jobfile` *<filename>*	Specify a text file using the following format: *<inputfile0>* *<outputfile0>* *<inputfile1>* *<outputfile1>* *<inputfile2>* *<outputfile2>* … If the filename <inputfile0> or <outputfile0> contains spaces, surround the path by double quotation marks (`"..."`). Each input-output pair will be run as a batch job consecutively. Other batch-specific options specified at the command line are applied to each of the listed jobs. In addition, the list can be updated continuously during the batch process.
`-methodcall` *<tag>* *<filename>*	Run a method call with the given tag. The file in *<filename>* contains the method call.
`-mode {batch}|desktop`	Ignore Batch and Cluster Computing settings. See Ignoring Batch and Cluster Computing Settings above.
`-norun`	Do not compute the model. This option is useful if you, for example, just want to run `-clearsolution` or `-clearmesh` on a model that already includes a solution or mesh and then save it, without a solution or mesh, without computing the model first.
`-nosave`	Do not save the resulting model.
`-operation progress|cancel|stop|update|clear|rerun`	The operation to run on the batch job.
`-outputdir`	Sets the location on the file system where output files produced by a batch run will be stored. If not used, the files will be stored in the same directory as the output model, or if the output model is stored in the database, in the standard batch directory (specified by the preference setting **Computing** > **Cluster** > **Batch directory**).
`-outputfile` *<filename>*	Save a Model MPH-file using the given filename. If output is not given, the input file is overwritten with the output. Also supports a model version location (`dbmodel:///` URI) to save a model version to a Model Manager database. See Running COMSOL Batch with Models in Databases for more details. Note that a class file as input cannot currently be combined with a model version location as output.
`-paramfile` *<filename>*	Table file containing parameter names in the first row and corresponding parameter value tuples in the following rows. That is, the parameter names should be on the first row (space separated), and the parameter values (if only one tuple) should be space separated on the second row. If you want to solve for more tuples, more rows are added in the same manner.
`-pindex` *<parameter indices>*	Comma-separated list of parameter indices (integers). The number of indices given has to correspond to the number of arguments given by `-plist`.
`-plist` *<parameter value>*	Comma-separated list of parameter values.
`-pname` *<parameter name>*	Comma-separated list of parameter names.
`-port` *<port name>*	Connect to port *<port name>*.
`-prodargs`	Add extra command-line arguments using `-prodargs` followed by the arguments last in the call to COMSOL batch.

TABLE 22-40: COMSOL BATCH-SPECIFIC ARGUMENTS.

COMSOL BATCH OPTIONS	DESCRIPTION
`-recover`	Recover and continue computation. See The Recover Option below.
`-resethistory`	Compact the history before saving. This argument can be useful, together with `-clearmesh` and `-clearsolution`, to reduce the size of the saved file.
`-stop`	Stop the current solver when it has finished, returning available data. See below.
`-stoptime` *<time to stop>*	Stop the batch job after a certain time (in seconds).
`-study` *<study tag>*	The study to compute. See The Study Option below.
`-usebatchlic`	Use batch license (requires batch licenses). See The Usebatchlic Option below.

Example

To use the COMSOL Multiphysics software in batch mode to solve a model, run the following command:

```
comsol batch -inputfile in.mph -outputfile out.mph -study std1
```

This command starts COMSOL in batch mode, solves the model in the Model MPH-file with the given filename using the active solver settings in the model, and stores the solution in the `out.mph`.

The Study Option

The `-study` option directs COMSOL Multiphysics to run a certain study. The study is identified by its tag. In the COMSOL Desktop, select **Show Name and Tag** under **Model Builder Node Label** to see the tags of the jobs under **Study** within curly braces in the Model Builder. In the model object, determine the tags of the jobs by the command `model.study().tags()`. You can determine the name of each study by `model.study(`*<tag>*`).name()` using one of the job tags.

The Job Option

The `-job` option works similar to the `-study` option. It directs COMSOL Multiphysics to start a certain job. The job is identified by its tag. In the model object, determine the tags of the jobs by the command `model.batch().tags()`. You can determine the name of each job by `model.batch(`*<tag>*`).name()` using one of the job tags.

The Usebatchlic Option

The `-usebatchlic` option makes COMSOL use batch licenses for the job. This option is equivalent to the **Use batch license** checkbox available in the **Cluster Computing** and **Cluster Sweep** study nodes. For floating network licenses (FNL), a separate set of batch features are available for COMSOL Multiphysics and the licensed add-on products. Using batch licenses for a cluster computing or cluster sweep job means that you can continue working in the COMSOL Desktop locally while running batch jobs on remote computers and clusters using only a single FNL license.

Stopping and Canceling a Batch Job

You can stop a batch job using the following command:

```
comsol batch -stop <level> -inputfile <filename>
```

where *<level>* is the level to stop the process on. Set the level to a high value in order to stop as soon as possible. By default, it is set to 100. The `-inputfile` option indicates the filename of the model that another process is running. The inputfile arguments should be consistent with the one specified to launch another process. That is, either the same inputfile arguments should be provided or the `-inputfile` should be the same as the `-outputfile` specified to launch another process.

You can cancel a batch job using the following command:

```
comsol batch -cancel -inputfile <filename>
```

The `-inputfile` option indicates the filename of the model that another process is running. The inputfile arguments should be consistent with the one specified to launch another process. That is, either the same inputfile arguments should be provided or the `-inputfile` should be the same as the `-outputfile` specified to launch another process.

The Recover Option

For the `-recover` option, the working directory (where all .log, and .status files are generated) will contain the recovery file, which contains information about the recovery folder in the case that the COMSOL software stops working. If the `-recover` option is specified, the model from the recovery directory will be opened. If opening that model succeeds, a continue operation will be performed; otherwise, the input filename model will be simulated.

THE COMSOL COMPILE COMMAND

The `comsol compile` command compiles a model file for Java for use by the COMSOL batch command or for loading class files into the GUI. With the COMSOL Compiler, you can also use it to compile COMSOL applications into standalone executable applications. The macOS syntax for the COMSOL compile command is

```
comsol [<options>] compile [<target arguments>] <file>.java
```

The Java file is mandatory. The following optional target arguments are available‘

TABLE 22-41: COMSOL COMPILE OPTIONS.

COMSOL COMPILE OPTIONS	DESCRIPTION
`-classpathadd` *<classpath>*	Additional classpath
`-jdkroot` *<path>*	Path to the JDK root
`-verbose`	Verbose output

To compile an application in an MPH-file into a standalone executable application using COMSOL Compiler, use

```
comsol compile <full path to MPH-file> [<compile arguments>]
```

Compiling applications requires a license for COMSOL Compiler™.

The following arguments are available:

TABLE 22-42: COMSOL COMPILE ARGUMENTS FOR COMPILING APPLICATIONS.

COMSOL COMPILE ARGUMENTS	DESCRIPTION
`-icon` *<path>*	Path to image file for application icon.
`-libraries cad,weatherdata`	Optional data to include. Specify as a comma-separated list. CAD data is only applicable with the CAD Import Module or CAD LiveLink products. Weather data is only applicable with the Heat Transfer Module.
`-outputdir` *<path>*	Specify where the compiled application should be saved. The default is the directory where the application’s MPH-file is located.
`-platforms windows,linux,macos`	The platforms to compile for. Specify as a comma-separated list. The default is the platform where the compiler is run.
`-runtime default` | `ask` | *<path>*	Specify where to store the runtime when running the application. The `default` option is the platform’s default location. The `ask` option asks the user for the location of the runtime when running the application. The *<path>* option provides a location where the runtime should be unpacked and stored. Only specify a path when compiling for a single platform.
`-runtimewindows` *<path>*	Specify where the runtime should be unpacked on Windows.
`-runtimelinux` *<path>*	Specify where the runtime should be unpacked on Linux.

TABLE 22-42: COMSOL COMPILE ARGUMENTS FOR COMPILING APPLICATIONS.

COMSOL COMPILE ARGUMENTS	DESCRIPTION
`-runtimemacOS <path>`	Specify where the runtime should be unpacked on macOS.
`-runtimetype {download} | embed`	The type of runtime to include when compiling.
`-splash <path>`	Path to image file for splash screen.

Options not given are taken from the application's **Compiler** node, except for `-outputdir` and `-platforms`.

COMSOL MATLAB COMMAND

Use the COMSOL MATLAB command to access the COMSOL API through MATLAB. Type:

```
comsol mphserver matlab [<options>]
```

which launches a COMSOL Multiphysics server in a console window, starts MATLAB, and connects MATLAB to the COMSOL Multiphysics server.

The following options are available for the `comsol mphserver matlab` command:

TABLE 22-43: COMSOL MATLAB OPTIONS.

COMSOL MATLAB OPTIONS	DESCRIPTION
`-desktop`	Start with Desktop.
`-graphics`	Start the server with graphics libraries. This enables plotting on the server. Available only when running `comsolmphserver matlab [<options>]`.
`-host <hostname>`	Connect to host.
`-mlnosplash`	Start without MATLAB splash screen.
`-mlroot <path>`	MATLAB installation directory.
`-mlstartdir <path>`	Start in directory path *<path>*.
`-nodesktop`	Start without Desktop.
`-port <hostname>`	Connect to port.

THE COMSOL TRUST COMMAND

Use the `comsol trust` command to trust methods used in add-ins. The following commands are supported:

- `comsol trust list`, to list the content of the trust store.
- `comsol trust add -addinmethods <path_to_addin> [<method_name1> ...]`, to trust the listed methods for an add-in. If no methods are given, all methods in the add-in are trusted. A TrustID is created for the trusted methods
- `comsol trust revoke <TrustID>`, to revoke the trust in the methods for the named TrustID.

23

Glossary

This Glossary of Terms contains terms related to finite element modeling, mathematics, geometry, and CAD as they relate to the COMSOL Multiphysics® software and documentation. For more application-specific terms, see the glossaries in the documentation for most of the add-on modules. For references to further information about a term, see the index.

Glossary of Terms

adaptive mesh refinement A method of improving solution accuracy by adapting the mesh to the problem's physical behavior.

affine transformations Geometric transformations that are combinations of linear transformations and translations.

algebraic multigrid (AMG) An *algebraic multigrid* solver or preconditioner that performs one or more cycles of a multigrid method using a coarsening of the discretization based on the coefficient matrix. Compare to *geometric multigrid (GMG)*.

anisotropy Variation of material properties with direction.

application program interface (API) An *API* provides a set of documented functions and methods for interacting with a software product.

arbitrary Lagrangian-Eulerian formulation (ALE formulation) A formulation where an Eulerian equation is transformed into an equation written with respect to a mesh, which can be moving in relation to both the Eulerian frame and the Lagrangian frame. The COMSOL Multiphysics solvers have built-in support for the necessary transformation of derivatives.

arc A segment of the circumference of a circle or ellipse.

Argyris element A 2D, 6-node triangular finite element with a 5th-order *basis function* providing continuous derivatives between elements.

aspect ratio The ratio between the longest and shortest element or geometry dimension.

assemble Taking the local element stiffnesses, masses, loads, and constraints to form the *stiffness matrix*, *mass matrix*, load vector, constraint matrix, and constraint residual vector.

associativity An algorithm that maps data associated with a *geometric model* to the new *geometric entities* when the *geometric model* is modified.

backward differentiation formula (BDF) A multistep formula based on numerical differentiation for solutions to *ordinary differential equations*. A BDF method of order n computes the solution using an nth-grade polynomial in terms of backward differences.

basis function A function φ_i in the *finite element space* such that the ith degree of freedom is 1, while all other degrees of freedom are 0. For the Lagrange finite element space, φ_i is a linear or higher-order polynomial on each mesh element with value 1 in node i and 0 in all other nodes.

BEM See *Galerkin boundary element method*.

Bernstein polynomial See *Bézier basis*.

Bézier basis A set of polynomial functions that occur in the definition of a *Bézier curve*. These polynomial functions are often called *Bernstein polynomials*.

Bézier curve A *rational Bézier curve* is a parameterized *curve* formed as the quotient of two polynomials expressed in the Bézier basis. It is a vector-valued function of one variable. The coefficients of a rational Bézier curve

are geometrically interpreted as *control points* and *control weights*. A *nonrational Bézier curve* is a rational Bézier curve with all weights equal, thereby making the denominator polynomial equal to a constant. A nonrational Bézier curve is also called an *integer Bézier curve*.

Bézier patch, Bézier surface A *Bézier patch* or *Bézier surface* is a surface extension of a *Bézier curve*. A *Bézier patch* is a function of two variables with an array of control points.

bidirectional constraint A constraint enforced by reaction terms affecting both equations in a constraint of the type $u_1 = u_2$. *Symmetric constraints* are an important special case. See also *reaction terms* and *constraint*.

Boolean operations Boolean operations are used to construct a *geometry object* from other geometry objects. At least two primary geometry objects are required to create a resultant new geometry object. That new object depends on the type of Boolean operation:

- Union (add): the resultant geometry object occupies all the space of the initial geometry objects.
- Difference (subtract): the resultant geometry object occupies all the space of the first geometry object except for the space inside the second geometry object.
- Intersection: the resultant geometry object occupies only the space common to the initial geometry objects.

boundary A *geometric entity* with a dimension one less than the space dimension for the geometry (a *face* in a 3D geometry, an *edge* in a 2D geometry, and a *vertex* in a 1D geometry). In a mathematical context, the symbol $\partial\Omega$ represents the boundary of the domain Ω. Sometimes *boundary* is used in a narrower sense meaning an *exterior boundary*. See also *interior boundary*, *exterior boundary*.

boundary element method See *Galerkin boundary element method*.

boundary modeling A geometry modeling method to create a geometry by defining its boundaries. Compare to *solid modeling* and *surface modeling*.

brick element See *hexahedral element*.

chamfer A CAD operation that trims off a corner with a plane or straight line.

Cholesky factorization A memory-saving version of *LU factorization* where U is the transpose of L. It requires that the coefficient matrix A ($A = LU$) be a symmetric positive definite matrix. See also *LU factorization* and *positive definiteness*.

coefficient form PDE A PDE in the coefficient form is a PDE formulation suited for linear PDEs.

$$\begin{cases} e_a \dfrac{\partial^2 u}{\partial t^2} + d_a \dfrac{\partial u}{\partial t} + \nabla \cdot (-c\nabla u - \alpha u + \gamma) + \beta \cdot \nabla u + au = f & \text{in } \Omega \\ \mathbf{n} \cdot (c\nabla u + \alpha u - \gamma) + qu = g - h^T \mu & \text{on } \partial\Omega \\ hu = r & \text{on } \partial\Omega \end{cases}$$

component coupling See *nonlocal coupling*.

component's geometric model The *geometric model* of the component on which the physics settings are applied.

composite geometry object Geometric objects made up by combining *primitive geometry objects* and other composite objects. See also *constructive solid geometry*, *primitive geometry object*, and *Boolean operations*.

COMSOL Application Server For each application launched from a *COMSOL Server* ™ installation, a separate COMSOL Application Server process is started to run the application. A COMSOL Application Server process contains functionality that is similar to a *COMSOL Multiphysics Server* together with functionality to generate the application's user interface accessed from a web browser or a *COMSOL Client*.

COMSOL Client A Windows® client that runs an implementation of a COMSOL application, created with the Application Builder, and that connects to a *COMSOL Server*™.

COMSOL Desktop The COMSOL Desktop® is an integrated simulation environment for the COMSOL products with a number of windows such as the Model Builder window, the Graphics window, and each model tree node's Settings window.

COMSOL binary file A binary data file with the extension `.mphbin` that contains geometry objects or mesh objects.

COMSOL text file A text data file with the extension `.mphtxt` that contains geometry objects or mesh objects.

COMSOL Multiphysics server The COMSOL Multiphysics server is a single user server allowing multiple sessions of the same user, one session at a time.

COMSOL Server A COMSOL Server™ license make it possible to deploy and run COMSOL applications in major web browsers. Using the Windows® operating system, you can also run COMSOL applications by connecting to a COMSOL Server with an COMSOL Client.

condition number A measure of the possible error in a solution due to ill-conditioning of the equations. See also *ill-conditioning*.

constant A named model property that has a constant numeric value. The built-in constants in COMSOL Multiphysics include *mathematical and numerical constants* and *physical constants*.

constraint Restriction imposed on the dependent variables on the form $R(u_1,u_2,...) = 0$. A *Dirichlet boundary condition* is a special case. *Neumann boundary conditions* are not regarded as constraints. When a constraint is added, the finite element algorithm adds corresponding *reaction terms* to the system of equations. These generalized *reaction forces* modify the *flux conditions* so that the resulting model becomes solvable.

constructive solid geometry (CSG) A solid-modeling method that combines simple solid shapes, or *primitives*, to build more complex models using Boolean operations. See also *solid modeling* and *primitive*.

contributing node A boundary condition or source is *contributing* when it adds to other boundary conditions or sources defined on the same geometric entity. Examples of contributing boundary conditions are loads in structural mechanics and heat flux components in heat transfer. See also *exclusive nodes*.

control point *Bézier* and *NURBS* curves and surfaces are defined by a set of points known as *control points*. The locations of these points control the curve's shape.

control weight Scalar values assigned to *control points* to further control the shape of a curve or surface.

contour plot A plot that shows the variation of a solution component or other quantity. Points with equal values of the plotted quantity are connected with contour lines.

convergence The tendency for a finite element solution to approach the exact solution within well-defined and specified tolerances, for example, by reducing the mesh element size or the time step.

cosimulation A simulation technique where different subsystems that form a coupled problem are modeled and simulated in a distributed manner. It includes the ability for a run-time coupling of a COMSOL simulation with another simulation program.

Costabel FEM-BEM coupling A symmetric coupling method for combining finite elements and boundary elements, where the coupling to the finite elements makes it possible to solve problems where the coefficients of the differential operator are not constant.

curl element See *vector element*.

curve The path of a point moving through space. See also *Bézier curve*, *NURBS*, and *manifold*.

curve object A geometry object consisting of only *edges* and *vertices* (where no vertex is isolated), for example, a geometry object representing a *curve*.

curve segment An individual polynomial or rational polynomial curve. Compounded curves consist of several *curve segments*.

curved mesh element See *mesh element*.

degree of freedom (DOF) One of the unknowns in a discretized finite element model. A degree of freedom is defined by a name and a *node point*. The degree of freedom names often coincide with the names of the dependent variables. The local degrees of freedom are all degrees of freedom whose node points are in one mesh element.

deformed geometry A geometry where the shape changes with a moving-mesh algorithm. It is also the name of a *physics interface* for modeling deforming geometries. This is similar to the Parameterized Geometry interface in earlier versions of COMSOL Multiphysics.

deformation gradient In solid mechanics, it contains the complete information about the local straining and rotation of the material. It is a nonsingular matrix with positive determinant, as long as material cannot be annihilated.

dependent variable A varying quantity whose changes are arbitrary but regarded as produced by changes in other variables on which the varying quantity depends. For example, temperature is a function of the spatial coordinates and time. In a narrower sense, the dependent variables, or *solution components*, are the unknowns in a mathematical PDE model. Compare to *independent variable*.

differential-algebraic equation (DAE) A set of equations that includes both differential and algebraic equations. A DAE is classified in terms of its *index*, a positive integer, which is related to the minimum number of differentiations needed to transform a DAE to an ODE form.

direct solver A solver for a system of linear equations that uses some variant of Gaussian elimination. Compare to *iterative solver*.

Dirichlet boundary condition A Dirichlet boundary condition specifies the value of the function (dependent variable) on a boundary. Dirichlet boundary conditions are sometimes called *essential boundary conditions* or *constraints*. See also *constraint*.

discretization The process of dividing a continuous system into a finite number of elements with finite size. The difference between the finite-element representation and the real system, the discretization error, drops as the size of the elements decreases. For a time-dependent analysis, a discretization of time into steps provides an idealized behavior of the variations in the solution during these steps.

divergence element A finite element with properties suitable for representing certain electromagnetic vector fields. The degrees of freedom on the boundary of a mesh element correspond to normal components of the field.

domain A topological part of the modeling space in a *geometric model*. The geometric representation of a domain is a line segment (interval) in 1D, an area in 2D, and a volume in 3D. In a mathematical context, the symbol Ω represents the domain where the equations are defined.

domain decomposition Domain decomposition is a solver method that divides the modeling domain into subdomains where the equations in the subdomains are easier to solve. The total solution is then obtained by iterating between the computed solutions for each subdomain using the currently known solutions from the other subdomains as boundary conditions.

drop tolerance A nonnegative scalar used in the incomplete LU preconditioner for the iterative solvers. See *incomplete LU factorization*.

dynamic model See *time-dependent model*.

edge, edge segment A *geometric entity* representing a bounded part of a *curve*. An *edge* or *edge segment* is a *boundary* in a 2D geometry. See also *domain*.

edge element See *vector element*.

eigenvalue PDE A PDE that describes an eigenvalue problem with unknown eigenmodes (eigenfunctions) u and eigenvalues λ. The *coefficient form* eigenvalue PDE is:

$$\lambda^2 e_a u - \lambda d_a u + \nabla \cdot (-c\nabla u - \alpha u) + \beta \cdot \nabla u + a u = 0$$

elliptic PDE A linear stationary second-order elliptic PDE has the form

$$\nabla \cdot (-c\nabla u - \alpha u + \gamma) + \beta \cdot \nabla u + a u = f$$

where c is positive or negative definite (for example, Poisson's equation).

embed To insert a 2D geometry into a 3D *geometry sequence*.

error Deviations from the correct solution, primarily due to: poor modeling; *discretization* (such as insufficiently fine mesh, poor elements, or insufficiently short time steps); and roundoff and truncation (depending on numerical representation, *ill-conditioning*, or the solution algorithms).

error estimate An estimation of the error in the numeric solution to a problem, either locally or globally, primarily for use by an adaptive mesh refinement. See also *adaptive mesh refinement*, *error*.

equivalent boundaries *Boundaries* that are rigid transformations of each other and have compatible meshes. See also *periodic boundary condition*.

essential boundary condition See *Dirichlet boundary condition*.

Eulerian formulation An Eulerian formulation means that the partial differential equations that describe some physics are formulated in a *spatial frame* (coordinate system), with coordinate axes fixed in space. An Eulerian formulation is common for fluid flow when the focus is on specific locations in space through which fluid flows. Compare to *Lagrangian formulation*.

exclusive node A boundary condition or material model in a domain is *exclusive* when there can only be one such node defined for a given geometric entity. Adding another exclusive boundary condition to the same boundary, for example, the last added boundary condition (last in the Model Builder tree) overrides any other similar boundary condition defined on the same boundary. Examples of exclusive boundary conditions are prescribed displacements in structural mechanics and specified temperature in heat transfer. See also *contributing node*.

extended mesh A data structure that includes the full finite element mesh. See also *mesh*, *node point*.

extended multiphysics A model that includes nonlocal couplings and dependencies between variables, where the value at a point is the result of a computation elsewhere in the domain or in another geometry defined in the same model. *Coupling operators* provide the ability to project or extrude values from one geometry or domain to another. Compare to *multiphysics*.

exterior boundary An *exterior boundary* for a dependent variable u is a *boundary* such that u is defined only on one of the adjacent domains, that is, a boundary to the computational domain. See also *boundary*.

extra dimension An extra, abstract spatial dimension added to the model in addition to the dimensions of the model geometry.

extrude To create a 3D geometry object from a 2D geometry object in a *work plane* or a planar face in 3D by translating (extruding) it in the normal direction.

extrusion nonlocal coupling A coupling defined in the destination that takes values from the source by interpolation at points that depend on the position of the evaluation points in the destination.

face A *geometric entity* describing a bounded part of a *surface* in a 3D geometry. A *face* is a *boundary* in a 3D geometry. See also *domain*.

fallback feature Used with the pair node to enable pairs to have the option to add additional subnodes with conditions for nonoverlapping parts of the pair.

FEM See *finite element method*.

Fick's law The first law relates the concentration gradients to the diffusive flux of a solute infinitely diluted in a solvent. The second law introduces the first law into a differential material balance for the solute.

field variables Dependent variables and variables derived from them, defined as fields — functions of x, y, z, and t in a general time-dependent 3D case.

fillet A curved transition from one boundary to another, creating a rounded corner.

finalized geometry The resulting *geometric model* that can be used for assigning materials and physics. COMSOL Multiphysics creates the finalized geometry by forming a union of the *geometry objects* defined in the *geometry sequence* or by forming an assembly where the *geometry objects* are treated as individual parts. The finalized geometry consists of one object only.

finalized mesh Only for meshes that define their own *geometric model*. This *geometric model* can be used for assigning materials and physics.

finite element In the mathematical sense, a *mesh element* together with a set of *shape functions* and corresponding *degrees of freedom*. The linear combinations of the shape functions form a space of functions called the *finite*

element space. In the traditional FEA sense, the concept of a finite element also includes the discretized form of the PDEs that govern the physics. COMSOL generally uses *finite element* in the mathematical sense.

finite element analysis (FEA) A computer-based analysis method for field problems using the *finite element method*.

finite element method (FEM) A computational method that subdivides an object into very small but finite-size elements. The physics of one element is approximately described by a finite number of *degrees of freedom (DOFs)*. Each element is assigned a set of characteristic equations (describing physical properties, boundary conditions, and imposed forces), which are then solved as a set of simultaneous equations to predict the object's behavior.

finite element space The linear space of functions where the finite element approximation to the solution of a PDE problem is sought. The functions in the finite element space are linear combinations of *basis functions* (*shape functions*).

finite volume method (FVM) A computation method that, in ways similar to the *finite element method*, computes values at discrete places on a meshed geometry. Finite volume refers to the small volume surrounding each node point in a mesh.

finite void A finite volume in the geometry that is not defined as a solid domain and that cannot contain a volumetric finite element mesh; only physics interfaces based on the *boundary element method* can be active in finite voids.

flux condition A boundary condition that specifies the value of the *normal flux* across a boundary, also known as a *natural boundary condition*. A (generalized) *Neumann boundary condition* is a special case.

flux vector The general flux vector is as below, with three terms: the first term describes diffusion, the second term describes convection with a velocity $-\alpha$, and the third term γ is a source term. See also *generalized Neumann boundary condition* and *normal flux*.

$$\Gamma = -c\nabla u - \alpha u + \gamma$$

frame A *frame* is a coordinate system that is fixed in space, to a material, to the geometry, or to a mesh. The frames make it possible to use an *Eulerian formulation* or a *Lagrangian formulation* for various physics in a model or using the arbitrary Lagrangian-Eulerian (ALE) method. The following frame types are available: *material frame* (*reference frame*), *geometry frame*, *mesh frame*, and *spatial frame*.

function COMSOL Multiphysics supports *user-defined functions*, which can be analytic, piecewise, and interpolation functions as well as special types of common functions that implement, for example, steps, ramps, and other wave forms. There are also common built-in *mathematical functions* such as trigonometric functions, logarithms, and special functions.

Gauss point A *Gauss point* is an integration point in the special case of numerical integration using Gaussian quadrature. Sometimes, *Gauss point* is improperly used as a synonym for *integration point*. See also *integration point*.

Galerkin boundary element method A variant (the Galerkin method) of the method for solving linear partial differential equations that have been formulated as integral equations (the boundary element method) in which the integrals over the source and field patches are the same.

general form PDE A PDE in the general form is a PDE formulation suited for nonlinear PDEs:

$$\begin{cases} e_a\dfrac{\partial^2 u}{\partial t^2} + d_a\dfrac{\partial u}{\partial t} + \nabla \cdot \Gamma = F & \text{in } \Omega \\ -\mathbf{n} \cdot \Gamma = G + \left(\dfrac{\partial R}{\partial u}\right)^T \mu & \text{on } \partial\Omega \\ 0 = R & \text{on } \partial\Omega \end{cases}$$

generalized Neumann boundary condition A generalized Neumann boundary condition (also called a *mixed boundary condition* or a *Robin boundary condition*) specifies the value of a linear combination of the *normal flux* and the *dependent variables* on a boundary. For a coefficient form PDE, the generalized Neumann boundary condition is

$$\mathbf{n} \cdot (c\nabla u + \alpha u - \gamma) + qu = g - h^T\mu$$

The generalized Neumann condition is often called just *Neumann condition* in the documentation.

generalized reaction force see *reaction term*.

geometric entities The basic parts that constitute the *geometric model* and define its position and shape: In 3D, they are divided into the following four types or *geometric entity levels*: *domains*, *boundaries* (*faces*), *edges*, and *points* (*vertices*). In 2D, there are no *faces*, and the *edges* are the *boundaries*. In 1D, there are only *domains* and *points*, which are also the *boundaries*.

geometric entity level The *geometric entity levels* are the *vertex*, *edge*, *face*, and *domain* levels (in 3D). An entity of dimension one less than the space dimension is referred to as a *boundary*. See also *geometric entities*.

geometric model A collection of *geometric entities*, their geometric shape, and their connection to each other. Each *geometry sequence* defines a *geometric model*. Each *meshing sequence* that is not conforming with the *geometric model* of a *geometry sequence* also defines a *geometric model*.

geometric multigrid (GMG) A *geometric multigrid* solver or preconditioner performs one or more cycles of a multigrid method, using a coarsening of the discretization based on a coarsening of the mesh or a reduction in the order of the shape functions. Compare to *algebraic multigrid (AMG)*.

geometry frame In the geometry frame (coordinate system), the domain is fixed and identical to the original geometry. No physics is formulated directly in the geometry frame — only the *material frame* and *spatial frame* have physical significance. The geometry frame is used only as a reference for the Deformed Geometry interface and for postprocessing. When there is no Deformed Geometry interface present, the geometry frame is identical to the material frame.

geometry object An object generated by a geometry feature. See also *point object*, *curve object*, *surface object*, *primitive geometry object*, *solid object*, and *mixed object*.

geometry sequence The sequence of geometry features that define a *geometric model*. In the Model Builder, this is represented by the Geometry node and its child nodes.

grid A *grid* usually refers to sets of evenly-spaced parallel lines at particular angles to each other in a plane, or the intersections of such lines. Compare to *mesh*.

Hermite element A finite element similar to the *Lagrange element*. The difference is that there are degrees of freedom for the (first-order) space derivatives at the mesh vertices. See also *Lagrange element*.

hexahedral element A 3D mesh element with eight corners and six faces, also referred to as *brick element*; sometimes also called *hex element* as a short form.

higher-order element A finite element with *basis functions* that consists of polynomials of degree 2 or higher.

hybrid geometry modeling Creating a geometry by using a combination of *boundary modeling/surface modeling* and *solid modeling*.

hyperbolic PDE A typical example of a linear second-order hyperbolic PDEs is the *wave equation*

$$e_a\frac{\partial^2 u}{\partial t^2} + \nabla \cdot (-c\nabla u - \alpha u + \gamma) + \beta \cdot \nabla u + au = f$$

where e_a and c are positive.

IGES file An *IGES file* contains 3D CAD data, including the 3D geometry, in an open format according to the *Initial Graphics Exchange Specification*. IGES files can be imported into COMSOL Multiphysics using the CAD Import Module.

ill-conditioning An ill-conditioned system is sensitive to small changes in the inputs and is susceptible to roundoff errors. See also *condition number*.

imprint An imprint of the usually smaller boundary on the larger boundary that makes the parts in a *pair* match. An imprint inserts points on the boundary in 2D and creates edges on the boundary in 3D.

incomplete LU factorization An approximate *LU factorization* where small matrix elements are discarded to save memory and computation time. The *drop tolerance* is a relative measure of the smallness of the elements that should be discarded. See also *LU factorization*.

independent variable A variable that can cause variation in a second, *dependent variable*. The independent variables are most often spatial coordinates and time. Compare to *dependent variable*.

index, for DAE See *differential-algebraic equation*.

infinite void A single unbounded region, surrounding the geometry, that cannot contain a volumetric finite element mesh; only physics interfaces based on the *boundary element method* can be active in an infinite void.

initial condition The starting values for the dependent variables in a time-dependent analysis and for *nonlinear iterations* or other iterative solvers.

integration nonlocal coupling A coupling that evaluates integrals of expressions over the source and returns a single scalar value when used in the destination, which for this type of nonlocal coupling is the entire model. Similar functionality is available to evaluate the average, minimum, and maximum values.

integration order The order (a nonnegative integer) in a *numerical integration formula* where evaluation points and weights are chosen such that result of the numerical integration is exact for all expressions that are polynomials of an order that is no higher than the specified *integration order*.

integration point See *numerical integration formula*.

interactive meshing Building a mesh in an incremental fashion where each meshing operation acts on a set of geometry domains.

interior boundary An *interior boundary* for a dependent variable u is a *boundary* such that u is defined on both adjacent domains or in no adjacent domain. See also *boundary*.

interior mesh boundary An *interior mesh boundary* is the set of mesh faces or mesh edges between mesh elements within a domain.

interval The domain between two vertices (points) in a 1D geometry. Also called a *domain*.

inverted curved element An *inverted curved element* occurs when a *curved mesh element* inverts locally when more node points are added to better approximate the shape of the geometry. There are many possible geometrical causes, but the element is often too large compared to the geometry feature size.

isoparametric element A finite element that uses the same *shape function* for the element shape coordinates as for the *dependent variables*.

isosceles triangle A triangle with at least two equal sides (and two equal angles).

iteration See *iterative solver*.

iterative solver A solver for a system of linear equations that uses an iterative method, calculating a sequence of more and more accurate approximations to the solution. Each step in this sequence is one *linear iteration*. This should not be confused with the Newtons iterations (*nonlinear iterations*) that occur in the solution of a nonlinear system of equations. Compare to *direct solver* and *nonlinear iteration*.

Jacobian matrix A matrix containing the first derivative of a vector-valued function of a vector variable. In particular, it is the derivative of the *residual vector* with respect to the *solution vector*. When used in this narrower sense, the term *stiffness matrix* is sometimes used.

Lagrange element A *finite element* with polynomial shape functions of a certain *order* (degree). The value of the function is used as the *degree of freedom*, and the node points are the *Lagrange points*.

Lagrange multiplier An extra dependent variable introduced in the *flux conditions* when a constraint is added. The Lagrange multiplier often has a physical meaning and an interpretation as a (generalized) *reaction force*. See also *constraint*.

Lagrange point In a mesh element, the *Lagrange points* of order k are the points whose local (element) coordinates are integer multiples of $1/k$. These points are used as node points for the *Lagrange element*. For example, the Lagrange points of order 1 are the corners of the mesh element.

Lagrangian formulation A Lagrangian formulation means that the partial differential equations that describe some physics are formulated in a *material frame* (coordinate system) with coordinate axes fixed to the material in its reference configuration and following the material as it deforms. The Lagrangian formulation is common for solid mechanics because it makes anisotropic material properties independent of the current spatial orientation of the material. Compare to *Eulerian formulation*.

linear iteration A step in a linear iterative solver. See *iterative solver*. Compare to *nonlinear iteration*.

linear PDE An equation where both sides are sums of a known function, the unknown functions, and their partial derivatives, multiplied by known coefficients that only depend on the *independent variables*. Other PDEs are called *nonlinear*.

LU factorization For a linear system of equations, a version of Gaussian elimination that produces a factorization $A = LU$ of the coefficient matrix, where L and U are the lower and upper triangular matrices, respectively. This makes it easy to quickly solve a number of systems with the same coefficient matrix. See also *direct solver*.

mapped mesh A *structured mesh* with *quadrilateral elements* generated by mapping using transfinite interpolation.

mapped mesher The mesh generator creating *mapped meshes*.

mass matrix The matrix E that multiplies the second time derivative of the *solution vector* in the linearized discretized form of a PDE problem. If there are no second time derivatives (that is, if $E = 0$), then the term mass matrix is often used for the matrix D that multiplies the first derivative of the solution vector (the D matrix is otherwise called the *damping matrix*).

material frame The material frame defines a coordinate system that is fixed to the material in its reference configuration and follows the material as it deforms. The material frame is used in connection with a *Lagrangian formulation*. This frame is also referred to as a *reference frame*.

mathematical and numerical constants Built-in common mathematical constants such as π and i and numerical constants such as the machine precision or machine epsilon.

mesh A subdivision of the entities of a geometric model into, for example, triangles (2D) or tetrahedra (3D). These are examples of *mesh elements*. See also *grid*, *structured mesh*, and *unstructured mesh*.

mesh element The individual elements in the mesh that together form a partitioning of the geometry, for example, *triangular elements* and *tetrahedral elements*. See also *finite element*. A *curved mesh element* is a mesh element that is extended with additional node points to better approximate the shape of the geometry.

mesh frame In the mesh frame (coordinate system), the domain is fixed until an automatic or manual remeshing operation is performed, as well as between remeshing events. When remeshing is not used, the mesh frame is identical to the *geometry frame*.

mesh vertex An endpoint or corner of a mesh element. See also *node point* and *vertex*.

mesher The mesh generator. There are operations to create both *structured mesh* and *unstructured* mesh.

meshing sequence The sequence of mesh features that builds a *mesh*. In the Model Builder, this is represented by the Mesh node and its child nodes. The *mesh* can either be conforming with the component's geometry, or define its own *geometric model*.

method of lines A method for solving a time-dependent PDE through a space discretization, resulting in a set of ODEs.

mixed boundary condition See *generalized Neumann boundary condition*.

mixed object A nonempty *geometry object* that is not a *solid object*, *surface object*, *curve object*, or *point object*. For example, the union of a solid object and a curve object is a mixed object.

mode reduction A model-reduction technique for reducing systems with many degrees of freedom, such as large finite element models, to a form with fewer degrees of freedom for dynamic system simulations and analysis. See also *state-space model*.

model coupling See *nonlocal coupling*.

model input *Model inputs* are fields such as temperature and velocities or other physical properties that act as inputs for material properties and model equations. The model inputs can be fields computed by other physics interfaces or user-defined values.

model file for Java A file that contains Java® commands calling on the COMSOL *API*. Use a text editor to extend and modify the model file. Compiling and running a model file for Java creates the COMSOL Multiphysics model.

model file for MATLAB A text file containing commands that create a COMSOL Multiphysics model. A model file for MATLAB is a text file (M-file) that is similar to a *model file for Java* and that can be modified and used with MATLAB. If you have a MATLAB license and a license for LiveLink™ *for* MATLAB®, the COMSOL Desktop can load a model file for MATLAB. Compare with *Model MPH-file*.

Model MPH-file A binary data file with the extension `.mph` that contains a COMSOL Multiphysics model or application. Often also just called model file or application file.

model object An object (data structure) that contains all data for a model. This is the fundamental data structure in a COMSOL Multiphysics model.

Model Wizard Part of the COMSOL Desktop that is used to start building a model. It contains the Select Space Dimension, Select Physics, and Select Study Type pages.

MRI data *Magnet resonance imaging (MRI) data* is an image data format, primarily for medical use. MRI produces high-quality images of the inside of the human body. 3D MRI data is usually represented as a sequence of 2D images.

multigrid A solver or preconditioner for a linear system of equations that computes a sequence of increasingly accurate approximations of the solution by using a hierarchy of coarsened versions of the linear system (having fewer degrees of freedom). See also *algebraic multigrid*, *geometric multigrid*.

multiphysics Multiphysics models include more than one equation and variable from different types of physics. These variables can be defined in different domains. The equations can be coupled together through equation coefficients that depend on variables from other equations. Compare to *extended multiphysics*.

natural boundary condition See *Neumann boundary condition*.

Neumann boundary condition A Neumann boundary condition specifies the value of the *normal flux* across a boundary. Neumann boundary conditions are sometimes called *natural boundary conditions*. Compare to *generalized Neumann conditions*.

Newton's method An iterative solver method, also called the *Newton-Raphson method*, for solving nonlinear equations. See also *nonlinear iterations*.

Newton-Raphson method See *Newton's method*.

node point Any point in the mesh element where the degrees of freedom are defined. The node points often include the mesh vertices and possibly interior or midpoint locations. See also *degree of freedom* (DOF) and *mesh vertex*.

nonlinear iteration A Newton step in the solution of a nonlinear PDE problem. Each nonlinear iteration involves the solution of a linear system of equations. Compare to *linear iteration*.

nonlinear PDE See *linear PDE*.

nonlocal coupling User-defined nonlocal couplings are used to couple data within a model component (geometry) or between different model components (geometries). See also *extrusion nonlocal coupling*, *projection nonlocal coupling*, and *integration nonlocal coupling*. Nonlocal couplings can be reused with different arguments (for example, for integrating different quantities over the same domain).

norm A scalar measure of the magnitude of a vector or a matrix. Several types of norms are used to measure the accuracy of numerical solutions.

numerical integration formula A numerical integration method that approximates an integral by taking the weighted sum of the integrand evaluated at a finite number of points, the *integration points* (sometimes improperly called *Gauss points*). Also called *quadrature formula*.

normal flux The normal component of the *flux vector* at a boundary.

NURBS The *nonuniform rational B-spline (NURBS)* is a curve and surface representation scheme. A NURBS representation can be divided into a number of *rational Bézier curves* or surfaces.

online model reduction In the context of model reduction, *online* refers to using the reduced order for evaluations rather than producing them.

operator, operator function A user-defined *operator function*, or just *operator*, is similar to a *function* but behaves differently. For example, COMSOL Multiphysics includes differentiation operators that take expressions as input arguments to define a derivative of an expression with respect to a variable. There are also built-in arithmetic, relational, and logical operators.

order of a finite element The degree of the polynomials that define the *shape functions* (*basis functions*).

ordinary differential equation (ODE) An equation involving functions and their derivatives. The derivatives are with respect to one independent variable only. Compare to *partial differential equation (PDE)*.

parabolic PDE A typical example of a linear 2nd-order parabolic PDE is the *heat equation*

$$d_a\frac{\partial u}{\partial t} + \nabla \cdot (-c\nabla u - \alpha u + \gamma) + \beta \cdot \nabla u + au = f$$

where d_a and c are positive.

parameter A constant that can take on different values for each model in a parametric analysis. See also *constant*.

partial differential equation (PDE) An equation involving functions and their partial derivatives; that is, an equation that includes derivatives with respect to more than one independent variable. Compare to *ordinary differential equation (ODE)*.

periodic boundary condition A boundary condition where the values of the solution appear in a periodic pattern, typically so that the value of the solution on one boundary is equal to the value on another boundary. See also *equivalent boundaries*.

phasor A complex number or a vector of complex numbers representing a sinusoidally varying current or voltage.

physical quantity A quantity (quantifiable property) that can be used in the mathematical equations of science and technology.

physics interfaces Sets of physics nodes for different types of physics in the COMSOL Desktop environment. The physics interfaces (sometimes referred to as the *physics*) contain predefined equations and boundary conditions and a set of nodes for setting up models for that type of physics.

pivot Usually a value on the main diagonal of the *stiffness matrix*. *Pivoting* is the interchanging of rows and columns in order to place a particularly large element in the diagonal position. The value of the diagonal element when it is used to eliminate values below it is called the *pivot value*.

point A location in space. Often used in a narrower sense with the same meaning as *vertex*.

point object A geometry object with only *vertices*.

positive definiteness A symmetric matrix is *positive definite* when all its eigenvalues are positive.

preconditioner The convergence rate of iterative methods depends on the spectral properties of the coefficient matrix. A *preconditioner* is a matrix that transforms the linear system into one that has the same solution but that has more favorable spectral properties. See also *algebraic multigrid*, *geometric multigrid*, *incomplete LU factorization*, *iterative solver*, and *SSOR*.

preselection A selection of one or more geometric entities, such as domains or boundaries, that is not assigned to a physics feature or any other node in the model tree. Such a preselection can then be assigned to, for example, a physics feature that you add to the model tree from a ribbon toolbar or context menu.

primitive, primitive geometry object A geometry object with a basic shape such as a cube or a sphere. Add primitives to a model, using arbitrary sizes and positions, and combine them to form complex shapes. See also *constructive solid geometry*, *composite geometry object*, and *Boolean operations*.

prism element A 3D mesh element with six corners and five faces, also referred to as *wedge element*.

projection nonlocal coupling A coupling that takes values from the source by evaluating line integrals over lines whose positions are dependent on the position of the evaluation points in the destination.

quad mesher The mesh generator creating unstructured quadrilateral meshes.

quadrature formula See *numerical integration formula*.

quadrilateral element A 2D mesh element with four corners and four edges; sometimes also called *quad element* as a short form.

rational Bézier curve See *Bézier curve*.

reaction force see *reaction term*.

reaction term Terms that are automatically added to the system of equations in order to enforce a *constraint*. Reaction terms from boundary constraints appear as a *flux condition* and share the same physical meaning. Using an analogy from structural mechanics, reaction terms are sometimes referred to as (generalized) reaction forces.

reference frame See *material frame*.

residual vector The vector L in the discretized form of a PDE problem. In the absence of *constraints*, the discrete form of a stationary equation is $0 = L(U)$ where U is the *solution vector*.

revolve To create a 3D geometry object from a planar face by rotating it about an axis.

Robin boundary condition See *generalized Neumann boundary condition*.

shadow mapping A process by which direct shadows are added to 3D graphics by first generating shadow maps from the light sources' perspectives.

shape function A *basis function* described in local element coordinates. See also *basis function*.

shift A value σ around which an eigensolver searches for eigenvalues.

simplex element *Triangle element* in 2D and *tetrahedral element* in 3D.

solid See *solid object*.

solid modeling A 3D geometry modeling method that describes both the boundary and interior of the geometry using solid objects. See also *constructive solid geometry (CSG)* and *solid object*.

solid object A geometry object whose *vertices*, *edges*, and *faces* all have an adjacent *domain*.

solution component See *dependent variable*.

solution matrix A matrix that contains a sequence of solutions as columns. A steady-state problem results in a *solution vector*, but eigenvalue problems, time-dependent problems, and parametric analyses produce a *solution matrix*.

solution vector A vector with components that contain all the *degrees of freedom* (values of the *dependent variables*) as its components. See also *solution matrix*.

solver sequence A sequence of named solver settings and commands that can be replayed by a single solver call.

sparse matrix Matrix for which the number of zero elements is large enough to justify special data types and algorithms that avoid operations on zero elements.

spatial frame The spatial frame defines a coordinate system with coordinate axes fixed in space. The spatial frame (also called the Eulerian frame) is used in connection with a *Eulerian formulation*.

split To divide a geometry object into its minimal parts.

stability A solver for a time-dependent model is *unconditionally stable* if the initial conditions are not amplified artificially and the roundoff errors do not grow, regardless of the size of the time step. A solver is *conditionally stable* if there is a maximum value of the time step above which the numerical solution is unstable.

state-space model A linear time-invariant representation of a dynamic system as a set of first-order *ODEs* of the form

$$\begin{aligned} \dot{x} &= Ax + Bu \\ y &= Cx + Du \end{aligned}$$

where x is the state vector, u is the input, and y is the output. A, B, C, and D are the constant dynamics, input, output, and direct transmission matrices, respectively.

static model See *stationary model*.

stationary model A model where the dependent variables do not change over time. It typically represents a steady-state solution. Also called *static model* or *steady model*.

steady model See *stationary model*.

stiffness matrix See *Jacobian matrix*.

streakline The locus of particles that have earlier passed through a prescribed point in space. See also *streamline*.

streamline A curve that is tangent to the vector field everywhere (in particular a velocity field) at a given instant of time. Sometimes called a *flow line* or *flux line*. See also *streakline*.

streamline-diffusion stabilization A numerical technique for stabilization of the numeric solution to a PDE by artificially adding diffusion in the direction of the *streamlines*.

strong form A partial differential equation in the *strong form* is the standard formulation as an equality of functions. The strong form is divided into the *coefficient form* and the *general form*. Compare to *coefficient form*, *general form*, and *weak form*.

structured mesh A mesh for which all elements and nodes have the same topology. Compare to *unstructured mesh*.

surface A smooth mathematical function from 2D to 3D space.

surface normal A vector perpendicular to the surface.

surface modeling A 3D geometry modeling method to describe a geometry by defining its bounding surfaces. Compare to *boundary modeling* and *solid modeling*.

surface object A geometry object without domains, isolated edges, or isolated vertices. Typically a trimmed surface is represented as a surface object.

swept mesh A 3D mesh generated by sweeping a face mesh along a domain, creating a mesh that is structured in the sweep direction. Compare to *structured mesh*.

swept mesher Mesh generator creating a *swept mesh*.

symmetric matrix A matrix that equals its own transpose.

symmetric successive overrelaxation (SSOR) A *symmetric successive overrelaxation (SSOR)* preconditioner uses classic SSOR iterations.

symmetry The invariance of an object attribute or of the object itself under a transformation such as inversion, rotation, or reflection. A *symmetry* allows for a reduction of the model geometry so that appropriate boundary conditions account for the redundant portions of the geometry. Axial symmetry is a common type of *symmetry*.

symmetric constraint A *constraint* that is enforced by *reaction terms* chosen so as to preserve the symmetry of symmetric unconstrained systems. This choice of reaction terms is unique and leads to a *bidirectional constraint* that modifies the equations corresponding to all dependent variables appearing in the constrained expression.

symmetry boundaries See *equivalent boundaries*.

test function See *weak form*.

tet mesher The mesh generator creating unstructured tetrahedral meshes. See *unstructured mesh*.

tetrahedral element A 3D mesh element with four corners, six edges, and four triangular faces.

time-dependent model See *transient model*.

transient model A model where at least one of the dependent variables changes over time, for example, the heat equation or the wave equation. Also called *dynamic model*, *time-dependent model*, or *unsteady model*.

triangle mesher The mesh generator creating unstructured triangular meshes. See *unstructured mesh*.

triangular element A 2D mesh element with three corners and three edges.

trimmed surface If the parameter space of a surface is divided into "valid" and "invalid" regions, the image of the valid regions is called the *trimmed surface*. This corresponds to the part of the surface limited by a closed loop of edges lying on the surface.

unidirectional constraint A constraint enforced by *reaction terms* that only affect one of the dependent variables in a constraint of type $u_1 = u_2$. The other dependent variables are treated as independent with respect to the unidirectional constraint. Compare to *symmetric constraint*. See also *constraint*.

unstructured mesh A mesh without a specific pattern where the elements can have different shapes and the nodes can have different connectivities. An unstructured mesh can represent any geometry and can be created using a *triangle mesher*, a *quad mesher*, or a *tet mesher*. Compare to *structured mesh* and *mapped mesh*.

unsteady model See *time-dependent model*.

user-defined variable A user-defined variable can be defined on a global level or on any geometric entity in terms of *dependent variables*, *independent variables*, *parameters*, *constants*, and other *variables*.

vector element A finite element often used for electromagnetic vector fields. Each mesh element has degrees of freedom corresponding only to tangential components of the field. Also called *curl element*, *Nédélec's edge element*, or just *edge element*.

vertex A point in a *geometric model*, often an endpoint of an *edge* or an intersection of *geometric entities* of a higher degree such as *edges* or *faces*. A vertex is referred to as a *point* for the specification of point sources and other PDE modeling. See also *domain*.

weak constraint A reformulation of a *constraint* as a *weak form* equation. When using a weak constraint, the corresponding *Lagrange multiplier* becomes a *solution component* (*dependent variable*).

weak form A partial differential equation in the *weak form* is a more general formulation than the strong form. It is produced by multiplying the *strong form* PDE with an arbitrary function called the *test function* and integrating over the computational domain. Physics interfaces in COMSOL Multiphysics are implemented using a weak form. Compare to *strong form*.

wedge element See *prism element*.

well-posed A well-posed mathematical problem has a unique solution and depends continuously on its input, such as initial conditions, source terms, and boundary conditions.

work plane An embedded 2D workspace that can be positioned relative to the coordinate planes or an already existing 3D geometry. Using *work planes* makes it possible to define a geometry in terms of previously created geometry objects such as *points*, *edges*, and *faces*. From a work plane with a 2D geometry, 3D geometry objects can be created using *extrude* or *revolve* operations.
